Sun Performance Library(TM) Reference Manual

Sun WorkShop(TM) 6 update 2

This reference manual is a PDF version of the section 3P man pages. For additional information, see the *Sun Performance Library User's Guide*, available on `docs.sun.com`, or the *LAPACK Users' Guide*, available from the Society for Industrial and Applied Mathematics (SIAM).

[available_threads](#) - returns information about current thread usage

[bcomm](#) - bcomm, sbcomm, dbcomm - block coordinate matrix-matrix multiply

[bdimm](#) - bdimm, sbdimm, dbdimm - block diagonal format matrix-matrix multiply

[bdism](#) - bdism, sbdism, dbdism - block diagonal format triangular solve

[belmm](#) - belmm, sbelmm, dbelmm - block Ellpack format matrix-matrix multiply

[belsm](#) - belsm, sbelsm, dbelsm - block Ellpack format triangular solve

[bscmm](#) - bscmm, sbscmm, dbscmm - block sparse column matrix-matrix multiply

[bscsm](#) - bscsm, sbcsm, dbcsm - block sparse column format triangular solve

[bsrmm](#) - bsrmm, sbsrmm, dbsrmm - block sparse row format matrix-matrix multiply

[bsrsm](#) - bsrsm, sbsrsm, dbsrsm - block sparse row format triangular solve

[coomm](#) - coomm, scoomm, dcoomm - coordinate matrix-matrix multiply

[cscmm](#) - cscmm, scscmm, dcscmm - compressed sparse column format matrix-matrix multiply

[cscsm](#) - cscsm, scscsm, dcscsm - compressed sparse column format triangular solve

[csrmm](#) - csrmm, scsrmm, dcsrmm - compressed sparse row format matrix-matrix multiply

[csrsm](#) - csrsm, scsrsm, dcsrsm - compressed sparse row format triangular solve

[caxpy](#) - compute $y := \alpha * x + y$

[caxpyi](#) - caxpyi, daxpyi, saxpyi, zaxpyi - Compute $y := \alpha * x + y$

[cbdsqr](#) - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

[cchdc](#) (obsolete)- compute the Cholesky decomposition of a symmetric positive definite matrix A.

[cchdd](#) (obsolete)- downdate an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

[cchex](#) (obsolete)- compute the Cholesky decomposition of a symmetric positive definite matrix A.

[cchud](#) (obsolete)- update an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

[ccnvcor](#) - compute the convolution or correlation of complex vectors

[ccnvcor2](#) - compute the convolution or correlation of complex matrices

[ccopy](#) - Copy x to y

[cdotc](#) - compute the dot product of two vectors x and conjg(y).

[cdotci](#) - cdotci, cdotui, ddoti, sdoti, zdotci, zdotui - Compute the dot product of two vectors x and y

[cdotu](#) - compute the dot product of two vectors x and y.

[cfft2b](#) - compute a periodic sequence from its Fourier coefficients. The xFFT operations are unnormalized, so a call of xFFT2F followed by a call of xFFT2B will multiply the input sequence by M*N.

[cfft2f](#) - compute the Fourier coefficients of a periodic sequence. The xFFT operations are unnormalized, so a call of

xFFT2F followed by a call of xFFT2B will multiply the input sequence by M^*N .

[cfft2i](#) - initialize the array WSAVE, which is used in both the forward and backward transforms.

[cfft3b](#) - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFT3F followed by a call of CFFT3B will multiply the input sequence by M^*N^*K .

[cfft3f](#) - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFT3F followed by a call of CFFT3B will multiply the input sequence by M^*N^*K .

[cfft3i](#) - initialize the array WSAVE, which is used in both CFFT3F and CFFT3B.

[cfft6b](#) - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFT6F followed by a call of CFFT6B will multiply the input sequence by N .

[cfft6f](#) - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFT6F followed by a call of CFFT6B will multiply the input sequence by N .

[cfft6i](#) - initialize the array WSAVE, which is used in both CFFT6F and CFFT6B.

[cffttop](#) - compute the length of the closest fast FFT

[cgbbnd](#) - reduce a complex general m -by- n band matrix A to real upper bidiagonal form B by a unitary transformation

[cgbcu](#) (obsolete)- compute the LU factorization and condition number of a general matrix A in banded storage. If the condition number is not needed then xGBFA is slightly faster. It is typical to follow a call to xGBCU with a call to xGBSL to solve $Ax = b$ or to xGBDI to compute the determinant of A .

[cgbcn](#) - estimate the reciprocal of the condition number of a complex general band matrix A , in either the 1-norm or the infinity-norm,

[cgbd](#) (obsolete)- compute the determinant of a general matrix A in banded storage, which has been LU-factored by GBCU or GBFA.

[cgbequ](#) - compute row and column scalings intended to equilibrate an M -by- N band matrix A and reduce its condition number

[cgbfa](#) (obsolete)- compute the LU factorization of a matrix A in banded storage. It is typical to follow a call to GBFA with a call to GBSL to solve $Ax = b$ or to GBDI to compute the determinant of A .

[cgbm](#) - perform one of the matrix-vector operations $y := \alpha^*A^*x + \beta^*y$, or $y := \alpha^*A^*x + \beta^*y$, or $y := \alpha^*\text{conj}(A^*)^*x + \beta^*y$

[cgbrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

[cgbsl](#) (obsolete)- solve the linear system $Ax = b$ for a matrix A in banded storage, which has been LU-factored by GBCU or GBFA, and vectors b and x .

[cgbsv](#) - compute the solution to a complex system of linear equations $A^*X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N -by- $NRHS$ matrices

[cgbsvx](#) - use the LU factorization to compute the solution to a complex system of linear equations $A^*X = B$, $A^{**T}^*X = B$, or $A^{**H}^*X = B$,

[cgbtf2](#) - compute an LU factorization of a complex m -by- n band matrix A using partial pivoting with row interchanges

[cgbtrf](#) - compute an LU factorization of a complex m -by- n band matrix A using partial pivoting with row interchanges

[cgbtrs](#) - solve a system of linear equations $A^*X = B$, $A^{**T}^*X = B$, or $A^{**H}^*X = B$ with a general band matrix A using the LU factorization computed by CGBTRF

[cgebak](#) - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

[cgebal](#) - balance a general complex matrix A

[cgebrd](#) - reduce a general complex M -by- N matrix A to upper or lower bidiagonal form B by a unitary

transformation

[cgeco](#) (obsolete)- compute the LU factorization and estimate the condition number of a general matrix A. If the condition number is not needed then CGEFA is slightly faster. It is typical to follow a call to CGECO with a call to CGESL to solve $Ax = b$ or to CGEDI to compute the determinant and inverse of A.

[cgecon](#) - estimate the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF

[cgedi](#) (obsolete)- compute the determinant and inverse of a general matrix A, which has been LU-factored by CGECO or CGEFA.

[cgeequ](#) - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

[cgees](#) - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

[cgeesx](#) - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

[cgeev](#) - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[cgeevx](#) - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[cgefa](#) (obsolete)- compute the LU factorization of a general matrix A. It is typical to follow a call to CGEFA with a call to CGESL to solve $Ax = b$ or to CGEDI to compute the determinant of A.

[cgegs](#) - routine is deprecated and has been replaced by routine CGGES

[cgegv](#) - routine is deprecated and has been replaced by routine CGGEV

[cgehrd](#) - reduce a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation

[cgeqf](#) - compute an LQ factorization of a complex M-by-N matrix A

[cgels](#) - solve overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A

[cgelsd](#) - compute the minimum-norm solution to a real linear least squares problem

[cgelss](#) - compute the minimum norm solution to a complex linear least squares problem

[cgelsx](#) - routine is deprecated and has been replaced by routine CGELSY

[cgelsy](#) - compute the minimum-norm solution to a complex linear least squares problem

[cgemm](#) - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

[cgemv](#) - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$

[cgeqlf](#) - compute a QL factorization of a complex M-by-N matrix A

[cgeqp3](#) - compute a QR factorization with column pivoting of a matrix A

[cgeqpf](#) - routine is deprecated and has been replaced by routine CGEQP3

[cgeqrf](#) - compute a QR factorization of a complex M-by-N matrix A

[cgerc](#) - perform the rank 1 operation $A := \alpha * x * \text{conjg}(y') + A$

[cgerfs](#) - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

[cgerqf](#) - compute an RQ factorization of a complex M-by-N matrix A

[cgeru](#) - perform the rank 1 operation $A := \alpha * x * y' + A$

[cgesdd](#) - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing

the left and/or right singular vectors, by using divide-and-conquer method

[cgesl](#) (obsolete)- solve the linear system $Ax = b$ for a general matrix A , which has been LU- factored by CGECO or CGEFA, and vectors b and x .

[cgesv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[cgesvd](#) - compute the singular value decomposition (SVD) of a complex M-by-N matrix A , optionally computing the left and/or right singular vectors

[cgesvx](#) - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$,

[cgetf2](#) - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

[cgetrf](#) - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

[cgetri](#) - compute the inverse of a matrix using the LU factorization computed by CGETRF

[cgetrs](#) - solve a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general N-by-N matrix A using the LU factorization computed by CGETRF

[cggbak](#) - form the right or left eigenvectors of a complex generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL

[cggbal](#) - balance a pair of general complex matrices (A,B)

[cgges](#) - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR)

[cggesx](#) - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T),

[cggev](#) - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

[cggevx](#) - compute for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

[cgglm](#) - solve a general Gauss-Markov linear model (GLM) problem

[cgghrd](#) - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

[cgglse](#) - solve the linear equality-constrained least squares (LSE) problem

[cgqrf](#) - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B .

[cggrqf](#) - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

[cggsvd](#) - compute the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B

[cggsvp](#) - compute unitary matrices U , V and Q such that $N-K-L \begin{matrix} K & L \\ U^*A*Q & K \end{matrix} \begin{matrix} 0 & A_{12} & A_{13} \end{matrix}$ if $M-K-L \geq 0$

[cgtcon](#) - estimate the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF

[cgthr](#) - cgthr, dgthr, sgthr, zgthr - Gathers specified elements from y into x

[cgthrz](#) - cgthrz, dgthrz, sgthrz, zgthrz - Gathers specified elements from y into x and sets gathered elements in y to zero

[cgtfrs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

[cgtsl](#) (obsolete)- solve the linear system $Ax = b$ for a tridiagonal matrix A and vectors b and x .

[cgtsv](#) - solve the equation $A*X = B$,

[cgtsvx](#) - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[cgttrf](#) - compute an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges

[cgtrfs](#) - solve one of the systems of equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[chbev](#) - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[chbevd](#) - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[chbevz](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[chbgst](#) - reduce a complex Hermitian-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$,

[chbgv](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$

[chbgvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$

[chbgvx](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$

[chbmV](#) - perform the matrix-vector operation $y := \alpha*A*x + \beta*y$

[chbtrd](#) - reduce a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

[checon](#) - estimate the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U*D*U^{**H}$ or $A = L*D*L^{**H}$ computed by CHETRF

[cheev](#) - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[cheevd](#) - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[cheevr](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T

[cheevz](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[chegs2](#) - reduce a complex Hermitian-definite generalized eigenproblem to standard form

[chegst](#) - reduce a complex Hermitian-definite generalized eigenproblem to standard form

[chegv](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chegvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chegvx](#) - compute selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[chemm](#) - perform one of the matrix-matrix operations $C := \alpha*A*B + \beta*C$ or $C := \alpha*B*A + \beta*C$

[chemv](#) - perform the matrix-vector operation $y := \alpha*A*x + \beta*y$

[cher](#) - perform the hermitian rank 1 operation $A := \alpha*x*\text{conjg}(x') + A$

[cher2](#) - perform the hermitian rank 2 operation $A := \alpha*x*\text{conjg}(y') + \text{conjg}(\alpha)*y*\text{conjg}(x') + A$

[cher2k](#) - perform one of the Hermitian rank 2k operations $C := \alpha*A*\text{conjg}(B') + \text{conjg}(\alpha)*B*\text{conjg}(A') + \beta*C$ or $C := \alpha*\text{conjg}(A')*B + \text{conjg}(\alpha)*\text{conjg}(B')*A + \beta*C$

[cherfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution

[cherk](#) - perform one of the Hermitian rank k operations $C := \alpha*A*\text{conjg}(A') + \beta*C$ or $C := \alpha*\text{conjg}(A')*A + \beta*C$

[chesv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[chesvx](#) - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A *$

$X = B$,

[chetf2](#) - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

[chetrd](#) - reduce a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

[chetrf](#) - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

[chetri](#) - compute the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

[chetrs](#) - solve a system of linear equations $A^*X = B$ with a complex Hermitian matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

[chgeqz](#) - implement a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation $\det(A-w(i)B) = 0$. If $\text{JOB}='S'$, then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary transformation (usually called Q) on the left and another (usually called Z) on the right

[chico](#) (obsolete)- compute the UDU factorization and condition number of a Hermitian matrix A . If the condition number is not needed then xHIFA is slightly faster. It is typical to follow a call to xHICO with a call to xHISL to solve $Ax = b$ or to xHIDI to compute the determinant, inverse, and inertia of A .

[chidi](#) (obsolete)- compute the determinant, inertia, and inverse of a Hermitian matrix A , which has been UDU-factored by CHICO or CHIFA.

[chifa](#) (obsolete)- compute the UDU factorization of a Hermitian matrix A . It is typical to follow a call to CHIFA with a call to CHISL to solve $Ax = b$ or to CHIDI to compute the determinant, inverse, and inertia of A .

[chisl](#) (obsolete)- solve the linear system $Ax = b$ for a Hermitian matrix A , which has been UDU-factored by CHICO or CHIFA, and vectors b and x .

[chpco](#) (obsolete)- compute the UDU factorization and condition number of a Hermitian matrix A in packed storage. If the condition number is not needed then xHPFA is slightly faster. It is typical to follow a call to xHPCO with a call to xHPSL to solve $Ax = b$ or to xHPDI to compute the determinant, inverse, and inertia of A .

[chpcon](#) - estimate the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF

[chpdi](#) (obsolete)- compute the determinant, inertia, and inverse of a Hermitian matrix A in packed storage, which has been UDU-factored by CHPCO or CHPFA.

[chpev](#) - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage

[chpevd](#) - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

[chpevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

[chpfa](#) (obsolete)- compute the UDU factorization of a Hermitian matrix A in packed storage. It is typical to follow a call to CHPFA with a call to CHPSL to solve $Ax = b$ or to CHPDI to compute the determinant, inverse, and inertia of A .

[chpgst](#) - reduce a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage

[chpgv](#) - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[chpgvd](#) - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[chpgvx](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[chpmv](#) - perform the matrix-vector operation $y := \alpha A^*x + \beta y$

[chpr](#) - perform the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$

[chpr2](#) - perform the Hermitian rank 2 operation $A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A$

[chprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution

[chpsl](#) (obsolete)- solve the linear system $Ax = b$ for a Hermitian matrix A in packed storage, which has been UDU-factored by CHPCO or CHPFA, and vectors b and x .

[chpsv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[chpsvx](#) - use the diagonal pivoting factorization $A = U * D * U ** H$ or $A = L * D * L ** H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices

[chptrd](#) - reduce a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation

[chptrf](#) - compute the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method

[chptri](#) - compute the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U * D * U ** H$ or $A = L * D * L ** H$ computed by CHPTRF

[chptrs](#) - solve a system of linear equations $A * X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U * D * U ** H$ or $A = L * D * L ** H$ computed by CHPTRF

[chsein](#) - use inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H

[chseqr](#) - compute the eigenvalues of a complex upper Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H = Z * T * Z ** H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors

[clarz](#) - apply a complex elementary reflector H to a complex M-by-N matrix C , from either the left or the right

[clarzb](#) - apply a complex block reflector H or its transpose $H ** H$ to a complex distributed M-by-N C from the left or the right

[clarzt](#) - form the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors

[clatzm](#) - routine is deprecated and has been replaced by routine CUNMRZ

[cosqb](#) - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

[cosqf](#) - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

[cosqi](#) - initialize the array WSAVE, which is used in both COSQF and COSQB.

[cost](#) - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by $2 * (N-1)$.

[costi](#) - initialize the array WSAVE, which is used in COST.

[cpbco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in banded storage. If the condition number is not needed then xPBFA is slightly faster. It is typical to follow a call to xPBCO with a call to xPBSL to solve $Ax = b$ or to xPBDI to compute the determinant of A .

[cpbcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U ** H * U$ or $A = L * L ** H$ computed by CPBTRF

[cpbdi](#) (obsolete)- compute the determinant of a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by CPBCO or CPBFA.

[cpbequ](#) - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

[cpbfa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A in banded storage. It is typical to follow a call to CPBFA with a call to CPBSL to solve $Ax = b$ or to CPBDI to compute the determinant of A.

[cpbrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution

[cpbsl](#) (obsolete)- section solve the linear system $Ax = b$ for a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by CPBCO or CPBFA, and vectors b and x.

[cpbstf](#) - compute a split Cholesky factorization of a complex Hermitian positive definite band matrix A

[cpbsv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[cpbsvx](#) - use the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ to compute the solution to a complex system of linear equations $A * X = B$,

[cpbtf2](#) - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

[cpbtrf](#) - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

[cpbtrs](#) - solve a system of linear equations $A*X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPBTRF

[cpoco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A. If the condition number is not needed then xPOFA is slightly faster. It is typical to follow a call to xPOCO with a call to xPOSL to solve $Ax = b$ or to xPODI to compute the determinant and inverse of A.

[cpocon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPOTRF

[cpodi](#) (obsolete)- compute the determinant and inverse of a symmetric positive definite matrix A, which has been Cholesky-factored by CPOCO, CPOFA, or CQRDC.

[cpoequ](#) - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

[cpofa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A. It is typical to follow a call to CPOFA with a call to CPOSL to solve $Ax = b$ or to CPODI to compute the determinant and inverse of A.

[cporfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite,

[cposl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A, which has been Cholesky-factored by CPOCO or CPOFA, and vectors b and x.

[cposv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[cposvx](#) - use the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ to compute the solution to a complex system of linear equations $A * X = B$,

[cpotf2](#) - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

[cpotrf](#) - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

[cpotri](#) - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPOTRF

[cpotrs](#) - solve a system of linear equations $A*X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPOTRF

[cppco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in packed storage. If the condition number is not needed then CPPFA is slightly faster. It is typical to follow a call to CPPCO with a call to CPPSL to solve $Ax = b$ or to CPPDI to compute the determinant and inverse of A.

[cppcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPPTRF

[cppdi](#) (obsolete)- compute the determinant and inverse of a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by CPPCO or CPPFA.

[cppequ](#) - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

[cppfa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A in packed storage. It is typical to follow a call to CPPFA with a call to CPPSL to solve $Ax = b$ or to CPPDI to compute the determinant and inverse of A.

[cpprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution

[cppsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by CPPCO or CPPFA, and vectors b and x.

[cppsv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[cppsvx](#) - use the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ to compute the solution to a complex system of linear equations $A * X = B$,

[cpptrf](#) - compute the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format

[cpptri](#) - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPPTRF

[cpptrs](#) - solve a system of linear equations $A*X = B$ with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPPTRF

[cptcon](#) - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L*D*L**H$ or $A = U**H*D*U$ computed by CPTTRF

[cpteqr](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor

[cptrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

[cptsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite tridiagonal matrix A and vectors b and x.

[cptsv](#) - compute the solution to a complex system of linear equations $A*X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

[cptsvx](#) - use the factorization $A = L*D*L**H$ to compute the solution to a complex system of linear equations $A*X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

[cpttrf](#) - compute the $L*D*L'$ factorization of a complex Hermitian positive definite tridiagonal matrix A

[cpttrs](#) - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U'*D*U$ or $A = L*D*L'$ computed by CPTTRF

[cptts2](#) - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U'*D*U$ or $A = L*D*L'$ computed by CPTTRF

[cqrdc](#) (obsolete)- compute the QR factorization of a general matrix A. It is typical to follow a call to CQRDC with a call to CQRSL to solve $Ax = b$ or to CPODI to compute the determinant of A.

[cqrsl](#) (obsolete)- solve the linear system $Ax = b$ for a general matrix A, which has been QR- factored by CQRDC, and vectors b and x.

[crot](#) - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors CX and CY are complex

[crotg](#) - Construct a Given's plane rotation

[cscal](#) - Compute $y := \alpha * y$

[csctr](#) - csctr, dsctr, ssctr, zsctr - Scatters elements from x into y

[csico](#) (obsolete)- compute the UDU factorization and condition number of a symmetric matrix A. If the condition number is not needed then CSIFA is slightly faster. It is typical to follow a call to CSICO with a call to CSISL to solve $Ax = b$ or to CSIDI to compute the determinant, inverse, and inertia of A.

[csidi](#) (obsolete)- compute the determinant, inertia, and inverse of a symmetric matrix A, which has been UDU-factored by CSICO or CSIFA.

[csifa](#) (obsolete)- compute the UDU factorization of a symmetric matrix A. It is typical to follow a call to CSIFA with a call to CSISL to solve $Ax = b$ or to CSIDI to compute the determinant, inverse, and inertia of A.

[csisl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric matrix A, which has been UDU-factored by CSICO or CSIFA, and vectors b and x.

[cspco](#) (obsolete)- compute the UDU factorization and condition number of a symmetric matrix A in packed storage. If the condition number is not needed then CSPFA is slightly faster. It is typical to follow a call to CSPCO with a call to CSPSL to solve $Ax = b$ or to CSPDI to compute the determinant, inverse, and inertia of A.

[cspcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

[cspdi](#) (obsolete)- compute the determinant, inertia, and inverse of a symmetric matrix A in packed storage, which has been UDU-factored by CSPCO or CSPFA.

[cspf](#) (obsolete)- compute the UDU factorization of a symmetric matrix A in packed storage. It is typical to follow a call to CSPFA with a call to CSPSL to solve $Ax = b$ or to CSPDI to compute the determinant, inverse, and inertia of A.

[cspdfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

[cspsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric matrix A in packed storage, which has been UDU-factored by CSPCO or CSPFA, and vectors b and x.

[cspsv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[cspsvx](#) - use the diagonal pivoting factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

[csptrf](#) - compute the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

[csptri](#) - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

[csptrs](#) - solve a system of linear equations $A^*X = B$ with a complex symmetric matrix A stored in packed format using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

[csrot](#) - Apply a plane rotation.

[csscal](#) - Compute $y := \alpha * y$

[cstedc](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

[cstegr](#) - Compute $T\text{-sigma}_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

[cstein](#) - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

[cstegr](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

[cstsv](#) - compute the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix

[csttrf](#) - compute the factorization of a complex Hermitian tridiagonal matrix A

[csttrs](#) - computes the solution to a complex system of linear equations $A * X = B$

[csvdc](#) (obsolete)- compute the singular value decomposition of a general matrix A.

[cswap](#) - Exchange vectors x and y.

[csycon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ computed by CSYTRF

[csymm](#) - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

[csyr2k](#) - perform one of the symmetric rank 2k operations $C := \alpha * A * B' + \alpha * B * A' + \beta * C$ or $C := \alpha * A * A' + \beta * C$

[csyrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

[csyrk](#) - perform one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$

[csysv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[csysvx](#) - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

[csytf2](#) - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[csytrf](#) - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[csytri](#) - compute the inverse of a complex symmetric indefinite matrix A using the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ computed by CSYTRF

[csytrs](#) - solve a system of linear equations $A * X = B$ with a complex symmetric matrix A using the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ computed by CSYTRF

[ctbcon](#) - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

[ctbmv](#) - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ctbrfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

[ctbsv](#) - solve one of the systems of equations $A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$

[ctbtrs](#) - solve a triangular system of the form $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[ctgevc](#) - compute some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B)

[ctgexc](#) - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST

[ctgsen](#) - reorder the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B)

[ctgsja](#) - compute the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B

[ctgsna](#) - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B)

[ctgsyl](#) - solve the generalized Sylvester equation

[ctpcon](#) - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

[ctpmv](#) - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ctprfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

[ctpsv](#) - solve one of the systems of equations $A^*x = b$, or $A^*x = b$, or $\text{conjg}(A')^*x = b$

[ctptri](#) - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

[ctptrs](#) - solve a triangular system of the form $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[ctrans](#) - transpose and scale source matrix

[ctrco](#) (obsolete)- estimate the condition number of a triangular matrix A. It is typical to follow a call to xTRCO with a call to xTRSL to solve $Ax = b$ or to xTRDI to compute the determinant and inverse of A.

[ctrcon](#) - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

[ctrdi](#) (obsolete)- compute the determinant and inverse of a triangular matrix A.

[ctrevc](#) - compute some or all of the right and/or left eigenvectors of a complex upper triangular matrix T

[ctrex](#) - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**H}$, so that the diagonal element of T with row index IFST is moved to row ILST

[ctrrmm](#) - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

[ctrrmv](#) - perform one of the matrix-vector operations $x := A^*x$, or $x := A^*x$, or $x := \text{conjg}(A')^*x$

[ctrrfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

[ctrrsen](#) - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**H}$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace

[ctrsl](#) (obsolete)- solve the linear system $Ax = b$ for a triangular matrix A and vectors b and x.

[ctrsm](#) - solve one of the matrix equations $\text{op}(A)^*X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$

[ctrсна](#) - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q^*T^*Q^{**H}$ with Q unitary)

[ctrsv](#) - solve one of the systems of equations $A^*x = b$, or $A^*x = b$, or $\text{conjg}(A')^*x = b$

[ctrsyl](#) - solve the complex Sylvester matrix equation

[ctrti2](#) - compute the inverse of a complex upper or lower triangular matrix

[ctrtri](#) - compute the inverse of a complex upper or lower triangular matrix A

[ctrtrs](#) - solve a triangular system of the form $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[ctzrqf](#) - routine is deprecated and has been replaced by routine CTZRZF

[ctzrzf](#) - reduce the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations

[cung2l](#) - generate an m by n complex matrix Q with orthonormal columns,

[cung2r](#) - generate an m by n complex matrix Q with orthonormal columns,

[cungbr](#) - generate one of the complex unitary matrices Q or P^{**H} determined by CGEBRD when reducing a complex matrix A to bidiagonal form

[cunghr](#) - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

[cungl2](#) - generate an m-by-n complex matrix Q with orthonormal rows,

[cunglq](#) - generate an M-by-N complex matrix Q with orthonormal rows,

[cungql](#) - generate an M-by-N complex matrix Q with orthonormal columns,

[cungqr](#) - generate an M-by-N complex matrix Q with orthonormal columns,

[cungr2](#) - generate an m by n complex matrix Q with orthonormal rows,

[cungrq](#) - generate an M-by-N complex matrix Q with orthonormal rows,

[cungtr](#) - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

[cunmbr](#) - VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmhr](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunml2](#) - overwrite the general complex m-by-n matrix C with Q * C if SIDE = 'L' and TRANS = 'N', or Q'* C if SIDE = 'L' and TRANS = 'C', or C * Q if SIDE = 'R' and TRANS = 'N', or C * Q' if SIDE = 'R' and TRANS = 'C',

[cunmlq](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmq1](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmqr](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmr2](#) - overwrite the general complex m-by-n matrix C with Q * C if SIDE = 'L' and TRANS = 'N', or Q'* C if SIDE = 'L' and TRANS = 'C', or C * Q if SIDE = 'R' and TRANS = 'N', or C * Q' if SIDE = 'R' and TRANS = 'C',

[cunmrq](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmrz](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cunmtr](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cupgtr](#) - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

[cupmtr](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[cvmul](#) - compute the scaled product of complex vectors

[dasum](#) - Return the sum of the absolute values of a vector x.

[daxpy](#) - compute $y := \alpha * x + y$

[dbdsdc](#) - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B

[dbdsqr](#) - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

[dchdc](#) (obsolete)- compute the Cholesky decomposition of a symmetric positive definite matrix A.

[dchdd](#) (obsolete)- downdate an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

[dchex](#) (obsolete)- compute the Cholesky decomposition of a symmetric positive definite matrix A.

[dchud](#) (obsolete)- update an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

[dcnvcor](#) - compute the convolution or correlation of real vectors

[dcnvcor2](#) - compute the convolution or correlation of real matrices

[dcopy](#) - Copy x to y

[dcosqb](#) - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

[dcosqf](#) - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

[dcosqi](#) - initialize the array WSAVE, which is used in both COSQF and COSQB.

[dcost](#) - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by $2 * (N-1)$.

[dcosti](#) - initialize the array WSAVE, which is used in COST.

[ddisna](#) - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

[ddot](#) - compute the dot product of two vectors x and y.

[dezftb](#) - computes a periodic sequence from its Fourier coefficients. DEZFTB is a simplified but slower version of DFFTB.

[dezftf](#) - computes the Fourier coefficients of a periodic sequence. DEZFTF is a simplified but slower version of DFFTF.

[dezfti](#) - initializes the array WSAVE, which is used in both DEZFTF and DEZFTB.

[dffft2b](#) - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFT2F followed by a call of DFFT2B will multiply the input sequence by $M*N$.

[dffft2f](#) - compute the Fourier coefficients of a periodic sequence. The DFFT operations are unnormalized, so a call of DFFT2F followed by a call of DFFT2B will multiply the input sequence by $M*N$.

[dffft2i](#) - initialize the array WSAVE, which is used in both the forward and backward transforms.

[dffft3b](#) - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFT3F followed by a call of DFFT3B will multiply the input sequence by $M*N*K$.

[dffft3f](#) - compute the Fourier coefficients of a real periodic sequence. The DFFT operations are unnormalized, so a call of DFFT3F followed by a call of DFFT3B will multiply the input sequence by $M*N*K$.

[dffft3i](#) - initialize the array WSAVE, which is used in both DFFT3F and DFFT3B.

[dffftb](#) - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFTF followed by a call of DFFTB will multiply the input sequence by N.

[dffftf](#) - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of DFFTF followed by a call of DFFTB will multiply the input sequence by N.

[dfffti](#) - initialize the array WSAVE, which is used in both DFFTF and DFFTB.

[dffftopt](#) - compute the length of the closest fast FFT

[dgbbrd](#) - reduce a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation

[dgbco](#) (obsolete)- compute the LU factorization and condition number of a general matrix A in banded storage. If the condition number is not needed then SGBFA is slightly faster. It is typical to follow a call to SGBCO with a call to SGBSL to solve $Ax = b$ or to SGBDI to compute the determinant of A.

[dgbcon](#) - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

[dgbdi](#) (obsolete)- compute the determinant of a general matrix A in banded storage, which has been LU-factored by SGBCO or SGBFA.

[dgbegu](#) - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

[dgbfa](#) (obsolete)- compute the LU factorization of a matrix A in banded storage. It is typical to follow a call to SGBFA with a call to SGBSL to solve $Ax = b$ or to SGBDI to compute the determinant of A.

[dgbmv](#) - perform one of the matrix-vector operations $y := \alpha*A*x + \beta*y$ or $y := \alpha*A'*x + \beta*y$

[dgbtrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

[dgbsl](#) (obsolete)- solve the linear system $Ax = b$ for a matrix A in banded storage, which has been LU-factored by

SGBCO or SGBFA, and vectors b and x.

[dgbsv](#) - compute the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

[dgbsvx](#) - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{*H} * X = B$,

[dgbtf2](#) - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

[dgbtrf](#) - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

[dgbtrs](#) - solve a system of linear equations $A * X = B$ or $A' * X = B$ with a general band matrix A using the LU factorization computed by SGBTRF

[dgebak](#) - form the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL

[dgebal](#) - balance a general real matrix A

[dgebrd](#) - reduce a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation

[dgeco](#) (obsolete)- compute the LU factorization and estimate the condition number of a general matrix A. If the condition number is not needed then SGEFA is slightly faster. It is typical to follow a call to SGEFO with a call to SGEESL to solve $Ax = b$ or to SGEEDI to compute the determinant and inverse of A.

[dgecon](#) - estimate the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF

[dgedi](#) (obsolete)- compute the determinant and inverse of a general matrix A, which has been LU-factored by SGEFO or SGEFA.

[dgeequ](#) - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

[dgees](#) - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

[dgeesx](#) - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

[dgeev](#) - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[dgeevx](#) - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[dgefa](#) (obsolete)- compute the LU factorization of a general matrix A. It is typical to follow a call to SGEFA with a call to SGEESL to solve $Ax = b$ or to SGEEDI to compute the determinant of A.

[dgegs](#) - routine is deprecated and has been replaced by routine SGGES

[dgegv](#) - routine is deprecated and has been replaced by routine SGGEV

[dgehrd](#) - reduce a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation

[dgelqf](#) - compute an LQ factorization of a real M-by-N matrix A

[dgelss](#) - solve overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A

[dgelstd](#) - compute the minimum-norm solution to a real linear least squares problem

[dgelss](#) - compute the minimum norm solution to a real linear least squares problem

[dgelssx](#) - routine is deprecated and has been replaced by routine SGELSY

[dgelssy](#) - compute the minimum-norm solution to a real linear least squares problem

[dgemm](#) - perform one of the matrix-matrix operations $C := \alpha * op(A) * op(B) + \beta * C$

[dgemv](#) - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$

[dgeqlf](#) - compute a QL factorization of a real M-by-N matrix A

[dgeqp3](#) - compute a QR factorization with column pivoting of a matrix A

[dgeqpf](#) - routine is deprecated and has been replaced by routine SGEQP3

[dgeqrf](#) - compute a QR factorization of a real M-by-N matrix A

[dger](#) - perform the rank 1 operation $A := \alpha * x * y' + A$

[dgerfs](#) - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

[dgerqf](#) - compute an RQ factorization of a real M-by-N matrix A

[dgesdd](#) - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors

[dgesl](#) (obsolete)- solve the linear system $Ax = b$ for a general matrix A, which has been LU- factored by SGECO or SGEFA, and vectors b and x.

[dgesv](#) - compute the solution to a real system of linear equations $A * X = B$,

[dgesvd](#) - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors

[dgesvx](#) - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$,

[dgetf2](#) - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

[dgetrf](#) - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

[dgetri](#) - compute the inverse of a matrix using the LU factorization computed by SGETRF

[dgetrs](#) - solve a system of linear equations $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A using the LU factorization computed by SGETRF

[dggbak](#) - form the right or left eigenvectors of a real generalized eigenvalue problem $A * x = \lambda * B * x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL

[dggbal](#) - balance a pair of general real matrices (A,B)

[dggges](#) - compute for a pair of N-by-N real nonsymmetric matrices (A,B),

[dgggesx](#) - compute for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and,

[dgggev](#) - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

[dgggevx](#) - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

[dggglm](#) - solve a general Gauss-Markov linear model (GLM) problem

[dggghrd](#) - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

[dggglse](#) - solve the linear equality-constrained least squares (LSE) problem

[dggqrf](#) - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

[dggqrqf](#) - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

[dggsvd](#) - compute the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B

[dggsvp](#) - compute orthogonal matrices U, V and Q such that $N-K-L \begin{pmatrix} K & L & U' * A * Q \\ 0 & A_{12} & A_{13} \end{pmatrix}$ if $M-K-L \geq 0$

[dgssco](#) - Condition number estimate

[dgssda](#) - Deallocate working storage

[dgssfa](#) - Numeric factorization

[dgssfs](#) - One call interface

[dgssin](#) - Initialize the sparse solver

[dgssor](#) - Orders and symbolically factors

[dgssps](#) - Print solver statics

[dgssrp](#) - Return permutation

[dgsssl](#) - Solve

[dgssuo](#) - User supplied permutation for ordering

[dgtcon](#) - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF

[dgtfrs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

[dgtsl](#) (obsolete)- solve the linear system $Ax = b$ for a tridiagonal matrix A and vectors b and x.

[dgtsv](#) - solve the equation $A^*X = B$,

[dgtsvx](#) - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$,

[dgttrf](#) - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

[dgttrs](#) - solve one of the systems of equations $A^*X = B$ or $A'^*X = B$,

[dhgeqz](#) - implement a single-/double-shift version of the QZ method for finding the generalized eigenvalues $w(j)=(ALPHAR(j) + i*ALPHAI(j))/BETAR(j)$ of the equation $\det(A-w(i) B) = 0$ In addition, the pair A,B may be reduced to generalized Schur form

[dhsein](#) - use inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H

[dhseqr](#) - compute the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors

[diamm](#) - diamm, sdiamm, ddiamm - diagonal format matrix-matrix multiply

[diasm](#) - diasmm, sdiasmm, ddiasmm - diagonal format triangular solve

[dlagtf](#) - factorize the matrix $(T-\lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as $T-\lambda I = PLU$

[dlamrg](#) - will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order

[dlarz](#) - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right

[dlarzb](#) - applies a real block reflector H or its transpose H^{**T} to a real distributed M-by-N C from the left or the right

[dlarzt](#) - form the triangular factor T of a real block reflector H of order $> n$, which is defined as a product of k elementary reflectors

[dlasrt](#) - the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D')

[dlatzm](#) - routine is deprecated and has been replaced by routine SORMRZ

[dnrm2](#) - Return the Euclidian norm of a vector.

[dopgtr](#) - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by SSPTRD using packed storage

[dopmtr](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dorg2l](#) - generate an m by n real matrix Q with orthonormal columns,

[dorg2r](#) - generate an m by n real matrix Q with orthonormal columns,

[dorgbr](#) - generate one of the real orthogonal matrices Q or P**T determined by SGEBRD when reducing a real matrix A to bidiagonal form

[dorghr](#) - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD

[dorgl2](#) - generate an m by n real matrix Q with orthonormal rows,

[dorglq](#) - generate an M-by-N real matrix Q with orthonormal rows,

[dorgql](#) - generate an M-by-N real matrix Q with orthonormal columns,

[dorgqr](#) - generate an M-by-N real matrix Q with orthonormal columns,

[dogr2](#) - generate an m by n real matrix Q with orthonormal rows,

[dogrq](#) - generate an M-by-N real matrix Q with orthonormal rows,

[dogrtr](#) - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD

[dormbr](#) - VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormhr](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormlq](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormql](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormqr](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormrq](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormrz](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dormtr](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[dpbco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in banded storage. If the condition number is not needed then SPBFA is slightly faster. It is typical to follow a call to SPBCO with a call to SPBSL to solve $Ax = b$ or to SPBDI to compute the determinant of A.

[dpbcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPBTRF

[dpbdi](#) (obsolete)- compute the determinant of a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by SPBCO or SPBFA.

[dpbequ](#) - compute row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm)

[dpbfa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A in banded storage. It is typical to follow a call to SPBFA with a call to SPBSL to solve $Ax = b$ or to SPBDI to compute the determinant of A.

[dpbrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution

[dpbsl](#) (obsolete)- section solve the linear system $Ax = b$ for a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by SPBCO or SPBFA, and vectors b and x.

[dpbstf](#) - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

[dpbsv](#) - compute the solution to a real system of linear equations $A * X = B$,

[dpbsvx](#) - use the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[dpbtf2](#) - compute the Cholesky factorization of a real symmetric positive definite band matrix A

[dpbtrf](#) - compute the Cholesky factorization of a real symmetric positive definite band matrix A

[dpbtrs](#) - solve a system of linear equations $A^*X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPBTRF

[dpoco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A. If the condition number is not needed then SPOFA is slightly faster. It is typical to follow a call to SPOCO with a call to SPOSL to solve $Ax = b$ or to SPODI to compute the determinant and inverse of A.

[dpocn](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPOTRF

[dpodi](#) (obsolete)- compute the determinant and inverse of a symmetric positive definite matrix A, which has been Cholesky-factored by SPOCO, SPOFA, or SQRDC.

[dpoequ](#) - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

[dpofa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A. It is typical to follow a call to SPOFA with a call to SPOSL to solve $Ax = b$ or to SPODI to compute the determinant and inverse of A.

[dporfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite,

[dposl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A, which has been Cholesky-factored by SPOCO or SPOFA, and vectors b and x.

[dposv](#) - compute the solution to a real system of linear equations $A^* X = B$,

[dposvx](#) - use the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ to compute the solution to a real system of linear equations $A^* X = B$,

[dpotf2](#) - compute the Cholesky factorization of a real symmetric positive definite matrix A

[dpotrf](#) - compute the Cholesky factorization of a real symmetric positive definite matrix A

[dpotri](#) - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPOTRF

[dpotrs](#) - solve a system of linear equations $A^*X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPOTRF

[dppco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in packed storage. If the condition number is not needed then SPPFA is slightly faster. It is typical to follow a call to SPPCO with a call to SPPSL to solve $Ax = b$ or to SPPDI to compute the determinant and inverse of A.

[dppcn](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPPTRF

[dppdi](#) (obsolete)- compute the determinant and inverse of a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by SPPCO or SPPFA.

[dppequ](#) - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

[dppfa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A in packed storage. It is typical to follow a call to SPPFA with a call to SPPSL to solve $Ax = b$ or to SPPDI to compute the determinant and inverse of A.

[dpprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution

[dppsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by SPPCO or SPPFA, and vectors b and x.

[dppsv](#) - compute the solution to a real system of linear equations $A^* X = B$,

[dppsvx](#) - use the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ to compute the solution to a real system of

linear equations $A * X = B$,

[dpptrf](#) - compute the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format

[dpptri](#) - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPPTRF

[dpptrs](#) - solve a system of linear equations $A*X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPPTRF

[dptcon](#) - compute the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L*D*L^{**T}$ or $A = U^{**T}D*U$ computed by SPTTRF

[dpteqr](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor

[dptrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

[dptsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite tridiagonal matrix A and vectors b and x.

[dptsv](#) - compute the solution to a real system of linear equations $A*X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

[dptsvx](#) - use the factorization $A = L*D*L^{**T}$ to compute the solution to a real system of linear equations $A*X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

[dpttrf](#) - compute the $L*D*L'$ factorization of a real symmetric positive definite tridiagonal matrix A

[dpttrs](#) - solve a tridiagonal system of the form $A * X = B$ using the $L*D*L'$ factorization of A computed by SPTTRF

[dptts2](#) - solve a tridiagonal system of the form $A * X = B$ using the $L*D*L'$ factorization of A computed by SPTTRF

[dqdota](#) - compute a double precision constant plus an extended precision constant plus the extended precision dot product of two double precision vectors x and y.

[dqdoti](#) - compute a constant plus the extended precision dot product of two double precision vectors x and y.

[dqrdc](#) (obsolete)- compute the QR factorization of a general matrix A. It is typical to follow a call to SQRDC with a call to SQRSL to solve $Ax = b$ or to SPODI to compute the determinant of A.

[dqrs](#) (obsolete)- solve the linear system $Ax = b$ for a general matrix A, which has been QR- factored by SQRDC, and vectors b and x.

[drot](#) - Apply a Given's rotation constructed by SROTG.

[drotg](#) - Construct a Given's plane rotation

[droti](#) - droti, sroti - Apply a Givens rotation to x and y

[drotm](#) - Apply a Gentleman's modified Given's rotation constructed by SROTMG.

[drotmg](#) - Construct a Gentleman's modified Given's plane rotation

[dsbev](#) - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[dsbevd](#) - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[dsbevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[dsbgst](#) - reduce a real symmetric-definite banded generalized eigenproblem $A*x = \text{lambda}*B*x$ to standard form $C*y = \text{lambda}*y$,

[dsbgv](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\text{lambda})*B*x$

[dsbgvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\text{lambda})*B*x$

[dsbgvx](#) - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded

eigenproblem, of the form $A*x=(\text{lambda})*B*x$

[dsbmv](#) - perform the matrix-vector operation $y := \alpha*A*x + \beta*y$

[dsbtrd](#) - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

[dscal](#) - Compute $y := \alpha * y$

[dsdot](#) - compute the double precision dot product of two single precision vectors x and y.

[dsecnd](#) - return the user time for a process in seconds

[dsico](#) (obsolete)- compute the UDU factorization and condition number of a symmetric matrix A. If the condition number is not needed then SSIFA is slightly faster. It is typical to follow a call to SSICO with a call to SSISL to solve $Ax = b$ or to SSIDI to compute the determinant, inverse, and inertia of A.

[dsidi](#) (obsolete)- compute the determinant, inertia, and inverse of a symmetric matrix A, which has been UDU-factored by SSICO or SSIFA.

[dsifa](#) (obsolete)- compute the UDU factorization of a symmetric matrix A. It is typical to follow a call to SSIFA with a call to SSISL to solve $Ax = b$ or to SSIDI to compute the determinant, inverse, and inertia of A.

[dsinqb](#) - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by $4 * N$.

[dsinqf](#) - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by $4 * N$.

[dsinqi](#) - initialize the array xWSAVE, which is used in both SINQF and SINQB.

[dsint](#) - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by $2 * (N+1)$.

[dsinti](#) - initialize the array WSAVE, which is used in subroutine SINT.

[dsisl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric matrix A, which has been UDU-factored by SSICO or SSIFA, and vectors b and x.

[dspco](#) (obsolete)- compute the UDU factorization and condition number of a symmetric matrix A in packed storage. If the condition number is not needed then SSPFA is slightly faster. It is typical to follow a call to DSPCO with a call to DSPSL to solve $Ax = b$ or to DSPDI to compute the determinant, inverse, and inertia of A.

[dspcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by SSPTRF

[dspdi](#) (obsolete)- compute the determinant, inertia, and inverse of a symmetric matrix A in packed storage, which has been UDU-factored by DSPCO or SSPFA.

[dspev](#) - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[dspevd](#) - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[dspevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[dspfa](#) (obsolete)- compute the UDU factorization of a symmetric matrix A in packed storage. It is typical to follow a call to DSPFA with a call to DSPSL to solve $Ax = b$ or to DSPDI to compute the determinant, inverse, and inertia of A.

[dspgst](#) - reduce a real symmetric-definite generalized eigenproblem to standard form, using packed storage

[dspgv](#) - compute all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\text{lambda})*B*x$, $A*Bx=(\text{lambda})*x$, or $B*A*x=(\text{lambda})*x$

[dspgvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\text{lambda})*B*x$, $A*Bx=(\text{lambda})*x$, or $B*A*x=(\text{lambda})*x$

[dspgvx](#) - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite

eigenproblem, of the form $A*x=(\text{lambda})*B*x$, $A*Bx=(\text{lambda})*x$, or $B*A*x=(\text{lambda})*x$

[dspmv](#) - perform the matrix-vector operation $y := \text{alpha}*A*x + \text{beta}*y$

[dspr](#) - perform the symmetric rank 1 operation $A := \text{alpha}*x*x' + A$

[dspr2](#) - perform the symmetric rank 2 operation $A := \text{alpha}*x*y' + \text{alpha}*y*x' + A$

[dsprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

[dspsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric matrix A in packed storage, which has been UDU-factored by SSPCO or SSPFA, and vectors b and x .

[dspsv](#) - compute the solution to a real system of linear equations $A * X = B$,

[dspsvx](#) - use the diagonal pivoting factorization $A = U*D*U**T$ or $A = L*D*L**T$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

[dsptrd](#) - reduce a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation

[dsptrf](#) - compute the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

[dsptri](#) - compute the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF

[dsptrs](#) - solve a system of linear equations $A*X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF

[dstebz](#) - compute the eigenvalues of a symmetric tridiagonal matrix T

[dstedc](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

[dstegr](#) - (a) Compute $T\text{-sigma}_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

[dstein](#) - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

[dstegr](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

[dsterf](#) - compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm

[dstev](#) - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[dstevd](#) - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix

[dstevr](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

[dstevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[dstsv](#) - compute the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix

[dsttrf](#) - compute the factorization of a symmetric tridiagonal matrix A

[dsttrs](#) - computes the solution to a real system of linear equations $A * X = B$

[dsvdc](#) (obsolete)- compute the singular value decomposition of a general matrix A .

[dswap](#) - Exchange vectors x and y .

[dsycon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF

[dsyev](#) - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[dsyevd](#) - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[dsyevr](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

[dsyevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[dsygs2](#) - reduce a real symmetric-definite generalized eigenproblem to standard form

[dsygst](#) - reduce a real symmetric-definite generalized eigenproblem to standard form

[dsygv](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[dsygvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[dsygvx](#) - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[dsymm](#) - perform one of the matrix-matrix operations $C := \alpha*A*B + \beta*C$ or $C := \alpha*B*A + \beta*C$

[dsymv](#) - perform the matrix-vector operation $y := \alpha*A*x + \beta*y$

[dsyr](#) - perform the symmetric rank 1 operation $A := \alpha*x*x' + A$

[dsyr2](#) - perform the symmetric rank 2 operation $A := \alpha*x*y' + \alpha*y*x' + A$

[dsyr2k](#) - perform one of the symmetric rank 2k operations $C := \alpha*A*B' + \alpha*B*A' + \beta*C$ or $C := \alpha*A'*B + \alpha*B'*A + \beta*C$

[dsyrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

[dsyrk](#) - perform one of the symmetric rank k operations $C := \alpha*A*A' + \beta*C$ or $C := \alpha*A'*A + \beta*C$

[dsysv](#) - compute the solution to a real system of linear equations $A * X = B$,

[dsysvx](#) - use the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$,

[dsytd2](#) - reduce a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

[dsytf2](#) - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[dsytrd](#) - reduce a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation

[dsytrf](#) - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[dsytri](#) - compute the inverse of a real symmetric indefinite matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF

[dsytrs](#) - solve a system of linear equations $A*X = B$ with a real symmetric matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSYTRF

[dtbcon](#) - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

[dtbmv](#) - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$

[dtbrfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

[dtbsv](#) - solve one of the systems of equations $A*x = b$, or $A'*x = b$

[dtbtrs](#) - solve a triangular system of the form $A * X = B$ or $A**T * X = B$,

[dtgevc](#) - compute some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B)

[dtgexc](#) - reorder the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation $(A, B) = Q * (A, B) * Z'$,

[dtgsen](#) - reorder the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q^* (A, B) Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B

[dtgsja](#) - compute the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B

[dtgsna](#) - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q^*A^*Z', Q^*B^*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z)

[dtgsyl](#) - solve the generalized Sylvester equation

[dtpcon](#) - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

[dtpmv](#) - perform one of the matrix-vector operations $x := A^*x$, or $x := A'^*x$

[dtpfrs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

[dtpsv](#) - solve one of the systems of equations $A^*x = b$, or $A'^*x = b$

[dtptri](#) - compute the inverse of a real upper or lower triangular matrix A stored in packed format

[dtptrs](#) - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

[dtrans](#) - transpose and scale source matrix

[dtrco](#) (obsolete)- estimate the condition number of a triangular matrix A. It is typical to follow a call to STRCO with a call to STRSL to solve $Ax = b$ or to STRDI to compute the determinant and inverse of A.

[dtrcon](#) - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

[dtrdi](#) (obsolete)- compute the determinant and inverse of a triangular matrix A.

[dtrevc](#) - compute some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T

[dtrexc](#) - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**T}$, so that the diagonal block of T with row index IFST is moved to row ILST

[dtrmm](#) - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$

[dtrmv](#) - perform one of the matrix-vector operations $x := A^*x$, or $x := A'^*x$

[dtrrfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

[dtrsen](#) - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**T}$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T,

[dtrsl](#) (obsolete)- solve the linear system $Ax = b$ for a triangular matrix A and vectors b and x.

[dtrsm](#) - solve one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$

[dtrсна](#) - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q^*T^*Q^{**T}$ with Q orthogonal)

[dtrsv](#) - solve one of the systems of equations $A^*x = b$, or $A'^*x = b$

[dtrsyl](#) - solve the real Sylvester matrix equation

[dtrti2](#) - compute the inverse of a real upper or lower triangular matrix

[dtrtri](#) - compute the inverse of a real upper or lower triangular matrix A

[dtrtrs](#) - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

[dtzrqf](#) - routine is deprecated and has been replaced by routine STZRZF

[dtzrzf](#) - reduce the M-by-N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of

orthogonal transformations

[dwiener](#) - perform Wiener deconvolution of two signals

[dzasum](#) - Return the sum of the absolute values of a vector x.

[dznrm2](#) - Return the Euclidian norm of a vector.

[ellmm](#) - ellmm, sellmm, dellmm - Ellpack format matrix-matrix multiply

[ellsm](#) - ellsm, sellsm, dellsm - Ellpack format triangular solve

[ezfftb](#) - computes a periodic sequence from its Fourier coefficients. EZFFTB is a simplified but slower version of RFFTB.

[ezfftf](#) - computes the Fourier coefficients of a periodic sequence. EZFFTF is a simplified but slower version of RFFTF.

[ezffti](#) - initializes the array WSAVE, which is used in both EZFFTF and EZFFTB.

[icamax](#) - return the index of the element with largest absolute value.

[idamax](#) - return the index of the element with largest absolute value.

[ilaenv](#) - The name of the calling subroutine, in either upper case or lower case.

[isamax](#) - return the index of the element with largest absolute value.

[izamax](#) - return the index of the element with largest absolute value.

[jadmm](#) - jadmm, sjadmm, djadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

[jadrp](#) - jadrp, sjadrp, djadrp - right permutation of a jagged diagonal matrix

[jadsm](#) - jadsm, sjadsm, djadsm - Jagged diagonal format triangular solve

[lsame](#) - returns .TRUE. if CA is the same letter as CB regardless of case

[rfft2b](#) - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by M*N.

[rfft2f](#) - compute the Fourier coefficients of a periodic sequence. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by M*N.

[rfft2i](#) - initialize the array WSAVE, which is used in both the forward and backward transforms.

[rfft3b](#) - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by M*N*K.

[rfft3f](#) - compute the Fourier coefficients of a real periodic sequence. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by M*N*K.

[rfft3i](#) - initialize the array WSAVE, which is used in both RFFT3F and RFFT3B.

[rfftb](#) - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFTF followed by a call of RFFTB will multiply the input sequence by N.

[rfftf](#) - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of RFFTF followed by a call of RFFTB will multiply the input sequence by N.

[rffti](#) - initialize the array WSAVE, which is used in both RFFTF and RFFTB.

[rfftopt](#) - compute the length of the closest fast FFT

[sasum](#) - Return the sum of the absolute values of a vector x.

[saxpy](#) - compute $y := \alpha * x + y$

[sbdsdc](#) - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B

[sbdsqr](#) - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

[scasum](#) - Return the sum of the absolute values of a vector x.

[schdc](#) (obsolete)- compute the Cholesky decomposition of a symmetric positive definite matrix A.

[schdd](#) (obsolete)- downdate an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

[schex](#) (obsolete)- compute the Cholesky decomposition of a symmetric positive definite matrix A.

[schud](#) (obsolete)- update an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

[scnrm2](#) - Return the Euclidian norm of a vector.

[scnvcor](#) - compute the convolution or correlation of real vectors

[scnvcor2](#) - compute the convolution or correlation of real matrices

[scopy](#) - Copy x to y

[sdisna](#) - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

[sdot](#) - compute the dot product of two vectors x and y.

[sdsdot](#) - compute a constant plus the double precision dot product of two single precision vectors x and y

[second](#) - return the user time for a process in seconds

[sgbbnd](#) - reduce a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation

[sgbco](#) (obsolete)- compute the LU factorization and condition number of a general matrix A in banded storage. If the condition number is not needed then SGBFA is slightly faster. It is typical to follow a call to SGBCO with a call to SGBSL to solve $Ax = b$ or to SGBDI to compute the determinant of A.

[sgbcon](#) - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

[sgbdi](#) (obsolete)- compute the determinant of a general matrix A in banded storage, which has been LU-factored by SGBCO or SGBFA.

[sgbequ](#) - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

[sgbfa](#) (obsolete)- compute the LU factorization of a matrix A in banded storage. It is typical to follow a call to SGBFA with a call to SGBSL to solve $Ax = b$ or to SGBDI to compute the determinant of A.

[sgbmv](#) - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$

[sgbrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

[sgbsl](#) (obsolete)- solve the linear system $Ax = b$ for a matrix A in banded storage, which has been LU-factored by SGBCO or SGBFA, and vectors b and x.

[sgbsv](#) - compute the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

[sgbsvx](#) - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[sgbtf2](#) - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

[sgbtrf](#) - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

[sgbtrs](#) - solve a system of linear equations $A * X = B$ or $A' * X = B$ with a general band matrix A using the LU factorization computed by SGBTRF

[sgebak](#) - form the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL

[sgebal](#) - balance a general real matrix A

[sgebrd](#) - reduce a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal

transformation

[sgeco](#) (obsolete)- compute the LU factorization and estimate the condition number of a general matrix A. If the condition number is not needed then SGEFA is slightly faster. It is typical to follow a call to SGECO with a call to SGESL to solve $Ax = b$ or to SGEDI to compute the determinant and inverse of A.

[sgecon](#) - estimate the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF

[sgedi](#) (obsolete)- compute the determinant and inverse of a general matrix A, which has been LU-factored by SGECO or SGEFA.

[sgeequ](#) - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

[sgees](#) - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

[sgeesx](#) - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

[sgeev](#) - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[sgeevx](#) - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[sgefa](#) (obsolete)- compute the LU factorization of a general matrix A. It is typical to follow a call to SGEFA with a call to SGESL to solve $Ax = b$ or to SGEDI to compute the determinant of A.

[sgegs](#) - routine is deprecated and has been replaced by routine SGGES

[sgegv](#) - routine is deprecated and has been replaced by routine SGGEV

[sgehrd](#) - reduce a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation

[sgeqlf](#) - compute an LQ factorization of a real M-by-N matrix A

[sgeels](#) - solve overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A

[sgeelsd](#) - compute the minimum-norm solution to a real linear least squares problem

[sgeelss](#) - compute the minimum norm solution to a real linear least squares problem

[sgeelsx](#) - routine is deprecated and has been replaced by routine SGELSY

[sgeelsy](#) - compute the minimum-norm solution to a real linear least squares problem

[sgemm](#) - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

[sgemv](#) - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$

[sgeqlf](#) - compute a QL factorization of a real M-by-N matrix A

[sgeqp3](#) - compute a QR factorization with column pivoting of a matrix A

[sgeqpf](#) - routine is deprecated and has been replaced by routine SGEQP3

[sgeqrf](#) - compute a QR factorization of a real M-by-N matrix A

[sger](#) - perform the rank 1 operation $A := \alpha * x * y' + A$

[sgerfs](#) - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

[sgerqf](#) - compute an RQ factorization of a real M-by-N matrix A

[sgesdd](#) - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors

[sgesl](#) (obsolete)- solve the linear system $Ax = b$ for a general matrix A, which has been LU- factored by SGECO or

SGEFA, and vectors b and x.

[sgesv](#) - compute the solution to a real system of linear equations $A * X = B$,

[sgesvd](#) - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors

[sgesvx](#) - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$,

[sgetf2](#) - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

[sgetrf](#) - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

[sgetri](#) - compute the inverse of a matrix using the LU factorization computed by SGETRF

[sgetrs](#) - solve a system of linear equations $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A using the LU factorization computed by SGETRF

[sggbak](#) - form the right or left eigenvectors of a real generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL

[sggbal](#) - balance a pair of general real matrices (A,B)

[sgges](#) - compute for a pair of N-by-N real nonsymmetric matrices (A,B),

[sggesx](#) - compute for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and,

[sggev](#) - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

[sggevx](#) - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

[sggglm](#) - solve a general Gauss-Markov linear model (GLM) problem

[sgghrd](#) - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

[sgglse](#) - solve the linear equality-constrained least squares (LSE) problem

[sggqrf](#) - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

[sggrqf](#) - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

[sggsvd](#) - compute the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B

[sggsvp](#) - compute orthogonal matrices U, V and Q such that $N-K-L \begin{matrix} K & L & U^* & A^* & Q \end{matrix} = \begin{matrix} K & (0 & A_{12} & A_{13}) \end{matrix}$ if $M-K-L \geq 0$

[sgtcon](#) - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTTRF

[sgtrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

[sgtsl](#) (obsolete)- solve the linear system $Ax = b$ for a tridiagonal matrix A and vectors b and x.

[sgtsv](#) - solve the equation $A*X = B$,

[sgtsvx](#) - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$,

[sgttrf](#) - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

[sgttrs](#) - solve one of the systems of equations $A*X = B$ or $A^*X = B$,

[shgeqz](#) - implement a single-/double-shift version of the QZ method for finding the generalized eigenvalues $w(j)=(ALPHAR(j) + i*ALPHAI(j))/BETAR(j)$ of the equation $\det(A-w(i) B) = 0$ In addition, the pair A,B may be reduced to generalized Schur form

[shsein](#) - use inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H

[shseqr](#) - compute the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the

Schur decomposition $H = Z T Z^{**T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors

[singb](#) - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by $4 * N$.

[singf](#) - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by $4 * N$.

[sinqi](#) - initialize the array xWSAVE, which is used in both SINQF and SINQB.

[sint](#) - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by $2 * (N+1)$.

[sinti](#) - initialize the array WSAVE, which is used in subroutine SINT.

[skymm](#) - skymm, sskymm, dskymm - Skyline format matrix-matrix multiply

[skysm](#) - skysm, sskysm, dskysm - Skyline format triangular solve

[slagtf](#) - factorize the matrix $(T - \lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as $T - \lambda I = PLU$

[slamrg](#) - will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order

[slarz](#) - applies a real elementary reflector H to a real M -by- N matrix C , from either the left or the right

[slarzb](#) - applies a real block reflector H or its transpose H^{**T} to a real distributed M -by- N C from the left or the right

[slarzt](#) - form the triangular factor T of a real block reflector H of order $> n$, which is defined as a product of k elementary reflectors

[slasrt](#) - the numbers in D in increasing order (if $ID = 'I'$) or in decreasing order (if $ID = 'D'$)

[slatzm](#) - routine is deprecated and has been replaced by routine SORMRZ

[snrm2](#) - Return the Euclidian norm of a vector.

[sopgtr](#) - generate a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by SSPTRD using packed storage

[sopmtr](#) - overwrite the general real M -by- N matrix C with $SIDE = 'L'$ $SIDE = 'R'$ $TRANS = 'N'$

[sorg2l](#) - generate an m by n real matrix Q with orthonormal columns,

[sorg2r](#) - generate an m by n real matrix Q with orthonormal columns,

[sorgbr](#) - generate one of the real orthogonal matrices Q or P^{**T} determined by SGEBRD when reducing a real matrix A to bidiagonal form

[sorghr](#) - generate a real orthogonal matrix Q which is defined as the product of $IHI-ILO$ elementary reflectors of order N , as returned by SGEHRD

[sorgl2](#) - generate an m by n real matrix Q with orthonormal rows,

[sorglq](#) - generate an M -by- N real matrix Q with orthonormal rows,

[sorgql](#) - generate an M -by- N real matrix Q with orthonormal columns,

[sorgqr](#) - generate an M -by- N real matrix Q with orthonormal columns,

[sorgr2](#) - generate an m by n real matrix Q with orthonormal rows,

[sorgrq](#) - generate an M -by- N real matrix Q with orthonormal rows,

[sorgtr](#) - generate a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by SSYTRD

[sormbr](#) - VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormhr](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormlq](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormql](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormqr](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormrq](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormrz](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[sormtr](#) - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[spbco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in banded storage. If the condition number is not needed then SPBFA is slightly faster. It is typical to follow a call to SPBCO with a call to SPBSL to solve $Ax = b$ or to SPBDI to compute the determinant of A.

[spbcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPBTRF

[spbdi](#) (obsolete)- compute the determinant of a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by SPBCO or SPBFA.

[spbegu](#) - compute row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm)

[spbfa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A in banded storage. It is typical to follow a call to SPBFA with a call to SPBSL to solve $Ax = b$ or to SPBDI to compute the determinant of A.

[spbfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution

[spbsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by SPBCO or SPBFA, and vectors b and x.

[spbstf](#) - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

[spbsv](#) - compute the solution to a real system of linear equations $A * X = B$,

[spbsvx](#) - use the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[spbtf2](#) - compute the Cholesky factorization of a real symmetric positive definite band matrix A

[spbtrf](#) - compute the Cholesky factorization of a real symmetric positive definite band matrix A

[spbtrs](#) - solve a system of linear equations $A * X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPBTRF

[spoco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A. If the condition number is not needed then SPOFA is slightly faster. It is typical to follow a call to SPOCO with a call to SPOSL to solve $Ax = b$ or to SPODI to compute the determinant and inverse of A.

[spocon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPOTRF

[spodi](#) (obsolete)- compute the determinant and inverse of a symmetric positive definite matrix A, which has been Cholesky-factored by SPOCO, SPOFA, or SQRDC.

[spoegu](#) - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

[spofa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A. It is typical to follow a call to SPOFA with a call to SPOSL to solve $Ax = b$ or to SPODI to compute the determinant and inverse of A.

[sporfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric

positive definite,

[sposl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A , which has been Cholesky-factored by SPOCO or SPOFA, and vectors b and x .

[sposv](#) - compute the solution to a real system of linear equations $A * X = B$,

[sposvx](#) - use the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[spotf2](#) - compute the Cholesky factorization of a real symmetric positive definite matrix A

[spotrf](#) - compute the Cholesky factorization of a real symmetric positive definite matrix A

[spotri](#) - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPOTRF

[spotrs](#) - solve a system of linear equations $A * X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPOTRF

[sppco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in packed storage. If the condition number is not needed then SPPFA is slightly faster. It is typical to follow a call to SPPCO with a call to SPPSL to solve $Ax = b$ or to SPPDI to compute the determinant and inverse of A .

[sppcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPPTRF

[sppdi](#) (obsolete)- compute the determinant and inverse of a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by SPPCO or SPPFA.

[sppegu](#) - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

[sppfa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A in packed storage. It is typical to follow a call to SPPFA with a call to SPPSL to solve $Ax = b$ or to SPPDI to compute the determinant and inverse of A .

[spprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution

[sppsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by SPPCO or SPPFA, and vectors b and x .

[sppsv](#) - compute the solution to a real system of linear equations $A * X = B$,

[sppsvx](#) - use the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$,

[spptrf](#) - compute the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format

[spptri](#) - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPPTRF

[spptrs](#) - solve a system of linear equations $A * X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$ computed by SPPTRF

[sptcon](#) - compute the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L^*D^*L^{**T}$ or $A = U^{**T}D^*U$ computed by SPTTRF

[spteqr](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor

[sptrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

[sptsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite tridiagonal matrix A and vectors b and x .

[sptsv](#) - compute the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric positive definite tridiagonal matrix, and X and B are N -by- N matrices.

[sptsvx](#) - use the factorization $A = L^*D^*L^{**T}$ to compute the solution to a real system of linear equations $A^*X = B$, where A is an N -by- N symmetric positive definite tridiagonal matrix and X and B are N -by- N -RHS matrices

[spttrf](#) - compute the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A

[spttrs](#) - solve a tridiagonal system of the form $A^*X = B$ using the L^*D^*L' factorization of A computed by SPTTRF

[sptts2](#) - solve a tridiagonal system of the form $A^*X = B$ using the L^*D^*L' factorization of A computed by SPTTRF

[sqrdc](#) (obsolete)- compute the QR factorization of a general matrix A . It is typical to follow a call to SQRDC with a call to SQRSL to solve $Ax = b$ or to SPODI to compute the determinant of A .

[sqrsl](#) (obsolete)- solve the linear system $Ax = b$ for a general matrix A , which has been QR- factored by SQRDC, and vectors b and x .

[srot](#) - Apply a Given's rotation constructed by SROTG.

[srotg](#) - Construct a Given's plane rotation

[srotm](#) - Apply a Gentleman's modified Given's rotation constructed by SROTMG.

[srotmg](#) - Construct a Gentleman's modified Given's plane rotation

[ssbev](#) - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[ssbevd](#) - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[ssbevz](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

[ssbgst](#) - reduce a real symmetric-definite banded generalized eigenproblem $A^*x = \lambda B^*x$ to standard form $C^*y = \lambda y$,

[ssbgv](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[ssbgvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[ssbgvx](#) - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A^*x = (\lambda B)^*x$

[ssbmvs](#) - perform the matrix-vector operation $y := \alpha A^*x + \beta y$

[ssbtrd](#) - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

[sscal](#) - Compute $y := \alpha * y$

[ssico](#) (obsolete)- compute the UDU factorization and condition number of a symmetric matrix A . If the condition number is not needed then SSIFA is slightly faster. It is typical to follow a call to SSICO with a call to SSISL to solve $Ax = b$ or to SSIDI to compute the determinant, inverse, and inertia of A .

[ssidi](#) (obsolete)- compute the determinant, inertia, and inverse of a symmetric matrix A , which has been UDU-factored by SSICO or SSIFA.

[ssifa](#) (obsolete)- compute the UDU factorization of a symmetric matrix A . It is typical to follow a call to SSIFA with a call to SSISL to solve $Ax = b$ or to SSIDI to compute the determinant, inverse, and inertia of A .

[ssisl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric matrix A , which has been UDU-factored by SSICO or SSIFA, and vectors b and x .

[sspcv](#) (obsolete)- compute the UDU factorization and condition number of a symmetric matrix A in packed storage. If the condition number is not needed then SSPFA is slightly faster. It is typical to follow a call to SSPCO with a call to SSPSL to solve $Ax = b$ or to SSPDI to compute the determinant, inverse, and inertia of A .

[sspcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSPTRF

[sspdi](#) (obsolete)- compute the determinant, inertia, and inverse of a symmetric matrix A in packed storage, which has been UDU-factored by SSPCO or SSPFA.

[sspev](#) - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[sspevd](#) - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[sspevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

[sspfa](#) (obsolete)- compute the UDU factorization of a symmetric matrix A in packed storage. It is typical to follow a call to SSPFA with a call to SSPSL to solve $Ax = b$ or to SSPDI to compute the determinant, inverse, and inertia of A.

[sspgst](#) - reduce a real symmetric-definite generalized eigenproblem to standard form, using packed storage

[sspgv](#) - compute all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[sspgvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[sspgvx](#) - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

[sspmv](#) - perform the matrix-vector operation $y := \alpha*A*x + \beta*y$

[sspr](#) - perform the symmetric rank 1 operation $A := \alpha*x*x' + A$

[sspr2](#) - perform the symmetric rank 2 operation $A := \alpha*x*y' + \alpha*y*x' + A$

[ssprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

[sspsti](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric matrix A in packed storage, which has been UDU-factored by SSPCO or SSPFA, and vectors b and x.

[sspsv](#) - compute the solution to a real system of linear equations $A * X = B$,

[sspsvx](#) - use the diagonal pivoting factorization $A = U*D*U**T$ or $A = L*D*L**T$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

[ssptrd](#) - reduce a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation

[ssptrf](#) - compute the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

[ssptri](#) - compute the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF

[ssptrs](#) - solve a system of linear equations $A*X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF

[sstebz](#) - compute the eigenvalues of a symmetric tridiagonal matrix T

[sstedc](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

[sstegr](#) - (a) Compute $T-\sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

[sstein](#) - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

[sstegr](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

[ssterr](#) - compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm

[sstev](#) - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[sstevd](#) - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix

[sstevr](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

[sstevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

[sstsv](#) - compute the solution to a system of linear equations $A * X = B$ where A is a symmetric tridiagonal matrix

[ssttrf](#) - compute the factorization of a symmetric tridiagonal matrix A

[ssttrs](#) - computes the solution to a real system of linear equations $A * X = B$

[ssvdc](#) (obsolete)- compute the singular value decomposition of a general matrix A.

[sswap](#) - Exchange vectors x and y.

[ssycon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ computed by SSYTRF

[ssyev](#) - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[ssyevd](#) - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[ssyevr](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

[ssyevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

[ssygs2](#) - reduce a real symmetric-definite generalized eigenproblem to standard form

[ssygst](#) - reduce a real symmetric-definite generalized eigenproblem to standard form

[ssygv](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A * x = (\text{lambda}) * B * x$, $A * Bx = (\text{lambda}) * x$, or $B * A * x = (\text{lambda}) * x$

[ssygvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A * x = (\text{lambda}) * B * x$, $A * Bx = (\text{lambda}) * x$, or $B * A * x = (\text{lambda}) * x$

[ssygvx](#) - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A * x = (\text{lambda}) * B * x$, $A * Bx = (\text{lambda}) * x$, or $B * A * x = (\text{lambda}) * x$

[ssymm](#) - perform one of the matrix-matrix operations $C := \text{alpha} * A * B + \text{beta} * C$ or $C := \text{alpha} * B * A + \text{beta} * C$

[ssymv](#) - perform the matrix-vector operation $y := \text{alpha} * A * x + \text{beta} * y$

[ssyr](#) - perform the symmetric rank 1 operation $A := \text{alpha} * x * x' + A$

[ssyr2](#) - perform the symmetric rank 2 operation $A := \text{alpha} * x * y' + \text{alpha} * y * x' + A$

[ssyr2k](#) - perform one of the symmetric rank 2k operations $C := \text{alpha} * A * B' + \text{alpha} * B * A' + \text{beta} * C$ or $C := \text{alpha} * A' * B + \text{alpha} * B' * A + \text{beta} * C$

[ssyrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

[ssyrk](#) - perform one of the symmetric rank k operations $C := \text{alpha} * A * A' + \text{beta} * C$ or $C := \text{alpha} * A' * A + \text{beta} * C$

[ssysv](#) - compute the solution to a real system of linear equations $A * X = B$,

[ssysvx](#) - use the diagonal pivoting factorization to compute the solution to a real system of linear equations $A * X = B$,

[ssytd2](#) - reduce a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

[ssytf2](#) - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[ssytrd](#) - reduce a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation

[ssytrf](#) - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[ssytri](#) - compute the inverse of a real symmetric indefinite matrix A using the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ computed by SSYTRF

[ssytrs](#) - solve a system of linear equations $A * X = B$ with a real symmetric matrix A using the factorization $A =$

$U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by SSYTRF

[stbcon](#) - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

[stbmv](#) - perform one of the matrix-vector operations $x := A^*x$, or $x := A'^*x$

[stbrfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

[stbsv](#) - solve one of the systems of equations $A^*x = b$, or $A'^*x = b$

[stbtrs](#) - solve a triangular system of the form $A^*X = B$ or $A'^**T^*X = B$,

[stgevc](#) - compute some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B)

[stgexc](#) - reorder the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation $(A, B) = Q^*(A, B)^*Z'$,

[stgsen](#) - reorder the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence transformation $Q'^*(A, B)^*Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B

[stgsja](#) - compute the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B

[stgsna](#) - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q^*A^*Z', Q^*B^*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z

[stgsyl](#) - solve the generalized Sylvester equation

[stpcon](#) - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

[stpmv](#) - perform one of the matrix-vector operations $x := A^*x$, or $x := A'^*x$

[stprfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

[stpsv](#) - solve one of the systems of equations $A^*x = b$, or $A'^*x = b$

[stptri](#) - compute the inverse of a real upper or lower triangular matrix A stored in packed format

[stptrs](#) - solve a triangular system of the form $A^*X = B$ or $A'^**T^*X = B$,

[strans](#) - transpose and scale source matrix

[strco](#) (obsolete)- estimate the condition number of a triangular matrix A. It is typical to follow a call to STRCO with a call to STRSL to solve $Ax = b$ or to STRDI to compute the determinant and inverse of A.

[strcon](#) - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

[strdi](#) (obsolete)- compute the determinant and inverse of a triangular matrix A.

[strevc](#) - compute some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T

[strex](#) - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**T}$, so that the diagonal block of T with row index IFST is moved to row ILST

[strmm](#) - perform one of the matrix-matrix operations $B := \alpha^*\text{op}(A)^*B$, or $B := \alpha^*B^*\text{op}(A)$

[strmv](#) - perform one of the matrix-vector operations $x := A^*x$, or $x := A'^*x$

[strrfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

[strsen](#) - reorder the real Schur factorization of a real matrix $A = Q^*T^*Q^{**T}$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T,

[strsl](#) (obsolete)- solve the linear system $Ax = b$ for a triangular matrix A and vectors b and x .

[strsm](#) - solve one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$

[strsna](#) - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix $Q * T * Q^{**T}$ with Q orthogonal)

[strsv](#) - solve one of the systems of equations $A * x = b$, or $A' * x = b$

[strsyl](#) - solve the real Sylvester matrix equation

[strti2](#) - compute the inverse of a real upper or lower triangular matrix

[strtri](#) - compute the inverse of a real upper or lower triangular matrix A

[strtrs](#) - solve a triangular system of the form $A * X = B$ or $A^{**T} * X = B$,

[stzrqf](#) - routine is deprecated and has been replaced by routine STZRZF

[stzrzf](#) - reduce the M -by- N ($M \leq N$) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations

[sunperf_version](#) - gets library information .HP 1i SUBROUTINE SUNPERF_VERSION(VERSION, PATCH, UPDATE) .HP 1i INTEGER VERSION, PATCH, UPDATE .HP 1i

[swiener](#) - perform Wiener deconvolution of two signals

[use_threads](#) - set the upper bound on the number of threads that the calling thread wants used

[using_threads](#) - returns the current Use number set by the USE_THREADS subroutine

[vbrmm](#) - vbrmm, svbrmm, dvbrmm - variable block sparse row format matrix-matrix multiply

[vbrsm](#) - vbrsm, svbrsm, dvbrsm - variable block sparse row format triangular solve

[vcfftb](#) - compute a periodic sequence from its Fourier coefficients. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

[vcfftf](#) - compute the Fourier coefficients of a periodic sequence. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

[vcffti](#) - initialize the array WSAVE, which is used in both VCFFTF and VCFFTB.

[vcosqb](#) - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

[vcosqf](#) - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

[vcosqi](#) - initialize the array WSAVE, which is used in both VCOSQF and VCOSQB.

[vcost](#) - compute the discrete Fourier cosine transform of an even sequence. The VCOST transform is normalized, so a call of VCOST followed by a call of VCOST will return the original sequence.

[vcosti](#) - initialize the array WSAVE, which is used in VCOST.

[vdcosqb](#) - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

[vdcosqf](#) - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

[vdcosqi](#) - initialize the array WSAVE, which is used in both VCOSQF and VCOSQB.

[vdcost](#) - compute the discrete Fourier cosine transform of an even sequence. The VCOST transform is normalized, so a call of VCOST followed by a call of VCOST will return the original sequence.

[vdcosti](#) - initialize the array WSAVE, which is used in VCOST.

[vdfftb](#) - compute a periodic sequence from its Fourier coefficients. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

[vdfftf](#) - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

[vdffti](#) - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

[vdsinqb](#) - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

[vdsinqf](#) - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

[vdsinqi](#) - initialize the array WSAVE, which is used in both VSINQF and VSINQB.

[vdsint](#) - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by $2 * (N+1)$. The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

[vdsinti](#) - initialize the array WSAVE, which is used in subroutine VSINT.

[vrfftb](#) - compute a periodic sequence from its Fourier coefficients. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

[vrfftf](#) - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

[vrffti](#) - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

[vsinqb](#) - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

[vsinqf](#) - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

[vsinqi](#) - initialize the array WSAVE, which is used in both VSINQF and VSINQB.

[vsint](#) - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by $2 * (N+1)$. The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

[vsinti](#) - initialize the array WSAVE, which is used in subroutine VSINT.

[vzfftb](#) - compute a periodic sequence from its Fourier coefficients. The VZFFT operations are normalized, so a call of VZFFTF followed by a call of VZFFTB will return the original sequence.

[vzfftf](#) - compute the Fourier coefficients of a periodic sequence. The VZFFT operations are normalized, so a call of VZFFTF followed by a call of VZFFTB will return the original sequence.

[vzffti](#) - initialize the array WSAVE, which is used in both VZFFTF and VZFFTB.

[zaxpy](#) - compute $y := \alpha * x + y$

[zbdsgqr](#) - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

[zchdc](#) (obsolete)- compute the Cholesky decomposition of a symmetric positive definite matrix A.

[zchdd](#) (obsolete)- downdate an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

[zchex](#) (obsolete)- compute the Cholesky decomposition of a symmetric positive definite matrix A.

[zchud](#) (obsolete)- update an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

[zcnvcor](#) - compute the convolution or correlation of complex vectors

[zcnvcor2](#) - compute the convolution or correlation of complex matrices

[zcopy](#) - Copy x to y

[zdotc](#) - compute the dot product of two vectors x and conjg(y).

[zdotu](#) - compute the dot product of two vectors x and y.

[zdrot](#) - Apply a plane rotation.

[zdscal](#) - Compute $y := \alpha * y$

[zfft2b](#) - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by $M*N$.

[zfft2f](#) - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by $M*N$.

[zfft2i](#) - initialize the array WSAVE, which is used in both the forward and backward transforms.

[zfft3b](#) - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT3F followed by a call of ZFFT3B will multiply the input sequence by $M*N*K$.

[zfft3f](#) - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFT3F followed by a call of ZFFT3B will multiply the input sequence by $M*N*K$.

[zfft3i](#) - initialize the array WSAVE, which is used in both ZFFT3F and ZFFT3B.

[zfftb](#) - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N.

[zfftf](#) - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N.

[zffti](#) - initialize the array WSAVE, which is used in both ZFFTF and ZFFTB.

[zfftopt](#) - compute the length of the closest fast FFT

[zgbbrd](#) - reduce a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation

[zgbco](#) (obsolete)- compute the LU factorization and condition number of a general matrix A in banded storage. If the condition number is not needed then xGBFA is slightly faster. It is typical to follow a call to xGBCO with a call to xGBSL to solve $Ax = b$ or to xGBDI to compute the determinant of A.

[zgbcon](#) - estimate the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm,

[zgbdi](#) (obsolete)- compute the determinant of a general matrix A in banded storage, which has been LU-factored by CGBCO or CGBFA.

[zgbegu](#) - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

[zgbfa](#) (obsolete)- compute the LU factorization of a matrix A in banded storage. It is typical to follow a call to CGBFA with a call to CGBSL to solve $Ax = b$ or to CGBDI to compute the determinant of A.

[zgbmv](#) - perform one of the matrix-vector operations $y := \alpha*A*x + \beta*y$, or $y := \alpha*A'*x + \beta*y$, or $y := \alpha*conjg(A')*x + \beta*y$

[zgbtrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

[zgbsl](#) (obsolete)- solve the linear system $Ax = b$ for a matrix A in banded storage, which has been LU-factored by CGBCO or CGBFA, and vectors b and x.

[zgbsv](#) - compute the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

[zgbsvx](#) - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

[zgbtf2](#) - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

[zgbtrf](#) - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

[zgbtrs](#) - solve a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general band matrix A using the LU factorization computed by CGBTRF

[zgebak](#) - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

[zgebal](#) - balance a general complex matrix A

[zgebrd](#) - reduce a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation

[zgeco](#) (obsolete)- compute the LU factorization and estimate the condition number of a general matrix A. If the condition number is not needed then CGEFA is slightly faster. It is typical to follow a call to ZGECO with a call to CGESL to solve $Ax = b$ or to CGEDI to compute the determinant and inverse of A.

[zgecon](#) - estimate the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF

[zgedi](#) (obsolete)- compute the determinant and inverse of a general matrix A, which has been LU-factored by ZGECO or CGEFA.

[zgeequ](#) - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

[zgees](#) - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

[zgeesx](#) - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

[zgeev](#) - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[zgeevx](#) - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

[zgefa](#) (obsolete)- compute the LU factorization of a general matrix A. It is typical to follow a call to CGEFA with a call to CGESL to solve $Ax = b$ or to CGEDI to compute the determinant of A.

[zgegs](#) - routine is deprecated and has been replaced by routine CGGES

[zgegv](#) - routine is deprecated and has been replaced by routine CGGEV

[zgehrd](#) - reduce a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation

[zgelqf](#) - compute an LQ factorization of a complex M-by-N matrix A

[zgels](#) - solve overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A

[zgelsd](#) - compute the minimum-norm solution to a real linear least squares problem

[zgelsz](#) - compute the minimum norm solution to a complex linear least squares problem

[zgelsx](#) - routine is deprecated and has been replaced by routine CGELSY

[zgelsy](#) - compute the minimum-norm solution to a complex linear least squares problem

[zgemm](#) - perform one of the matrix-matrix operations $C := \alpha * op(A) * op(B) + \beta * C$

[zgemv](#) - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * conjg(A') * x + \beta * y$

[zgeqlf](#) - compute a QL factorization of a complex M-by-N matrix A

[zgeqp3](#) - compute a QR factorization with column pivoting of a matrix A

[zgeqpf](#) - routine is deprecated and has been replaced by routine CGEQP3

[zgeqrf](#) - compute a QR factorization of a complex M-by-N matrix A

[zgerc](#) - perform the rank 1 operation $A := \alpha * x * \text{conjg}(y') + A$

[zgerfs](#) - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

[zgerqf](#) - compute an RQ factorization of a complex M-by-N matrix A

[zgeru](#) - perform the rank 1 operation $A := \alpha * x * y' + A$

[zgesdd](#) - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method

[zgesl](#) (obsolete)- solve the linear system $Ax = b$ for a general matrix A, which has been LU- factored by CGECO or CGEFA, and vectors b and x.

[zgesv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[zgesvd](#) - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors

[zgesvx](#) - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$,

[zgetf2](#) - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

[zgetrf](#) - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

[zgetri](#) - compute the inverse of a matrix using the LU factorization computed by CGETRF

[zgetrs](#) - solve a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general N-by-N matrix A using the LU factorization computed by CGETRF

[zggbak](#) - form the right or left eigenvectors of a complex generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL

[zggbal](#) - balance a pair of general complex matrices (A,B)

[zggess](#) - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR)

[zggessx](#) - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T),

[zggeev](#) - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

[zggevx](#) - compute for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

[zggglm](#) - solve a general Gauss-Markov linear model (GLM) problem

[zggghrd](#) - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

[zgglsq](#) - solve the linear equality-constrained least squares (LSE) problem

[zggqrf](#) - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

[zggqrqf](#) - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

[zggsvd](#) - compute the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B

[zggsvp](#) - compute unitary matrices U, V and Q such that $N-K-L \begin{matrix} K & L \\ U^* & A^* & Q \end{matrix} = \begin{matrix} K & 0 & A_{12} & A_{13} \end{matrix}$ if $M-K-L \geq 0$

[zgtcon](#) - estimate the reciprocal of the condition number of a complex tridiagonal matrix A using the LU

factorization as computed by CGTTRF

[zgtrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

[zgtsl](#) (obsolete) - solve the linear system $Ax = b$ for a tridiagonal matrix A and vectors b and x .

[zgtsv](#) - solve the equation $A^*X = B$,

[zgtsvx](#) - use the LU factorization to compute the solution to a complex system of linear equations $A^*X = B$, $A^{**T}^*X = B$, or $A^{**H}^*X = B$,

[zgttrf](#) - compute an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges

[zgttrs](#) - solve one of the systems of equations $A^*X = B$, $A^{**T}^*X = B$, or $A^{**H}^*X = B$,

[zhbev](#) - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[zhbevd](#) - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[zhbevz](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

[zhbgst](#) - reduce a complex Hermitian-definite banded generalized eigenproblem $A^*x = \lambda B^*x$ to standard form $C^*y = \lambda y$,

[zhbgv](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda)B^*x$

[zhbgvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda)B^*x$

[zhbgvx](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A^*x = (\lambda)B^*x$

[zhbmz](#) - perform the matrix-vector operation $y := \alpha A^*x + \beta y$

[zhbtrd](#) - reduce a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

[zhecon](#) - estimate the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

[zheev](#) - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[zheevd](#) - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[zheevr](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T

[zheevz](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

[zhegs2](#) - reduce a complex Hermitian-definite generalized eigenproblem to standard form

[zhegst](#) - reduce a complex Hermitian-definite generalized eigenproblem to standard form

[zhegv](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x = (\lambda)B^*x$, $A^*Bx = (\lambda)x$, or $B^*A^*x = (\lambda)x$

[zhegvd](#) - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x = (\lambda)B^*x$, $A^*Bx = (\lambda)x$, or $B^*A^*x = (\lambda)x$

[zhegvz](#) - compute selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x = (\lambda)B^*x$, $A^*Bx = (\lambda)x$, or $B^*A^*x = (\lambda)x$

[zhemm](#) - perform one of the matrix-matrix operations $C := \alpha A^*B + \beta C$ or $C := \alpha B^*A + \beta C$

[zhemv](#) - perform the matrix-vector operation $y := \alpha A^*x + \beta y$

[zher](#) - perform the hermitian rank 1 operation $A := \alpha x^* \text{conjg}(x') + A$

[zher2](#) - perform the hermitian rank 2 operation $A := \alpha x^* \text{conjg}(y') + \text{conjg}(\alpha) y^* \text{conjg}(x') + A$

[zher2k](#) - perform one of the Hermitian rank 2k operations $C := \alpha A^* \text{conjg}(B') + \text{conjg}(\alpha) B^* \text{conjg}(A') +$

$\beta * C$ or $C := \alpha * \text{conjg}(A') * B + \text{conjg}(\alpha) * \text{conjg}(B') * A + \beta * C$

[zherfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution

[zherk](#) - perform one of the Hermitian rank k operations $C := \alpha * A * \text{conjg}(A') + \beta * C$ or $C := \alpha * \text{conjg}(A') * A + \beta * C$

[zhesv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[zhesvx](#) - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

[zhetf2](#) - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

[zhetrd](#) - reduce a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

[zhetrf](#) - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

[zhetri](#) - compute the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U * D * U ** H$ or $A = L * D * L ** H$ computed by CHETRF

[zhetrs](#) - solve a system of linear equations $A * X = B$ with a complex Hermitian matrix A using the factorization $A = U * D * U ** H$ or $A = L * D * L ** H$ computed by CHETRF

[zhgeqz](#) - implement a single-shift version of the QZ method for finding the generalized eigenvalues $w(i) = \text{ALPHA}(i) / \text{BETA}(i)$ of the equation $\det(A - w(i) B) = 0$. If $\text{JOB} = 'S'$, then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary transformation (usually called Q) on the left and another (usually called Z) on the right

[zhico](#) (obsolete)- compute the UDU factorization and condition number of a Hermitian matrix A. If the condition number is not needed then xHIFA is slightly faster. It is typical to follow a call to xHICO with a call to xHISL to solve $Ax = b$ or to xHIDI to compute the determinant, inverse, and inertia of A.

[zhidi](#) (obsolete)- compute the determinant, inertia, and inverse of a Hermitian matrix A, which has been UDU-factored by CHICO or CHIFA.

[zhifa](#) (obsolete)- compute the UDU factorization of a Hermitian matrix A. It is typical to follow a call to CHIFA with a call to CHISL to solve $Ax = b$ or to CHIDI to compute the determinant, inverse, and inertia of A.

[zhisl](#) (obsolete)- solve the linear system $Ax = b$ for a Hermitian matrix A, which has been UDU-factored by CHICO or CHIFA, and vectors b and x.

[zhpc0](#) (obsolete)- compute the UDU factorization and condition number of a Hermitian matrix A in packed storage. If the condition number is not needed then xHPFA is slightly faster. It is typical to follow a call to xHPCO with a call to xHPSL to solve $Ax = b$ or to xHPDI to compute the determinant, inverse, and inertia of A.

[zhpcon](#) - estimate the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U * D * U ** H$ or $A = L * D * L ** H$ computed by CHPTRF

[zhpdi](#) (obsolete)- compute the determinant, inertia, and inverse of a Hermitian matrix A in packed storage, which has been UDU-factored by HPCO or HPFA.

[zhpev](#) - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage

[zhpevd](#) - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

[zhpevx](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

[zhpfa](#) (obsolete)- compute the UDU factorization of a Hermitian matrix A in packed storage. It is typical to follow a call to HPFA with a call to CHPSL to solve $Ax = b$ or to HPDI to compute the determinant, inverse, and inertia of A.

[zhpgst](#) - reduce a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage

[zhpgv](#) - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[zhpgvd](#) - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[zhpgvx](#) - compute selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A^*x=(\lambda)B^*x$, $A^*Bx=(\lambda)x$, or $B^*A^*x=(\lambda)x$

[zhpmv](#) - perform the matrix-vector operation $y := \alpha^*A^*x + \beta^*y$

[zhpr](#) - perform the hermitian rank 1 operation $A := \alpha^*x^*\text{conj}(x') + A$

[zhpr2](#) - perform the Hermitian rank 2 operation $A := \alpha^*x^*\text{conj}(y') + \text{conj}(\alpha)^*y^*\text{conj}(x') + A$

[zhprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution

[zhpsl](#) (obsolete)- solve the linear system $Ax = b$ for a Hermitian matrix A in packed storage, which has been UDU-factored by CHPCO or CHPFA, and vectors b and x .

[zhpsv](#) - compute the solution to a complex system of linear equations $A^*X = B$,

[zhpsvx](#) - use the diagonal pivoting factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices

[zhptrd](#) - reduce a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation

[zhptrf](#) - compute the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method

[zhptri](#) - compute the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ computed by CHPTRF

[zhptrs](#) - solve a system of linear equations $A^*X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ computed by CHPTRF

[zhsein](#) - use inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H

[zhseqr](#) - compute the eigenvalues of a complex upper Hessenberg matrix H , and, optionally, the matrices T and Z from the Schur decomposition $H = Z^*T^*Z^{**}H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors

[zlarz](#) - apply a complex elementary reflector H to a complex M-by-N matrix C , from either the left or the right

[zlarzb](#) - apply a complex block reflector H or its transpose $H^{**}H$ to a complex distributed M-by-N C from the left or the right

[zlarzt](#) - form the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors

[zlatzm](#) - routine is deprecated and has been replaced by routine CUNMRZ

[zpbco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in banded storage. If the condition number is not needed then xPBFA is slightly faster. It is typical to follow a call to xPBCO with a call to xPBSL to solve $Ax = b$ or to xPBDI to compute the determinant of A .

[zpbcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U^{**}H^*U$ or $A = L^*L^{**}H$ computed by CPBTRF

[zpbdi](#) (obsolete)- compute the determinant of a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by CPBCO or CPBFA.

[zpbegu](#) - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

[zpbfa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A in banded storage. It is typical to follow a call to CPBFA with a call to CPBSL to solve $Ax = b$ or to CPBDI to compute the determinant of

A.

[zpbdfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution

[zpbsl](#) (obsolete)- section solve the linear system $Ax = b$ for a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by CPBCO or CPBFA, and vectors b and x .

[zpbstf](#) - compute a split Cholesky factorization of a complex Hermitian positive definite band matrix A

[zpbsv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[zpbsvx](#) - use the Cholesky factorization $A = U^{**}H^*U$ or $A = L^*L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[zpbtf2](#) - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

[zpbtrf](#) - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

[zpbtrs](#) - solve a system of linear equations $A^*X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U^{**}H^*U$ or $A = L^*L^{**}H$ computed by CPBTRF

[zpoco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A . If the condition number is not needed then xPOFA is slightly faster. It is typical to follow a call to xPOCO with a call to xPOSL to solve $Ax = b$ or to xPODI to compute the determinant and inverse of A .

[zpocon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^{**}H^*U$ or $A = L^*L^{**}H$ computed by CPOTRF

[zpodl](#) (obsolete)- compute the determinant and inverse of a symmetric positive definite matrix A , which has been Cholesky-factored by CPOCO, CPOFA, or CQRDC.

[zpoegu](#) - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

[zpofoa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A . It is typical to follow a call to CPOFA with a call to CPOSL to solve $Ax = b$ or to CPODI to compute the determinant and inverse of A .

[zporfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite,

[zposl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A , which has been Cholesky-factored by CPOCO or CPOFA, and vectors b and x .

[zposv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[zposvx](#) - use the Cholesky factorization $A = U^{**}H^*U$ or $A = L^*L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[zpotf2](#) - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

[zpotrf](#) - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

[zpotri](#) - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H^*U$ or $A = L^*L^{**}H$ computed by CPOTRF

[zpotrs](#) - solve a system of linear equations $A^*X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H^*U$ or $A = L^*L^{**}H$ computed by CPOTRF

[zppco](#) (obsolete)- compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in packed storage. If the condition number is not needed then CPPFA is slightly faster. It is typical to follow a call to CPPCO with a call to CPPSL to solve $Ax = b$ or to CPPDI to compute the determinant and inverse of A .

[zppcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^{**}H^*U$ or $A = L^*L^{**}H$ computed by CPPTRF

[zppdi](#) (obsolete)- compute the determinant and inverse of a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by CPPCO or CPPFA.

[zppegu](#) - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

[zppfa](#) (obsolete)- compute a Cholesky factorization of a symmetric positive definite matrix A in packed storage. It is typical to follow a call to CPPFA with a call to CPPSL to solve $Ax = b$ or to CPPDI to compute the determinant and inverse of A .

[zpprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution

[zppsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by CPPCO or CPPFA, and vectors b and x .

[zppsv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[zppsvx](#) - use the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

[zpptrf](#) - compute the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format

[zpptri](#) - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPPTRF

[zpptrs](#) - solve a system of linear equations $A * X = B$ with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPPTRF

[zptcon](#) - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L^{*}D^{*}L^{**}H$ or $A = U^{**}H^{*}D^{*}U$ computed by CPTTRF

[zpteqr](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor

[zptrfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

[zptsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric positive definite tridiagonal matrix A and vectors b and x .

[zptsv](#) - compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix, and X and B are N -by- N -RHS matrices.

[zptsvx](#) - use the factorization $A = L^{*}D^{*}L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix and X and B are N -by- N -RHS matrices

[zpttrf](#) - compute the $L^{*}D^{*}L'$ factorization of a complex Hermitian positive definite tridiagonal matrix A

[zpttrs](#) - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U^{*}D^{*}U$ or $A = L^{*}D^{*}L'$ computed by CPTTRF

[zptts2](#) - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U^{*}D^{*}U$ or $A = L^{*}D^{*}L'$ computed by CPTTRF

[zqrdc](#) (obsolete)- compute the QR factorization of a general matrix A . It is typical to follow a call to CQRDC with a call to CQRSL to solve $Ax = b$ or to CPODI to compute the determinant of A .

[zqrsl](#) (obsolete)- solve the linear system $Ax = b$ for a general matrix A , which has been QR- factored by CQRDC, and vectors b and x .

[zrot](#) - apply a plane rotation, where the \cos (C) is real and the \sin (S) is complex, and the vectors CX and CY are complex

[zrotg](#) - Construct a Given's plane rotation

[zscal](#) - Compute $y := \alpha * y$

[zsico](#) (obsolete)- compute the UDU factorization and condition number of a symmetric matrix A . If the condition number is not needed then CSIFA is slightly faster. It is typical to follow a call to CSICO with a call to CSISL to solve $Ax = b$ or to CSIDI to compute the determinant, inverse, and inertia of A .

[zsidi](#) (obsolete)- compute the determinant, inertia, and inverse of a symmetric matrix A , which has been UDU-factored by CSICO or CSIFA.

[zsifa](#) (obsolete)- compute the UDU factorization of a symmetric matrix A . It is typical to follow a call to CSIFA with a call to CSISL to solve $Ax = b$ or to CSIDI to compute the determinant, inverse, and inertia of A .

[zsisl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric matrix A , which has been UDU-factored by CSICO or CSIFA, and vectors b and x .

[zspco](#) (obsolete)- compute the UDU factorization and condition number of a symmetric matrix A in packed storage. If the condition number is not needed then CSPFA is slightly faster. It is typical to follow a call to ZSPCO with a call to CSPSL to solve $Ax = b$ or to CSPDI to compute the determinant, inverse, and inertia of A .

[zspcon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

[zspdi](#) (obsolete)- compute the determinant, inertia, and inverse of a symmetric matrix A in packed storage, which has been UDU-factored by ZSPCO or CSPFA.

[zspfa](#) (obsolete)- compute the UDU factorization of a symmetric matrix A in packed storage. It is typical to follow a call to ZSPFA with a call to CSPSL to solve $Ax = b$ or to CSPDI to compute the determinant, inverse, and inertia of A .

[zsprfs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

[zspsl](#) (obsolete)- solve the linear system $Ax = b$ for a symmetric matrix A in packed storage, which has been UDU-factored by ZSPCO or ZSPFA, and vectors b and x .

[zspsv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[zspsvx](#) - use the diagonal pivoting factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix stored in packed format and X and B are N -by- N RHS matrices

[zsptrf](#) - compute the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

[zsptri](#) - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

[zsptrs](#) - solve a system of linear equations $A * X = B$ with a complex symmetric matrix A stored in packed format using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

[zstedc](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

[zstegr](#) - Compute $T\text{-sigma}_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

[zstein](#) - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

[zsteqr](#) - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

[zstsv](#) - compute the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix

[zsttrf](#) - compute the factorization of a complex Hermitian tridiagonal matrix A

[zsttrs](#) - computes the solution to a complex system of linear equations $A * X = B$

[zsvdc](#) (obsolete)- compute the singular value decomposition of a general matrix A .

[zswap](#) - Exchange vectors x and y .

[zsycon](#) - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSYTRF

[zsymm](#) - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

[zsyrr2k](#) - perform one of the symmetric rank 2k operations $C := \alpha * A * B' + \alpha * B * A' + \beta * C$ or $C := \alpha * A * B + \alpha * B * A + \beta * C$

[zsyrrs](#) - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

[zsyrrk](#) - perform one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$

[zsysv](#) - compute the solution to a complex system of linear equations $A * X = B$,

[zsysvx](#) - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

[zsytf2](#) - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[zsytrf](#) - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

[zsytri](#) - compute the inverse of a complex symmetric indefinite matrix A using the factorization $A = U * D * U' * T$ or $A = L * D * L' * T$ computed by CSYTRF

[zsytrs](#) - solve a system of linear equations $A * X = B$ with a complex symmetric matrix A using the factorization $A = U * D * U' * T$ or $A = L * D * L' * T$ computed by CSYTRF

[ztbcon](#) - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

[ztbmv](#) - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ztbrfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

[ztbsv](#) - solve one of the systems of equations $A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$

[ztbtrs](#) - solve a triangular system of the form $A * X = B$, $A' * X = B$, or $\text{conjg}(A') * X = B$,

[ztgevc](#) - compute some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B)

[ztgexc](#) - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST

[ztgsen](#) - reorder the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B)

[ztgsja](#) - compute the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B

[ztgsna](#) - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B)

[ztgsyl](#) - solve the generalized Sylvester equation

[ztpcon](#) - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

[ztpmv](#) - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ztprfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

[ztpsv](#) - solve one of the systems of equations $A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$

[ztptri](#) - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

[ztptrs](#) - solve a triangular system of the form $A * X = B$, $A' * X = B$, or $\text{conjg}(A') * X = B$,

[ztrans](#) - transpose and scale source matrix

[ztrco](#) (obsolete)- estimate the condition number of a triangular matrix A. It is typical to follow a call to xTRCO with a call to xTRSL to solve $Ax = b$ or to xTRDI to compute the determinant and inverse of A.

[ztrcon](#) - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

[ztrdi](#) (obsolete)- compute the determinant and inverse of a triangular matrix A.

[ztrevc](#) - compute some or all of the right and/or left eigenvectors of a complex upper triangular matrix T

[ztrexc](#) - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that the diagonal element of T with row index IFST is moved to row ILST

[ztrmm](#) - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

[ztrmv](#) - perform one of the matrix-vector operations $x := A * x$, or $x := A' * x$, or $x := \text{conjg}(A') * x$

[ztrrfs](#) - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

[ztrsen](#) - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace

[ztrsI](#) (obsolete)- solve the linear system $Ax = b$ for a triangular matrix A and vectors b and x.

[ztrsm](#) - solve one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$

[ztrсна](#) - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q^*T^*Q^{**}H$ with Q unitary)

[ztrsv](#) - solve one of the systems of equations $A * x = b$, or $A' * x = b$, or $\text{conjg}(A') * x = b$

[ztrsyl](#) - solve the complex Sylvester matrix equation

[zrti2](#) - compute the inverse of a complex upper or lower triangular matrix

[ztrri](#) - compute the inverse of a complex upper or lower triangular matrix A

[ztrrs](#) - solve a triangular system of the form $A * X = B$, $A^{**}T * X = B$, or $A^{**}H * X = B$,

[ztrzqf](#) - routine is deprecated and has been replaced by routine CTZRZF

[ztrzrf](#) - reduce the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations

[zung2l](#) - generate an m by n complex matrix Q with orthonormal columns,

[zung2r](#) - generate an m by n complex matrix Q with orthonormal columns,

[zungbr](#) - generate one of the complex unitary matrices Q or $P^{**}H$ determined by CGEBRD when reducing a complex matrix A to bidiagonal form

[zunghr](#) - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

[zungl2](#) - generate an m-by-n complex matrix Q with orthonormal rows,

[zunglq](#) - generate an M-by-N complex matrix Q with orthonormal rows,

[zungql](#) - generate an M-by-N complex matrix Q with orthonormal columns,

[zungqr](#) - generate an M-by-N complex matrix Q with orthonormal columns,

[zungr2](#) - generate an m by n complex matrix Q with orthonormal rows,

[zungrq](#) - generate an M-by-N complex matrix Q with orthonormal rows,

[zungtr](#) - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

[zunmbr](#) - VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmhr](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunml2](#) - overwrite the general complex m-by-n matrix C with $Q * C$ if SIDE = 'L' and TRANS = 'N', or $Q^* C$ if SIDE = 'L' and TRANS = 'C', or $C * Q$ if SIDE = 'R' and TRANS = 'N', or $C * Q^*$ if SIDE = 'R' and TRANS = 'C',

[zunmlq](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmqj](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmqr](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmr2](#) - overwrite the general complex m-by-n matrix C with $Q * C$ if SIDE = 'L' and TRANS = 'N', or $Q^* C$ if SIDE = 'L' and TRANS = 'C', or $C * Q$ if SIDE = 'R' and TRANS = 'N', or $C * Q^*$ if SIDE = 'R' and TRANS = 'C',

[zunmrq](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmrz](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zunmtr](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zupgtr](#) - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

[zupmtr](#) - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

[zvmul](#) - compute the scaled product of complex vectors

NAME

available_threads - returns information about current thread usage

SYNOPSIS

```
SUBROUTINE AVAILABLE_THREADS( NTOTAL, NUSING)
INTEGER NTOTAL, NUSING
```

```
SUBROUTINE AVAILABLE_THREADS_64( NTOTAL, NUSING)
INTEGER*8 NTOTAL, NUSING
```

F95 INTERFACE

```
SUBROUTINE AVAILABLE_THREADS( NTOTAL, NUSING)
INTEGER :: NTOTAL, NUSING
```

```
SUBROUTINE AVAILABLE_THREADS_64( NTOTAL, NUSING)
INTEGER(8) :: NTOTAL, NUSING
```

C INTERFACE

```
#include <sunperf.h>
```

```
void available_threads(int *ntotal, int *nusing);
```

```
void available_threads_64(long *ntotal, long *nusing);
```

PURPOSE

available_threads returns NTOTAL, which is the total number of CPUs available to the job (generally the number of CPUs presently on-line in the partition), and NUSING, which is the sum of the current Use numbers for all threads specified in USE_THREADS. If NTOTAL < NUSING then the system is potentially overcommitted.

ARGUMENTS

* *NTOTAL (output)*

Total number of CPUs available.

* *NUSING (output)*

Sum of current Use numbers for all threads specified in USE_THREADS.

NAME

bcomm, sbcomm, dbcomm - block coordinate matrix-matrix multiply

SYNOPSIS

```
SUBROUTINE SBCOMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*                VAL, BINDX, BJNDX, BNNZ, LB,  
*                B, LDB, BETA, C, LDC, WORK, LWORK )  
INTEGER*4 TRANSA, MB, N, KB, DESCRA(5), BNNZ, LB,  
*        LDB, LDC, LWORK  
INTEGER*4 BINDX(BNNZ), BJNDX(BNNZ)  
REAL*4    ALPHA, BETA  
REAL*4    VAL(LB*LB*BNNZ), B(LDB,*), C(LDC,*), WORK(LWORK)  
SUBROUTINE DBCOMM( TRANSA, MB, N, KB, ALPHA, DESCRA,  
*                VAL, BINDX, BJNDX, BNNZ, LB,  
*                B, LDB, BETA, C, LDC, WORK, LWORK )  
INTEGER*4 TRANSA, MB, N, KB, DESCRA(5), BNNZ, LB,  
*        LDB, LDC, LWORK  
INTEGER*4 BINDX(BNNZ), BJNDX(BNNZ)  
REAL*8    ALPHA, BETA  
REAL*8    VAL(LB*LB*BNNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

DESCRIPTION

```
C <- alpha A B + beta C  
C <- alpha A'B + beta C
```

(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
MB	Number of block rows in matrix A
N	Number of columns in matrix C
KB	Number of block columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure

0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti)-Symmetric
 5 : Diagonal
 DESCRA(2) upper/lower triangular indicator (NOT IMPLEMENTED)
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type (NOT IMPLEMENTED)
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices
 VAL() scalar array of length LB*LB*BNNZ containing
 matrix entries stored column-major within each
 dense block.
 BINDX() integer array of length BNNZ consisting of the
 block row indices of the block entries of A.
 BJNDX() integer array of length BNNZ consisting of the
 block column indices of the block entries of A.
 BNNZ number of block entries
 LB dimension of dense blocks composing A.
 B() rectangular array with first dimension LDB.
 LDB leading dimension of B
 BETA Scalar parameter
 C() rectangular array with first dimension LDC.
 LDC leading dimension of C
 WORK() scratch array of length LWORK. LWORK should be at least
 MAX(MB*LB*LB,N).
 LWORK length of WORK array

C <- ALPHA inv(A) D B + BETA C    C <- ALPHA inv(A') D B + BETA C
                                   ( ' indicates matrix transpose)
where D is a scaling block diagonal matrix
```

ARGUMENTS

TRANSA Indicates how to operate with the sparse matrix
 0 : operate with matrix
 1 : operate with transpose matrix

MB Number of block rows in matrix A

N Number of columns in matrix C

UNITD Type of scaling:
 1 : Identity matrix (argument DV[] is ignored)
 2 : Scale on left (row scaling)
 3 : Scale on right (column scaling)

DV() Array of length MB*LB*LB containing the elements of
 the diagonal blocks of the matrix D. The size of each
 square block is LB*LB and each block contains matrix
 entries stored column-major within each dense diagonal
 block

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array

DESCRA(1) matrix structure
 0 : General (NOT IMPLEMENTED)
 1 : Symmetric (NOT IMPLEMENTED)
 2 : Hermitian (NOT IMPLEMENTED)
 3 : Triangular
 4 : Skew(Anti)-Symmetric (NOT IMPLEMENTED)
 5 : Diagonal (NOT IMPLEMENTED)

DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper

DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() Scalar array of length LB*LB*BLDA*NBDIAG containing
 matrix entries, stored column-major within each dense
 block.

BLDA Leading block dimension of VAL(). Should be greater
 than or equal to MB.

IBDIAG() Integer array of length NBDIAG consisting of the
 corresponding indices of the non-zero block
 diagonals of A in VAL().

NBDIAG The number of non-zero block diagonals in A.

LB Dimension of dense blocks composing A.

B() Rectangular array with first dimension LDB.

LDB Leading dimension of B.

BETA Scalar parameter.

C() Rectangular array with first dimension LDC.

LDC Leading dimension of C.

WORK() Scratch array of length LWORK. LWORK should be at least
 MB*LB*MIN(LB,N). For good performance, LWORK should
 generally be larger.

LWORK Length of WORK array.
 If LWORK = -1, then a workspace query is assumed; the routine
 only calculates the optimal size of the WORK array, returns
 this value as the first entry of the WORK array, and no error

message related to LWORK is issued by XERBLA.

REAL*8    VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
where NNZ = PNTRE(K)-PNTRB(1)
```

DESCRIPTION

```
C <- alpha A B + beta C
C <- alpha A'B + beta C
```

(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array

DESCRA(1) matrix structure
 0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti)-Symmetric
 5 : Diagonal

DESCRA(2) upper/lower triangular indicator (NOT IMPLEMENTED)
 1 : lower
 2 : upper

DESCRA(3) main diagonal type (NOT IMPLEMENTED)
 0 : non-unit
 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices

VAL() scalar array of length NNZ containing matrix entries.
 INDX() integer array of length NNZ containing row indices.
 (row indices MUST be sorted)

PNTRB() integer array of length K such that PNTRB(J)-PNTRB(1)+1
 points to location in VAL of the first nonzero element
 in column J.

PNTRE() integer array of length K such that PNTRE(J)-PNTRE(1)
 points to location in VAL of the last nonzero element
 in column J.

B() rectangular array with first dimension LDB.
 LDB leading dimension of B
 BETA Scalar parameter
 C() rectangular array with first dimension LDC.
 LDC leading dimension of C
 WORK() scratch array of length LWORK. LWORK should be at least
 MAX(M,N).
 LWORK length of WORK array

NAME

cscsm, scscsm, dcscsm - compressed sparse column format triangular solve

SYNOPSIS

```
SUBROUTINE SCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*                VAL, INDX, PNTRB, PNTRE,
*                B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, UNITD, DESCRA(5),
*        LDB, LDC, LWORK
INTEGER*4 INDX(NNZ), PNTRB(K), PNTRE(K)
REAL*4    ALPHA, BETA
REAL*4    DV(M), VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
SUBROUTINE DCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*                VAL, INDX, PNTRB, PNTRE,
*                B, LDB, BETA, C, LDC, WORK, LWORK )
INTEGER*4 TRANSA, M, N, UNITD, DESCRA(5),
*        LDB, LDC, LWORK
INTEGER*4 INDX(NNZ), PNTRB(K), PNTRE(K)
REAL*8    ALPHA, BETA
REAL*8    DV(M), VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
where NNZ = PNTRE(K)-PNTRB(1)
```

DESCRIPTION

```
C <- alpha D inv(A) B + beta C      C <- alpha D inv(A') B + beta C
C <- alpha inv(A) D B + beta C      C <- alpha inv(A') D B + beta C
                                     ( ' indicates matrix transpose)
```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling)

3 : Scale on right (column scaling)
 DV() Array of length M containing the diagonal entries of the diagonal matrix D.
 ALPHA Scalar parameter
 DESCRA() Descriptor argument. Five element integer array
 DESCRA(1) matrix structure
 0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti-Symmetric)
 5 : Diagonal
 DESCRA(2) upper/lower triangular indicator
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices
 VAL() scalar array of length NNZ containing matrix entries.
 INDX() integer array of length NNZ containing row indices.
 (row indices MUST be sorted)
 PNTRB() integer array of length K such that PNTRB(J)-PNTRB(1)+1
 points to location in VAL of the first nonzero element
 in column J.
 PNTRE() integer array of length K such that PNTRE(J)-PNTRE(1)
 points to location in VAL of the last nonzero element
 in column J.
 B() rectangular array with first dimension LDB.
 LDB leading dimension of B
 BETA Scalar parameter
 C() rectangular array with first dimension LDC.
 LDC leading dimension of C
 WORK() scratch array of length LWORK.
 On exit, if LWORK = -1, WORK(1) returns the optimal LWORK.
 LWORK length of WORK array. LWORK should be at least M.
 For good performance, LWORK should generally be larger.
 If LWORK = -1, then a workspace query is assumed; the routine
 only calculates the optimal size of the WORK array, returns
 this value as the first entry of the WORK array, and no error
 message related to LWORK is issued by XERBLA.

NOTES/BUGS

The NIST FORTRAN Sparse BLAS are currently at version 0.5. Some features (including the ones so noted) may not yet be implemented.

NAME

caxpy - compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE CAXPY( N, ALPHA, X, INCX, Y, INCY)
  COMPLEX ALPHA
  COMPLEX X(*), Y(*)
  INTEGER N, INCX, INCY
```

```
SUBROUTINE CAXPY_64( N, ALPHA, X, INCX, Y, INCY)
  COMPLEX ALPHA
  COMPLEX X(*), Y(*)
  INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE AXPY( [N], ALPHA, X, [INCX], Y, [INCY])
  COMPLEX :: ALPHA
  COMPLEX, DIMENSION(:) :: X, Y
  INTEGER :: N, INCX, INCY
```

```
SUBROUTINE AXPY_64( [N], ALPHA, X, [INCX], Y, [INCY])
  COMPLEX :: ALPHA
  COMPLEX, DIMENSION(:) :: X, Y
  INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void caxpy(int n, complex alpha, complex *x, int incx, complex *y, int incy);
```

```
void caxpy_64(long n, complex alpha, complex *x, long incx, complex *y, long incy);
```

PURPOSE

caxpy compute $y := \alpha * x + y$ where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *X (input)*

array of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

array of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

caxpyi, daxpyi, saxpyi, zaxpyi - Compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE CAXPYI( NZ, A, X, INDX, Y)
  COMPLEX A
  COMPLEX X(*), Y(*)
  INTEGER NZ
  INTEGER INDX(*)
```

```
SUBROUTINE CAXPYI_64( NZ, A, X, INDX, Y)
  COMPLEX A
  COMPLEX X(*), Y(*)
  INTEGER*8 NZ
  INTEGER*8 INDX(*)
```

F95 INTERFACE

```
SUBROUTINE AXPYI( [NZ], [A], X, INDX, Y)
  COMPLEX :: A
  COMPLEX, DIMENSION(:) :: X, Y
  INTEGER :: NZ
  INTEGER, DIMENSION(:) :: INDX
```

```
SUBROUTINE AXPYI_64( [NZ], [A], X, INDX, Y)
  COMPLEX :: A
  COMPLEX, DIMENSION(:) :: X, Y
  INTEGER(8) :: NZ
  INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

caxpyi Compute $y := \alpha * x + y$ where α is a scalar, x is a sparse vector, and y is a vector in full storage form

```
do 10, i = 1, n
  y(indx(i)) = alpha * x(i) + y(indx(i))
10 continue
```

ARGUMENTS

* *NZ (input)*

- INTEGER

Number of elements in the compressed form. Unchanged on exit.

* *A (input)*

On entry, ALPHA specifies the scaling value. Unchanged on exit.

* *X (input)*

Vector containing the values of the compressed form. Unchanged on exit.

* *INDX (input)*

- INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

* *Y (output)*

Vector on input which contains the vector Y in full storage form. On exit, only the elements corresponding to the indices in INDX have been modified.

NAME

cbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

SYNOPSIS

```
SUBROUTINE CBDSQR( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU,
*   C, LDC, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX VT(LDVT,*), U(LDU,*), C(LDC,*)
INTEGER N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL D(*), E(*), WORK(*)

SUBROUTINE CBDSQR_64( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U,
*   LDU, C, LDC, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX VT(LDVT,*), U(LDU,*), C(LDC,*)
INTEGER*8 N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE BDSQR( UPLO, [N], [NCVT], [NRU], [NCC], D, E, VT, [LDVT],
*   U, [LDU], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: VT, U, C
INTEGER :: N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL, DIMENSION(:) :: D, E, WORK

SUBROUTINE BDSQR_64( UPLO, [N], [NCVT], [NRU], [NCC], D, E, VT,
*   [LDVT], U, [LDU], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: VT, U, C
INTEGER(8) :: N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL, DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cbdsqr(char uplo, int n, int ncv, int nru, int ncc, float *d, float *e, complex *vt, int ldvt, complex *u, int ldu, complex *c, int ldc, int *info);
```

```
void cbdsqr_64(char uplo, long n, long ncv, long nru, long ncc, float *d, float *e, complex *vt, long ldvt, complex *u, long
```

ldu, complex *c, long ldc, long *info);

PURPOSE

cbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = Q * S * P'$ (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes $U * Q$, $P' * VT$, or $Q' * C$, for given complex input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and

"Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix B. $N \geq 0$.

* **NCVT** (*input*)

The number of columns of the matrix VT. $NCVT \geq 0$.

* **NRU** (*input*)

The number of rows of the matrix U. $NRU \geq 0$.

* **NCC** (*input*)

The number of columns of the matrix C. $NCC \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

* **E** (*input/output*)

On entry, the elements of E contain the offdiagonal elements of of the bidiagonal matrix whose SVD is desired. On normal exit (INFO = 0), E is destroyed. If the algorithm does not converge (INFO > 0), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. E(N) is used for workspace.

* **VT** (*input/output*)

On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by $P' * VT$. VT is not referenced if $NCVT = 0$.

* **LDVT** (*input*)

The leading dimension of the array VT. $LDVT \geq \max(1, N)$ if $NCVT > 0$; $LDVT \geq 1$ if $NCVT = 0$.

* **U** (*input/output*)

On entry, an NRU-by-N matrix U. On exit, U is overwritten by $U * Q$. U is not referenced if $NRU = 0$.

* **LDU** (*input*)

The leading dimension of the array U. $LDU \geq \max(1, NRU)$.

* **C** (*input/output*)

On entry, an N-by-NCC matrix C. On exit, C is overwritten by $Q' * C$. C is not referenced if $NCC = 0$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, N)$ if $NCC > 0$; $LDC \geq 1$ if $NCC = 0$.

* **WORK** (*workspace*)

* **INFO** (*output*)

NAME

cchdc - (obsolete) compute the Cholesky decomposition of a symmetric positive definite matrix A.

SYNOPSIS

```
SUBROUTINE CCHDC( A, LDA, N, WORK, IPIVOT, JOB, INFO)
COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, JOB, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CCHDC_64( A, LDA, N, WORK, IPIVOT, JOB, INFO)
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, JOB, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cchdc(complex *a, int lda, int n, int *ipivot, int job, int *info);
```

```
void cchdc_64(complex *a, long lda, long n, long *ipivot, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of A. On exit, the upper triangle of the Cholesky factor, as permuted by pivoting if pivoting was selected. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **IPIVOT** (*input*)

If JOB selected no pivoting then IPIVOT is not referenced. On entry, if JOB selected pivoting, IPIVOT contains integers representing array indices that control the selection of pivot elements from the diagonal of A according to the system below:

$IPIVOT(k) > 0$ $A(k,k)$ is an initial element.

$IPIVOT(k) = 0$ $A(k,k)$ is a free element.

$IPIVOT(k) < 0$ $A(k,k)$ is a final element.

Before the decomposition is computed, symmetric row and column interchanges are used to move initial elements to the beginning of A and final elements to the end of A . During the computation, symmetric row and column interchanges are used to move the largest remaining free diagonal element into the pivot position. On exit, $IPIVOT(k)$ contains the index of the diagonal element of A that was moved into the k th position.

*** *JOB* (input)**

Determines how decomposition is done:

0 without pivoting

not 0 with pivoting

*** *INFO* (output)**

On exit: Returns the index of the last positive diagonal element of the Cholesky factor. The subroutine was successful if $INFO = N$.

NAME

cchdd - (obsolete) downdate an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

SYNOPSIS

```
SUBROUTINE CCHDD( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN, INFO)
COMPLEX A(LDA,*), X(*), Z(LDZ,*), Y(*), SIN(*)
INTEGER LDA, N, LDZ, NZ, INFO
REAL RHO(*), COS(*)
```

```
SUBROUTINE CCHDD_64( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN,
* INFO)
COMPLEX A(LDA,*), X(*), Z(LDZ,*), Y(*), SIN(*)
INTEGER*8 LDA, N, LDZ, NZ, INFO
REAL RHO(*), COS(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cchdd(complex *a, int lda, int n, complex *x, complex *z, int ldz, int nz, complex *y, float *rho, float *cos, complex *sin, int *info);
```

```
void cchdd_64(complex *a, long lda, long n, complex *x, complex *z, long ldz, long nz, complex *y, float *rho, float *cos, complex *sin, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangular matrix A. On exit, A has been downdated. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

*** N (input)**

Order of the matrix A. N \geq 0.

*** X (input)**

Row to be added to A.

*** Z (input/output)**

Vectors to be downdated with A.

* ***LDZ (input)***

Leading dimension on the array Z as specified in a dimension or type statement. $LDZ \geq \max(1, N)$.

* ***NZ (input)***

Number of vectors to be downdated with A. $NZ \geq 0$. If $NZ = 0$ then Z, Y, and RHO are not used.

* ***Y (input)***

Scalars for downdating the vectors in Z.

* ***RHO (input/output)***

On entry, the norms of the residual vectors that are to be downdated. On exit, RHO has been downdated. If $RHO(i)$ is negative on entry then it is not changed.

* ***COS (input/output)***

Cosines of the transforming rotations.

* ***SIN (output)***

Sines of the transforming rotations.

* ***INFO (output)***

On exit:

INFO = 0 Subroutine completed normally.

INFO = -1 A could not be downdated; all values are left unchanged.

INFO = 1 Some RHOs could not be downdated; all RHOs that could not be downdated are changed to -1.

NAME

cchex - (obsolete) compute the Cholesky decomposition of a symmetric positive definite matrix A.

SYNOPSIS

```
SUBROUTINE CCHEX( A, LDA, N, K, L, Z, LDZ, NZ, COS, SIN, JOB)
COMPLEX A(LDA,*), Z(LDZ,*), SIN(*)
INTEGER LDA, N, K, L, LDZ, NZ, JOB
REAL COS(*)
```

```
SUBROUTINE CCHEX_64( A, LDA, N, K, L, Z, LDZ, NZ, COS, SIN, JOB)
COMPLEX A(LDA,*), Z(LDZ,*), SIN(*)
INTEGER*8 LDA, N, K, L, LDZ, NZ, JOB
REAL COS(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cchex(complex *a, int lda, int n, int k, int l, complex *z, int ldz, int nz, float *cos, complex *sin, int job);
```

```
void cchex_64(complex *a, long lda, long n, long k, long l, complex *z, long ldz, long nz, float *cos, complex *sin, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, the upper triangle of A contains the upper triangle of the updated factor. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** K (input)**

First column to be permuted. $1 \leq K \leq L$.

*** L (input)**

Last column to be permuted; must be strictly greater than K. $K \leq L \leq N$.

*** Z (input/output)**

Array of vectors into which the transformation U is multiplied. Not used if NZ = 0.

* **LDZ (input)**

Leading dimension of the array Z as specified in a dimension or type statement. LDZ \geq max(1,N).

* **NZ (input)**

Number of columns in the matrix Z. NZ \geq 0.

* **COS (input)**

Cosines of the transforming rotations.

* **SIN (output)**

Sines of the transforming rotations.

* **JOB (input)**

Determines the type of permutation:

1 right circular shift

2 left circular shift

NAME

cchud - (obsolete) update an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

SYNOPSIS

```
SUBROUTINE CCHUD( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN)
COMPLEX A(LDA,*), X(*), Z(LDZ,*), Y(*), SIN(*)
INTEGER LDA, N, LDZ, NZ
REAL RHO(*), COS(*)
```

```
SUBROUTINE CCHUD_64( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN)
COMPLEX A(LDA,*), X(*), Z(LDZ,*), Y(*), SIN(*)
INTEGER*8 LDA, N, LDZ, NZ
REAL RHO(*), COS(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cchud(complex *a, int lda, int n, complex *x, complex *z, int ldz, int nz, complex *y, float *rho, float *cos, complex *sin);
```

```
void cchud_64(complex *a, long lda, long n, complex *x, complex *z, long ldz, long nz, complex *y, float *rho, float *cos, complex *sin);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangular matrix A. On exit, A has been updated. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

*** N (input)**

Order of the matrix A. N \geq 0.

*** X (input)**

Row to be added to A.

*** Z (input/output)**

Vectors to be updated with A.

*** LDZ (input)**

Leading dimension on the array Z as specified in a dimension or type statement. LDZ \geq max(1,N).

* ***NZ (input)***

Number of vectors to be updated with A. NZ \geq 0. If NZ = 0 then Z, Y, and RHO are not used.

* ***Y (input)***

Scalars for updating the vectors in Z.

* ***RHO (input/output)***

On entry, the norms of the residual vectors that are to be updated. On exit, RHO has been updated. If RHO(i) is negative on entry then it is not changed.

* ***COS (input)***

Cosines of the transforming rotations.

* ***SIN (input)***

Sines of the transforming rotations.

NAME

ccnvcor - compute the convolution or correlation of complex vectors

SYNOPSIS

```
SUBROUTINE CCNVCOR( CNVCOR, FOUR, NX, X, IFX, INCX, NY, NPRE, M, Y,
*      IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, LWORK)
CHARACTER * 1 CNVCOR, FOUR
COMPLEX X(*), Y(*), Z(*), WORK(*)
INTEGER NX, IFX, INCX, NY, NPRE, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK

SUBROUTINE CCNVCOR_64( CNVCOR, FOUR, NX, X, IFX, INCX, NY, NPRE, M,
*      Y, IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, LWORK)
CHARACTER * 1 CNVCOR, FOUR
COMPLEX X(*), Y(*), Z(*), WORK(*)
INTEGER*8 NX, IFX, INCX, NY, NPRE, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK
```

F95 INTERFACE

```
SUBROUTINE CNVCOR( CNVCOR, FOUR, NX, X, IFX, [INCX], NY, NPRE, M, Y,
*      IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, [LWORK])
CHARACTER(LEN=1) :: CNVCOR, FOUR
COMPLEX, DIMENSION(:) :: X, Y, Z, WORK
INTEGER :: NX, IFX, INCX, NY, NPRE, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK

SUBROUTINE CNVCOR_64( CNVCOR, FOUR, NX, X, IFX, [INCX], NY, NPRE, M,
*      Y, IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, [LWORK])
CHARACTER(LEN=1) :: CNVCOR, FOUR
COMPLEX, DIMENSION(:) :: X, Y, Z, WORK
INTEGER(8) :: NX, IFX, INCX, NY, NPRE, M, IFY, INC1Y, INC2Y, NZ, K, IFZ, INC1Z, INC2Z, LWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ccnvcor(char cnvcor, char four, int nx, complex *x, int ifx, int incx, int ny, int npre, int m, complex *y, int ify, int inc1y, int inc2y, int nz, int k, complex *z, int ifz, int inc1z, int inc2z, complex *work, int lwork);
```

```
void ccnvcor_64(char cnvcor, char four, long nx, complex *x, long ifx, long incx, long ny, long npre, long m, complex *y, long ify, long inc1y, long inc2y, long nz, long k, complex *z, long ifz, long inc1z, long inc2z, complex *work, long lwork);
```

PURPOSE

ccnvcor computes the convolution or correlation of complex vectors.

ARGUMENTS

* **CNVCOR** (*input*)

CHARACTER

'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

* **FOUR** (*input*)

CHARACTER

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the real and imaginary parts of the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

* **NX** (*input*)

Length of the filter vector. $NX \geq 0$. CCNVCOR will return immediately if $NX = 0$.

* **X** (*input*)

dimension(*)

Filter vector.

* **IFX** (*input*)

Index of the first element of X. $NX \geq IFX \geq 1$.

* **INCX** (*input*)

Stride between elements of the filter vector in X. $INCX > 0$.

* **NY** (*input*)

Length of the input vectors. $NY \geq 0$. CCNVCOR will return immediately if $NY = 0$.

* **NPRE** (*input*)

The number of implicit zeros prepended to the Y vectors. $NPRE \geq 0$.

* **M** (*input*)

Number of input vectors. $M \geq 0$. CCNVCOR will return immediately if $M = 0$.

* **Y** (*input*)

dimension(*)

Input vectors.

* **IFY** (*input*)

Index of the first element of Y. $NY \geq IFY \geq 1$.

* **INCIY** (*input*)

Stride between elements of the input vectors in Y. $INC1Y > 0$.

* **INC2Y** (*input*)

Stride between the input vectors in Y. $INC2Y > 0$.

* ***NZ (input)***

Length of the output vectors. $NZ \geq 0$. CCNVCOR will return immediately if $NZ = 0$. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

* ***K (input)***

Number of Z vectors. $K \geq 0$. If $K = 0$ then CCNVCOR will return immediately. If $K < M$ then only the first K input vectors will be processed. If $K > M$ then M input vectors will be processed.

* ***Z (output)***

dimension(*)

Result vectors.

* ***IFZ (input)***

Index of the first element of Z . $NZ \geq IFZ \geq 1$.

* ***INC1Z (input)***

Stride between elements of the output vectors in Z . $INC1Z > 0$.

* ***INC2Z (input)***

Stride between the output vectors in Z . $INC2Z > 0$.

* ***WORK (input/output)***

(input/scratch) dimension(LWORK)

Scratch space. Before the first call to CCNVCOR with particular values of the integer arguments the first element of $WORK$ must be set to zero. If $WORK$ is written between calls to CCNVCOR or if CCNVCOR is called with different values of the integer arguments then the first element of $WORK$ must again be set to zero before each call. If $WORK$ has not been written and the same values of the integer arguments are used then the first element of $WORK$ to zero. This can avoid certain initializations that store their results into $WORK$, and avoiding the initialization can make CCNVCOR run faster.

* ***LWORK (input)***

Length of $WORK$. $LWORK \geq 2 * \text{MAX}(NX, NY, NZ) + 8$.

NAME

ccnvcor2 - compute the convolution or correlation of complex matrices

SYNOPSIS

```
SUBROUTINE CCNVCOR2( CNVCOR, METHOD, TRANSX, SCRATCHX, TRANSY,
*   SCRATCHY, MX, NX, X, LDX, MY, NY, MPRE, NPRES, Y, LDY, MZ, NZ, Z,

INTEGER(8) :: MX, NX, LDX, MY, NY, MPRE, NPRES, LDY, MZ, NZ, LDZ, LWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ccnvcor2(char cnvcor, char method, char transx, char scratchx, char transy, char scratchy, int mx, int nx, complex *x, int ldx, int my, int ny, int mpre, int npre, complex *y, int ldy, int mz, int nz, complex *z, int ldz, complex *work, int lwork);
```

```
void ccncor2_64(char cncor, char method, char transx, char scratchx, char transy, char scratchy, long mx, long nx,
complex *x, long ldx, long my, long ny, long mpre, long npre, complex *y, long ldy, long mz, long nz, complex *z, long ldz,
complex *work, long lwork);
```

PURPOSE

ccncor2 computes the convolution or correlation of complex matrices.

ARGUMENTS

* **CNVCOR** (*input*)

'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

* **METHOD** (*input*)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

* **TRANSX** (*input*)

'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

* **SCRATCHX** (*input*)

'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

* **TRANSY** (*input*)

'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

* **SCRATCHY** (*input*)

'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

* **MX** (*input*)

Number of rows in the filter matrix. MX >= 0.

* **NX** (*input*)

Number of columns in the filter matrix. NX >= 0.

* **X** (*input*)

On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

* **LDX** (*input*)

Leading dimension of the array that contains the filter matrix.

* **MY** (*input*)

Number of rows in the input matrix. MY >= 0.

* **NY** (*input*)

Number of columns in the input matrix. NY >= 0.

* **MPRE** (*input*)

Number of implicit zeros to prepend to each row of the input matrix. MPRE >= 0.

* **NPRE** (*input*)

Number of implicit zeros to prepend to each column of the input matrix. NPRES \geq 0.

*** Y (input)**

Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

*** LDY (input)**

Leading dimension of the array that contains the input matrix.

*** MZ (input)**

Number of rows in the output matrix. MZ \geq 0. CCNVCOR2 will return immediately if MZ = 0.

*** NZ (input)**

Number of columns in the output matrix. NZ \geq 0. CCNVCOR2 will return immediately if NZ = 0.

*** Z (output)**

dimension(LDZ, *)

Result matrix.

*** LDZ (input)**

Leading dimension of the array that contains the result matrix. LDZ \geq MAX(1,MZ).

*** WORK (input/output)**

(input/scratch) dimension(LWORK)

On entry for the first call to CCNVCOR2, WORK(1) must contain CMPLX(0.0,0.0). After the first call, WORK(1) must be set to CMPLX(0.0,0.0) iff WORK has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

*** LWORK (input)**

Length of the work vector. If the FFT is to be used then for best performance LWORK should be at least 30 words longer than the amount of memory needed to hold the trig tables. If the FFT is not used, the value of LWORK is unimportant.

NAME

ccopy - Copy x to y

SYNOPSIS

```
SUBROUTINE CCOPY( N, X, INCX, Y, INCY)
COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE CCOPY_64( N, X, INCX, Y, INCY)
COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE COPY( [N], X, [INCX], Y, [INCY])
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE COPY_64( [N], X, [INCX], Y, [INCY])
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ccopy(int n, complex *x, int incx, complex *y, int incy);
```

```
void ccopy_64(long n, complex *x, long incx, complex *y, long incy);
```

PURPOSE

ccopy Copy x to y where x and y are n-vectors.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** *X (input)***

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** *Y (input/output)***

of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.

*** *INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

cdotc - compute the dot product of two vectors x and conjg(y).

SYNOPSIS

```
COMPLEX FUNCTION CDOTC( N, X, INCX, Y, INCY)
COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
COMPLEX FUNCTION CDOTC_64( N, X, INCX, Y, INCY)
COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX FUNCTION DOTC( [N], X, [INCX], Y, [INCY])
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
COMPLEX FUNCTION DOTC_64( [N], X, [INCX], Y, [INCY])
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
complex cdotc(int n, complex *x, int incx, complex *y, int incy);
```

```
complex cdotc_64(long n, complex *x, long incx, complex *y, long incy);
```

PURPOSE

cdotc compute the dot product of x and $\text{conjg}(y)$ where x and y are n -vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

* *X (input)*

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. On entry, the incremented array X must contain the vector x . Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X . INCX must not be zero. Unchanged on exit.

* *Y (input)*

of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y . Unchanged on exit.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y . INCY must not be zero. Unchanged on exit.

NAME

cdotci, cdotui, ddoti, sdoti, zdotci, zdotui - Compute the dot product of two vectors x and y

SYNOPSIS

```
COMPLEX FUNCTION CDOTCI( NZ, X, INDX, Y)
COMPLEX X(*), Y(*)
INTEGER NZ
INTEGER INDX(*)
```

```
COMPLEX FUNCTION CDOTCI_64( NZ, X, INDX, Y)
COMPLEX X(*), Y(*)
INTEGER*8 NZ
INTEGER*8 INDX(*)
```

F95 INTERFACE

```
COMPLEX FUNCTION DOTCI( [NZ], X, INDX, Y)
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX
```

```
COMPLEX FUNCTION DOTCI_64( [NZ], X, INDX, Y)
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

cdotci Compute the dot product of a real sparse vector x stored in compressed form with a real vector y in full storage form.

```
dot = 0
do 10, i = 1, n
    dot = dot + x(i) * y(indx(i))
10 continue
```

ARGUMENTS

* *NZ (input)*

Number of elements in the compressed form. Unchanged on exit.

* *X (input)*

Vector in compressed form. Unchanged on exit.

* *INDX (input)*

Vector containing the indices of the compressed form. It is assumed that the elements in *INDX* are distinct and greater than zero. Unchanged on exit.

* *Y (input)*

Vector in full storage form. Only the elements corresponding to the indices in *INDX* will be accessed.

NAME

cdotu - compute the dot product of two vectors x and y.

SYNOPSIS

```
COMPLEX FUNCTION CDOTU( N, X, INCX, Y, INCY)
COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
COMPLEX FUNCTION CDOTU_64( N, X, INCX, Y, INCY)
COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX FUNCTION DOT( [N], X, [INCX], Y, [INCY])
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
COMPLEX FUNCTION DOT_64( [N], X, [INCX], Y, [INCY])
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
complex cdotu(int n, complex *x, int incx, complex *y, int incy);
```

```
complex cdotu_64(long n, complex *x, long incx, complex *y, long incy);
```

PURPOSE

cdotu compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

* *X (input)*

of DIMENSION at least $(1 + (n - 1) * \text{abs}(\text{INCX}))$. On entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input)*

of DIMENSION at least $(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. Unchanged on exit.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

cfft2b - compute a periodic sequence from its Fourier coefficients. The xFFT operations are unnormalized, so a call of xFFT2F followed by a call of xFFT2B will multiply the input sequence by $M*N$.

SYNOPSIS

```
SUBROUTINE CFFT2B( M, N, A, LDA, WORK, LWORK)
  COMPLEX A(LDA,*)
  INTEGER M, N, LDA, LWORK
  REAL WORK(*)
```

```
SUBROUTINE CFFT2B_64( M, N, A, LDA, WORK, LWORK)
  COMPLEX A(LDA,*)
  INTEGER*8 M, N, LDA, LWORK
  REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B( [M], [N], A, [LDA], WORK, LWORK)
  COMPLEX, DIMENSION(:,*) :: A
  INTEGER :: M, N, LDA, LWORK
  REAL, DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT2B_64( [M], [N], A, [LDA], WORK, LWORK)
  COMPLEX, DIMENSION(:,*) :: A
  INTEGER(8) :: M, N, LDA, LWORK
  REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cfft2b(int m, int n, complex *a, int lda, float *work, int lwork);
```

```
void cfft2b_64(long m, long n, complex *a, long lda, float *work, long lwork);
```

ARGUMENTS

* ***M (input)***

Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

* ***N (input)***

Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***A (input/output)***

On entry, a two-dimensional array A(M,N) that contains the sequences to be transformed.

* ***LDA (input)***

Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

* ***WORK (input)***

On input, workspace WORK must have been initialized by CFFT2I.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq (4 * (M + N) + 30)$

NAME

cfft2f - compute the Fourier coefficients of a periodic sequence. The xFFT operations are unnormalized, so a call of xFFT2F followed by a call of xFFT2B will multiply the input sequence by $M*N$.

SYNOPSIS

```
SUBROUTINE CFFT2F( M, N, A, LDA, WORK, LWORK)
  COMPLEX A(LDA,*)
  INTEGER M, N, LDA, LWORK
  REAL WORK(*)
```

```
SUBROUTINE CFFT2F_64( M, N, A, LDA, WORK, LWORK)
  COMPLEX A(LDA,*)
  INTEGER*8 M, N, LDA, LWORK
  REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2F( [M], [N], A, [LDA], WORK, LWORK)
  COMPLEX, DIMENSION(:,*) :: A
  INTEGER :: M, N, LDA, LWORK
  REAL, DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT2F_64( [M], [N], A, [LDA], WORK, LWORK)
  COMPLEX, DIMENSION(:,*) :: A
  INTEGER(8) :: M, N, LDA, LWORK
  REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cfft2f(int m, int n, complex *a, int lda, float *work, int lwork);
```

```
void cfft2f_64(long m, long n, complex *a, long lda, float *work, long lwork);
```

ARGUMENTS

* ***M (input)***

Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

* ***N (input)***

Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***A (input/output)***

On entry, a two-dimensional array A(M,N) that contains the sequences to be transformed.

* ***LDA (input)***

Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

* ***WORK (input)***

On input, workspace WORK must have been initialized by CFFT2I.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq (4 * (M + N) + 30)$

NAME

cfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

SYNOPSIS

```
SUBROUTINE CFFT2I( M, N, WORK)
  INTEGER M, N
  REAL WORK(*)

SUBROUTINE CFFT2I_64( M, N, WORK)
  INTEGER*8 M, N
  REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE CFFT2I( M, N, WORK)
  INTEGER :: M, N
  REAL, DIMENSION(:) :: WORK

SUBROUTINE CFFT2I_64( M, N, WORK)
  INTEGER(8) :: M, N
  REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void cfft2i(int m, int n, float *work);

void cfft2i_64(long m, long n, float *work);
```

ARGUMENTS

* ***M*** (*input*)

Number of rows to be transformed. $M \geq 0$.

* ***N*** (*input*)

Number of columns to be transformed. $N \geq 0$.

* ***WORK*** (*input/output*)

On entry, an array of dimension $(4 * (M + N) + 30)$ or greater. CFFT2I needs to be called only once to initialize array WORK before calling CFFT2F and/or CFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

cfft3b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFT3F followed by a call of CFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE CFFT3B( M, N, K, A, LDA, LD2A, WORK, LWORK)
COMPLEX A(LDA,LD2A,*)
INTEGER M, N, K, LDA, LD2A, LWORK
REAL WORK(*)
```

```
SUBROUTINE CFFT3B_64( M, N, K, A, LDA, LD2A, WORK, LWORK)
COMPLEX A(LDA,LD2A,*)
INTEGER*8 M, N, K, LDA, LD2A, LWORK
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3B( [M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
COMPLEX, DIMENSION(:, :, :) :: A
INTEGER :: M, N, K, LDA, LD2A, LWORK
REAL, DIMENSION(:) :: WORK
```

```
SUBROUTINE FFT3B_64( [M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
COMPLEX, DIMENSION(:, :, :) :: A
INTEGER(8) :: M, N, K, LDA, LD2A, LWORK
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cfft3b(int m, int n, int k, complex *a, int lda, int ld2a, float *work, int lwork);
```

```
void cfft3b_64(long m, long n, long k, complex *a, long lda, long ld2a, float *work, long lwork);
```

ARGUMENTS

* ***M (input)***

Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

* ***N (input)***

Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***K (input)***

Number of planes to be transformed. These subroutines are most efficient when K is a product of small primes. $K \geq 0$.

* ***A (input/output)***

On entry, a three-dimensional array A(LDA,LD2A,K) that contains the sequences to be transformed.

* ***LDA (input)***

Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

* ***LD2A (input)***

Second dimension of the array containing the data to be transformed. $LD2A \geq N$.

* ***WORK (input)***

On input, workspace WORK must have been initialized by CFFT3I.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq (4 * (M + N + K) + 45)$.

NAME

cfft3f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFT3F followed by a call of CFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE CFFT3F( M, N, K, A, LDA, LD2A, WORK, LWORK)
COMPLEX A(LDA,LD2A,*)
INTEGER M, N, K, LDA, LD2A, LWORK
REAL WORK(*)
```

```
SUBROUTINE CFFT3F_64( M, N, K, A, LDA, LD2A, WORK, LWORK)
COMPLEX A(LDA,LD2A,*)
INTEGER*8 M, N, K, LDA, LD2A, LWORK
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3F( [M], [N], [K], A, [LDA], LD2A, WORK, LWORK)
COMPLEX, DIMENSION(:, :, :) :: A

```

```
void cfft3f(int m, int n, int k, complex *a, int lda, int ld2a, float *work, int lwork);
```

```
void cfft3f_64(long m, long n, long k, complex *a, long lda, long ld2a, float *work, long lwork);
```

ARGUMENTS

* ***M (input)***

Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. $M \geq 0$.

* ***N (input)***

Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. $N \geq 0$.

* ***K (input)***

Number of planes to be transformed. These subroutines are most efficient when K is a product of small primes. $K \geq 0$.

* ***A (input/output)***

On entry, a three-dimensional array $A(M,N,K)$ that contains the sequences to be transformed.

* ***LDA (input)***

Leading dimension of the array containing the data to be transformed. $LDA \geq M$.

* ***LD2A (input)***

Second dimension of the array containing the data to be transformed. $LD2A \geq N$.

* ***WORK (input)***

On input, workspace WORK must have been initialized by CFFT3I.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq (4 * (M + N + K) + 45)$.

NAME

cfft3i - initialize the array WSAVE, which is used in both CFFT3F and CFFT3B.

SYNOPSIS

```
SUBROUTINE CFFT3I( M, N, K, WORK)
INTEGER M, N, K
REAL WORK(*)

SUBROUTINE CFFT3I_64( M, N, K, WORK)
INTEGER*8 M, N, K
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE CFFT3I( M, N, K, WORK)
INTEGER :: M, N, K
REAL, DIMENSION(:) :: WORK

SUBROUTINE CFFT3I_64( M, N, K, WORK)
INTEGER(8) :: M, N, K
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void cfft3i(int m, int n, int k, float *work);

void cfft3i_64(long m, long n, long k, float *work);
```

ARGUMENTS

* ***M*** (*input*)

Number of rows to be transformed. $M \geq 0$.

* ***N*** (*input*)

Number of columns to be transformed. $N \geq 0$.

* ***K*** (*input*)

Number of planes to be transformed. $K \geq 0$.

* ***WORK*** (*input/output*)

On entry, an array of dimension $(4 * (M + N + K) + 45)$ or greater. CFFT3I needs to be called only once to initialize array *WORK* before calling CFFT3F and/or CFFT3B if *M*, *N*, *K* and *WORK* remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

cfft - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFTF followed by a call of CFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE CFFTB( N, X, WSAVE)
COMPLEX X(*)
INTEGER N
REAL WSAVE(*)

SUBROUTINE CFFTB_64( N, X, WSAVE)
COMPLEX X(*)
INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB( [N], X, WSAVE)
COMPLEX, DIMENSION(:) :: X
INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE FFTB_64( [N], X, WSAVE)
COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cfft(int n, complex *x, float *wsave);

void cfft_64(long n, complex *x, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input)*

On entry, an array of length N containing the sequence to be transformed.

* *WSAVE (input/output)*

On entry, WSAVE must be an array of dimension $(4 * N + 15)$ or greater and must have been initialized by CFFT1.

NAME

cfft - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFTF followed by a call of CFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE CFFTF( N, X, WSAVE)
COMPLEX X(*)
INTEGER N
REAL WSAVE(*)
```

```
SUBROUTINE CFFTF_64( N, X, WSAVE)
COMPLEX X(*)
INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE F95_CFFTF( [N], X, WSAVE)
COMPLEX, DIMENSION(:) :: X
INTEGER :: N
REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE F95_CFFTF_64( [N], X, WSAVE)
COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cfft(int n, complex *x, float *wsave);
```

```
void cfft_64(long n, complex *x, float *wsave);
```

ARGUMENTS

*** *N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
 $N \geq 0$.

*** *X (input)***

On entry, an array of length N containing the sequence to be transformed.

*** *WSAVE (input)***

On entry, *WSAVE* must be an array of dimension $(4 * N + 15)$ or greater and must have been initialized by *CFFTI*.

NAME

cfft - initialize the array WSAVE, which is used in both CFFTF and CFFTB.

SYNOPSIS

```
SUBROUTINE CFFTI( N, WSAVE)
INTEGER N
REAL WSAVE(*)

SUBROUTINE CFFTI_64( N, WSAVE)
INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE CFFTI( N, WSAVE)
INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE CFFTI_64( N, WSAVE)
INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cfft(int n, float *wsave);

void cfft_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input/output)*

On entry, an array of dimension $(4 * N + 15)$ or greater. CFFTI needs to be called only once to initialize array WORK before calling CFFTF and/or CFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

cfftopt - compute the length of the closest fast FFT

SYNOPSIS

```
INTEGER FUNCTION CFFTOPT( LEN)
INTEGER LEN
```

```
INTEGER*8 FUNCTION CFFTOPT_64( LEN)
INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION CFFTOPT( LEN)
INTEGER :: LEN
```

```
INTEGER(8) FUNCTION CFFTOPT_64( LEN)
INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>
```

```
int cfftopt(int len);
```

```
long cfftopt_64(long len);
```

PURPOSE

cfftopt computes the length of the closest fast FFT. Fast Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length $32=2*2*2*2$ will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

CFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. CFFTOPT will return 16 for an input of $N=16$ and return $18=2*3*3$ for an input of $N=17$.

Note that the length computed here is not guaranteed to be optimal, only to be a product of small primes. Also, the value

returned may change as the underlying FFTs become capable of handling larger primes. For example, passing in $N=51$ today will return $52=2*2*13$ rather than $51=3*17$ because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added and then $N=51$ will return 51.

ARGUMENTS

NAME

cgbbird - reduce a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation

SYNOPSIS

```
SUBROUTINE CGBBRD( VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ,
*   PT, LDPT, C, LDC, WORK, RWORK, INFO)
CHARACTER * 1 VECT

INTEGER*8 M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL D(*), E(*), RWORK(*)
```

F95 INTERFACE

```
SUBROUTINE GBBRD( VECT, [M], [N], [NCC], KL, KU, AB, [LDAB], D, E,
*   Q, [LDQ], PT, [LDPT], C, [LDC], [WORK], [RWORK], [INFO])
CHARACTER(LEN=1) :: VECT
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,) :: AB, Q, PT, C
INTEGER :: M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL, DIMENSION(:) :: D, E, RWORK

SUBROUTINE GBBRD_64( VECT, [M], [N], [NCC], KL, KU, AB, [LDAB], D,
*   E, Q, [LDQ], PT, [LDPT], C, [LDC], [WORK], [RWORK], [INFO])
CHARACTER(LEN=1) :: VECT
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,) :: AB, Q, PT, C
INTEGER(8) :: M, N, NCC, KL, KU, LDAB, LDQ, LDPT, LDC, INFO
REAL, DIMENSION(:) :: D, E, RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbbird(char vect, int m, int n, int ncc, int kl, int ku, complex *ab, int ldab, float *d, float *e, complex *q, int ldq,
complex *pt, int ldpt, complex *c, int ldc, int *info);
```

```
void cgbbrd_64(char vect, long m, long n, long ncc, long kl, long ku, complex *ab, long ldab, float *d, float *e, complex *q, long ldq, complex *pt, long ldpt, complex *c, long ldc, long *info);
```

PURPOSE

cgbbrd reduces a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation: $Q' * A * P = B$.

The routine computes B, and optionally forms Q or P', or computes $Q'*C$ for a given matrix C.

ARGUMENTS

* **VECT** (*input*)

Specifies whether or not the matrices Q and P' are to be formed.

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* **NCC** (*input*)

The number of columns of the matrix C. $NCC \geq 0$.

* **KL** (*input*)

The number of subdiagonals of the matrix A. $KL \geq 0$.

* **KU** (*input*)

The number of superdiagonals of the matrix A. $KU \geq 0$.

* **AB** (*input/output*)

On entry, the m-by-n band matrix A, stored in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$. On exit, A is overwritten by values generated during the reduction.

* **LDAB** (*input*)

The leading dimension of the array A. $LDAB \geq KL+KU+1$.

* **D** (*output*)

The diagonal elements of the bidiagonal matrix B.

* **E** (*output*)

The superdiagonal elements of the bidiagonal matrix B.

* **Q** (*output*)

If VECT = 'Q' or 'B', the m-by-m unitary matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. $LDQ \geq \max(1,M)$ if VECT = 'Q' or 'B'; $LDQ \geq 1$ otherwise.

* **PT** (*output*)

If VECT = 'P' or 'B', the n-by-n unitary matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

* **LDPT** (*input*)

The leading dimension of the array PT. LDPT $\geq \max(1, N)$ if VECT = 'P' or 'B'; LDPT ≥ 1 otherwise.

* **C (input/output)**

On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^*C . C is not referenced if NCC = 0.

* **LDC (input)**

The leading dimension of the array C. LDC $\geq \max(1, M)$ if NCC > 0; LDC ≥ 1 if NCC = 0.

* **WORK (workspace)**

dimension(MAX(M,N))

* **RWORK (workspace)**

dimension(MAX(M,N))

* **INFO (output)**

NAME

cgbc - (obsolete) compute the LU factorization and condition number of a general matrix A in banded storage. If the condition number is not needed then xGBFA is slightly faster. It is typical to follow a call to xGBCO with a call to xGBSL to solve $Ax = b$ or to xGBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE CGBCO( A, LDA, N, NSUB, NSUPER, IPIVOT, RCOND, WORK)
COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, NSUB, NSUPER
INTEGER IPIVOT(*)
REAL RCOND
```

```
SUBROUTINE CGBCO_64( A, LDA, N, NSUB, NSUPER, IPIVOT, RCOND, WORK)
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, NSUB, NSUPER
INTEGER*8 IPIVOT(*)
REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbc(complex *a, int lda, int n, int nsub, int nsuper, int *ipivot, float *rcond);
```

```
void cgbc_64(complex *a, long lda, long n, long nsub, long nsuper, long *ipivot, float *rcond);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, an LU factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

* ***IPIVOT*** (*output*)

On exit, a vector of pivot indices.

* ***RCOND*** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* ***WORK*** (*workspace*)

Scratch array with a dimension of N.

NAME

cgbcon - estimate the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm,

SYNOPSIS

```
SUBROUTINE CGBCON( NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,  
*      RCOND, WORK, WORK2, INFO)  
CHARACTER * 1 NORM  
COMPLEX A(LDA,*), WORK(*)  
INTEGER N, NSUB, NSUPER, LDA, INFO  
INTEGER IPIVOT(*)  
REAL ANORM, RCOND  
REAL WORK2(*)
```

```
SUBROUTINE CGBCON_64( NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,  
*      RCOND, WORK, WORK2, INFO)  
CHARACTER * 1 NORM  
COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, NSUB, NSUPER, LDA, INFO  
INTEGER*8 IPIVOT(*)  
REAL ANORM, RCOND  
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE GBCON( NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT, ANORM,  
*      RCOND, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, NSUB, NSUPER, LDA, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE GBCON_64( NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT,  
*      ANORM, RCOND, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, NSUB, NSUPER, LDA, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL :: ANORM, RCOND  
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbcon(char norm, int n, int nsub, int nsuper, complex *a, int lda, int *ipivot, float anorm, float *rcond, int *info);
```

```
void cgbcon_64(char norm, long n, long nsub, long nsuper, complex *a, long lda, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

cgbcon estimates the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $\text{NSUB} \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $\text{NSUPER} \geq 0$.

* **A** (*input*)

Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $\text{NSUB} + \text{NSUPER}$ superdiagonals in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$, and the multipliers used during the factorization are stored in rows $\text{NSUB} + \text{NSUPER} + 2$ to $2 * \text{NSUB} + \text{NSUPER} + 1$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **ANORM** (*input*)

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cgbd - (obsolete) compute the determinant of a general matrix A in banded storage, which has been LU-factored by CGBCO or CGBFA.

SYNOPSIS

```
SUBROUTINE CGBDI( A, LDA, N, NSUB, NSUPER, IPIVOT, DET)
  COMPLEX A(LDA,*), DET(*)
  INTEGER LDA, N, NSUB, NSUPER
  INTEGER IPIVOT(*)
```

```
SUBROUTINE CGBDI_64( A, LDA, N, NSUB, NSUPER, IPIVOT, DET)
  COMPLEX A(LDA,*), DET(*)
  INTEGER*8 LDA, N, NSUB, NSUPER
  INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbd(complex *a, int lda, int n, int nsub, int nsuper, int *ipivot, complex *det);
```

```
void cgbd_64(complex *a, long lda, long n, long nsub, long nsuper, long *ipivot, complex *det);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A, as computed by CGBCO or CGBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (input)**

Pivot vector as computed by CGBCO or CGBFA.

*** *DET (output)***

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**}expon)$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) = 0.0$.

NAME

cgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE CGBEQU( M, N, NSUB, NSUPER, A, LDA, ROWSC, COLSC, ROWCND,
*      COLCND, AMAX, INFO)
COMPLEX A(LDA,*)
INTEGER M, N, NSUB, NSUPER, LDA, INFO
REAL ROWCND, COLCND, AMAX
REAL ROWSC(*), COLSC(*)

SUBROUTINE CGBEQU_64( M, N, NSUB, NSUPER, A, LDA, ROWSC, COLSC,
*      ROWCND, COLCND, AMAX, INFO)
COMPLEX A(LDA,*)
INTEGER*8 M, N, NSUB, NSUPER, LDA, INFO
REAL ROWCND, COLCND, AMAX
REAL ROWSC(*), COLSC(*)
```

F95 INTERFACE

```
SUBROUTINE GBEQU( [M], [N], NSUB, NSUPER, A, [LDA], ROWSC, COLSC,
*      ROWCND, COLCND, AMAX, [INFO])
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: M, N, NSUB, NSUPER, LDA, INFO
REAL :: ROWCND, COLCND, AMAX
REAL, DIMENSION(:) :: ROWSC, COLSC

SUBROUTINE GBEQU_64( [M], [N], NSUB, NSUPER, A, [LDA], ROWSC, COLSC,
*      ROWCND, COLCND, AMAX, [INFO])
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INFO
REAL :: ROWCND, COLCND, AMAX
REAL, DIMENSION(:) :: ROWSC, COLSC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbequ(int m, int n, int nsub, int nsuper, complex *a, int lda, float *rowsc, float *colsc, float *rowcnd, float *colcnd, float *amax, int *info);
```

```
void cgbequ_64(long m, long n, long nsub, long nsuper, complex *a, long lda, float *rowsc, float *colsc, float *rowcnd, float *colcnd, float *amax, long *info);
```

PURPOSE

cgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

*** NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

*** A (input)**

The band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

*** ROWSC (output)**

If $INFO = 0$, or $INFO > M$, ROWSC contains the row scale factors for A.

*** COLSC (output)**

If $INFO = 0$, COLSC contains the column scale factors for A.

*** ROWCND (output)**

If $INFO = 0$ or $INFO > M$, ROWCND contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If $ROWCND \geq 0.1$ and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

*** COLCND (output)**

If $INFO = 0$, COLCND contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If $COLCND \geq 0.1$, it is not worth scaling by COLSC.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

cgbfa - (obsolete) compute the LU factorization of a matrix A in banded storage. It is typical to follow a call to CGBFA with a call to CGBSL to solve $Ax = b$ or to CGBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE CGBFA( A, LDA, N, NSUB, NSUPER, IPIVOT, INFO)
COMPLEX A(LDA,*)
INTEGER LDA, N, NSUB, NSUPER, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CGBFA_64( A, LDA, N, NSUB, NSUPER, IPIVOT, INFO)
COMPLEX A(LDA,*)
INTEGER*8 LDA, N, NSUB, NSUPER, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbfa(complex *a, int lda, int n, int nsub, int nsuper, int *ipivot, int *info);
```

```
void cgbfa_64(complex *a, long lda, long n, long nsub, long nsuper, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, an LU factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that CGBSL will divide by zero if called.

NAME

cgbmv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$

SYNOPSIS

```
SUBROUTINE CGBMV( TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,  
*      INCX, BETA, Y, INCY)  
CHARACTER * 1 TRANSA  
COMPLEX ALPHA, BETA  
COMPLEX A(LDA,*), X(*), Y(*)  
INTEGER M, N, NSUB, NSUPER, LDA, INCX, INCY
```

```
SUBROUTINE CGBMV_64( TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,  
*      INCX, BETA, Y, INCY)  
CHARACTER * 1 TRANSA  
COMPLEX ALPHA, BETA  
COMPLEX A(LDA,*), X(*), Y(*)  
INTEGER*8 M, N, NSUB, NSUPER, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE GBMV( [TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],  
*      X, [INCX], BETA, Y, [INCY])  
CHARACTER(LEN=1) :: TRANSA  
COMPLEX :: ALPHA, BETA  
COMPLEX, DIMENSION(:) :: X, Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: M, N, NSUB, NSUPER, LDA, INCX, INCY
```

```
SUBROUTINE GBMV_64( [TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],  
*      X, [INCX], BETA, Y, [INCY])  
CHARACTER(LEN=1) :: TRANSA  
COMPLEX :: ALPHA, BETA  
COMPLEX, DIMENSION(:) :: X, Y  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbmv(char transa, int m, int n, int nsub, int nsuper, complex alpha, complex *a, int lda, complex *x, int incx, complex beta, complex *y, int incy);
```

```
void cgbmv_64(char transa, long m, long n, long nsub, long nsuper, complex alpha, complex *a, long lda, complex *x, long incx, complex beta, complex *y, long incy);
```

PURPOSE

cgbmv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A^T x + \beta y$, or $y := \alpha \text{conjg}(A) x + \beta y$ where α and β are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

ARGUMENTS

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A^T x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha \text{conjg}(A) x + \beta y$.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

* *NSUB* (input)

On entry, NSUB specifies the number of sub-diagonals of the matrix A. NSUB must satisfy $0 \leq \text{NSUB}$. Unchanged on exit.

* *NSUPER* (input)

On entry, NSUPER specifies the number of super-diagonals of the matrix A. NSUPER must satisfy $0 \leq \text{NSUPER}$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry, the leading $(kl + ku + 1)$ by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(ku + 1)$ of the array, the first super-diagonal starting at position 2 in row ku , the first sub-diagonal starting at position 1 in row $(ku + 2)$, and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to

band storage:

```
DO 20, J = 1, N
  K = NSUPER + 1 - J
  DO 10, I = MAX( 1, J - NSUPER ), MIN( M, J + NSUB )
    A( K + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (kl + ku + 1). Unchanged on exit.

*** X (input)**

(1 + (n - 1) * abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1) * abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

*** Y (input/output)**

(1 + (m - 1) * abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1) * abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

void cgbfrfs_64(char transa, long n, long nsub, long nsuper, long nrhs, complex *a, long lda, complex *af, long ldaf, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cgbfrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The original band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(n,j+kl)$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

* **AF** (*input*)

Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq 2*NSUB*NSUPER+1$.

* **IPIVOT** (*input*)

The pivot indices from CGBTRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CGBTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cgbsl - (obsolete) solve the linear system $Ax = b$ for a matrix A in banded storage, which has been LU-factored by CGBCO or CGBFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CGBSL( A, LDA, N, NSUB, NSUPER, IPIVOT, B, JOB)
COMPLEX A(LDA,*), B(*)
INTEGER LDA, N, NSUB, NSUPER, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE CGBSL_64( A, LDA, N, NSUB, NSUPER, IPIVOT, B, JOB)
COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N, NSUB, NSUPER, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbsl(complex *a, int lda, int n, int nsub, int nsuper, int *ipivot, complex *b, int job);
```

```
void cgbsl_64(complex *a, long lda, long n, long nsub, long nsuper, long *ipivot, complex *b, long job);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A , as computed by CGBCO or CGBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A . $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A . $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (input)**

Pivot vector as computed by CGBCO or CGBFA.

* ***B*** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* ***JOB*** (*input*)

Determines which operation this subroutine will perform:

0 solve the system $Ax = b$

not 0 solve the linear system $AHx = b$ Note that $ATx = AHx$ for real matrices.

NAME

cgbsv - compute the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

SYNOPSIS

```
SUBROUTINE CGBSV( N, NSUB, NSUPER, NRHS, A, LDA, IPIVOT, B, LDB,
*              INFO)
COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER IPIVOT(*)

SUBROUTINE CGBSV_64( N, NSUB, NSUPER, NRHS, A, LDA, IPIVOT, B, LDB,
*              INFO)
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GBSV( [N], NSUB, NSUPER, [NRHS], A, [LDA], IPIVOT, B,
*              [LDB], [INFO])
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE GBSV_64( [N], NSUB, NSUPER, [NRHS], A, [LDA], IPIVOT, B,
*              [LDB], [INFO])
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbsv(int n, int nsub, int nsuper, int nrhs, complex *a, int lda, int *ipivot, complex *b, int ldb, int *info);
```

```
void cgbsv_64(long n, long nsub, long nsuper, long nrhs, complex *a, long lda, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cgbsv computes the solution to a complex system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N -by- $NRHS$ matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with $KL+KU$ superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** N (input)**

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

*** $NSUB$ (input)**

The number of subdiagonals within the band of A . $NSUB \geq 0$.

*** $NSUPER$ (input)**

The number of superdiagonals within the band of A . $NSUPER \geq 0$.

*** $NRHS$ (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** A (input/output)**

On entry, the matrix A in band storage, in rows $NSUB+1$ to $2*NSUB+NSUPER+1$; rows 1 to $NSUB$ of the array need not be set. The j -th column of A is stored in the j -th column of the array A as follows:
 $A(NSUB+NSUPER+1+i-j,j) = A(i,j)$ for $\max(1,j-NSUPER) \leq i \leq \min(N,j+NSUB)$ On exit, details of the factorization: U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. See below for further details.

*** LDA (input)**

The leading dimension of the array A . $LDA \geq 2*NSUB+NSUPER+1$.

*** $IPIVOT$ (output)**

The pivot indices that define the permutation matrix P ; row i of the matrix was interchanged with row $IPIVOT(i)$.

*** B (input/output)**

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1,N)$.

*** $INFO$ (output)**

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbsvx(char fact, char transa, int n, int nsub, int nsuper, int nrhs, complex *a, int lda, complex *af, int ldaf, int *ipivot,
char equed, float *rowsc, float *colsc, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int
*info);
```

```
void cgbsvx_64(char fact, char transa, long n, long nsub, long nsuper, long nrhs, complex *a, long lda, complex *af, long
ldaf, long *ipivot, char equed, float *rowsc, float *colsc, complex *b, long ldb, complex *x, long ldx, float *rcond, float
*ferr, float *berr, long *info);
```

PURPOSE

cgbsvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
TRANS = 'T':  (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
TRANS = 'C':  (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

```
A = L * U,
where L is a product of permutation and unit lower triangular
matrices with KL subdiagonals, and U is upper triangular with
KL+KU superdiagonals.
```

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if $\text{TRANS} = 'N'$) or $\text{diag}(R)$ (if $\text{TRANS} = 'T'$ or $'C'$) so that it solves the original system before equilibration.

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $\text{NSUB} \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $\text{NSUPER} \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $\text{NRHS} \geq 0$.

* **A** (*input/output*)

On entry, the matrix A in band storage, in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(\text{NSUPER} + 1 + i - j, j) = A(i, j)$ for $\max(1, j - \text{NSUPER}) \leq i \leq \min(N, j + \text{NSUB})$

If $\text{FACT} = 'F'$ and EQUED is not $'N'$, then A must have been equilibrated by the scaling factors in ROWSC and/or COLSC . A is not modified if $\text{FACT} = 'F'$ or $'N'$, or if $\text{FACT} = 'E'$ and $\text{EQUED} = 'N'$ on exit.

On exit, if $\text{EQUED} \neq 'N'$, A is scaled as follows: $\text{EQUED} = 'ROWSC': A := \text{diag}(\text{ROWSC}) * A$

$\text{EQUED} = 'COLSC': A := A * \text{diag}(\text{COLSC})$

$\text{EQUED} = 'B': A := \text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \text{NSUB} + \text{NSUPER} + 1$.

* **AF** (*input/output*)

If $\text{FACT} = 'F'$, then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $\text{NSUB} + \text{NSUPER}$ superdiagonals in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$, and the multipliers used during the factorization are stored in rows $\text{NSUB} + \text{NSUPER} + 2$ to $2 * \text{NSUB} + \text{NSUPER} + 1$. If $\text{EQUED} \neq 'N'$, then AF is the factored form of the equilibrated matrix A.

If $\text{FACT} = 'N'$, then AF is an output argument and on exit returns details of the LU factorization of A.

If $\text{FACT} = 'E'$, then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* **LDAF** (*input*)

The leading dimension of the array AF. $\text{LDAF} \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

* **IPIVOT** (*input*)

If $\text{FACT} = 'F'$, then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A =$

$L*U$ as computed by CGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the original matrix A .

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L*U$ of the equilibrated matrix A .

* **EQUED (input)**

Specifies the form of equilibration that was done.

* **ROWSC (input/output)**

The row scale factors for A . If EQUED = 'ROWSC' or 'B', A is multiplied on the left by $\text{diag}(\text{ROWSC})$; if EQUED = 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT = 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

* **COLSC (input/output)**

The column scale factors for A . If EQUED = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

* **B (input/output)**

On entry, the right hand side matrix B . On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC})*B$; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC})*B$.

* **LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **X (output)**

If INFO = 0 or INFO = $N+1$, the N -by- N RHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC}))*X$ if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC}))*X$ if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

* **LDX (input)**

The leading dimension of the array X . $LDX \geq \max(1,N)$.

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR (output)**

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK (workspace)**

$\text{dimension}(2*N)$

* **WORK2 (workspace)**

On exit, WORK2(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X , condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A .

** INFO (output)*

NAME

cgbtf2 - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE CGBTF2( M, N, KL, KU, AB, LDAB, IPIV, INFO)
COMPLEX AB(LDAB,*)
INTEGER M, N, KL, KU, LDAB, INFO
INTEGER IPIV(*)
```

INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE GBTF2_64( [M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
COMPLEX, DIMENSION(:,*) :: AB
INTEGER(8) :: M, N, KL, KU, LDAB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgbtf2(int m, int n, int kl, int ku, complex *ab, int ldab, int *ipiv, int *info);
```

```
void cgbtf2_64(long m, long n, long kl, long ku, complex *ab, long ldab, long *ipiv, long *info);
```

PURPOSE

cgbtf2 computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** KL (input)**

The number of subdiagonals within the band of A. $KL \geq 0$.

*** KU (input)**

The number of superdiagonals within the band of A. $KU \geq 0$.

*** AB (input/output)**

On entry, the matrix A in band storage, in rows $KL+1$ to $2*KL+KU+1$; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with $KL+KU$ superdiagonals in rows 1 to $KL+KU+1$, and the multipliers used during the factorization are stored in rows $KL+KU+2$ to $2*KL+KU+1$. See below for further details.

*** LDAB (input)**

The leading dimension of the array AB. $LDAB \geq 2*KL+KU+1$.

*** IPIV (output)**

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row IPIV(i).

*** INFO (output)**

NAME

void cgbtrf_64(long m, long n, long nsub, long nsuper, complex *a, long lda, long *ipivot, long *info);
```

PURPOSE

cgbtrf computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

*** NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

*** A (input/output)**

On entry, the matrix A in band storage, in rows $NSUB+1$ to $2*NSUB+NSUPER+1$; rows 1 to $NSUB$ of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. See below for further details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row $IPIVOT(i)$.

*** INFO (output)**

NAME

cgbtrs - solve a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general band matrix A using the LU factorization computed by CGBTRF

SYNOPSIS

```

```
void cgbtrs_64(char transa, long n, long nsub, long nsuper, long nrhs, complex *a, long lda, long *ipivot, complex *b, long
```

ldb, long *info);

PURPOSE

cgbtrs solves a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general band matrix A using the LU factorization computed by CGBTRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

cgebak - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

SYNOPSIS

```
SUBROUTINE CGEBAK( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
CHARACTER * 1 JOB, SIDE
COMPLEX V(LDV,*)
INTEGER N, ILO, IHI, M, LDV, INFO
REAL SCALE(*)
```

```
SUBROUTINE CGEBAK_64( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV,
* INFO)
CHARACTER * 1 JOB, SIDE
COMPLEX V(LDV,*)
INTEGER*8 N, ILO, IHI, M, LDV, INFO
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAK( JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
* [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX, DIMENSION(:, :) :: V
INTEGER :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: SCALE

SUBROUTINE GEBAK_64( JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
* [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX, DIMENSION(:, :) :: V
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgebak(char job, char side, int n, int ilo, int ihi, float *scale, int m, complex *v, int ldv, int *info);
```

```
void cgebak_64(char job, char side, long n, long ilo, long ihi, float *scale, long m, complex *v, long ldv, long *info);
```

PURPOSE

cgebak forms the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL.

ARGUMENTS

* ***JOB*** (*input*)

Specifies the type of backward transformation required:

* ***SIDE*** (*input*)

* ***N*** (*input*)

The number of rows of the matrix V. $N \geq 0$.

* ***ILO*** (*input*)

The integer ILO determined by CGEBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI*** (*input*)

The integer IHI determined by CGEBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***SCALE*** (*input*)

Details of the permutation and scaling factors, as returned by CGEBAL.

* ***M*** (*input*)

The number of columns of the matrix V. $M \geq 0$.

* ***V*** (*input/output*)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by CHSEIN or CTREVC. On exit, V is overwritten by the transformed eigenvectors.

* ***LDV*** (*input*)

The leading dimension of the array V. $LDV \geq \max(1,N)$.

* ***INFO*** (*output*)

NAME

cgebal - balance a general complex matrix A

SYNOPSIS

```
SUBROUTINE CGEBAL( JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
CHARACTER * 1 JOB
COMPLEX A(LDA,*)
INTEGER N, LDA, ILO, IHI, INFO
REAL SCALE(*)
```

```
SUBROUTINE CGEBAL_64( JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
CHARACTER * 1 JOB
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, ILO, IHI, INFO
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL( JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
CHARACTER(LEN=1) :: JOB
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: N, LDA, ILO, IHI, INFO
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE GEBAL_64( JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
CHARACTER(LEN=1) :: JOB
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: N, LDA, ILO, IHI, INFO
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgebal(char job, int n, complex *a, int lda, int *ilo, int *ihi, float *scale, int *info);
```

```
void cgebal_64(char job, long n, complex *a, long lda, long *ilo, long *ihi, float *scale, long *info);
```

PURPOSE

cgabal balances a general complex matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

*** JOB (input)**

Specifies the operations to be performed on A:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** ILO (output)**

ILO and IHI are set to integers such that on exit $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

*** IHI (output)**

ILO and IHI are set to integers such that on exit $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

*** SCALE (output)**

Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then $SCALE(j) = P(j)$ for $j = 1, \dots, ILO-1$

*** INFO (output)**

NAME

cgebrd - reduce a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation

SYNOPSIS

```
SUBROUTINE CGEBRD( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,
*                INFO)
  COMPLEX A(LDA,*), TAUQ(*), TAUP(*), WORK(*)
  INTEGER M, N, LDA, LWORK, INFO
  REAL D(*), E(*)

SUBROUTINE CGEBRD_64( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,
*                   INFO)
  COMPLEX A(LDA,*), TAUQ(*), TAUP(*), WORK(*)
  INTEGER*8 M, N, LDA, LWORK, INFO
  REAL D(*), E(*)
```

F95 INTERFACE

  COMPLEX, DIMENSION(:) :: TAUQ, TAUP, WORK
  COMPLEX, DIMENSION(:, :) :: A
  INTEGER :: M, N, LDA, LWORK, INFO
  REAL, DIMENSION(:) :: D, E

SUBROUTINE GEBRD_64( [M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],
*                  [LWORK], [INFO])
  COMPLEX, DIMENSION(:) :: TAUQ, TAUP, WORK
  COMPLEX, DIMENSION(:, :) :: A
  INTEGER(8) :: M, N, LDA, LWORK, INFO
  REAL, DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgebrd(int m, int n, complex *a, int lda, float *d, float *e, complex *tauq, complex *taup, int *info);
```

```
void cgebrd_64(long m, long n, complex *a, long lda, float *d, float *e, complex *tauq, complex *taup, long *info);
```

PURPOSE

cgebrd reduces a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation: Q^*H
* $A * P = B$.

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

ARGUMENTS

* **M (input)**

The number of rows in the matrix A. $M \geq 0$.

* **N (input)**

The number of columns in the matrix A. $N \geq 0$.

* **A (input/output)**

On entry, the M-by-N general matrix to be reduced. On exit, if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors. See Further Details.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **D (output)**

The diagonal elements of the bidiagonal matrix B: $D(i) = A(i, i)$.

* **E (output)**

The off-diagonal elements of the bidiagonal matrix B: if $m \geq n$, $E(i) = A(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $E(i) = A(i+1, i)$ for $i = 1, 2, \dots, m-1$.

* **TAUQ (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

* **TAUP (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The length of the array WORK. $LWORK \geq \max(1, M, N)$. For optimum performance $LWORK \geq (M+N)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

NAME

cgeco - (obsolete) compute the LU factorization and estimate the condition number of a general matrix A. If the condition number is not needed then CGEFA is slightly faster. It is typical to follow a call to CGEFA with a call to CGESL to solve $Ax = b$ or to CGEDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE CGECO( A, LDA, N, IPIVOT, RCOND, WORK)
COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N
INTEGER IPIVOT(*)
REAL RCOND
```

```
SUBROUTINE CGECO_64( A, LDA, N, IPIVOT, RCOND, WORK)
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeco(complex *a, int lda, int n, int *ipivot, float *rcond);
```

```
void cgeco_64(complex *a, long lda, long n, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, an LU factorization of A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets

smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

cgecon - estimate the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF

SYNOPSIS

```
SUBROUTINE CGECON( NORM, N, A, LDA, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM
COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
REAL ANORM, RCOND
REAL WORK2(*)
```

```
SUBROUTINE CGECON_64( NORM, N, A, LDA, ANORM, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 NORM
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
REAL ANORM, RCOND
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE GECON( NORM, [N], A, [LDA], ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE GECON_64( NORM, [N], A, [LDA], ANORM, RCOND, [WORK],
* [WORK2], [INFO])
CHARACTER(LEN=1) :: NORM
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgecon(char norm, int n, complex *a, int lda, float anorm, float *rcond, int *info);
```

```
void cgecon_64(char norm, long n, complex *a, long lda, float anorm, float *rcond, long *info);
```

PURPOSE

cgecon estimates the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

*** NORM (input)**

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** ANORM (input)**

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

cgedi - (obsolete) compute the determinant and inverse of a general matrix A, which has been LU-factored by CGECO or CGEFA.

SYNOPSIS

```
SUBROUTINE CGEDI( A, LDA, N, IPIVOT, DET, WORK, JOB)
COMPLEX A(LDA,*), DET(*), WORK(*)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE CGEDI_64( A, LDA, N, IPIVOT, DET, WORK, JOB)
COMPLEX A(LDA,*), DET(*), WORK(*)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgedi(complex *a, int lda, int n, int *ipivot, complex *det, int job);
```

```
void cgedi_64(complex *a, long lda, long n, long *ipivot, complex *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the LU factorization of the matrix A, as computed by CGECO or CGEFA. On exit, the inverse of the original matrix A if the inverse was requested, otherwise it is unchanged.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CGECO or CGEFA.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**}expon)$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \geq |DET(1)| \geq 10.0$ or $DET(1) = 0.0$.

*** WORK (workspace)**

Scratch array with a dimension of N.

* ***JOB (input)***

Determines which operation the subroutine will perform:

- 11 both determinant and inverse
- 01 inverse only
- 10 determinant only

NAME

cgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE CGEEQU( M, N, A, LDA, ROWSC, COLSC, ROWCND, COLCND, AMAX,
*                INFO)
  COMPLEX A(LDA,*)
  INTEGER M, N, LDA, INFO
  REAL ROWCND, COLCND, AMAX
  REAL ROWSC(*), COLSC(*)

SUBROUTINE CGEEQU_64( M, N, A, LDA, ROWSC, COLSC, ROWCND, COLCND,
*                   AMAX, INFO)
  COMPLEX A(LDA,*)
  INTEGER*8 M, N, LDA, INFO
  REAL ROWCND, COLCND, AMAX
  REAL ROWSC(*), COLSC(*)
```

F95 INTERFACE

```
SUBROUTINE GEEQU( [M], [N], A, [LDA], ROWSC, COLSC, ROWCND, COLCND,
*               AMAX, [INFO])
  COMPLEX, DIMENSION(:,*) :: A
  INTEGER :: M, N, LDA, INFO
  REAL :: ROWCND, COLCND, AMAX
  REAL, DIMENSION(:) :: ROWSC, COLSC

SUBROUTINE GEEQU_64( [M], [N], A, [LDA], ROWSC, COLSC, ROWCND,
*                  COLCND, AMAX, [INFO])
  COMPLEX, DIMENSION(:,*) :: A
  INTEGER(8) :: M, N, LDA, INFO
  REAL :: ROWCND, COLCND, AMAX
  REAL, DIMENSION(:) :: ROWSC, COLSC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeequ(int m, int n, complex *a, int lda, float *rowsc, float *colsc, float *rowcnd, float *colcnd, float *amax, int *info);
```

```
void cgeequ_64(long m, long n, complex *a, long lda, float *rowsc, float *colsc, float *rowcnd, float *colcnd, float *amax, long *info);
```

PURPOSE

`cgeequ` computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between `SMLNUM` = smallest safe number and `BIGNUM` = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input)***

The M-by-N matrix whose equilibration factors are to be computed.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***ROWSC (output)***

If `INFO` = 0 or `INFO` > M, `ROWSC` contains the row scale factors for A.

* ***COLSC (output)***

If `INFO` = 0, `COLSC` contains the column scale factors for A.

* ***ROWCND (output)***

If `INFO` = 0 or `INFO` > M, `ROWCND` contains the ratio of the smallest `ROWSC(i)` to the largest `ROWSC(i)`. If `ROWCND` ≥ 0.1 and `AMAX` is neither too large nor too small, it is not worth scaling by `ROWSC`.

* ***COLCND (output)***

If `INFO` = 0, `COLCND` contains the ratio of the smallest `COLSC(i)` to the largest `COLSC(i)`. If `COLCND` ≥ 0.1 , it is not worth scaling by `COLSC`.

* ***AMAX (output)***

Absolute value of largest matrix element. If `AMAX` is very close to overflow or very close to underflow, the matrix should be scaled.

* ***INFO (output)***

NAME

cgees - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

SYNOPSIS

```

CHARACTER(LEN=1) :: JOBZ, SORTEV  
COMPLEX, DIMENSION(:) :: W, WORK  
COMPLEX, DIMENSION(:, :) :: A, Z  
INTEGER :: N, LDA, NOUT, LDZ, LDWORK, INFO  
LOGICAL :: SELECT  
LOGICAL, DIMENSION(:) :: WORK3  
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE GEES_64( JOBZ, SORTEV, SELECT, [N], A, [LDA], NOUT, W, Z,  
*      [LDZ], [WORK], [LDWORK], [WORK2], [WORK3], [INFO])  
CHARACTER(LEN=1) :: JOBZ, SORTEV  
COMPLEX, DIMENSION(:) :: W, WORK  
COMPLEX, DIMENSION(:, :) :: A, Z  
INTEGER(8) :: N, LDA, NOUT, LDZ, LDWORK, INFO  
LOGICAL(8) :: SELECT  
LOGICAL(8), DIMENSION(:) :: WORK3  
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgees(char jobz, char sortev, logical(*select)(complex), int n, complex *a, int lda, int *nout, complex *w, complex *z, int ldz, int *info);
```

```
void cgees_64(char jobz, char sortev, logical(*select)(complex), long n, complex *a, long lda, long *nout, complex *w, complex *z, long ldz, long *info);
```

PURPOSE

cgees computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}H)$.

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

* **JOBZ** (*input*)

* **SORTEV** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

* **SELECT** (*input*)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. The eigenvalue W(j) is selected if SELECT(W(j)) is true.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten by its Schur form T.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **NOUT** (*output*)

If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues for which SELECT is true.

* **W** (*output*)

W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

* **Z** (*output*)

If JOBZ = 'V', Z contains the unitary matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. LDZ \geq 1; if JOBZ = 'V', LDZ \geq N.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK \geq max(1,2*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **WORK3** (*workspace*)

Not referenced if SORTEV = 'N'.

* **INFO** (*output*)

```
#include <sunperf.h>
```

```
void cgeesx(char jobz, char sortev, logical(*select)(complex), char sense, int n, complex *a, int lda, int *nout, complex *w, complex *z, int ldz, float *rcone, float *rconv, int *info);
```

```
void cgeesx_64(char jobz, char sortev, logical(*select)(complex), char sense, long n, complex *a, long lda, long *nout, complex *w, complex *z, long ldz, float *rcone, float *rconv, long *info);
```

PURPOSE

cgeesx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}H)$.

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

* **JOBZ** (*input*)

* **SORTEV** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

* **SELECT** (*input*)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue W(j) is selected if SELECT(W(j)) is true.

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrix A. N >= 0.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A is overwritten by its Schur form T.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **NOUT (output)**

If $SORTEV = 'N'$, $NOUT = 0$. If $SORTEV = 'S'$, $NOUT =$ number of eigenvalues for which $SELECT$ is true.

* **W (output)**

W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

* **Z (output)**

If $JOBZ = 'V'$, Z contains the unitary matrix Z of Schur vectors. If $JOBZ = 'N'$, Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq N$.

* **RCONE (output)**

If $SENSE = 'E'$ or $'B'$, RCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if $SENSE = 'N'$ or $'V'$.

* **RCONV (output)**

If $SENSE = 'V'$ or $'B'$, RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if $SENSE = 'N'$ or $'E'$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* **LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1, 2*N)$. Also, if $SENSE = 'E'$ or $'V'$ or $'B'$, $LDWORK \geq 2*NOUT*(N-NOUT)$, where NOUT is the number of selected eigenvalues computed by this routine. Note that $2*NOUT*(N-NOUT) \leq N*N/2$. For good performance, LDWORK must generally be larger.

* **WORK2 (workspace)**

* **BWORK3 (workspace)**

Not referenced if $SORTEV = 'N'$.

* **INFO (output)**

NAME

cggeev - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

SYNOPSIS

REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeev(char jobvl, char jobvr, int n, complex *a, int lda, complex *w, complex *vl, int ldvl, complex *vr, int ldvr, int *info);
```

```
void cgeev_64(char jobvl, char jobvr, long n, complex *a, long lda, complex *w, complex *vl, long ldvl, complex *vr, long ldvr, long *info);
```

PURPOSE

cgeev computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

W contains the computed eigenvalues.

* **VL** (*input*)

If **JOBVL** = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If **JOBVL** = 'N', VL is not referenced. $u(j) = VL(:,j)$, the j-th column of VL.

* **LDVL** (*input*)

The leading dimension of the array VL. LDVL \geq 1; if JOBVL = 'V', LDVL \geq N.

* **VR** (*input*)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. $v(j) = VR(:,j)$, the j-th column of VR.

* **LDVR** (*input*)

The leading dimension of the array VR. LDVR \geq 1; if JOBVR = 'V', LDVR \geq N.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK \geq max(1,2*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

```

PURPOSE

cgeevx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right

eigenvectors (RCONDV).

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D * A * D^{*-1}$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

* **BALANC** (*input*)

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the Schur form of the balanced version of the matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

W contains the computed eigenvalues.

* **VL** (*input*)

If JOBVL = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. $u(j) = VL(:, j)$, the j-th column of VL.

* **LDVL** (*input*)

The leading dimension of the array VL. $LDVL \geq 1$; if JOBVL = 'V', $LDVL \geq N$.

* **VR** (*input*)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. $v(j) = VR(:, j)$, the j-th column of VR.

* **LDVR** (*input*)

The leading dimension of the array VR. $LDVR \geq 1$; if JOBVR = 'V', $LDVR \geq N$.

* **ILO** (*output*)

ILO and IHI are integer values determined when A was balanced. The balanced $A(i, j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

* **IHI** (*output*)

ILO and IHI are integer values determined when A was balanced. The balanced $A(i, j) = 0$ if $I > J$ and $J = 1, \dots, ILO-1$ or $I = IHI+1, \dots, N$.

* **SCALE** (*output*)

Details of the permutations and scaling factors applied when balancing A. If $P(j)$ is the index of the row and column interchanged with row and column j, and $D(j)$ is the scaling factor applied to row and column j, then $SCALE(J) = P(J)$, for $J = 1, \dots, ILO-1$

* **ABNRM** (*output*)

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

* **RCONE** (*output*)

RCONE(j) is the reciprocal condition number of the j-th eigenvalue.

* **RCONV** (*output*)

RCONV(j) is the reciprocal condition number of the j-th right eigenvector.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK $\geq \max(1, 2*N)$, and if SENSE = 'V' or 'B', LDWORK $\geq N*N+2*N$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cgefa - (obsolete) compute the LU factorization of a general matrix A. It is typical to follow a call to CGEFA with a call to CGESL to solve $Ax = b$ or to CGEDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE CGEFA( A, LDA, N, IPIVOT, INFO)
COMPLEX A(LDA,*)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CGEFA_64( A, LDA, N, IPIVOT, INFO)
COMPLEX A(LDA,*)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgefa(complex *a, int lda, int n, int *ipivot, int *info);
```

```
void cgefa_64(complex *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, an LU factorization of A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that CGESL will divide by zero if called.

NAME

cgegs - routine is deprecated and has been replaced by routine CGGES

SYNOPSIS

#include <sunperf.h>
```

```
void cgegs(char jobvsl, char jobvsr, int n, complex *a, int lda, complex *b, int ldb, complex *alpha, complex *beta, complex *vsl, int ldvsl, complex *vsr, int ldvsr, int *info);
```

```
void cgegs_64(char jobvsl, char jobvsr, long n, complex *a, long lda, complex *b, long ldb, complex *alpha, complex *beta, complex *vsl, long ldvsl, complex *vsr, long ldvsr, long *info);
```

PURPOSE

cgegs routine is deprecated and has been replaced by routine CGGES.

CGGES computes for a pair of N-by-N complex nonsymmetric matrices A, B: the generalized eigenvalues (alpha, beta), the complex Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver CGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one unitary matrix and both on the right by another unitary matrix, these two unitary matrices being chosen so as to bring the pair of matrices into upper triangular form with the diagonal elements of B being non-negative real numbers (this is also called complex Schur form.)

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the unitary matrices which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**H A (VSR), (VSL)**H B (VSR))

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. $N \geq 0$.

* **A** (*input/output*)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A.

* **LDA** (*input*)

The leading dimension of A. $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be

computed. On exit, the generalized Schur form of B.

* **LDB (input)**

The leading dimension of B. $LDB \geq \max(1, N)$.

* **ALPHA (output)**

On exit, $ALPHA(j)/BETA(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. $ALPHA(j)$, $j=1, \dots, N$ and $BETA(j)$, $j=1, \dots, N$ are the diagonals of the complex Schur form (A,B) output by CGEGS. The $BETA(j)$ will be non-negative real.

Note: the quotients $ALPHA(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

* **BETA (output)**

See the description of ALPHA.

* **VSL (input)**

If $JOBVSL = 'V'$, VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if $JOBVSL = 'N'$.

* **LDVSL (input)**

The leading dimension of the matrix VSL. $LDVSL \geq 1$, and if $JOBVSL = 'V'$, $LDVSL \geq N$.

* **VSR (input)**

If $JOBVSR = 'V'$, VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if $JOBVSR = 'N'$.

* **LDVSR (input)**

The leading dimension of the matrix VSR. $LDVSR \geq 1$, and if $JOBVSR = 'V'$, $LDVSR \geq N$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* **LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1, 2*N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for CGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the blocksizes for CGEQRF, CUNMQR, and CUNGQR; the optimal LDWORK is $N*(NB+1)$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2 (workspace)**

* **INFO (output)**

```

PURPOSE

cgegv routine is deprecated and has been replaced by routine CGGEV.

CGGEV computes for a pair of N-by-N complex nonsymmetric matrices A and B, the generalized eigenvalues (alpha, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that $(A - w B) r = 0$. A left generalized eigenvector is a vector l such that $l^*H * (A - w B) = 0$, where l^*H is the

conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B. See "Further Details", below.

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VL, and VR. $N \geq 0$.

* **A** (*input/output*)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

* **LDA** (*input*)

The leading dimension of A. $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

* **LDB** (*input*)

The leading dimension of B. $LDB \geq \max(1,N)$.

* **ALPHA** (*output*)

On exit, $ALPHA(j)/VL(j)$, $j=1,\dots,N$, will be the generalized eigenvalues.

Note: the quotients $ALPHA(j)/VL(j)$ may easily over- or underflow, and $VL(j)$ may even be zero. Thus, the user should avoid naively computing the ratio α/β . However, ALPHA will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and VL always less than and usually comparable with $\text{norm}(B)$.

* **BETA** (*output*)

If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha = \beta = 0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVL = 'N'.

* **VL** (*output*)

If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha = \beta = 0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVL = 'N'.

* **LDVL** (*input*)

The leading dimension of the matrix VL. LDVL ≥ 1 , and if JOBVL = 'V', LDVL $\geq N$.

* **VR** (*output*)

If JOBVR = 'V', the right generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha = \beta = 0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVR = 'N'.

* **LDVR** (*input*)

The leading dimension of the matrix VR. LDVR ≥ 1 , and if JOBVR = 'V', LDVR $\geq N$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, 2*N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get block sizes (for CGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the block sizes for CGEQRF, CUNMQR, and CUNGQR; The optimal LDWORK is $\max(2*N, N*(NB+1))$.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cgehrd - reduce a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation

SYNOPSIS

```

```

```
void cgehrd_64(long n, long ilo, long ihi, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cgehrd reduces a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation: $Q' * A * Q = H$.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** ILO (input)**

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

*** IHI (input)**

See the description of ILO.

*** A (input/output)**

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** TAU (output)**

The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

*** WORKIN (workspace)**

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

*** LWORKIN (input)**

The length of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

*** INFO (output)**

NAME

cgelqf - compute an LQ factorization of a complex M-by-N matrix A

SYNOPSIS

```
SUBROUTINE CGELQF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE CGELQF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GELQF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GELQF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgelqf(int m, int n, complex *a, int lda, complex *tau, int *info);
```

```
void cgelqf_64(long m, long n, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cgelqf computes an LQ factorization of a complex M-by-N matrix A: $A = L * Q$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

NAME

cgels - solve overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A

SYNOPSIS

```
SUBROUTINE CGELS( TRANSA, M, N, NRHS, A, LDA, B, LDB, WORK, LDWORK,
*              INFO)
CHARACTER * 1 TRANSA
COMPLEX A(LDA,*), B(LDB,*), WORK(*)
INTEGER M, N, NRHS, LDA, LDB, LDWORK, INFO

SUBROUTINE CGELS_64( TRANSA, M, N, NRHS, A, LDA, B, LDB, WORK,
*              LDWORK, INFO)
CHARACTER * 1 TRANSA
COMPLEX A(LDA,*), B(LDB,*), WORK(*)
INTEGER*8 M, N, NRHS, LDA, LDB, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GELS( [TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
*              [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: TRANSA
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A, B
INTEGER :: M, N, NRHS, LDA, LDB, LDWORK, INFO

SUBROUTINE GELS_64( [TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
*              [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: TRANSA
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A, B
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgels(char transa, int m, int n, int nrhs, complex *a, int lda, complex *b, int ldb, int *info);
```

```
void cgels_64(char transa, long m, long n, long nrhs, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

cgels solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and $m \geq n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize $\| B - A * X \|$.
2. If TRANS = 'N' and $m < n$: find the minimum norm solution of an underdetermined system $A * X = B$.
3. If TRANS = 'C' and $m \geq n$: find the minimum norm solution of an undetermined system $A^{**H} * X = B$.
4. If TRANS = 'C' and $m < n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize $\| B - A^{**H} * X \|$.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

* **TRANSA** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input/output*)

On entry, the M-by-N matrix A. if $M \geq N$, A is overwritten by details of its QR factorization as returned by CGEQRF; if $M < N$, A is overwritten by details of its LQ factorization as returned by CGELQF.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANS = 'N', or N-by-NRHS if TRANS = 'C'. On exit, B is overwritten by the solution vectors, stored columnwise: if TRANS = 'N' and $m \geq n$, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANS = 'N' and $m < n$, rows 1 to N of B contain the minimum norm solution vectors; if TRANS = 'C' and $m \geq n$, rows 1 to M of B contain the minimum norm solution vectors; if TRANS = 'C' and $m < n$, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, MN + \max(MN, NRHS))$. For optimal performance, $LDWORK \geq \max(1, MN + \max(MN, NRHS) * NB)$. where $MN = \min(M, N)$ and NB is the optimum block size.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgelsd(int m, int n, int nrhs, complex *a, int lda, complex *b, int ldb, float *s, float rcond, int *rank, int *info);
```

```
void cgelsd_64(long m, long n, long nrhs, complex *a, long lda, complex *b, long ldb, float *s, float rcond, long *rank, long *info);
```

PURPOSE

cgelsd computes the minimum-norm solution to a real linear least squares problem: minimize $\|b - A*x\|_2$

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:

- (1) Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS)
- (2) Solve the BLS using a divide and conquer approach.
- (3) Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A has been destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* **S (output)**

The singular values of A in decreasing order. The condition number of A in the 2-norm = $S(1)/S(\min(m, n))$.

* **RCOND (input)**

RCOND is used to determine the effective rank of A. Singular values $S(i) \leq RCOND * S(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

* **RANK (output)**

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * S(1)$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq 1$. The exact minimum amount of workspace needed depends on M, N and NRHS. If $M \geq N$, $LWORK \geq 2 * N + N * NRHS$. If $M < N$, $LWORK \geq 2 * M + M * NRHS$. For good performance, LWORK should generally be larger.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

If $M \geq N$, $LRWORK \geq 8 * N + 2 * N * SMLSIZ + 8 * N * NLVL + N * NRHS$. If $M < N$, $LRWORK \geq 8 * M + 2 * M * SMLSIZ + 8 * M * NLVL + M * NRHS$. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and $NLVL = \text{INT}(\text{LOG}_2(\text{MIN}(M, N) / (SMLSIZ + 1))) + 1$

* **IWORK (workspace)**

$LIWORK \geq 3 * \text{MINMN} * NLVL + 11 * \text{MINMN}$, where $\text{MINMN} = \text{MIN}(M, N)$.

* **INFO (output)**

NAME

cgelss - compute the minimum norm solution to a complex linear least squares problem

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgelss(int m, int n, int nrhs, complex *a, int lda, complex *b, int ldb, float *sing, float rcond, int *irank, int *info);
```

```
void cgelss_64(long m, long n, long nrhs, complex *a, long lda, complex *b, long ldb, float *sing, float rcond, long *irank, long *info);
```

PURPOSE

cgelss computes the minimum norm solution to a complex linear least squares problem:

Minimize 2-norm($|b - A*x|$).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, the first $\min(m,n)$ rows of A are overwritten with its right singular vectors, stored rowwise.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** B (input/output)**

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,M,N)$.

*** SING (output)**

The singular values of A in decreasing order. The condition number of A in the 2-norm = $SING(1)/SING(\min(m,n))$.

*** RCOND (input)**

RCOND is used to determine the effective rank of A. Singular values $SING(i) \leq RCOND * SING(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

*** IRANK (output)**

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * SING(1)$.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK ≥ 1 , and also: LDWORK $\geq 2 \cdot \min(M,N) + \max(M,N, NRHS)$ For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void cgelsx(int m, int n, int nrhs, complex *a, int lda, complex *b, int ldb, int *jpivot, float rcond, int *irank, int *info);
```

```
void cgelsx_64(long m, long n, long nrhs, complex *a, long lda, complex *b, long ldb, long *jpivot, float rcond, long *irank, long *info);
```

PURPOSE

cgelsx routine is deprecated and has been replaced by routine CGELSY.

CGELSX computes the minimum-norm solution to a complex linear least squares problem:

$$\text{minimize } || A * X - B ||$$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting: $A * P = Q * [R11 R12]$

$$[\quad 0 \quad R22 \quad]$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***NRHS (input)***

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***B (input/output)***

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $N+1:M$ in that column.

* ***LDB (input)***

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* ***JPIVOT (input)***

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

* ***RCOND (input)***

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

* ***IRANK (output)***

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

* ***WORK (workspace)***

$(\min(M, N) + \max(N, 2 * \min(M, N) + NRHS))$,

* ***WORK2 (workspace)***

* ***INFO (output)***

PURPOSE

cgelsy computes the minimum-norm solution to a complex linear least squares problem: minimize $\| A * X - B \parallel$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting: $A * P = Q * [R11 \ R12]$

$$\begin{bmatrix} & 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

- o The permutation of matrix B (the right hand side) is faster and more simple.
 - o The call to the subroutine xGEQPF has been substituted by the the call to the subroutine xGEQP3. This subroutine is a Blas-3 version of the QR factorization with column pivoting.
 - o Matrix B (the right hand side) is updated with Blas-3.
-

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***NRHS (input)***

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***B (input/output)***

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

* ***LDB (input)***

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* ***JPVT (input/output)***

On entry, if $JPVT(i) \neq 0$, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if $JPVT(i) = k$, then the i-th column of A^*P was the k-th column of A.

* ***RCOND (input)***

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

* ***RANK (output)***

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. The unblocked strategy requires that: $LWORK \geq MN + \max(2 * MN, N + 1, MN + NRHS)$ where $MN = \min(M, N)$. The block algorithm requires that: $LWORK \geq MN + \max(2 * MN, NB * (N + 1), MN + MN * NB, MN + NB * NRHS)$ where NB is an upper bound on the blocksize returned by ILAENV for the routines CGEQP3, CTZRZF, CTZRQF, CUNMQR, and CUNMRZ.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***RWORK (workspace)***

dimension(2*N)

* ***INFO (output)***

NAME

cgemm - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

SYNOPSIS

CHARACTER(LEN=1) :: TRANSA, TRANSB
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER(8) :: M, N, K, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgemm(char transa, char transb, int m, int n, int k, complex alpha, complex *a, int lda, complex *b, int ldb, complex beta, complex *c, int ldc);
```

```
void cgemm_64(char transa, char transb, long m, long n, long k, complex alpha, complex *a, long lda, complex *b, long ldb,
```

complex beta, complex *c, long ldc);

PURPOSE

cgemmm performs one of the matrix-matrix operations

$C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

where $\text{op}(X)$ is one of

$\text{op}(X) = X$ or $\text{op}(X) = X'$ or $\text{op}(X) = \text{conjg}(X')$, alpha and beta are scalars, and A, B and C are matrices, with $\text{op}(A)$ an m by k matrix, $\text{op}(B)$ a k by n matrix and C an m by n matrix.

ARGUMENTS

* *TRANSA (input)*

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', $\text{op}(A) = A$.

TRANSA = 'T' or 't', $\text{op}(A) = A'$.

TRANSA = 'C' or 'c', $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

* *TRANSB (input)*

On entry, TRANSB specifies the form of $\text{op}(B)$ to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', $\text{op}(B) = B$.

TRANSB = 'T' or 't', $\text{op}(B) = B'$.

TRANSB = 'C' or 'c', $\text{op}(B) = \text{conjg}(B')$.

Unchanged on exit.

* *M (input)*

On entry, M specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C. $M \geq 0$. Unchanged on exit.

* *N (input)*

On entry, N specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

* *K (input)*

On entry, K specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. $K \geq 0$. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

K when TRANSA = 'N' or 'n', and is M otherwise. Before entry with TRANSA = 'N' or 'n', the leading M by K part

of the array A must contain the matrix A, otherwise the leading K by M part of the array A must contain the matrix A. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then $LDA \geq \max(1, M)$, otherwise $LDA \geq \max(1, K)$. Unchanged on exit.

*** B (input)**

n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then $LDB \geq \max(1, k)$, otherwise $LDB \geq \max(1, n)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

*** C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix $(\alpha * \text{op}(A) * \text{op}(B) + \text{beta} * C)$.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

NAME

cgemv - perform one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A' x + \beta y$, or $y := \alpha \text{conjg}(A') x + \beta y$

SYNOPSIS

```
SUBROUTINE CGEMV( TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,

SUBROUTINE GEMV( [TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
*              BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, INCX, INCY

SUBROUTINE GEMV_64( [TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
*              BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgemv(char transa, int m, int n, complex alpha, complex *a, int lda, complex *x, int incx, complex beta, complex *y, int incy);
```

```
void cgemv_64(char transa, long m, long n, complex alpha, complex *a, long lda, complex *x, long incx, complex beta, complex *y, long incy);
```

PURPOSE

cgemv performs one of the matrix-vector operations $y := \alpha * A * x + \beta * y$, or $y := \alpha * A' * x + \beta * y$, or $y := \alpha * \text{conjg}(A') * x + \beta * y$ where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

*** TRANSA (input)**

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha * A * x + \beta * y$.

TRANSA = 'T' or 't' $y := \alpha * A' * x + \beta * y$.

TRANSA = 'C' or 'c' $y := \alpha * \text{conjg}(A') * x + \beta * y$.

Unchanged on exit.

*** M (input)**

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

*** N (input)**

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

*** A (input)**

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

*** X (input)**

$(1 + (n - 1) * \text{abs}(INCX))$ when TRANSA = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(INCX))$ otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* ***Y*** (*input/output*)

$(1 + (m - 1) * \text{abs}(\text{ INCY }))$ when TRANS = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(\text{ INCY }))$ otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* ***INCY*** (*input*)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

cgeqlf - compute a QL factorization of a complex M-by-N matrix A

SYNOPSIS

```
SUBROUTINE CGEQLF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE CGEQLF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GEQLF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GEQLF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeqlf(int m, int n, complex *a, int lda, complex *tau, int *info);
```

```
void cgeqlf_64(long m, long n, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cgeqlf computes a QL factorization of a complex M-by-N matrix A: $A = Q * L$.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* ***A*** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $m \geq n$, the lower triangle of the subarray $A(m-n+1:m, 1:n)$ contains the N-by-N lower triangular matrix L; if $m < n$, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU*** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

cgeqp3 - compute a QR factorization with column pivoting of a matrix A

SYNOPSIS

```
SUBROUTINE CGEQP3( M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK,
*   INFO)
  COMPLEX A(LDA,*), TAU(*), WORK(*)
  INTEGER M, N, LDA, LWORK, INFO
  INTEGER JPVT(*)
  REAL RWORK(*)

SUBROUTINE CGEQP3_64( M, N, A, LDA, JPVT, TAU, WORK, LWORK, RWORK,
*   INFO)
  COMPLEX A(LDA,*), TAU(*), WORK(*)
  INTEGER*8 M, N, LDA, LWORK, INFO
  INTEGER*8 JPVT(*)
  REAL RWORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQP3( [M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
*   [RWORK], [INFO])
  COMPLEX, DIMENSION(:) :: TAU, WORK
  COMPLEX, DIMENSION(:, :) :: A
  INTEGER :: M, N, LDA, LWORK, INFO
  INTEGER, DIMENSION(:) :: JPVT
  REAL, DIMENSION(:) :: RWORK

SUBROUTINE GEQP3_64( [M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
*   [RWORK], [INFO])
  COMPLEX, DIMENSION(:) :: TAU, WORK
  COMPLEX, DIMENSION(:, :) :: A
  INTEGER(8) :: M, N, LDA, LWORK, INFO
  INTEGER(8), DIMENSION(:) :: JPVT
  REAL, DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeqp3(int m, int n, complex *a, int lda, int *jpvt, complex *tau, int *info);
```

```
void cgeqp3_64(long m, long n, complex *a, long lda, long *jpvt, complex *tau, long *info);
```

PURPOSE

cgeqp3 computes a QR factorization with column pivoting of a matrix A: $A^*P = Q^*R$ using Level 3 BLAS.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of $\min(M,N)$ elementary reflectors.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** JPVT (input/output)**

On entry, if $JPVT(J) \neq 0$, the J-th column of A is permuted to the front of A^*P (a leading column); if $JPVT(J)=0$, the J-th column of A is a free column. On exit, if $JPVT(J)=K$, then the J-th column of A^*P was the K-th column of A.

*** TAU (output)**

The scalar factors of the elementary reflectors.

*** WORK (workspace)**

On exit, if $INFO=0$, $WORK(1)$ returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq N+1$. For optimal performance $LWORK \geq (N+1)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** RWORK (workspace)**

dimension(2*N)

*** INFO (output)**

NAME

```
void cgeqpf_64(long m, long n, complex *a, long lda, long *jpivot, complex *tau, long *info);
```

PURPOSE

cgeqpf routine is deprecated and has been replaced by routine CGEQP3.

CGEQPF computes a QR factorization with column pivoting of a complex M-by-N matrix A: $A^*P = Q^*R$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of $\min(m,n)$ elementary reflectors.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***JPIVOT (input)***

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is permuted to the front of A^*P (a leading column); if $JPIVOT(i) = 0$, the i-th column of A is a free column. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

* ***TAU (output)***

The scalar factors of the elementary reflectors.

* ***WORK (workspace)***

dimension(N)

* ***WORK2 (workspace)***

* ***INFO (output)***

NAME

cgeqrf - compute a QR factorization of a complex M-by-N matrix A

SYNOPSIS

```
SUBROUTINE CGEQRF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LDWORK, INFO
```

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GEQRF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeqrf(int m, int n, complex *a, int lda, complex *tau, int *info);
```

```
void cgeqrf_64(long m, long n, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cgeqrf computes a QR factorization of a complex M-by-N matrix A: $A = Q * R$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(M,N)$ -by-N upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1,N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

NAME

cgerc - perform the rank 1 operation $A := \alpha * x * \text{conjg}(y') + A$

SYNOPSIS

```
SUBROUTINE CGERC( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
COMPLEX ALPHA
COMPLEX X(*), Y(*), A(LDA,*)
INTEGER M, N, INCX, INCY, LDA
```

```
SUBROUTINE CGERC_64( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
COMPLEX ALPHA
COMPLEX X(*), Y(*), A(LDA,*)
INTEGER*8 M, N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE GERC( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, INCX, INCY, LDA
```

```
SUBROUTINE GERC_64( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgerc(int m, int n, complex alpha, complex *x, int incx, complex *y, int incy, complex *a, int lda);
```

```
void cgerc_64(long m, long n, complex alpha, complex *x, long incx, complex *y, long incy, complex *a, long lda);
```

PURPOSE

cgerc performs the rank 1 operation $A := \alpha * x * \text{conjg}(y') + A$ where α is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

*** *M* (input)**

On entry, M specifies the number of rows of the matrix A . $M \geq 0$. Unchanged on exit.

*** *N* (input)**

On entry, N specifies the number of columns of the matrix A . $N \geq 0$. Unchanged on exit.

*** *ALPHA* (input)**

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

*** *X* (input)**

$(1 + (m - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the m element vector x . Unchanged on exit.

*** *INCX* (input)**

On entry, $INCX$ specifies the increment for the elements of X . $INCX$ must not be zero. Unchanged on exit.

*** *Y* (input)**

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

*** *INCY* (input)**

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

*** *A* (input/output)**

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

*** *LDA* (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

NAME

cgferfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

SYNOPSIS

void cgerfs_64(char transa, long n, long nrhs, complex *a, long lda, complex *af, long ldaf, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The original N-by-N matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CGETRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2*N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cgerqf - compute an RQ factorization of a complex M-by-N matrix A

SYNOPSIS

```
SUBROUTINE CGERQF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE CGERQF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GERQF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LDWORK, INFO
```

```
SUBROUTINE GERQF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgerqf(int m, int n, complex *a, int lda, complex *tau, int *info);
```

```
void cgerqf_64(long m, long n, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cgerqf computes an RQ factorization of a complex M-by-N matrix A: $A = R * Q$.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* ***A*** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $m \leq n$, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if $m \geq n$, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***TAU*** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1,M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

cgeru - perform the rank 1 operation $A := \alpha * x * y' + A$

SYNOPSIS

```
SUBROUTINE CGERU( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
COMPLEX ALPHA
COMPLEX X(*), Y(*), A(LDA,*)
INTEGER M, N, INCX, INCY, LDA
```

```
SUBROUTINE CGERU_64( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
COMPLEX ALPHA
COMPLEX X(*), Y(*), A(LDA,*)
INTEGER*8 M, N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE GER( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, INCX, INCY, LDA
```

```
SUBROUTINE GER_64( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeru(int m, int n, complex alpha, complex *x, int incx, complex *y, int incy, complex *a, int lda);
```

```
void cgeru_64(long m, long n, complex alpha, complex *x, long incx, complex *y, long incy, complex *a, long lda);
```

PURPOSE

cgeru performs the rank 1 operation $A := \alpha * x * y' + A$ where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

*** M (input)**

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

*** N (input)**

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

*** X (input)**

$(1 + (m - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** Y (input)**

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

*** A (input/output)**

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

NAME

cgesdd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method

SYNOPSIS

```
SUBROUTINE CGESDD( JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK,

REAL, DIMENSION(:) :: S, RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgesdd(char jobz, int m, int n, complex *a, int lda, float *s, complex *u, int ldu, complex *vt, int ldvt, int *info);
```

```
void cgesdd_64(char jobz, long m, long n, complex *a, long lda, float *s, complex *u, long ldu, complex *vt, long ldvt, long *info);
```

PURPOSE

cgesdd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method. The SVD is written = U * SIGMA * conjugate-transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns $VT = V^*H$, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** JOBZ (input)**

Specifies options for computing all or part of the matrix U:

*** M (input)**

The number of rows of the input matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the input matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if $M \geq N$; A is overwritten with the first M rows of V^*H (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** S (output)**

The singular values of A, sorted so that $S(i) \geq S(i+1)$.

*** U (output)**

UCOL = M if JOBZ = 'A' or JOBZ = 'O' and $M < N$; UCOL = min(M,N) if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and $M < N$, U contains the M-by-M unitary matrix U; if JOBZ = 'S', U contains the first min(M,N) columns of U

(the left singular vectors, stored columnwise); if JOBZ = 'O' and $M \geq N$, or JOBZ = 'N', U is not referenced.

* **LDU (input)**

The leading dimension of the array U. $LDU \geq 1$; if JOBZ = 'S' or 'A' or JOBZ = 'O' and $M < N$, $LDU \geq M$.

* **VT (output)**

If JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, VT contains the N-by-N unitary matrix V^*H ; if JOBZ = 'S', VT contains the first $\min(M,N)$ rows of V^*H (the right singular vectors, stored rowwise); if JOBZ = 'O' and $M < N$, or JOBZ = 'N', VT is not referenced.

* **LDVT (input)**

The leading dimension of the array VT. $LDVT \geq 1$; if JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, $LDVT \geq N$; if JOBZ = 'S', $LDVT \geq \min(M,N)$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq 1$. if JOBZ = 'N', $LWORK \geq 2 \cdot \min(M,N) + \max(M,N)$. if JOBZ = 'O', $LWORK \geq 2 \cdot \min(M,N) \cdot \min(M,N) + 2 \cdot \min(M,N) + \max(M,N)$. if JOBZ = 'S' or 'A', $LWORK \geq \min(M,N) \cdot \min(M,N) + 2 \cdot \min(M,N) + \max(M,N)$. For good performance, LWORK should generally be larger. If $LWORK < 0$ but other input arguments are legal, WORK(1) returns optimal LWORK.

* **RWORK (workspace)**

If JOBZ = 'N', $LRWORK \geq 7 \cdot \min(M,N)$. Otherwise, $LRWORK \geq 5 \cdot \min(M,N) \cdot \min(M,N) + 5 \cdot \min(M,N)$

* **IWORK (workspace)**

dimension($8 \cdot \min(M,N)$)

* **INFO (output)**

NAME

cgsl - (obsolete) solve the linear system $Ax = b$ for a general matrix A , which has been LU- factored by CGECO or CGEFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CGESL( A, LDA, N, IPIVOT, B, JOB)
COMPLEX A(LDA,*), B(*)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE CGESL_64( A, LDA, N, IPIVOT, B, JOB)
COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgsl(complex *a, int lda, int n, int *ipivot, complex *b, int job);
```

```
void cgsl_64(complex *a, long lda, long n, long *ipivot, complex *b, long job);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A , as computed by CGECO or CGEFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1,N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CGECO or CGEFA.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

*** JOB (input)**

Determines which operation the subroutine will perform:

o 0 Solve the system $Ax = b$.

not 0 Solve the linear system $AHx = b$. Note that $ATx = AHx$ for real matrices.

NAME

cgsv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE CGESV( N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CGESV_64( N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NRHS, LDA, LDB, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GESV( [N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GESV_64( [N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgsv(int n, int nrhs, complex *a, int lda, int *ipivot, complex *b, int ldb, int *info);
```

```
void cgsv_64(long n, long nrhs, complex *a, long lda, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cgsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = P * L * U,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

*** B (input/output)**

On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

cgesvd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors

SYNOPSIS

C INTERFACE

```
#include <sunperf.h>
```

```
void cgesvd(char jobu, char jobvt, int m, int n, complex *a, int lda, float *sing, complex *u, int ldu, complex *vt, int ldvt, int *info);
```

```
void cgesvd_64(char jobu, char jobvt, long m, long n, complex *a, long lda, float *sing, complex *u, long ldu, complex *vt, long ldvt, long *info);
```

PURPOSE

cgesvd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written = U * SIGMA * conjugate-transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**H, not V.

ARGUMENTS

*** JOBU (input)**

Specifies options for computing all or part of the matrix U:

*** JOBVT (input)**

Specifies options for computing all or part of the matrix V**H:

*** M (input)**

The number of rows of the input matrix A. M >= 0.

*** N (input)**

The number of columns of the input matrix A. N >= 0.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, if JOBU = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V**H (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

*** LDA (input)**

The leading dimension of the array A. LDA >= max(1,M).

*** SING (output)**

The singular values of A, sorted so that SING(i) >= SING(i+1).

*** U (input)**

(LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'SING'. If JOBU = 'A', U contains the M-by-M unitary matrix U; if JOBU = 'SING', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

*** LDU (input)**

The leading dimension of the array U. $LDU \geq 1$; if $JOBV = 'SING'$ or $'A'$, $LDU \geq M$.

* **VT (input)**

If $JOBVT = 'A'$, VT contains the N-by-N unitary matrix V^*H ; if $JOBVT = 'SING'$, VT contains the first $\min(m,n)$ rows of V^*H (the right singular vectors, stored rowwise); if $JOBVT = 'N'$ or $'O'$, VT is not referenced.

* **LDVT (input)**

The leading dimension of the array VT. $LDVT \geq 1$; if $JOBVT = 'A'$, $LDVT \geq N$; if $JOBVT = 'SING'$, $LDVT \geq \min(M,N)$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* **LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq 1$. $LDWORK \geq 2 * \min(M,N) + \max(M,N)$ For good performance, LDWORK should generally be larger.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2 (workspace)**

$DIMENSION(5 * \min(M,N))$. On exit, if $INFO > 0$, $WORK2(1:\min(M,N)-1)$ contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies $A = U * B * VT$, so it has the same singular values as A, and singular vectors related by U and VT.

* **INFO (output)**

NAME

cgsvx - use the LU factorization to compute the solution to a complex system of linear equations $A * X = B$.

C INTERFACE

```
#include <sunperf.h>
```

```
void cgesvx(char fact, char transa, int n, int nrhs, complex *a, int lda, complex *af, int ldaf, int *ipivot, char equed, float *rowsc, float *colsc, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void cgesvx_64(char fact, char transa, long n, long nrhs, complex *a, long lda, complex *af, long ldaf, long *ipivot, char equed, float *rowsc, float *colsc, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

cgesvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
TRANS = 'T':  (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
TRANS = 'C':  (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
```

Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(R)*A*\text{diag}(C)$ and B by $\text{diag}(R)*B$ (if TRANS='N') or $\text{diag}(C)*B$ (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

```
A = P * L * U,
```

where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if TRANS = 'N') or $\text{diag}(R)$ (if TRANS = 'T' or 'C') so that it solves the original system before equilibration.

ARGUMENTS

* *FACT (input)*

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *TRANS (input)*

Specifies the form of the system of equations:

* *N (input)*

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS (input)*

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A (input/output)*

On entry, the N-by-N matrix A. If *FACT* = 'F' and *EQUED* is not 'N', then A must have been equilibrated by the scaling factors in *ROWSC* and/or *COLSC*. A is not modified if *FACT* = 'F' or 'N', or if *FACT* = 'E' and *EQUED* = 'N' on exit.

On exit, if *EQUED* .ne. 'N', A is scaled as follows: *EQUED* = 'ROWSC': $A := \text{diag}(\text{ROWSC}) * A$

EQUED = 'COLSC': $A := A * \text{diag}(\text{COLSC})$

EQUED = 'B': $A := \text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *AF (input/output)*

If *FACT* = 'F', then *AF* is an input argument and on entry contains the factors L and U from the factorization $A = P * L * U$ as computed by CGETRF. If *EQUED* .ne. 'N', then *AF* is the factored form of the equilibrated matrix A.

If *FACT* = 'N', then *AF* is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A.

If *FACT* = 'E', then *AF* is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *LDAF (input)*

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* *IPIVOT (input)*

If *FACT* = 'F', then *IPIVOT* is an input argument and on entry contains the pivot indices from the factorization $A = P * L * U$ as computed by CGETRF; row i of the matrix was interchanged with row *IPIVOT*(i).

If *FACT* = 'N', then *IPIVOT* is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A.

If *FACT* = 'E', then *IPIVOT* is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the equilibrated matrix A.

* *EQUED (input)*

Specifies the form of equilibration that was done.

* *ROWSC (input/output)*

The row scale factors for A. If *EQUED* = 'ROWSC' or 'B', A is multiplied on the left by $\text{diag}(\text{ROWSC})$; if *EQUED* = 'N' or 'COLSC', *ROWSC* is not accessed. *ROWSC* is an input argument if *FACT* = 'F'; otherwise, *ROWSC* is an

output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

*** COLSC (input/output)**

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC}) * B$; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC}) * B$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED = 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC})) * X$ if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC})) * X$ if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

On exit, WORK2(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

*** INFO (output)**

NAME

cgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE CGETF2( M, N, A, LDA, IPIV, INFO)
COMPLEX A(LDA,*)
INTEGER M, N, LDA, INFO
INTEGER IPIV(*)
```

```
SUBROUTINE CGETF2_64( M, N, A, LDA, IPIV, INFO)
COMPLEX A(LDA,*)
INTEGER*8 M, N, LDA, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE GETF2_64( [M], [N], A, [LDA], IPIV, [INFO])
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgetf2(int m, int n, complex *a, int lda, int *ipiv, int *info);
```

```
void cgetf2_64(long m, long n, complex *a, long lda, long *ipiv, long *info);
```

PURPOSE

cgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** IPIV (output)**

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIV(i).

*** INFO (output)**

NAME

cgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

```

```
void cgetrf_64(long m, long n, complex *a, long lda, long *ipivot, long *info);
```

PURPOSE

cgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIVOT(i).

*** INFO (output)**

NAME

cgetri - compute the inverse of a matrix using the LU factorization computed by CGETRF

SYNOPSIS

```
SUBROUTINE CGETRI( N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CGETRI_64( N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, LDWORK, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI( [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE GETRI_64( [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgetri(int n, complex *a, int lda, int *ipivot, int *info);
```

```
void cgetri_64(long n, complex *a, long lda, long *ipivot, long *info);
```

PURPOSE

cgetri computes the inverse of a matrix using the LU factorization computed by CGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the factors L and U from the factorization $A = P*L*U$ as computed by CGETRF. On exit, if $\text{INFO} = 0$, the inverse of the original matrix A.

*** LDA (input)**

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

*** IPIVOT (input)**

The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

*** WORK (workspace)**

On exit, if $\text{INFO} = 0$, then $\text{WORK}(1)$ returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $\text{LDWORK} \geq \max(1, N)$. For optimal performance $\text{LDWORK} \geq N * \text{NB}$, where NB is the optimal blocksize returned by ILAENV.

If $\text{LDWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

cgetrs - solve a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general N-by-N matrix A using the LU factorization computed by CGETRF

SYNOPSIS

```
SUBROUTINE CGETRS( TRANSA, N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
CHARACTER * 1 TRANSA
COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO
INTEGER IPIVOT(*)
```

CHARACTER(LEN=1) :: TRANSA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgetrs(char transa, int n, int nrhs, complex *a, int lda, int *ipivot, complex *b, int ldb, int *info);
```

```
void cgetrs_64(char transa, long n, long nrhs, complex *a, long lda, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cgetrs solves a system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$ with a general N-by-N matrix A using the LU factorization computed by CGETRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The factors L and U from the factorization $A = P * L * U$ as computed by CGETRF.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

The pivot indices from CGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

cggbak - form the right or left eigenvectors of a complex generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL

SYNOPSIS

```
SUBROUTINE CGGBAK( JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V,
*      LDV, INFO)
CHARACTER * 1 JOB, SIDE
COMPLEX V(LDV,*)
INTEGER N, ILO, IHI, M, LDV, INFO
REAL LSCALE(*), RSCALE(*)

SUBROUTINE CGGBAK_64( JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V,
*      LDV, INFO)
CHARACTER * 1 JOB, SIDE
COMPLEX V(LDV,*)
INTEGER*8 N, ILO, IHI, M, LDV, INFO
REAL LSCALE(*), RSCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GGBAK( JOB, SIDE, [N], ILO, IHI, LSCALE, RSCALE, [M], V,
*      [LDV], [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX, DIMENSION(:,:) :: V
INTEGER :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE

SUBROUTINE GGBAK_64( JOB, SIDE, [N], ILO, IHI, LSCALE, RSCALE, [M],
*      V, [LDV], [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX, DIMENSION(:,:) :: V
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cggbak(char job, char side, int n, int ilo, int ihi, float *lscale, float *rscale, int m, complex *v, int ldv, int *info);
```

```
void cggbak_64(char job, char side, long n, long ilo, long ihi, float *lscale, float *rscale, long m, complex *v, long ldv, long
```

*info);

PURPOSE

cggbak forms the right or left eigenvectors of a complex generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL.

ARGUMENTS

* **JOB** (*input*)

Specifies the type of backward transformation required:

* **SIDE** (*input*)

* **N** (*input*)

The number of rows of the matrix V. $N \geq 0$.

* **ILO** (*input*)

The integers ILO and IHI determined by CGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* **IHI** (*input*)

The integers ILO and IHI determined by CGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* **LSCALE** (*input*)

Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by CGGBAL.

* **RSCALE** (*input*)

Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by CGGBAL.

* **M** (*input*)

The number of columns of the matrix V. $M \geq 0$.

* **V** (*input/output*)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by CTGEVC. On exit, V is overwritten by the transformed eigenvectors.

* **LDV** (*input*)

The leading dimension of the matrix V. $LDV \geq \max(1,N)$.

* **INFO** (*output*)

```
SUBROUTINE GGBAL( JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
*   RSCALE, [WORK], [INFO])
CHARACTER(LEN=1) :: JOB
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, LDA, LDB, ILO, IHI, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE, WORK

SUBROUTINE GGBAL_64( JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
*   RSCALE, [WORK], [INFO])
CHARACTER(LEN=1) :: JOB
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, LDA, LDB, ILO, IHI, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cggbal(char job, int n, complex *a, int lda, complex *b, int ldb, int *ilo, int *ihi, float *lscale, float *rscale, int *info);
```

```
void cggbal_64(char job, long n, complex *a, long lda, complex *b, long ldb, long *ilo, long *ihi, float *lscale, float *rscale, long *info);
```

PURPOSE

cggbal balances a pair of general complex matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first ILO to IHI and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

ARGUMENTS

*** JOB (input)**

Specifies the operations to be performed on A and B:

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input)**

On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** ILO (output)**

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

*** IHI (output)**

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$.

*** LSCALE (input)**

Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then $LSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$.

*** RSCALE (input)**

Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then $RSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$.

*** WORK (workspace)**

dimension(6*N)

*** INFO (output)**

*b, long ldb, long *sdim, complex *alpha, complex *beta, complex *vsl, long ldvsl, complex *vsr, long ldvsr, long *info);
```

PURPOSE

cgges computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A, B) = ((VSL) * S * (VSR) ** H, (VSL) * T * (VSR) ** H)$$

where (VSR)**H is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver CGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **SORT** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

* **SELCTG** (*input*)

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if SELCTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy $\text{SELCTG}(\text{ALPHA}(j), \text{BETA}(j)) = \text{.TRUE.}$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to $N+2$ (See INFO below).

* ***N (input)***

The order of the matrices A, B, VSL, and VSR. $N \geq 0$.

* ***A (input/output)***

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

* ***LDA (input)***

The leading dimension of A. $LDA \geq \max(1, N)$.

* ***B (input/output)***

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

* ***LDB (input)***

The leading dimension of B. $LDB \geq \max(1, N)$.

* ***SDIM (output)***

If $\text{SORT} = \text{'N'}$, $\text{SDIM} = 0$. If $\text{SORT} = \text{'S'}$, $\text{SDIM} =$ number of eigenvalues (after sorting) for which SELCTG is true.

* ***ALPHA (output)***

On exit, $\text{ALPHA}(j)/\text{BETA}(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. $\text{ALPHA}(j)$, $j=1, \dots, N$ and $\text{BETA}(j)$, $j=1, \dots, N$ are the diagonals of the complex Schur form (A,B) output by CGGES. The $\text{BETA}(j)$ will be non-negative real.

Note: the quotients $\text{ALPHA}(j)/\text{BETA}(j)$ may easily over- or underflow, and $\text{BETA}(j)$ may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and BETA always less than and usually comparable with $\text{norm}(B)$.

* ***BETA (output)***

See description of ALPHA.

* ***VSL (input)***

If $\text{JOBVSL} = \text{'V'}$, VSL will contain the left Schur vectors. Not referenced if $\text{JOBVSL} = \text{'N'}$.

* ***LDVSL (input)***

The leading dimension of the matrix VSL. $\text{LDVSL} \geq 1$, and if $\text{JOBVSL} = \text{'V'}$, $\text{LDVSL} \geq N$.

* ***VSR (input)***

If $\text{JOBVSR} = \text{'V'}$, VSR will contain the right Schur vectors. Not referenced if $\text{JOBVSR} = \text{'N'}$.

* ***LDVSR (input)***

The leading dimension of the matrix VSR. $\text{LDVSR} \geq 1$, and if $\text{JOBVSR} = \text{'V'}$, $\text{LDVSR} \geq N$.

* ***WORK (workspace)***

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. $\text{LWORK} \geq \max(1, 2*N)$. For good performance, LWORK must generally be larger.

If $\text{LWORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***RWORK (workspace)***

$\text{dimension}(8*N)$

* ***BWORK (workspace)***

Not referenced if $\text{SORT} = \text{'N'}$.

* ***INFO (output)***

lda, complex *b, long ldb, long *sdim, complex *alpha, complex *beta, complex *vsl, long ldvsl, complex *vsr, long ldvsr,
float *rconde, float *rcondv, long *info);
```

PURPOSE

cggexx computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization $A,B = (VSL) S (VSR)^{**H}, (VSL) T (VSR)^{**H}$

where $(VSR)^{**H}$ is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio $\alpha/\beta = w$, such that $A - w*B$ is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for $\beta=0$ or for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if T is upper triangular with non-negative diagonal and S is upper triangular.

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **SORT** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

* **SELCTG** (*input*)

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3 see INFO below).

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. $N \geq 0$.

* **A** (*input/output*)

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

* **LDA** (*input*)

The leading dimension of A. $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

* **LDB** (*input*)

The leading dimension of B. $LDB \geq \max(1,N)$.

* **SDIM** (*output*)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

* **ALPHA** (*output*)

On exit, ALPHA(j)/BETA(j), $j=1,\dots,N$, will be the generalized eigenvalues. ALPHA(j) and BETA(j), $j=1,\dots,N$ are the diagonals of the complex Schur form (S,T). BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **BETA** (*output*)

See description of ALPHA.

* **VSL** (*input*)

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

* **LDVSL** (*input*)

The leading dimension of the matrix VSL. $LDVSL \geq 1$, and if JOBVSL = 'V', $LDVSL \geq N$.

* **VSR** (*input*)

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

* **LDVSR** (*input*)

The leading dimension of the matrix VSR. $LDVSR \geq 1$, and if JOBVSR = 'V', $LDVSR \geq N$.

* **RCONDE** (*output*)

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of

the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

* ***RCONDV (output)***

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition number for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

* ***WORK (workspace)***

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. LWORK $\geq 2*N$. If SENSE = 'E', 'V', or 'B', LWORK $\geq \text{MAX}(2*N, 2*SDIM*(N-SDIM))$.

* ***RWORK (workspace)***

Real workspace.

* ***IWORK (workspace)***

Not referenced if SENSE = 'N'. On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* ***LIWORK (input)***

The dimension of the array WORK. LIWORK $\geq N+2$.

* ***BWORK (workspace)***

Not referenced if SORT = 'N'.

* ***INFO (output)***

```

PURPOSE

cggev computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right generalized eigenvector v(j) corresponding to the generalized eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j).$$

The left generalized eigenvector u(j) corresponding to the generalized eigenvalues lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VL, and VR. N >= 0.

* **A** (*input/output*)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **ALPHA** (*output*)

On exit, ALPHA(j)/BETA(j), $j=1,\dots,N$, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **BETA (output)**

See description of ALPHA.

* **VL (input)**

If JOBVL = 'V', the left generalized eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if JOBVL = 'N'.

* **LDVL (input)**

The leading dimension of the matrix VL. LDVL ≥ 1 , and if JOBVL = 'V', LDVL $\geq N$.

* **VR (input)**

If JOBVR = 'V', the right generalized eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$. Not referenced if JOBVR = 'N'.

* **LDVR (input)**

The leading dimension of the matrix VR. LDVR ≥ 1 , and if JOBVR = 'V', LDVR $\geq N$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK $\geq \max(1, 2*N)$. For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

dimension(8*N)

* **INFO (output)**

*abnrm, float *bbnrm, float *rconde, float *rcondv, long *info);
```

PURPOSE

cggev(x computes for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally, it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j) .$$

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B .$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

* **BALANC** (*input*)

Specifies the balance option to be performed:

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrices A, B, VL, and VR. $N \geq 0$.

* **A** (*input/output*)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the complex Schur form of the "balanced" versions of the input A and B.

* **LDA** (*input*)

The leading dimension of A. $LDA \geq \max(1,N)$.

* **B** (*input/output*)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the complex Schur form of the "balanced" versions of the input A and B.

* **LDB** (*input*)

The leading dimension of B. $LDB \geq \max(1,N)$.

* **ALPHA** (*output*)

On exit, $ALPHA(j)/BETA(j)$, $j=1,\dots,N$, will be the generalized eigenvalues.

Note: the quotient $ALPHA(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $ALPHA/BETA$. However, ALPHA will be always less than and usually comparable with $norm(A)$ in magnitude, and BETA always less than and usually comparable with $norm(B)$.

* **BETA** (*output*)

See description of ALPHA.

* **VL** (*output*)

If JOBVL = 'V', the left generalized eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if JOBVL = 'N'.

* **LDVL** (*input*)

The leading dimension of the matrix VL. $LDVL \geq 1$, and if JOBVL = 'V', $LDVL \geq N$.

* **VR** (*input*)

If JOBVR = 'V', the right generalized eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if JOBVR = 'N'.

* **LDVR** (*input*)

The leading dimension of the matrix VR. $LDVR \geq 1$, and if JOBVR = 'V', $LDVR \geq N$.

* **ILO** (*output*)

ILO is an integer value such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1,\dots,ILO-1$ or $i = IHI+1,\dots,N$. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

* **IHI** (*output*)

IHI is an integer value such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1,\dots,ILO-1$ or $i = IHI+1,\dots,N$. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

* **LSCALE** (output)

Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1

* **RSCALE** (output)

Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1

* **ABNRM** (output)

The one-norm of the balanced matrix A.

* **BBNRM** (output)

The one-norm of the balanced matrix B.

* **RCONDE** (output)

If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If SENSE = 'V', RCONDE is not referenced.

* **RCONDV** (output)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced. Not referenced if JOB = 'E'.

* **WORK** (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (input)

The dimension of the array WORK. LWORK $\geq \max(1, 2*N)$. If SENSE = 'N' or 'E', LWORK $\geq 2*N$. If SENSE = 'V' or 'B', LWORK $\geq 2*N*N + 2*N$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK** (workspace)

Real workspace.

* **IWORK** (workspace)

If SENSE = 'E', IWORK is not referenced.

* **BWORK** (workspace)

If SENSE = 'N', BWORK is not referenced.

* **INFO** (output)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgglm(int n, int m, int p, complex *a, int lda, complex *b, int ldb, complex *d, complex *x, complex *y, int *info);
```

```
void cgglm_64(long n, long m, long p, complex *a, long lda, complex *b, long ldb, complex *d, complex *x, complex *y, long *info);
```

PURPOSE

cgglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad || y ||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(A \ B) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad || \text{inv}(B)*(d-A*x) ||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

*** N (input)**

The number of rows of the matrices A and B. $N \geq 0$.

*** M (input)**

The number of columns of the matrix A. $0 \leq M \leq N$.

*** P (input)**

The number of columns of the matrix B. $P \geq N-M$.

*** A (input/output)**

On entry, the N-by-M matrix A. On exit, A is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the N-by-P matrix B. On exit, B is destroyed.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** D (input/output)**

On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

*** X (output)**

On exit, X and Y are the solutions of the GLM problem.

*** Y (output)**

On exit, X and Y are the solutions of the GLM problem.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, N+M+P)$. For optimum performance, LDWORK $\geq M + \min(N, P) + \max(N, P) * NB$, where NB is an upper bound for the optimal block sizes for CGEQRF, CGERQF, CUNMQR and CUNMRO.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

cgghrd - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

SYNOPSIS

```
SUBROUTINE GGHRD_64( COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB],  
* Q, [LDQ], Z, [LDZ], [INFO])  
CHARACTER(LEN=1) :: COMPQ, COMPZ  
COMPLEX, DIMENSION(:,*) :: A, B, Q, Z  
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgghrd(char compq, char compz, int n, int ilo, int ihi, complex *a, int lda, complex *b, int ldb, complex *q, int ldq,  
complex *z, int ldz, int *info);
```

```
void cgghrd_64(char compq, char compz, long n, long ilo, long ihi, complex *a, long lda, complex *b, long ldb, complex *q,  
long ldq, complex *z, long ldz, long *info);
```

PURPOSE

cgghrd reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are unitary, and ' means conjugate transpose.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1*Q) * H * (Z1*Z)' \quad 1 * B * Z1' = (Q1*Q) * T * (Z1*Z)'$$

ARGUMENTS

* *COMPQ (input)*

* *COMPZ (input)*

* *N (input)*

The order of the matrices A and B. $N \geq 0$.

* *ILO (input)*

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGGBAL; otherwise they should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

* *IHI (input)*

See description of ILO.

* *A (input/output)*

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* *B (input/output)*

On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix $T = Q' B Z$. The elements below the diagonal are set to zero.

* *LDB (input)*

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* *Q (input/output)*

If COMPQ='N': Q is not referenced.

If COMPQ='I': on entry, Q need not be set, and on exit it contains the unitary matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain a unitary matrix Q1, and on exit this is overwritten by $Q1*Q$.

* *LDQ (input)*

The leading dimension of the array Q. $LDQ \geq N$ if COMPQ='V' or 'I'; $LDQ \geq 1$ otherwise.

* *Z (input/output)*

If COMPZ='N': Z is not referenced.

If COMPZ='I': on entry, Z need not be set, and on exit it contains the unitary matrix Z, which is the product of the

Givens transformations which are applied to A and B on the right. If COMPZ='V': on entry, Z must contain a unitary matrix Z1, and on exit this is overwritten by Z1*Z.

* **LDZ** (*input*)

The leading dimension of the array Z. LDZ \geq N if COMPZ='V' or 'I'; LDZ \geq 1 otherwise.

* **INFO** (*output*)

NAME

cgglse - solve the linear equality-constrained least squares (LSE) problem

SYNOPSIS

```
SUBROUTINE CGGLSE( M, N, P, A, LDA, B, LDB, C, D, X, WORK, LDWORK,

SUBROUTINE GGLSE_64( [M], [N], [P], A, [LDA], B, [LDB], C, D, X,
*                  [WORK], [LDWORK], [INFO])
  COMPLEX, DIMENSION(:) :: C, D, X, WORK
  COMPLEX, DIMENSION(:,:) :: A, B
  INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgglse(int m, int n, int p, complex *a, int lda, complex *b, int ldb, complex *c, complex *d, complex *x, int *info);
```

```
void cgglse_64(long m, long n, long p, complex *a, long lda, complex *b, long ldb, complex *c, complex *d, complex *x, long *info);
```

PURPOSE

cgglse solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } || c - A*x ||_2 \quad \text{subject to} \quad B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that $P \leq N \leq M+P$, and

$$\text{rank}(B) = P \quad \text{and} \quad \text{rank} \left(\begin{array}{c} A \\ B \end{array} \right) = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrices A and B. $N \geq 0$.

*** P (input)**

The number of rows of the matrix B. $0 \leq P \leq N \leq M+P$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, B is destroyed.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** C (input/output)**

On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

*** D (input/output)**

On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

*** X (output)**

On exit, X is the solution of the LSE problem.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. LDWORK $\geq \max(1, M+N+P)$. For optimum performance LDWORK $\geq P + \min(M, N) + \max(M, N) * NB$, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (output)

*                   [WORK], [LWORK], [INFO])
  COMPLEX, DIMENSION(:) :: TAU, TAUB, WORK
  COMPLEX, DIMENSION(:, :) :: A, B
  INTEGER(8) :: N, M, P, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void eggqrf(int n, int m, int p, complex *a, int lda, complex *tau, complex *b, int ldb, complex *taub, int *info);
```

```
void eggqrf_64(long n, long m, long p, complex *a, long lda, complex *tau, complex *b, long ldb, complex *taub, long *info);
```

PURPOSE

cggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

$$A = Q^*R, \quad B = Q^*T^*Z,$$

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

if $N \geq M$, $R = \begin{pmatrix} R_{11} \\ 0 \end{pmatrix}$, or if $N < M$, $R = \begin{pmatrix} R_{11} & R_{12} \\ 0 \end{pmatrix}$, $\begin{pmatrix} 0 \\ 0 \end{pmatrix}$ N-M N M-N M

where R_{11} is upper triangular, and

if $N \leq P$, $T = \begin{pmatrix} 0 & T_{12} \\ 0 \end{pmatrix}$ N, or if $N > P$, $T = \begin{pmatrix} T_{11} \\ 0 \end{pmatrix}$ N-P, P-N N $\begin{pmatrix} T_{21} \\ 0 \end{pmatrix}$ P P

where T_{12} or T_{21} is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $\text{inv}(B)^*A$:

$$\text{inv}(B)^*A = Z'^*(\text{inv}(T)^*R)$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the conjugate transpose of matrix Z.

ARGUMENTS

*** N (input)**

The number of rows of the matrices A and B. $N \geq 0$.

*** M (input)**

The number of columns of the matrix A. $M \geq 0$.

*** P (input)**

The number of columns of the matrix B. $P \geq 0$.

*** A (input/output)**

On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(N,M)$ -by-M upper trapezoidal matrix R (R is upper triangular if $N \geq M$); the elements below the diagonal, with the array TAUA, represent the unitary matrix Q as a product of $\min(N,M)$ elementary reflectors (see Further Details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** TAUA (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

*** B (input/output)**

On entry, the N-by-P matrix B. On exit, if $N \leq P$, the upper triangle of the subarray $B(1:N,P-N+1:P)$ contains the N-by-N upper triangular matrix T; if $N > P$, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **TAUB (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, N, M, P)$. For optimum performance $LWORK \geq \max(N, M, P) * \max(NB1, NB2, NB3)$, where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of CUNMQR.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

NAME

cggrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

SYNOPSIS

*                   [WORK], [LWORK], [INFO])
  COMPLEX, DIMENSION(:) :: TAU, TAUB, WORK
  COMPLEX, DIMENSION(:, :) :: A, B
  INTEGER(8) :: M, P, N, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cggrqf(int m, int p, int n, complex *a, int lda, complex *tau, complex *b, int ldb, complex *taub, int *info);
```

```
void cggrqf_64(long m, long p, long n, complex *a, long lda, complex *tau, complex *b, long ldb, complex *taub, long *info);
```

PURPOSE

cggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N unitary matrix, Z is a P-by-P unitary matrix, and R and T assume one of the forms:

if $M \leq N$, $R = \begin{pmatrix} 0 & R_{12} \end{pmatrix} M$, or if $M > N$, $R = \begin{pmatrix} R_{11} \\ \end{pmatrix} M-N, N-M \begin{pmatrix} R_{21} \end{pmatrix} N-N$

where R_{12} or R_{21} is upper triangular, and

if $P \geq N$, $T = \begin{pmatrix} T_{11} \end{pmatrix} N$, or if $P < N$, $T = \begin{pmatrix} T_{11} & T_{12} \\ \end{pmatrix} P, \begin{pmatrix} 0 \end{pmatrix} P-N \begin{pmatrix} T_{21} & T_{22} \end{pmatrix} P-N$

where T_{11} is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A*inv(B)$:

$$A*inv(B) = (R*inv(T))*Z'$$

where $inv(B)$ denotes the inverse of the matrix B, and Z' denotes the conjugate transpose of the matrix Z.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** P (input)**

The number of rows of the matrix B. $P \geq 0$.

*** N (input)**

The number of columns of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, if $M \leq N$, the upper triangle of the subarray $A(1:M, N-M+1:N)$ contains the M-by-M upper triangular matrix R; if $M > N$, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** TAUA (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the $\min(P, N)$ -by-N upper trapezoidal matrix T (T is upper triangular if $P \geq N$); the elements below the diagonal, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** TAUB (output)**

The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK \geq $\max(1, N, M, P)$. For optimum performance LWORK \geq $\max(N, M, P) * \max(NB1, NB2, NB3)$, where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of CUNMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

```

PURPOSE

cggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B:

$$U' * A * Q = D1 * \begin{pmatrix} 0 & R \\ & \end{pmatrix}, \quad V' * B * Q = D2 * \begin{pmatrix} 0 & R \\ & \end{pmatrix}$$

where U, V and Q are unitary matrices, and Z' means the conjugate transpose of Z. Let K+L = the effective numerical rank of the matrix (A',B)', then R is a (K+L)-by-(K+L) nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

$$D1 = \begin{pmatrix} & & K & L \\ & K & (I & 0) \\ & & L & (0 & C) \\ M-K-L & (0 & 0) \end{pmatrix}$$
$$D2 = \begin{pmatrix} & & K & L \\ & L & (0 & S) \\ P-L & (0 & 0) \\ & N-K-L & K & L \end{pmatrix}$$
$$\begin{pmatrix} 0 & R \end{pmatrix} = \begin{pmatrix} K & (0 & R11 & R12) \\ L & (0 & 0 & R22) \end{pmatrix}$$

where

```
C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),  
S = diag( BETA(K+1), ... , BETA(K+L) ),  
C**2 + S**2 = I.  
R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

$$D1 = \begin{pmatrix} & & K & M-K & K+L-M \\ & K & (I & 0 & 0) \\ & M-K & (0 & C & 0) \\ & & & K & M-K & K+L-M \end{pmatrix}$$
$$D2 = \begin{pmatrix} & & M-K & (0 & S & 0) \\ & & K+L-M & (0 & 0 & I) \\ & & P-L & (0 & 0 & 0) \end{pmatrix}$$

*** L (output)**

On exit, K and L specify the dimension of the subblocks described in Purpose. $K + L =$ effective numerical rank of (A',B)'

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, B contains part of the triangular matrix R if $M - K - L < 0$. See Purpose for details.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** ALPHA (output)**

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$, $ALPHA(K+1:N) = 0$,

$BETA(1:K) = 0$, and if $M - K - L \geq 0$, $ALPHA(K+1:K+L) = C$,

$BETA(K+1:K+L) = S$, or if $M - K - L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$

$BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$ and $ALPHA(K+L+1:N) = 0$

$BETA(K+L+1:N) = 0$

*** BETA (output)**

See description of ALPHA.

*** U (output)**

If $JOB_U = 'U'$, U contains the M-by-M unitary matrix U. If $JOB_U = 'N'$, U is not referenced.

*** LDU (input)**

The leading dimension of the array U. $LDU \geq \max(1, M)$ if $JOB_U = 'U'$; $LDU \geq 1$ otherwise.

*** V (output)**

If $JOB_V = 'V'$, V contains the P-by-P unitary matrix V. If $JOB_V = 'N'$, V is not referenced.

*** LDV (input)**

The leading dimension of the array V. $LDV \geq \max(1, P)$ if $JOB_V = 'V'$; $LDV \geq 1$ otherwise.

*** Q (output)**

If $JOB_Q = 'Q'$, Q contains the N-by-N unitary matrix Q. If $JOB_Q = 'N'$, Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. $LDQ \geq \max(1, N)$ if $JOB_Q = 'Q'$; $LDQ \geq 1$ otherwise.

*** WORK (workspace)**

$\text{dimension}(\text{MAX}(3 * N, M, P) + N)$

*** WORK2 (workspace)**

*** IWORK3 (output)**

On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for $I = K + 1$, $\min(M, K + L)$ swap $ALPHA(I)$ and $ALPHA(IWORK3(I))$ endfor such that $ALPHA(1) \geq ALPHA(2) \geq \dots \geq ALPHA(N)$.

*** INFO (output)**

NAME

cggsvp - compute unitary matrices U, V and Q such that $N-K-L \times K \times L \times U^* \times A \times Q = K \times (0 \ A12 \ A13)$ if $M-K-L \geq 0$

```

PURPOSE

cggsvp computes unitary matrices U, V and Q such that $L \begin{pmatrix} 0 & 0 & A23 \end{pmatrix}$

$$V' * B * Q = \begin{pmatrix} M-K-L & 0 & 0 & 0 \\ & N-K-L & K & L \\ & K & 0 & A12 & A13 \\ & M-K & 0 & 0 & A23 \\ & & N-K-L & K & L \\ & L & 0 & 0 & B13 \\ & P-L & 0 & 0 & 0 \end{pmatrix} \quad \text{if } M-K-L < 0;$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if $M-K-L \geq 0$, otherwise A23 is (M-K)-by-L upper trapezoidal. $K+L$ = the effective numerical rank of the (M+P)-by-N matrix (A',B)'. Z' denotes the conjugate transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine CGGSVD.

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose

section.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B (input/output)**

On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

* **TOLA (input)**

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a subblock of A. Generally, they are set to $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

* **TOLB (input)**

See description of TOLA.

* **K (output)**

On exit, K and L specify the dimension of the subblocks described in Purpose section. $K + L =$ effective numerical rank of (A',B)'.
rank of (A',B)'.

* **L (output)**

See the description of K.

* **U (input)**

If JOBU = 'U', U contains the unitary matrix U. If JOBU = 'N', U is not referenced.

* **LDU (input)**

The leading dimension of the array U. $LDU \geq \max(1, M)$ if JOBU = 'U'; $LDU \geq 1$ otherwise.

* **V (input)**

If JOBV = 'V', V contains the unitary matrix V. If JOBV = 'N', V is not referenced.

* **LDV (input)**

The leading dimension of the array V. $LDV \geq \max(1, P)$ if JOBV = 'V'; $LDV \geq 1$ otherwise.

* **Q (input)**

If JOBQ = 'Q', Q contains the unitary matrix Q. If JOBQ = 'N', Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq \max(1, N)$ if JOBQ = 'Q'; $LDQ \geq 1$ otherwise.

* **IWORK (workspace)**

dimension(N)

* **RWORK (workspace)**

dimension(2*N)

* **TAU (workspace)**

dimension(N)

* **WORK (workspace)**

dimension(MAX(3*N, M, P))

* **INFO (output)**

REAL ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE GTCON( NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, [WORK], [INFO])  
CHARACTER(LEN=1) :: NORM  
COMPLEX, DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT  
REAL :: ANORM, RCOND  
  
SUBROUTINE GTCON_64( NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, [WORK], [INFO])  
CHARACTER(LEN=1) :: NORM  
COMPLEX, DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT  
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgtcon(char norm, int n, complex *low, complex *diag, complex *up1, complex *up2, int *ipivot, float anorm, float *rcond, int *info);
```

```
void cgtcon_64(char norm, long n, complex *low, complex *diag, complex *up1, complex *up2, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

cgtcon estimates the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **LOW** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

* **DIAG** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UP1** (*input*)

The (n-1) elements of the first superdiagonal of U.

* **UP2** (*input*)

The (n-2) elements of the second superdiagonal of U.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **ANORM** (*input*)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **INFO** (*output*)

NAME

cgthr, dgthr, sgthr, zgthr - Gathers specified elements from y into x

SYNOPSIS

```
SUBROUTINE CGTHR( NZ, Y, X, INDX)
COMPLEX Y(*), X(*)

INTEGER*8 INDX(*)
```

F95 INTERFACE

```
SUBROUTINE GTHR( [NZ], Y, X, INDX)
COMPLEX, DIMENSION(:) :: Y, X
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX
```

```
SUBROUTINE GTHR_64( [NZ], Y, X, INDX)
COMPLEX, DIMENSION(:) :: Y, X
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

cgthr xGTHR - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. Only the elements of y whose indices are listed in indx are referenced.

```
      do 10, i = 1, n
         x(i) = y(indx(i))
      10 continue
```

ARGUMENTS

* *NZ (input)*

- INTEGER

Number of elements in the compressed form. Unchanged on exit.

* *Y (input)*

Vector in full storage form. Unchanged on exit.

* *X (output)*

Vector in compressed form. Contains elements of y whose indices are listed in $indx$ on exit.

* *INDX (input)*

- INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in $INDX$ are distinct and greater than zero. Unchanged on exit.

NAME

cgthrz, dgthrz, sgthrz, zgthrz - Gathers specified elements from y into x and sets gathered elements in y to zero

SYNOPSIS

```
SUBROUTINE CGTHRZ( NZ, Y, X, INDX)
  COMPLEX Y(*), X(*)
  INTEGER NZ
  INTEGER INDX(*)

SUBROUTINE CGTHRZ_64( NZ, Y, X, INDX)
  COMPLEX Y(*), X(*)
  INTEGER*8 NZ
  INTEGER*8 INDX(*)
```

F95 INTERFACE

```
SUBROUTINE GTHRZ( [NZ], Y, X, INDX)
  COMPLEX, DIMENSION(:) :: Y, X
  INTEGER :: NZ
  INTEGER, DIMENSION(:) :: INDX

SUBROUTINE GTHRZ_64( [NZ], Y, X, INDX)
  COMPLEX, DIMENSION(:) :: Y, X
  INTEGER(8) :: NZ
  INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

cgthrz xGTHRZ - Gathers the specified elements from a vector y in full storage form into a vector x in compressed form. The gathered elements of y are set to zero. Only the elements of y whose indices are listed in indx are referenced.

```
do 10, i = 1, n
  x(i) = y(indx(i))
  y(indx(i)) = 0.0
10 continue
```

ARGUMENTS

* *NZ (input)*

- INTEGER

Number of elements in the compressed form. Unchanged on exit.

* *Y (input/output)*

Vector in full storage form. Gathered elements are set to zero.

* *X (output)*

Vector in compressed form. Contains elements of y whose indices are listed in `indx` on exit.

* *INDX (input)*

- INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in `INDX` are distinct and greater than zero. Unchanged on exit.

NAME

cgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE CGTRFS( TRANSA, N, NRHS, LOW, DIAG, UP, LOWF, DIAGF,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgtrfs(char transa, int n, int nrhs, complex *low, complex *diag, complex *up, complex *lowf, complex *diagf, complex *upf1, complex *upf2, int *ipivot, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

void cgtrfs_64(char transa, long n, long nrhs, complex *low, complex *diag, complex *up, complex *lowf, complex *diagf, complex *upf1, complex *upf2, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);

PURPOSE

cgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

*** TRANSA (input)**

Specifies the form of the system of equations:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** LOW (input)**

The (n-1) subdiagonal elements of A.

*** DIAG (input)**

The diagonal elements of A.

*** UP (input)**

The (n-1) superdiagonal elements of A.

*** LOWF (input)**

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

*** DIAGF (input)**

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

*** UPF1 (input)**

The (n-1) elements of the first superdiagonal of U.

*** UPF2 (input)**

The (n-2) elements of the second superdiagonal of U.

*** IPIVOT (input)**

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

*** B (input)**

The right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** X (input/output)**

On entry, the solution matrix X, as computed by CGTTRS. On exit, the improved solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that

makes $X(j)$ an exact solution).

- * **WORK** (*workspace*)
dimension($2*N$)
- * **WORK2** (*workspace*)
- * **INFO** (*output*)

NAME

cgtsl - (obsolete) solve the linear system $Ax = b$ for a tridiagonal matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE CGTSL( N, SUB, DIAG, SUPER, B, INFO)
COMPLEX SUB(*), DIAG(*), SUPER(*), B(*)
INTEGER N, INFO
```

```
SUBROUTINE CGTSL_64( N, SUB, DIAG, SUPER, B, INFO)
COMPLEX SUB(*), DIAG(*), SUPER(*), B(*)
INTEGER*8 N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgtsl(int n, complex *sub, complex *diag, complex *super, complex *b, int *info);
```

```
void cgtsl_64(long n, complex *sub, complex *diag, complex *super, complex *b, long *info);
```

ARGUMENTS

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *SUB* (*input*)

Subdiagonal of A . $SUB(2)$ through $SUB(N)$ contain the subdiagonal and $SUB(1)$ is not referenced.

* *DIAG* (*input*)

Diagonal of A .

* *SUPER* (*input*)

Superdiagonal of A . $SUPER(1)$ through $SUPER(N-1)$ contain the superdiagonal and $SUPER(N)$ is not referenced.

* *B* (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* *INFO* (*output*)

On exit:

$INFO = 0$ Subroutine completed normally.

INFO > 0 Returns a value k when the k th element of the diagonal becomes exactly zero.

NAME

cgtsv - solve the equation $A \cdot X = B$.

SYNOPSIS

```
SUBROUTINE CGTSV( N, NRHS, LOW, DIAG, UP, B, LDB, INFO)
COMPLEX LOW(*), DIAG(*), UP(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO
```

```
SUBROUTINE CGTSV_64( N, NRHS, LOW, DIAG, UP, B, LDB, INFO)
COMPLEX LOW(*), DIAG(*), UP(*), B(LDB,*)
INTEGER*8 N, NRHS, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE GTSV( [N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
COMPLEX, DIMENSION(:) :: LOW, DIAG, UP
COMPLEX, DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
```

```
SUBROUTINE GTSV_64( [N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
COMPLEX, DIMENSION(:) :: LOW, DIAG, UP
COMPLEX, DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgtsv(int n, int nrhs, complex *low, complex *diag, complex *up, complex *b, int ldb, int *info);
```

```
void cgtsv_64(long n, long nrhs, complex *low, complex *diag, complex *up, complex *b, long ldb, long *info);
```

PURPOSE

cgtsv solves the equation

where A is an N-by-N tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A^T X = B$ may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** LOW (input/output)**

On entry, LOW must contain the (n-1) subdiagonal elements of A. On exit, LOW is overwritten by the (n-2) elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

*** DIAG (input/output)**

On entry, DIAG must contain the diagonal elements of A. On exit, DIAG is overwritten by the n diagonal elements of U.

*** UP (input/output)**

On entry, UP must contain the (n-1) superdiagonal elements of A. On exit, UP is overwritten by the (n-1) elements of the first superdiagonal of U.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

```

PURPOSE

cgtsvx uses the LU factorization to compute the solution to a complex system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A as $A = L * U$, where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.
 2. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
 3. The system of equations is solved for X using the factored form of A.
 4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

*** FACT (input)**

Specifies whether or not the factored form of A has been supplied on entry.

*** TRANSA (input)**

Specifies the form of the system of equations:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** LOW (input)**

The (n-1) subdiagonal elements of A.

*** DIAG (input)**

The n diagonal elements of A.

*** UP (input)**

The (n-1) superdiagonal elements of A.

*** LOWF (input/output)**

If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

*** DIAGF (input/output)**

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the

LU factorization of A.

If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UPF1 (input/output)**

If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

* **UPF2 (input/output)**

If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

* **IPIVOT (input/output)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **B (input)**

The N-by-NRHS right hand side matrix B.

* **LDB (input)**

The leading dimension of the array B. LDB \geq max(1,N).

* **X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

* **LDX (input)**

The leading dimension of the array X. LDX \geq max(1,N).

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

* **FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK (workspace)**

dimension(2*N)

* **WORK2 (workspace)**

* **INFO (output)**

```

```
void cgtrf(int n, complex *low, complex *diag, complex *up1, complex *up2, int *ipivot, int *info);
```

```
void cgtrf_64(long n, complex *low, complex *diag, complex *up1, complex *up2, long *ipivot, long *info);
```

PURPOSE

cgtrf computes an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

*** N (input)**

The order of the matrix A.

*** LOW (input/output)**

On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

*** DIAG (input/output)**

On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

*** UP1 (input/output)**

On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

*** UP2 (output)**

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

*** INFO (output)**

```
void cgttrs_64(char transa, long n, long nrhs, complex *low, complex *diag, complex *up1, complex *up2, long *ipivot,
complex *b, long ldb, long *info);
```

PURPOSE

cgttrs solves one of the systems of equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, with a tridiagonal matrix A using the LU factorization computed by CGTTRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The order of the matrix A.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

* **LOW** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A.

* **DIAG** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UPI** (*input*)

The (n-1) elements of the first super-diagonal of U.

* **UP2** (*input*)

The (n-2) elements of the second super-diagonal of U.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **B** (*input/output*)

On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

* **LDB** (*input*)

The leading dimension of the array B. LDB >= max(1,N).

* **INFO** (*output*)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void chbev(char jobz, char uplo, int n, int ndiag, complex *a, int lda, float *w, complex *z, int ldz, int *info);
```

```
void chbev_64(char jobz, char uplo, long n, long ndiag, complex *a, long lda, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chbev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows NDIAG and NDIAG+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG + 1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension(N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void chbevd(char jobz, char uplo, int n, int kd, complex *ab, int ldab, float *w, complex *z, int ldz, int *info);
```

```
void chbevd_64(char jobz, char uplo, long n, long kd, complex *ab, long ldab, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chbevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and $KD+1$ of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KD + 1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i -th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least N. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** RWORK (workspace)**

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

*** LRWORK (input)**

The dimension of array RWORK. If $N \leq 1$, LRWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LRWORK must be at least N. If JOBZ = 'V' and $N > 1$, LRWORK must be at least $1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

```

PURPOSE

chbevz computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG + 1$.

* **Q** (*output*)

If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. If JOBZ = 'V', then $LDQ \geq \max(1,N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced

if RANGE = 'A' or 'I'.

*** VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** ABTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** NFOUND (input)**

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', $NFOUND = N$, and if RANGE = 'I', $NFOUND = IU - IL + 1$.

*** W (output)**

The first NFOUND elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If $JOBZ = 'V'$, then if $INFO = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If $JOBZ = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

*** WORK (workspace)**

dimension(N)

*** WORK2 (workspace)**

*** IWORK3 (workspace)**

*** IFAIL (output)**

If $JOBZ = 'V'$, then if $INFO = 0$, the first NFOUND elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If $JOBZ = 'N'$, then IFAIL is not referenced.

*** INFO (output)**

NAME

chbgst - reduce a complex Hermitian-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$,

SYNOPSIS

C INTERFACE

```
#include <sunperf.h>
```

```
void chbgst(char vect, char uplo, int n, int ka, int kb, complex *ab, int ldab, complex *bb, int ldbb, complex *x, int ldx, int *info);
```

```
void chbgst_64(char vect, char uplo, long n, long ka, long kb, complex *ab, long ldab, complex *bb, long ldbb, complex *x, long ldx, long *info);
```

PURPOSE

chbgst reduces a complex Hermitian-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$, such that C has the same bandwidth as A .

B must have been previously factorized as $S**H*S$ by CPBSTF, using a split Cholesky factorization. A is overwritten by $C = X**H*A*X$, where $X = S**(-1)*Q$ and Q is a unitary matrix chosen to preserve the bandwidth of A .

ARGUMENTS

* **VECT** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B . $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A , stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the transformed matrix $X**H*A*X$, stored in the same format as A .

* **LDAB** (*input*)

The leading dimension of the array AB . $LDAB \geq KA+1$.

* **BB** (*input*)

The banded factor S from the split Cholesky factorization of B , as returned by CPBSTF, stored in the first $kb+1$ rows of the array.

* **LDBB** (*input*)

The leading dimension of the array BB . $LDBB \geq KB+1$.

* **X** (*output*)

If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

* **LDX (input)**

The leading dimension of the array X. LDX \geq max(1,N) if VECT = 'V'; LDX \geq 1 otherwise.

* **WORK (workspace)**

dimension(N)

* **RWORK (workspace)**

dimension(N)

C INTERFACE

```
#include <sunperf.h>
```

```
void chbgv(char jobz, char uplo, int n, int ka, int kb, complex *ab, int ldab, complex *bb, int ldbb, float *w, complex *z, int ldz, int *info);
```

```
void chbgv_64(char jobz, char uplo, long n, long ka, long kb, complex *ab, long ldab, complex *bb, long ldbb, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chbgv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

* **LDBB** (*input*)

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **W** (*output*)

If $INFO = 0$, the eigenvalues in ascending order.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*H^*B^*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq N$.

* **WORK** (*workspace*)

dimension(N)

* **RWORK** (*workspace*)

dimension(3*N)

* **INFO** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void chbgvd(char jobz, char uplo, int n, int ka, int kb, complex *ab, int ldab, complex *bb, int ldbb, float *w, complex *z, int ldz, int *info);
```

```
void chbgvd_64(char jobz, char uplo, long n, long ka, long kb, complex *ab, long ldab, complex *bb, long ldbb, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chbgvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

* **LDBB (input)**

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **W (output)**

If $INFO = 0$, the eigenvalues in ascending order.

* **Z (input)**

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*H^*B^*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq N$.

* **WORK (workspace)**

On exit, if $INFO=0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. If $N \leq 1$, $LWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LWORK \geq 2*N**2$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

On exit, if $INFO=0$, $RWORK(1)$ returns the optimal LRWORK.

* **LRWORK (input)**

The dimension of array RWORK. If $N \leq 1$, $LRWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LRWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LRWORK \geq 1 + 5*N + 2*N**2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

* **IWORK (workspace)**

On exit, if $INFO=0$, $IWORK(1)$ returns the optimal LIWORK.

* **LIWORK (input)**

The dimension of array IWORK. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK \geq 1$. If $JOBZ = 'V'$ and $N > 1$, $LIWORK \geq 3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

*info);
```

PURPOSE

chbgvx computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*H^*S$, as returned by CPBSTF.

* **LDBB (input)**

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **Q (output)**

If JOBZ = 'V', the n-by-n matrix used in the reduction of $A^*x = (\lambda)B^*x$ to standard form, i.e. $C^*x = (\lambda)B^*x$, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. If JOBZ = 'N', $LDQ \geq 1$. If JOBZ = 'V', $LDQ \geq \max(1,N)$.

* **VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

* **M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W (output)**

If $INFO = 0$, the eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'V', then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*H^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

* **WORK (workspace)**

dimension(N)

* **RWORK (workspace)**

dimension(7*N)

* ***IWORK*** (*workspace*)

dimension(5*N)

* ***IFAIL*** (*output*)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* ***INFO*** (*output*)

NAME

chbmV - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE CHBMV( UPLO, N, NDIAG, ALPHA, A, LDA, X, INCX, BETA, Y,
*               INCY)
CHARACTER * 1 UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), X(*), Y(*)
INTEGER N, NDIAG, LDA, INCX, INCY

SUBROUTINE CHBMV_64( UPLO, N, NDIAG, ALPHA, A, LDA, X, INCX, BETA,
*                  Y, INCY)
CHARACTER * 1 UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), X(*), Y(*)
INTEGER*8 N, NDIAG, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE HBMV( UPLO, [N], NDIAG, ALPHA, A, [LDA], X, [INCX], BETA,
*               Y, [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INCX, INCY

SUBROUTINE HBMV_64( UPLO, [N], NDIAG, ALPHA, A, [LDA], X, [INCX],
*                  BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chbmV(char uplo, int n, int ndiag, complex alpha, complex *a, int lda, complex *x, int incx, complex beta, complex *y, int incy);
```

void chbmv_64(char uplo, long n, long ndiag, complex alpha, complex *a, long lda, complex *x, long incx, complex beta, complex *y, long incy);

PURPOSE

chbmv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$ where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian band matrix, with k super-diagonals.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry, NDIAG specifies the number of super-diagonals of the matrix A. NDIAG must satisfy $0 \leq \text{NDIAG}$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
DO 20, J = 1, N
  M = NDIAG + 1 - J
  DO 10, I = MAX( 1, J - NDIAG ), J
    A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
      O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

*** X (input)**

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

chbtrd - reduce a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

SYNOPSIS

C INTERFACE

```
#include <sunperf.h>
```

```
void chbtrd(char vect, char uplo, int n, int kd, complex *ab, int ldab, float *d, float *e, complex *q, int ldq, int *info);
```

```
void chbtrd_64(char vect, char uplo, long n, long kd, complex *ab, long ldab, float *d, float *e, complex *q, long ldq, long *info);
```

PURPOSE

chbtrd reduces a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

* **VECT** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if $KD > 0$, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KD+1$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = T(i,i+1)$ if UPLO = 'U'; $E(i) = T(i+1,i)$ if UPLO = 'L'.

* **Q** (*input/output*)

On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N unitary matrix Q; if VECT = 'U', Q contains the product $X*Q$; if VECT = 'N', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. $LDQ \geq 1$, and $LDQ \geq N$ if VECT = 'V' or 'U'.

* **WORK** (*workspace*)

dimension(N)

* *INFO (output)*

NAME

checon - estimate the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHETRF

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void checon(char uplo, int n, complex *a, int lda, int *ipivot, float anorm, float *rcond, int *info);
```

```
void checon_64(char uplo, long n, complex *a, long lda, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

checon estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

* **LDA** (*input*)

The leading dimension of the array A . $\text{LDA} \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHETRF.

* **ANORM** (*input*)

The 1-norm of the original matrix A .

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A , computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension($2*N$)

* **INFO** (*output*)

NAME

cheev - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

SYNOPSIS

```
SUBROUTINE CHEEV( JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, WORK2,

CHARACTER(LEN=1) :: JOBZ, UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: W, WORK2

SUBROUTINE HEEV_64( JOBZ, UPLO, [N], A, [LDA], W, [WORK], [LDWORK],
*             [WORK2], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: W, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cheev(char jobz, char uplo, int n, complex *a, int lda, float *w, int *info);
```

```
void cheev_64(char jobz, char uplo, long n, complex *a, long lda, float *w, long *info);
```

PURPOSE

cheev computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The length of the array WORK. $LDWORK \geq \max(1, 2*N-1)$. For optimal efficiency, $LDWORK \geq (NB+1)*N$, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

REAL, DIMENSION(:) :: W, RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cheevd(char jobz, char uplo, int n, complex *a, int lda, float *w, int *info);
```

```
void cheevd_64(char jobz, char uplo, long n, complex *a, long lda, float *w, long *info);
```

PURPOSE

cheevd computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The length of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $N + 1$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N + N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK** (*workspace*)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

*** LRWORK (input)**

The dimension of the array RWORK. If $N \leq 1$, LRWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LRWORK must be at least N . If JOBZ = 'V' and $N > 1$, LRWORK must be at least $1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. If $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

```

PURPOSE

cheevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, CHEEVR calls CSTEGR to compute the

eigenspectrum using Relatively Robust Representations. CSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" $L D L^T$ representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i -th unreduced block of T,

- (a) Compute $T - \sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation,
- (b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,
- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : CHEEVR calls CSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. CHEEVR calls SSTEGBZ and CSTEIN on non-ieee machines and

when partial spectrum requests are made.

Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **ABSTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

* **M** (*output*)

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W** (*output*)

The first M elements contain the selected eigenvalues in ascending order.

* **Z** (*output*)

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A

corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $W(i)$. If $JOBZ = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z ; if $RANGE = 'V'$, the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

*** ISUPPZ (output)**

The support of the eigenvectors in Z , i.e., the indices indicating the nonzero elements in Z . The i -th eigenvector is nonzero only in elements $ISUPPZ(2*i-1)$ through $ISUPPZ(2*i)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

*** LWORK (input)**

The length of the array $WORK$. $LWORK \geq \max(1, 2*N)$. For optimal efficiency, $LWORK \geq (NB+1)*N$, where NB is the max of the blocksize for $CHETRD$ and for $CUNMTR$ as returned by $ILAENV$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by $XERBLA$.

*** RWORK (workspace)**

On exit, if $INFO = 0$, $RWORK(1)$ returns the optimal (and minimal) $LRWORK$.

*** LRWORK (input)**

The length of the array $RWORK$. $LRWORK \geq \max(1, 24*N)$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $RWORK$ array, returns this value as the first entry of the $RWORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

*** IWORK (workspace)**

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal (and minimal) $LIWORK$.

*** LIWORK (input)**

The dimension of the array $IWORK$. $LIWORK \geq \max(1, 10*N)$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued by $XERBLA$.

*** INFO (output)**

```

PURPOSE

cheevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU$

$\leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

*** *ABTOL* (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If $ABTOL$ is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $ABTOL$ is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting $ABTOL$ to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** *NFOUND* (input)**

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If $RANGE = 'A'$, $NFOUND = N$, and if $RANGE = 'I'$, $NFOUND = IU - IL + 1$.

*** *W* (output)**

On normal exit, the first $NFOUND$ elements contain the selected eigenvalues in ascending order.

*** *Z* (input)**

If $JOBZ = 'V'$, then if $INFO = 0$, the first $NFOUND$ columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i -th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in $IFAIL$. If $JOBZ = 'N'$, then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z ; if $RANGE = 'V'$, the exact value of $NFOUND$ is not known in advance and an upper bound must be used.

*** *LDZ* (input)**

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

*** *WORK* (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

*** *LDWORK* (input)**

The length of the array $WORK$. $LDWORK \geq \max(1, 2 * N - 1)$. For optimal efficiency, $LDWORK \geq (NB + 1) * N$, where NB is the max of the blocksize for $CHETRD$ and for $CUNMTR$ as returned by $ILAENV$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

*** *WORK2* (workspace)**

*** *IWORK3* (workspace)**

*** *IFAIL* (output)**

If $JOBZ = 'V'$, then if $INFO = 0$, the first $NFOUND$ elements of $IFAIL$ are zero. If $INFO > 0$, then $IFAIL$ contains the indices of the eigenvectors that failed to converge. If $JOBZ = 'N'$, then $IFAIL$ is not referenced.

*** *INFO* (output)**

NAME

chegs2 - reduce a complex Hermitian-definite generalized eigenproblem to standard form

```

```
void chegs2(int itype, char uplo, int n, complex *a, int lda, complex *b, int ldb, int *info);
```

```
void chegs2_64(long itype, char uplo, long n, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

chegs2 reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U)*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L')$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U'$ or $L'*A*L$.

B must have been previously factorized as $U*U$ or $L*L'$ by CPOTRF.

ARGUMENTS

* *ITYPE (input)*

* *UPLO (input)*

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored, and how B has been factorized.

* *N (input)*

The order of the matrices A and B. $N \geq 0$.

* *A (input/output)*

On entry, the Hermitian matrix A. If $UPLO = 'U'$, the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *B (input)*

The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

* *LDB (input)*

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *INFO (output)*

```

```
void chegst_64(long itype, char uplo, long n, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

chegst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**H}$ or $L^{**H}*A*L$.

B must have been previously factorized as $U^{**H}*U$ or $L*L^{**H}$ by CPOTRF.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *A* (input/output)

On entry, the Hermitian matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *B* (input)

The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *INFO* (output)

```

```
void chegv_64(long itype, char jobz, char uplo, long n, complex *a, long lda, complex *b, long ldb, float *w, long *info);
```

PURPOSE

chegv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian and B is also

positive definite.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*H*B*Z = I$; if ITYPE = 3, $Z^*H*\text{inv}(B)*Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L^*L^*H$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** W (output)**

If $INFO = 0$, the eigenvalues in ascending order.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The length of the array WORK. LDWORK $\geq \max(1, 2*N-1)$. For optimal efficiency, LDWORK $\geq (NB+1)*N$, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

C INTERFACE

```
#include <sunperf.h>
```

```
void chegvd(int itype, char jobz, char uplo, int n, complex *a, int lda, complex *b, int ldb, float *w, int *info);
```

```
void chegvd_64(long itype, char jobz, char uplo, long n, complex *a, long lda, complex *b, long ldb, float *w, long *info);
```

PURPOSE

chegvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z^*H*B*Z = I$; if ITYPE = 3, $Z^*H*inv(B)*Z = I$. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if $INFO \leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $B = U^*H*U$ or $B = L*L^*H$.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **W (output)**

If INFO = 0, the eigenvalues in ascending order.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The length of the array WORK. If $N \leq 1$, LWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LWORK $\geq N + 1$. If JOBZ = 'V' and $N > 1$, LWORK $\geq 2*N + N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

* **LRWORK (input)**

The dimension of the array RWORK. If $N \leq 1$, LRWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LRWORK $\geq N$. If JOBZ = 'V' and $N > 1$, LRWORK $\geq 1 + 5*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

* **IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK (input)**

The dimension of the array IWORK. If $N \leq 1$, LIWORK ≥ 1 . If JOBZ = 'N' and $N > 1$, LIWORK ≥ 1 . If JOBZ = 'V' and $N > 1$, LIWORK $\geq 3 + 5*N$.

* **INFO (output)**

```

PURPOSE

chegvx computes selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** RANGE (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the Hermitian matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO $\leq N$, the part of B containing the matrix is overwritten by the triangular factor U or L from the

Cholesky factorization $B = U^*H^*U$ or $B = L^*L^{**}H$.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

* **M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W (output)**

The first M elements contain the selected eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^{**T}B^*Z = I$; if $ITYPE = 3$, $Z^{**T}inv(B)^*Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1,M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The length of the array WORK. $LWORK \geq \max(1,2*N-1)$. For optimal efficiency, $LWORK \geq (NB+1)*N$, where NB is the blocksize for CHETRD returned by ILAENV.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by

XERBLA.

* **RWORK** (*workspace*)

dimension(7*N)

* **IWORK** (*workspace*)

dimension(5*N)

* **IFAIL** (*output*)

If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* **INFO** (*output*)

NAME

chemm - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

SYNOPSIS

```
SUBROUTINE CHEMM( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
*             LDC)
CHARACTER * 1 SIDE, UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER M, N, LDA, LDB, LDC

SUBROUTINE CHEMM_64( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA,
*             C, LDC)
CHARACTER * 1 SIDE, UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 M, N, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE HEMM( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*             BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER :: M, N, LDA, LDB, LDC

SUBROUTINE HEMM_64( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*             BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER(8) :: M, N, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chemm(char side, char uplo, int m, int n, complex alpha, complex *a, int lda, complex *b, int ldb, complex beta,
complex *c, int ldc);
```

```
void chemm_64(char side, char uplo, long m, long n, complex alpha, complex *a, long lda, complex *b, long ldb, complex
```

beta, complex *c, long ldc);

PURPOSE

chemm performs one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$ where alpha and beta are scalars, A is an hermitian matrix and B and C are m by n matrices.

ARGUMENTS

* *SIDE* (input)

On entry, SIDE specifies whether the hermitian matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha * A * B + \beta * C$,

SIDE = 'R' or 'r' $C := \alpha * B * A + \beta * C$,

Unchanged on exit.

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the hermitian matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the hermitian matrix is to be referenced.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero. Unchanged on

exit.

* **LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'I' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

* **B (input)**

Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

* **LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least $\max(1, m)$. Unchanged on exit.

* **BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

* **C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry.

On exit, the array C is overwritten by the m by n updated matrix.

* **LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, m)$. Unchanged on exit.

NAME

chemv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE CHEMV( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), X(*), Y(*)
INTEGER N, LDA, INCX, INCY
```

```
SUBROUTINE CHEMV_64( UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), X(*), Y(*)
INTEGER*8 N, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE HEMV( UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, INCX, INCY
```

```
SUBROUTINE HEMV_64( UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chemv(char uplo, int n, complex alpha, complex *a, int lda, complex *x, int incx, complex beta, complex *y, int incy);
```

```
void chemv_64(char uplo, long n, complex alpha, complex *a, long lda, complex *x, long incx, complex beta, complex *y, long incy);
```

PURPOSE

chemv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$ where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N (input)*

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

* *LDA (input)*

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

* *X (input)*

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

* *BETA (input)*

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* *Y (input/output)*

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

cher - perform the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$

SYNOPSIS

```
SUBROUTINE CHER( UPLO, N, ALPHA, X, INCX, A, LDA)
  CHARACTER * 1 UPLO
  COMPLEX X(*), A(LDA,*)
  INTEGER N, INCX, LDA
  REAL ALPHA
```

```
SUBROUTINE CHER_64( UPLO, N, ALPHA, X, INCX, A, LDA)
  CHARACTER * 1 UPLO
  COMPLEX X(*), A(LDA,*)
  INTEGER*8 N, INCX, LDA
  REAL ALPHA
```

F95 INTERFACE

```
SUBROUTINE HER( UPLO, [N], ALPHA, X, [INCX], A, [LDA])
  CHARACTER(LEN=1) :: UPLO
  COMPLEX, DIMENSION(:) :: X
  COMPLEX, DIMENSION(:, :) :: A
  INTEGER :: N, INCX, LDA
  REAL :: ALPHA
```

```
SUBROUTINE HER_64( UPLO, [N], ALPHA, X, [INCX], A, [LDA])
  CHARACTER(LEN=1) :: UPLO
  COMPLEX, DIMENSION(:) :: X
  COMPLEX, DIMENSION(:, :) :: A
  INTEGER(8) :: N, INCX, LDA
  REAL :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cher(char uplo, int n, float alpha, complex *x, int incx, complex *a, int lda);
```

```
void cher_64(char uplo, long n, float alpha, complex *x, long incx, complex *a, long lda);
```

PURPOSE

cher performs the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$ where α is a real scalar, x is an n element vector and A is an n by n hermitian matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *A* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $\text{LDA} \geq \max(1, n)$. Unchanged on exit.

NAME

cher2 - perform the hermitian rank 2 operation $A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A$

SYNOPSIS

```
SUBROUTINE CHER2( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
CHARACTER * 1 UPLO
COMPLEX ALPHA
COMPLEX X(*), Y(*), A(LDA,*)
INTEGER N, INCX, INCY, LDA
```

```
SUBROUTINE CHER2_64( UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)
CHARACTER * 1 UPLO

INTEGER :: N, INCX, INCY, LDA
```

```
SUBROUTINE HER2_64( UPLO, [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cher2(char uplo, int n, complex alpha, complex *x, int incx, complex *y, int incy, complex *a, int lda);
```

```
void cher2_64(char uplo, long n, complex alpha, complex *x, long incx, complex *y, long incy, complex *a, long lda);
```

PURPOSE

cher2 performs the hermitian rank 2 operation $A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A$ where α is a scalar, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of A is to be referenced.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *Y* (input)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

* *A* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $\text{LDA} \geq \max(1, n)$. Unchanged on exit.

NAME

cher2k - perform one of the Hermitian rank 2k operations $C := \alpha * A * \text{conjg}(B') + \text{conjg}(\alpha) * B * \text{conjg}(A') + \beta * C$
or $C := \alpha * \text{conjg}(A') * B + \text{conjg}(\alpha) * \text{conjg}(B') * A + \beta * C$

SYNOPSIS

```
SUBROUTINE CHER2K( UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA,
*                C, LDC)
CHARACTER * 1 UPLO, TRANSA

COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER :: N, K, LDA, LDB, LDC
REAL :: BETA
```

```
SUBROUTINE HER2K_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,
*                  [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL :: BETA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cher2k(char uplo, char transa, int n, int k, complex alpha, complex *a, int lda, complex *b, int ldb, float beta, complex *c, int ldc);
```

```
void cher2k_64(char uplo, char transa, long n, long k, complex alpha, complex *a, long lda, complex *b, long ldb, float beta, complex *c, long ldc);
```

PURPOSE

cher2k K performs one of the Hermitian rank 2k operations $C := \alpha * A * \text{conjg}(B') + \text{conjg}(\alpha) * B * \text{conjg}(A') + \beta * C$ or $C := \alpha * \text{conjg}(A') * B + \text{conjg}(\alpha) * \text{conjg}(B') * A + \beta * C$ where alpha and beta are scalars with beta real, C is an n by n Hermitian matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * \text{conjg}(B') + \text{conjg}(\alpha) * B * \text{conjg}(A') + \beta * C$.

TRANSA = 'C' or 'c' $C := \alpha * \text{conjg}(A') * B + \text{conjg}(\alpha) * \text{conjg}(B') * A + \beta * C$.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

*** B (input)**

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. Unchanged on exit.

*** C (input/output)**

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

cherfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```

```

PURPOSE

cherfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{*H}$ or $A = L * D * L^{*H}$ as computed by CHETRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHETRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CHETRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cherk - perform one of the Hermitian rank k operations $C := \alpha * A * \text{conjg}(A') + \beta * C$ or $C := \alpha * \text{conjg}(A') * A + \beta * C$

SYNOPSIS

```
SUBROUTINE CHERK( UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)
CHARACTER * 1 UPLO, TRANSA
COMPLEX A(LDA,*), C(LDC,*)
INTEGER N, K, LDA, LDC
REAL ALPHA, BETA
```

```
SUBROUTINE CHERK_64( UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C,
*                   LDC)
CHARACTER * 1 UPLO, TRANSA
COMPLEX A(LDA,*), C(LDC,*)
INTEGER*8 N, K, LDA, LDC
REAL ALPHA, BETA
```

F95 INTERFACE

```
SUBROUTINE HERK( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA, C,
*              [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX, DIMENSION(:,*) :: A, C
INTEGER :: N, K, LDA, LDC
REAL :: ALPHA, BETA
```

```
SUBROUTINE HERK_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
*                  C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX, DIMENSION(:,*) :: A, C
INTEGER(8) :: N, K, LDA, LDC
REAL :: ALPHA, BETA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cherk(char uplo, char transa, int n, int k, float alpha, complex *a, int lda, float beta, complex *c, int ldc);
```

```
void cherk_64(char uplo, char transa, long n, long k, float alpha, complex *a, long lda, float beta, complex *c, long ldc);
```

PURPOSE

cherk performs one of the Hermitian rank k operations $C := \alpha * A * \text{conjg}(A') + \beta * C$ or $C := \alpha * \text{conjg}(A') * A + \beta * C$ where alpha and beta are real scalars, C is an n by n Hermitian matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA (input)*

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * \text{conjg}(A') + \beta * C$.

TRANSA = 'C' or 'c' $C := \alpha * \text{conjg}(A') * A + \beta * C$.

Unchanged on exit.

* *N (input)*

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K (input)*

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA (input)*

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *BETA (input)*

On entry, BETA specifies the scalar beta. Unchanged on exit.

* *C (input/output)*

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with `UPLO = 'L'` or `'l'`, the leading n by n lower triangular part of the array `C` must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of `C` is not referenced. On exit, the lower triangular part of the array `C` is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

* ***LDC (input)***

On entry, `LDC` specifies the first dimension of `C` as declared in the calling (sub) program. `LDC` must be at least $\max(1, n)$. Unchanged on exit.

NAME

chesv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE CHESV( UPLO, N, NRHS, A, LDA, IPIVOT, B, LDB, WORK,
* LDWORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*), WORK(*)
INTEGER N, NRHS, LDA, LDB, LDWORK, INFO
INTEGER IPIVOT(*)

SUBROUTINE CHESV_64( UPLO, N, NRHS, A, LDA, IPIVOT, B, LDB, WORK,
* LDWORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*), WORK(*)
INTEGER*8 N, NRHS, LDA, LDB, LDWORK, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE HESV( UPLO, [N], [NRHS], A, [LDA], IPIVOT, B, [LDB],
* [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,) :: A, B
INTEGER :: N, NRHS, LDA, LDB, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE HESV_64( UPLO, [N], [NRHS], A, [LDA], IPIVOT, B, [LDB],
* [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chesv(char uplo, int n, int nrhs, complex *a, int lda, int *ipivot, complex *b, int ldb, int *info);
```

```
void chesv_64(char uplo, long n, long nrhs, complex *a, long lda, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

chesv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**H}, & \text{if UPLO} = 'U', & \text{ or} \\ A &= L * D * L^{**H}, & \text{if UPLO} = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**H}$ or $A = L * D * L^{**H}$ as computed by CHETRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by CHETRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The length of WORK. LDWORK ≥ 1 , and for best performance LDWORK $\geq N \cdot NB$, where NB is the optimal blocksize for CHETRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

chesvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE CHESVX( FACT, UPLO, N, NRHS, A, LDA, AF, LDAF, IPIVOT, B,

#include <sunperf.h>
```

```
void chesvx(char fact, char uplo, int n, int nrhs, complex *a, int lda, complex *af, int ldaf, int *ipivot, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void chesvx_64(char fact, char uplo, long n, long nrhs, complex *a, long lda, complex *af, long ldaf, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

chesvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A . The form of the factorization is

```
A = U * D * U**H,  if UPLO = 'U', or
A = L * D * L**H,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is Hermitian and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* ***FACT*** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* ***UPLO*** (*input*)

* ***N*** (*input*)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* ***NRHS*** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

*** A (input)**

The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

*** LDA (input)**

The leading dimension of the array A. LDA \geq max(1,N).

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ as computed by CHETRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$.

*** LDAF (input)**

The leading dimension of the array AF. LDAF \geq max(1,N).

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHETRF. If IPIVOT(k) $>$ 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) $<$ 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) $<$ 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHETRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. LDB \geq max(1,N).

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. LDX \geq max(1,N).

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of WORK. LDWORK $\geq 2*N$, and for best performance LDWORK $\geq N*NB$, where NB is the optimal blocksize for CHETRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

chetf2 - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE CHETF2( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
INTEGER IPIV(*)
```

```
SUBROUTINE CHETF2_64( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE HETF2( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE HETF2_64( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chetf2(char uplo, int n, complex *a, int lda, int *ipiv, int *info);
```

```
void chetf2_64(char uplo, long n, complex *a, long lda, long *ipiv, long *info);
```

PURPOSE

chetf2 computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U' \quad \text{or} \quad A = L^*D^*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIV (output)**

Details of the interchanges and the block structure of D. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** INFO (output)**

*                   [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chetrd(char uplo, int n, complex *a, int lda, float *d, float *e, complex *tau, int *info);
```

```
void chetrd_64(char uplo, long n, complex *a, long lda, float *d, float *e, complex *tau, long *info);
```

PURPOSE

chetrd reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation:
 $Q^{*H} * A * Q = T$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T: $D(i) = A(i, i)$.

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i, i+1)$ if UPLO = 'U', $E(i) = A(i+1, i)$ if UPLO = 'L'.

* **TAU** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $LWORK \geq 1$. For optimum performance $LWORK \geq N * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void chetrf(char uplo, int n, complex *a, int lda, int *ipivot, int *info);
```

```
void chetrf_64(char uplo, long n, complex *a, long lda, long *ipivot, long *info);
```

PURPOSE

chetrf computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U * D * U^{*H} \quad \text{or} \quad A = L * D * L^{*H}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A . If $UPLO = 'U'$, the leading N -by- N upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N -by- N lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A . $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D . If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

*** LDWORK (input)**

The length of $WORK$. $LDWORK \geq 1$. For best performance $LDWORK \geq N * NB$, where NB is the block size returned by $ILAENV$.

*** INFO (output)**

NAME

chetri - compute the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ computed by CHETRF

SYNOPSIS

```
SUBROUTINE CHETRI( UPLO, N, A, LDA, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CHETRI_64( UPLO, N, A, LDA, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE HETRI( UPLO, [N], A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE HETRI_64( UPLO, [N], A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chetri(char uplo, int n, complex *a, int lda, int *ipivot, int *info);
```

```
void chetri_64(char uplo, long n, complex *a, long lda, long *ipivot, long *info);
```

PURPOSE

chetri computes the inverse of a complex Hermitian indefinite matrix A using the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ computed by CHETRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHETRF.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

chetrs - solve a system of linear equations $A*X = B$ with a complex Hermitian matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHETRF

SYNOPSIS

```
SUBROUTINE CHETRS( UPLO, N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CHETRS_64( UPLO, N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NRHS, LDA, LDB, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE HETRS( UPLO, [N], [NRHS], A, [LDA], IPIVOT, B, [LDB],
* [INFO])
CHARACTER(LEN=1) :: UPLO

INTEGER :: N, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE HETRS_64( UPLO, [N], [NRHS], A, [LDA], IPIVOT, B, [LDB],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chetrs(char uplo, int n, int nrhs, complex *a, int lda, int *ipivot, complex *b, int ldb, int *info);
```

```
void chetrs_64(char uplo, long n, long nrhs, complex *a, long lda, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

chetrs solves a system of linear equations $A \cdot X = B$ with a complex Hermitian matrix A using the factorization $A = U \cdot D \cdot U^* \cdot H$ or $A = L \cdot D \cdot L^* \cdot H$ computed by CHETRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHETRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

chgeqz - implement a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation $\det(A-w(i)B) = 0$. If $\text{JOB}='S'$, then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary transformation (usually called Q) on the left and another (usually called Z) on the right.

SYNOPSIS

```
SUBROUTINE CHGEQZ( JOB, COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB,  
*      ALPHA, BETA, Q, LDQ, Z, LDZ, WORK, LWORK, RWORK, INFO)  
CHARACTER * 1 JOB, COMPQ, COMPZ  
COMPLEX A(LDA,*), B(LDB,*), ALPHA(*), BETA(*), Q(LDQ,*), Z(LDZ,*), WORK(*)  
INTEGER N, ILO, IHI, LDA, LDB, LDQ, LDZ, LWORK, INFO  
REAL RWORK(*)
```

```
SUBROUTINE CHGEQZ_64( JOB, COMPQ, COMPZ, N, ILO, IHI, A, LDA, B,  
*      LDB, ALPHA, BETA, Q, LDQ, Z, LDZ, WORK, LWORK, RWORK, INFO)  
CHARACTER * 1 JOB, COMPQ, COMPZ

INTEGER*8 N, ILO, IHI, LDA, LDB, LDQ, LDZ, LWORK, INFO  
REAL RWORK(*)
```

F95 INTERFACE

```
SUBROUTINE HGEQZ( JOB, COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B,  
*      [LDB], ALPHA, BETA, Q, [LDQ], Z, [LDZ], [WORK], [LWORK], [RWORK],  
*      [INFO])  
CHARACTER(LEN=1) :: JOB, COMPQ, COMPZ  
COMPLEX, DIMENSION(:) :: ALPHA, BETA, WORK  
COMPLEX, DIMENSION(:, :) :: A, B, Q, Z  
INTEGER :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, LWORK, INFO  
REAL, DIMENSION(:) :: RWORK
```

```
SUBROUTINE HGEQZ_64( JOB, COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B,  
*      [LDB], ALPHA, BETA, Q, [LDQ], Z, [LDZ], [WORK], [LWORK], [RWORK],  
*      [INFO])  
CHARACTER(LEN=1) :: JOB, COMPQ, COMPZ  
COMPLEX, DIMENSION(:) :: ALPHA, BETA, WORK  
COMPLEX, DIMENSION(:, :) :: A, B, Q, Z  
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, LWORK, INFO  
REAL, DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chgeqz(char job, char compq, char compz, int n, int ilo, int ihi, complex *a, int lda, complex *b, int ldb, complex *alpha, complex *beta, complex *q, int ldq, complex *z, int ldz, int *info);
```

```
void chgeqz_64(char job, char compq, char compz, long n, long ilo, long ihi, complex *a, long lda, complex *b, long ldb, complex *alpha, complex *beta, complex *q, long ldq, complex *z, long ldz, long *info);
```

PURPOSE

chgeqz implements a single-shift version of the QZ method for finding the generalized eigenvalues $w(i)=\text{ALPHA}(i)/\text{BETA}(i)$ of the equation A are then $\text{ALPHA}(1),\dots,\text{ALPHA}(N)$, and of B are $\text{BETA}(1),\dots,\text{BETA}(N)$.

If $\text{JOB}='S'$ and COMPQ and COMPZ are 'V' or 'T', then the unitary transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:

$$(\text{in}) A(\text{in}) Z(\text{in})^* = Q(\text{out}) A(\text{out}) Z(\text{out})^* \quad (\text{in}) B(\text{in}) Z(\text{in})^* = Q(\text{out}) B(\text{out}) Z(\text{out})^*$$

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrix Eigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

* **JOB** (input)

* **COMPQ** (input)

* **COMPZ** (input)

* **N** (input)

The order of the matrices A , B , Q , and Z . $N \geq 0$.

* **ILO** (input)

It is assumed that A is already upper triangular in rows and columns $1:\text{ILO}-1$ and $\text{IHI}+1:N$. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

* **IHI** (input)

It is assumed that A is already upper triangular in rows and columns $1:\text{ILO}-1$ and $\text{IHI}+1:N$. $1 \leq \text{ILO} \leq \text{IHI} \leq N$, if $N > 0$; $\text{ILO}=1$ and $\text{IHI}=0$, if $N=0$.

* **A** (input)

On entry, the N -by- N upper Hessenberg matrix A . Elements below the subdiagonal must be zero. If $\text{JOB}='S'$, then on exit A and B will have been simultaneously reduced to upper triangular form. If $\text{JOB}='E'$, then on exit A will have been destroyed.

* **LDA** (input)

The leading dimension of the array A . $\text{LDA} \geq \max(1, N)$.

* **B** (input)

On entry, the N -by- N upper triangular matrix B . Elements below the diagonal must be zero. If $\text{JOB}='S'$, then on exit A and B will have been simultaneously reduced to upper triangular form. If $\text{JOB}='E'$, then on exit B will have been destroyed.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **ALPHA (output)**

The diagonal elements of A when the pair (A,B) has been reduced to Schur form. $ALPHA(i)/BETA(i)$ $i=1,\dots,N$ are the generalized eigenvalues.

* **BETA (output)**

The diagonal elements of B when the pair (A,B) has been reduced to Schur form. $ALPHA(i)/BETA(i)$ $i=1,\dots,N$ are the generalized eigenvalues. A and B are normalized so that $BETA(1),\dots,BETA(N)$ are non-negative real numbers.

* **Q (input/output)**

If $COMPQ='N'$, then Q will not be referenced. If $COMPQ='V'$ or $'I'$, then the conjugate transpose of the unitary transformations which are applied to A and B on the left will be applied to the array Q on the right.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$. If $COMPQ='V'$ or $'I'$, then $LDQ \geq N$.

* **Z (input/output)**

If $COMPZ='N'$, then Z will not be referenced. If $COMPZ='V'$ or $'I'$, then the unitary transformations which are applied to A and B on the right will be applied to the array Z on the right.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$. If $COMPZ='V'$ or $'I'$, then $LDZ \geq N$.

* **WORK (workspace)**

On exit, if $INFO \geq 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1,N)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK (workspace)**

dimension(N)

* **INFO (output)**

NAME

chico - (obsolete) compute the UDU factorization and condition number of a Hermitian matrix A. If the condition number is not needed then xHIFA is slightly faster. It is typical to follow a call to xHICO with a call to xHISL to solve $Ax = b$ or to xHIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE CHICO( A, LDA, N, IPIVOT, RCOND, WORK)
  COMPLEX A(LDA,*), WORK(*)
  INTEGER LDA, N
  INTEGER IPIVOT(*)
  REAL RCOND
```

```
SUBROUTINE CHICO_64( A, LDA, N, IPIVOT, RCOND, WORK)
  COMPLEX A(LDA,*), WORK(*)
  INTEGER*8 LDA, N
  INTEGER*8 IPIVOT(*)
  REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chico(complex *a, int lda, int n, int *ipivot, float *rcond);
```

```
void chico_64(complex *a, long lda, long n, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq \text{RCOND} \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $\text{RCOND} + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

chidi - (obsolete) compute the determinant, inertia, and inverse of a Hermitian matrix A, which has been UDU-factored by CHICO or CHIFA.

SYNOPSIS

```
SUBROUTINE CHIDI( A, LDA, N, IPIVOT, DET, INERT, WORK, JOB)
COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*), INERT(*)
REAL DET(*)
```

```
SUBROUTINE CHIDI_64( A, LDA, N, IPIVOT, DET, INERT, WORK, JOB)
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*), INERT(*)
REAL DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chidi(complex *a, int lda, int n, int *ipivot, float *det, int *inert, int job);
```

```
void chidi_64(complex *a, long lda, long n, long *ipivot, float *det, long *inert, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by CHICO or CHIFA. On exit, if the c digit of JOB <> 0, then the upper triangle of A contains the upper triangle of the inverse of the original matrix A if the inverse was requested, otherwise unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA >= max(1,N).

*** N (input)**

Order of the original matrix A. N >= 0.

*** IPIVOT (input)**

Pivot vector as computed by CHICO or CHIFA.

*** DET (output)**

On exit, if the b digit of JOB ≥ 0 , then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or DET(1) = 0.0. If the b digit of JOB < 0 , DET is not referenced.

* **INERT** (*output*)

On exit, if the a digit of JOB $\neq 0$, then INERT contains an integer triplet where:

INERT(1) = number of positive eigenvalues

INERT(2) = number of negative eigenvalues

INERT(3) = number of zero eigenvalues

If the a digit of JOB = 0 then INERT is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form abc; determines operation the subroutine will perform:

a $\neq 0$	Compute the inertia.
b $\neq 0$	Compute the determinant.
c $\neq 0$	Compute the inverse.

NAME

chifa - (obsolete) compute the UDU factorization of a Hermitian matrix A. It is typical to follow a call to CHIFA with a call to CHISL to solve $Ax = b$ or to CHIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE CHIFA( A, LDA, N, IPIVOT, INFO)
COMPLEX A(LDA,*)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CHIFA_64( A, LDA, N, IPIVOT, INFO)
COMPLEX A(LDA,*)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chifa(complex *a, int lda, int n, int *ipivot, int *info);
```

```
void chifa_64(complex *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that CHISL or CHIDI will divide by zero if called.

NAME

chisl - (obsolete) solve the linear system $Ax = b$ for a Hermitian matrix A , which has been UDU-factored by CHICO or CHIFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CHISL( A, LDA, N, IPIVOT, B)
  COMPLEX A(LDA,*), B(*)
  INTEGER LDA, N
  INTEGER IPIVOT(*)

SUBROUTINE CHISL_64( A, LDA, N, IPIVOT, B)
  COMPLEX A(LDA,*), B(*)
  INTEGER*8 LDA, N
  INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>

void chisl(complex *a, int lda, int n, int *ipivot, complex *b);
void chisl_64(complex *a, long lda, long n, long *ipivot, complex *b);
```

ARGUMENTS

- * **A** (*input*)
UDU factorization of the matrix A , as computed by CHICO or CHIFA.
- * **LDA** (*input*)
Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.
- * **N** (*input*)
Order of the matrix A . $N \geq 0$.
- * **IPIVOT** (*input*)
Pivot vector as computed by CHICO or CHIFA.
- * **B** (*input/output*)
On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

chpco - (obsolete) compute the UDU factorization and condition number of a Hermitian matrix A in packed storage. If the condition number is not needed then xHPFA is slightly faster. It is typical to follow a call to xHPCO with a call to xHPSL to solve $Ax = b$ or to xHPDI to compute the determinant, inverse, and inertia of A .

SYNOPSIS

```
SUBROUTINE CHPCO( A, N, IPIVOT, RCOND, WORK)
  COMPLEX A(*), WORK(*)
  INTEGER N
  INTEGER IPIVOT(*)
  REAL RCOND
```

```
SUBROUTINE CHPCO_64( A, N, IPIVOT, RCOND, WORK)

```

```
void chpco_64(complex *a, long n, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A . On exit, a UDU factorization of the matrix A .

* **N** (*input*)

Order of the matrix A . $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A . $0.0 \leq RCOND \leq 1.0$. As the value of $RCOND$ gets smaller, operations with A such as solving $Ax = b$ may become less stable. If $RCOND$ satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

chpcon - estimate the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U*D*U**H$ or $A = L*D*L**H$ computed by CHPTRF

SYNOPSIS

```
SUBROUTINE CHPCON( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), WORK(*)
INTEGER N, INFO
INTEGER IPIVOT(*)
REAL ANORM, RCOND

SUBROUTINE CHPCON_64( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
REAL ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE HPCON( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND

SUBROUTINE HPCON_64( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpcon(char uplo, int n, complex *a, int *ipivot, float anorm, float *rcond, int *info);
```

```
void chpcon_64(char uplo, long n, complex *a, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

chpcon estimates the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

*** UPLO (input)**

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

*** IPIVOT (input)**

Details of the interchanges and the block structure of D as determined by CHPTRF.

*** ANORM (input)**

The 1-norm of the original matrix A.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

*** WORK (workspace)**

$\text{dimension}(2*N)$

*** INFO (output)**

NAME

chpdi - (obsolete) compute the determinant, inertia, and inverse of a Hermitian matrix A in packed storage, which has been UDU-factored by CHPCO or CHPFA.

SYNOPSIS

```
SUBROUTINE CHPDI( A, N, IPIVOT, DET, INERT, WORK, JOB)
COMPLEX A(*), WORK(*)
INTEGER N, JOB
INTEGER IPIVOT(*), INERT(*)
REAL DET(*)
```

```
SUBROUTINE CHPDI_64( A, N, IPIVOT, DET, INERT, WORK, JOB)
COMPLEX A(*), WORK(*)
INTEGER*8 N, JOB
INTEGER*8 IPIVOT(*), INERT(*)
REAL DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpdi(complex *a, int n, int *ipivot, float *det, int *inert, int job);
```

```
void chpdi_64(complex *a, long n, long *ipivot, float *det, long *inert, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix, as computed by CHPCO or CHPFA. On exit, if the c digit of JOB <> 0, then A contains the upper triangle of the inverse of the original matrix A; otherwise unchanged.

*** N (input)**

Order of the original matrix A. N >= 0.

*** IPIVOT (input)**

Pivot vector as computed by CHPCO or CHPFA.

*** DET (output)**

On exit, if the b digit of JOB <> 0, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or DET(1) = 0.0. If the b digit of JOB = 0, DET is not referenced.

*** INERT (output)**

On exit, if the a digit of JOB \neq 0, then INERT contains an integer triplet where:

INERT(1) = number of positive eigenvalues

INERT(2) = number of negative eigenvalues

INERT(3) = number of zero eigenvalues

If the a digit of JOB = 0 then INERT is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form abc; determines operation subroutine will perform:

a \neq 0 Compute the inertia.
b \neq 0 Compute the determinant.
c \neq 0 Compute the inverse.

NAME

chpev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage

SYNOPSIS

```

#include <sunperf.h>
```

```
void chpev(char jobz, char uplo, int n, complex *a, float *w, complex *z, int ldz, int *info);
```

```
void chpev_64(char jobz, char uplo, long n, complex *a, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chpev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension($\max(1,2*N-1)$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

REAL, DIMENSION(:) :: W, RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpevd(char jobz, char uplo, int n, complex *ap, float *w, complex *z, int ldz, int *info);
```

```
void chpevd_64(char jobz, char uplo, long n, complex *ap, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chpevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **AP** (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least N. If JOBZ = 'V' and $N > 1$, LWORK must be at least $2*N$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

* ***RWORK (workspace)***

dimension ($LRWORK$) On exit, if $INFO = 0$, $RWORK(1)$ returns the optimal $LRWORK$.

* ***LRWORK (input)***

The dimension of array $RWORK$. If $N \leq 1$, $LRWORK$ must be at least 1. If $JOBZ = 'N'$ and $N > 1$, $LRWORK$ must be at least N . If $JOBZ = 'V'$ and $N > 1$, $LRWORK$ must be at least $1 + 5*N + 2*N**2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $RWORK$ array, returns this value as the first entry of the $RWORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

* ***IWORK (workspace)***

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal $LIWORK$.

* ***LIWORK (input)***

The dimension of array $IWORK$. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK$ must be at least 1. If $JOBZ = 'V'$ and $N > 1$, $LIWORK$ must be at least $3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued by $XERBLA$.

* ***INFO (output)***

```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpevx(char jobz, char range, char uplo, int n, complex *a, float vl, float vu, int il, int iu, float abtol, int *nfound, float *w, complex *z, int ldz, int *ifail, int *info);
```

```
void chpevx_64(char jobz, char range, char uplo, long n, complex *a, float vl, float vu, long il, long iu, float abtol, long *nfound, float *w, complex *z, long ldz, long *ifail, long *info);
```

PURPOSE

chpevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **ABTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

$ABTOL + EPS * \max(|a|, |b|)$,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** NFOUND (input)**

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

*** W (output)**

If INFO = 0, the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** IWORK3 (workspace)**

*** IFAIL (output)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

chpfa - (obsolete) compute the UDU factorization of a Hermitian matrix A in packed storage. It is typical to follow a call to CHPFA with a call to CHPSL to solve $Ax = b$ or to CHPDI to compute the determinant, inverse, and inertia of A .

SYNOPSIS

```
SUBROUTINE CHPFA( A, N, IPIVOT, INFO)
  COMPLEX A(*)
  INTEGER N, INFO
  INTEGER IPIVOT(*)

SUBROUTINE CHPFA_64( A, N, IPIVOT, INFO)
  COMPLEX A(*)
  INTEGER*8 N, INFO
  INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>

void chpfa(complex *a, int n, int *ipivot, int *info);
void chpfa_64(complex *a, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A . On exit, a UDU factorization of the matrix A .

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the k th pivot block is singular to indicate that CHPSL or CHPDI will divide by zero if called.

NAME

chpgst - reduce a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage

SYNOPSIS

```
SUBROUTINE CHPGST( ITYPE, UPLO, N, AP, BP, INFO)
CHARACTER * 1 UPLO
COMPLEX AP(*), BP(*)
INTEGER ITYPE, N, INFO
```

```
SUBROUTINE CHPGST_64( ITYPE, UPLO, N, AP, BP, INFO)
CHARACTER * 1 UPLO
COMPLEX AP(*), BP(*)
INTEGER*8 ITYPE, N, INFO
```

F95 INTERFACE

```
SUBROUTINE HPGST( ITYPE, UPLO, N, AP, BP, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: AP, BP
INTEGER :: ITYPE, N, INFO
```

```
SUBROUTINE HPGST_64( ITYPE, UPLO, N, AP, BP, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: AP, BP
INTEGER(8) :: ITYPE, N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpgst(int itype, char uplo, int n, complex *ap, complex *bp, int *info);
```

```
void chpgst_64(long itype, char uplo, long n, complex *ap, complex *bp, long *info);
```

PURPOSE

chpgst reduces a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U^{**H})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**H})$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**H}$ or $L^{**H}*A*L$.

B must have been previously factorized as $U^{**H}*U$ or $L*L^{**H}$ by `CPPTRF`.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

* *N* (input)

The order of the matrices A and B . $N \geq 0$.

* *AP* (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array AP as follows: if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A .

* *BP* (input)

The triangular factor from the Cholesky factorization of B , stored in the same format as A , as returned by `CPPTRF`.

* *INFO* (output)

NAME

chpgv - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

SYNOPSIS

```
SUBROUTINE CHPGV( ITYPE, JOBZ, UPLO, N, A, B, W, Z, LDZ, WORK,  
*      WORK2, INFO)

SUBROUTINE HPGV_64( ITYPE, JOBZ, UPLO, [N], A, B, W, Z, [LDZ], [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
COMPLEX, DIMENSION(:) :: A, B, WORK  
COMPLEX, DIMENSION(:, :) :: Z  
INTEGER(8) :: ITYPE, N, LDZ, INFO  
REAL, DIMENSION(:) :: W, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpgv(int itype, char jobz, char uplo, int n, complex *a, complex *b, float *w, complex *z, int ldz, int *info);
```

```
void chpgv_64(long itype, char jobz, char uplo, long n, complex *a, complex *b, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chpgv computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of A are destroyed.

*** B (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array B as follows: if UPLO = 'U', $B(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $B(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**H*U$ or $B = L*L**H$, in the same storage format as B.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**H*B*Z = I$; if ITYPE = 3, $Z**H*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

*** WORK (workspace)**

dimension(MAX(1,2*N-1))

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

chpgvd - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$

SYNOPSIS

```
SUBROUTINE CHPGVD( ITYPE, JOBZ, UPLO, N, AP, BP, W, Z, LDZ, WORK,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpgvd(int itype, char jobz, char uplo, int n, complex *ap, complex *bp, float *w, complex *z, int ldz, int *info);
```

```
void chpgvd_64(long itype, char jobz, char uplo, long n, complex *ap, complex *bp, float *w, complex *z, long ldz, long *info);
```

PURPOSE

chpgvd computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** AP (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

*** BP (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U*U^H$ or $B = L*L^H$, in the same storage format as B.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** Z (input)**

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^{*}H^{*}B^{*}Z = I$; if $ITYPE = 3$, $Z^{*}H^{*}inv(B)^{*}Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

*** LDZ (input)**

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

*** LWORK (input)**

The dimension of array $WORK$. If $N \leq 1$, $LWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LWORK \geq 2 * N$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by $XERBLA$.

*** RWORK (workspace)**

On exit, if $INFO = 0$, $RWORK(1)$ returns the optimal $LRWORK$.

*** LRWORK (input)**

The dimension of array $RWORK$. If $N \leq 1$, $LRWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LRWORK \geq N$. If $JOBZ = 'V'$ and $N > 1$, $LRWORK \geq 1 + 5 * N + 2 * N^{*}2$.

If $LRWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $RWORK$ array, returns this value as the first entry of the $RWORK$ array, and no error message related to $LRWORK$ is issued by $XERBLA$.

*** IWORK (workspace)**

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal $LIWORK$.

*** LIWORK (input)**

The dimension of array $IWORK$. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK \geq 1$. If $JOBZ = 'V'$ and $N > 1$, $LIWORK \geq 3 + 5 * N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued by $XERBLA$.

*** INFO (output)**

```

PURPOSE

chpgvx computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** RANGE (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B . $N \geq 0$.

*** AP (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array AP as follows: if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

*** BP (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix B , packed columnwise in a linear array. The j -th column of B is stored in the array BP as follows: if $UPLO = 'U'$, $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**H*U$ or $B = L*L**H$, in the same storage format as B .

*** VL (input)**

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

*** VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|, |b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2 * SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2 * SLAMCH('S')$.

*** M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

*** W (output)**

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z^* H^* B^* Z = I$; if $ITYPE = 3$, $Z^* H^* \text{inv}(B)^* Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** WORK (workspace)**

dimension($2 * N$)

*** RWORK (workspace)**

dimension($7 * N$)

*** IWORK (workspace)**

dimension($5 * N$)

*** IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first M elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

chpmv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE CHPMV( UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
COMPLEX ALPHA, BETA
COMPLEX A(*), X(*), Y(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE CHPMV_64( UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
COMPLEX ALPHA, BETA
COMPLEX A(*), X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE HPMV( UPLO, [N], ALPHA, A, X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: A, X, Y
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE HPMV_64( UPLO, [N], ALPHA, A, X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: A, X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpmv(char uplo, int n, complex alpha, complex *a, complex *x, int incx, complex beta, complex *y, int incy);
```

```
void chpmv_64(char uplo, long n, complex alpha, complex *a, complex *x, long incx, complex beta, complex *y, long incy);
```

PURPOSE

chpmv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$ where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A.

Unchanged on exit.

* *N (input)*

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

* *X (input)*

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

* *BETA (input)*

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* *Y (input/output)*

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

chpr - perform the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$

SYNOPSIS

```
SUBROUTINE CHPR( UPLO, N, ALPHA, X, INCX, A)
CHARACTER * 1 UPLO
COMPLEX X(*), A(*)
INTEGER N, INCX
REAL ALPHA
```

```
SUBROUTINE CHPR_64( UPLO, N, ALPHA, X, INCX, A)
CHARACTER * 1 UPLO
COMPLEX X(*), A(*)
INTEGER*8 N, INCX
REAL ALPHA
```

F95 INTERFACE

```
SUBROUTINE HPR( UPLO, [N], ALPHA, X, [INCX], A)
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: X, A
INTEGER :: N, INCX
REAL :: ALPHA
```

```
SUBROUTINE HPR_64( UPLO, [N], ALPHA, X, [INCX], A)
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: X, A
INTEGER(8) :: N, INCX
REAL :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpr(char uplo, int n, float alpha, complex *x, int incx, complex *a);
```

```
void chpr_64(char uplo, long n, float alpha, complex *x, long incx, complex *a);
```

PURPOSE

chpr performs the hermitian rank 1 operation $A := \alpha * x * \text{conjg}(x') + A$ where α is a real scalar, x is an n element vector and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *A* (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

NAME

chpr2 - perform the Hermitian rank 2 operation $A := \alpha * x * \text{conj}(y') + \text{conj}(\alpha) * y * \text{conj}(x') + A$

SYNOPSIS

```
SUBROUTINE CHPR2( UPLO, N, ALPHA, X, INCX, Y, INCY, A)
CHARACTER * 1 UPLO
COMPLEX ALPHA
COMPLEX X(*), Y(*), A(*)
INTEGER N, INCX, INCY

void chpr2(char uplo, int n, complex alpha, complex *x, int incx, complex *y, int incy, complex *a);
```

```
void chpr2_64(char uplo, long n, complex alpha, complex *x, long incx, complex *y, long incy, complex *a);
```

PURPOSE

chpr2 performs the Hermitian rank 2 operation $A := \alpha * x * \text{conjg}(y') + \text{conjg}(\alpha) * y * \text{conjg}(x') + A$ where α is a scalar, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *Y* (input)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

* *A* (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

```

```
void chprfs(char uplo, int n, int nrhs, complex *a, complex *af, int *ipivot, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void chprfs_64(char uplo, long n, long nrhs, complex *a, complex *af, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

chprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by CHPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CHPTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CHPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($2*N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

chpsl - (obsolete) solve the linear system $Ax = b$ for a Hermitian matrix A in packed storage, which has been UDU-factored by CHPCO or CHPFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CHPSL( A, N, IPIVOT, B)
  COMPLEX A(*), B(*)
  INTEGER N
  INTEGER IPIVOT(*)

SUBROUTINE CHPSL_64( A, N, IPIVOT, B)
  COMPLEX A(*), B(*)
  INTEGER*8 N
  INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>

void chpsl(complex *a, int n, int *ipivot, complex *b);
void chpsl_64(complex *a, long n, long *ipivot, complex *b);
```

ARGUMENTS

- * **A** (*input*)
On entry, the UDU factorization of the matrix A , as computed by CHPCO or CHPFA.
- * **N** (*input*)
Order of the matrix A . $N \geq 0$.
- * **IPIVOT** (*input*)
Pivot vector as computed by CHPCO or CHPFA.
- * **B** (*input/output*)
On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

chpsv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE CHPSV( UPLO, N, NRHS, A, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CHPSV_64( UPLO, N, NRHS, A, IPIVOT, B, LDB, INFO)

INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE HPSV( UPLO, [N], [NRHS], A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE HPSV_64( UPLO, [N], [NRHS], A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chpsv(char uplo, int n, int nrhs, complex *a, int *ipivot, complex *b, int ldb, int *info);
```

```
void chpsv_64(char uplo, long n, long nrhs, complex *a, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

chpsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**H}, & \text{if UPLO} = 'U', & \text{ or} \\ A &= L * D * L^{**H}, & \text{if UPLO} = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**H}$ or $A = L * D * L^{**H}$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by CHPTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

chpsvx - use the diagonal pivoting factorization $A = U*D*U**H$ or $A = L*D*L**H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices

C INTERFACE

```
#include <sunperf.h>
```

```
void chpsvx(char fact, char uplo, int n, int nrhs, complex *a, complex *af, int *ipivot, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void chpsvx_64(char fact, char uplo, long n, long nrhs, complex *a, complex *af, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

chpsvx uses the diagonal pivoting factorization $A = U*D*U^{**H}$ or $A = L*D*L^{**H}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as $A = U * D * U^{**H}$, if $UPLO = 'U'$, or

```
    A = L * D * L^{**H},    if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is Hermitian and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
 3. The system of equations is solved for X using the factored form of A .
 4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* ***FACT*** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* ***UPLO*** (*input*)

* ***N*** (*input*)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* ***NRHS*** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

*** A (input)**

The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^*H$ or $A = L*D*L^*H$ as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHPTRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1,N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

*** FERR (output)**

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

chptrd - reduce a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation

SYNOPSIS

```
SUBROUTINE CHPTRD( UPLO, N, AP, D, E, TAU, INFO)

```

F95 INTERFACE

```
SUBROUTINE HPTRD( UPLO, [N], AP, D, E, TAU, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: AP, TAU
INTEGER :: N, INFO
REAL, DIMENSION(:) :: D, E
```

```
SUBROUTINE HPTRD_64( UPLO, [N], AP, D, E, TAU, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: AP, TAU
INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chptrd(char uplo, int n, complex *ap, float *d, float *e, complex *tau, int *info);
```

```
void chptrd_64(char uplo, long n, complex *ap, float *d, float *e, complex *tau, long *info);
```

PURPOSE

chptrd reduces a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation: $Q^*H * A * Q = T$.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A . $N \geq 0$.

* *AP* (input)

On entry, the upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array AP as follows: if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. On exit, if $UPLO = 'U'$, the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array TAU , represent the unitary matrix Q as a product of elementary reflectors; if $UPLO$

* *D* (output)

The diagonal elements of the tridiagonal matrix T : $D(i) = A(i,i)$.

* *E* (output)

The off-diagonal elements of the tridiagonal matrix T : $E(i) = A(i,i+1)$ if $UPLO = 'U'$, $E(i) = A(i+1,i)$ if $UPLO = 'L'$.

* *TAU* (output)

The scalar factors of the elementary reflectors (see Further Details).

* *INFO* (output)

NAME

chptrf - compute the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chptrf(char uplo, int n, complex *a, int *ipivot, int *info);
```

```
void chptrf_64(char uplo, long n, complex *a, long *ipivot, long *info);
```

PURPOSE

chptf computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{*H} \quad \text{or} \quad A = L^*D^*L^{*H}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A . $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L , stored as a packed triangular matrix overwriting A (see below for further details).

* *IPIVOT* (*output*)

Details of the interchanges and the block structure of D . If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

* *INFO* (*output*)

NAME

chptri - compute the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF

SYNOPSIS

```
SUBROUTINE CHPTRI( UPLO, N, A, IPIVOT, WORK, INFO)

void chptri(char uplo, int n, complex *a, int *ipivot, int *info);

void chptri_64(char uplo, long n, complex *a, long *ipivot, long *info);
```

PURPOSE

chptri computes the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**H}$ or $A = L^*D^*L^{**H}$ computed by CHPTRF.

ARGUMENTS

*** UPLO (input)**

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of $\text{inv}(A)$ is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = \text{inv}(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = \text{inv}(A)(i,j)$ for $j \leq i \leq n$.

*** IPIVOT (input)**

Details of the interchanges and the block structure of D as determined by CHPTRF.

*** WORK (workspace)**

dimension(N)

*** INFO (output)**

NAME

chptrs - solve a system of linear equations $A^*X = B$ with a complex Hermitian matrix A stored in packed format using the factorization $A = U^*D^*U^{**}H$ or $A = L^*D^*L^{**}H$ computed by CHPTRF

SYNOPSIS

```

#include <sunperf.h>
```

```
void chsein(char side, char eigsrc, char initv, logical *select, int n, complex *h, int ldh, complex *w, complex *vl, int ldvl, complex *vr, int ldvr, int mm, int *m, int *ifaill, int *ifailr, int *info);
```

```
void chsein_64(char side, char eigsrc, char initv, logical *select, long n, complex *h, long ldh, complex *w, complex *vl, long ldvl, complex *vr, long ldvr, long mm, long *m, long *ifaill, long *ifailr, long *info);
```

PURPOSE

chsein uses inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

$$H * x = w * x, \quad y^{*h} * H = w * y^{*h}$$

where y**h denotes the conjugate transpose of the vector y.

ARGUMENTS

* *SIDE* (input)

* *EIGSRC* (input)

Specifies the source of eigenvalues supplied in W:

* *INITV* (input)

* *SELECT* (input)

Specifies the eigenvectors to be computed. To select the eigenvector corresponding to the eigenvalue W(j), SELECT(j) must be set to .TRUE..

* *N* (input)

The order of the matrix H. N >= 0.

* *H* (input)

The upper Hessenberg matrix H.

* *LDH* (input)

The leading dimension of the array H. LDH >= max(1,N).

* *W* (input/output)

On entry, the eigenvalues of H. On exit, the real parts of W may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

* *VL* (input/output)

On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. LDVL $\geq \max(1, N)$ if SIDE = 'L' or 'B'; LDVL ≥ 1 otherwise.

*** VR (input/output)**

On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

*** LDVR (input)**

The leading dimension of the array VR. LDVR $\geq \max(1, N)$ if SIDE = 'R' or 'B'; LDVR ≥ 1 otherwise.

*** MM (input)**

The number of columns in the arrays VL and/or VR. MM $\geq M$.

*** M (output)**

The number of columns in the arrays VL and/or VR required to store the eigenvectors (= the number of .TRUE. elements in SELECT).

*** WORK (workspace)**

dimension(N*N)

*** RWORK (workspace)**

dimension(N)

*** IFAILL (output)**

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'R', IFAILL is not referenced.

*** IFAILR (output)**

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'L', IFAILR is not referenced.

*** INFO (output)**

NAME

chseqr - compute the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{*} H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors

SYNOPSIS

```
SUBROUTINE CHSEQR( JOB, COMPZ, N, ILO, IHI, H, LDH, W, Z, LDZ, WORK,
*                LWORK, INFO)

SUBROUTINE HSEQR_64( JOB, COMPZ, N, ILO, IHI, H, [LDH], W, Z, [LDZ],
*                [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: JOB, COMPZ
COMPLEX, DIMENSION(:) :: W, WORK
COMPLEX, DIMENSION(:, :) :: H, Z
INTEGER(8) :: N, ILO, IHI, LDH, LDZ, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chseqr(char job, char compz, int n, int ilo, int ihi, complex *h, int ldh, complex *w, complex *z, int ldz, int *info);
```

```
void chseqr_64(char job, char compz, long n, long ilo, long ihi, complex *h, long ldh, complex *w, complex *z, long ldz, long *info);
```

PURPOSE

chseqr computes the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**}H$, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input unitary matrix Q, so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the unitary matrix Q: $A = Q^*H^*Q^{**}H = (QZ)^*T^*(QZ)^{**}H$.

ARGUMENTS

* **JOB** (input)

* **COMPZ** (input)

* **N** (input)

The order of the matrix H. $N \geq 0$.

* **ILO** (input)

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL, and then passed to CGEHRD when the matrix output by CGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

* **IHI** (input)

See the description of ILO.

* **H** (input/output)

On entry, the upper Hessenberg matrix H. On exit, if JOB = 'S', H contains the upper triangular matrix T from the Schur decomposition (the Schur form). If JOB = 'E', the contents of H are unspecified on exit.

* **LDH** (input)

The leading dimension of the array H. $LDH \geq \max(1, N)$.

* **W** (output)

The computed eigenvalues. If JOB = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with $W(i) = H(i, i)$.

* **Z** (input)

If COMPZ = 'N': Z is not referenced.

If COMPZ = 'I': on entry, Z need not be set, and on exit, Z contains the unitary matrix Z of the Schur vectors of H. If COMPZ = 'V': on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix Z(ILO:IHI, ILO:IHI); on exit Z contains Q^*Z . Normally Q is the unitary matrix generated by CUNGHR after the call to CGEHRD which formed the Hessenberg matrix H.

* **LDZ** (input)

The leading dimension of the array Z. $LDZ \geq \max(1, N)$ if COMPZ = 'I' or 'V'; $LDZ \geq 1$ otherwise.

* **WORK** (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (input)

The dimension of the array WORK. $LWORK \geq \max(1, N)$.

If `LWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LWORK` is issued by XERBLA.

* ***INFO*** (*output*)

NAME

clarz - apply a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right

SYNOPSIS

```
SUBROUTINE CLARZ( SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
CHARACTER * 1 SIDE
COMPLEX TAU
COMPLEX V(*), C(LDC,*), WORK(*)
INTEGER M, N, L, INCV, LDC

SUBROUTINE CLARZ_64( SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
CHARACTER * 1 SIDE
COMPLEX TAU
COMPLEX V(*), C(LDC,*), WORK(*)
INTEGER*8 M, N, L, INCV, LDC
```

F95 INTERFACE

```
SUBROUTINE LARZ( SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])
CHARACTER(LEN=1) :: SIDE
COMPLEX :: TAU
COMPLEX, DIMENSION(:) :: V, WORK
COMPLEX, DIMENSION(:, :) :: C
INTEGER :: M, N, L, INCV, LDC

SUBROUTINE LARZ_64( SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC],
* [WORK])
CHARACTER(LEN=1) :: SIDE
COMPLEX :: TAU
COMPLEX, DIMENSION(:) :: V, WORK
COMPLEX, DIMENSION(:, :) :: C
INTEGER(8) :: M, N, L, INCV, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void clarz(char side, int m, int n, int l, complex *v, int incv, complex tau, complex *c, int ldc);
```

```
void clarz_64(char side, long m, long n, long l, complex *v, long incv, complex tau, complex *c, long ldc);
```

PURPOSE

clarz applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

$$H = I - \tau * v * v'$$

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H' (the conjugate transpose of H), supply conjg(tau) instead tau.

H is a product of k elementary reflectors as returned by CTZRZF.

ARGUMENTS

* **SIDE** (*input*)

* **M** (*input*)

The number of rows of the matrix C.

* **N** (*input*)

The number of columns of the matrix C.

* **L** (*input*)

The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

* **V** (*input*)

The vector v in the representation of H as returned by CTZRZF. V is not used if TAU = 0.

* **INCV** (*input*)

The increment between elements of v. INCV <> 0.

* **TAU** (*input*)

The value tau in the representation of H.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

* **LDC** (*input*)

The leading dimension of the array C. LDC >= max(1,M).

* **WORK** (*workspace*)

(N) if SIDE = 'L' or (M) if SIDE = 'R'. SH FURTHER DETAILS Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

long ldt, complex *c, long ldc, long ldwork);
```

PURPOSE

clarzb applies a complex block reflector H or its transpose H^*H to a complex distributed M -by- N C from the left or the right.

Currently, only $STOREV = 'R'$ and $DIRECT = 'B'$ are supported.

ARGUMENTS

* ***SIDE (input)***

* ***TRANS (input)***

* ***DIRECT (input)***

Indicates how H is formed from a product of elementary reflectors

* ***STOREV (input)***

Indicates how the vectors which define the elementary reflectors are stored:

* ***M (input)***

The number of rows of the matrix C .

* ***N (input)***

The number of columns of the matrix C .

* ***K (input)***

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

* ***L (input)***

The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If $SIDE = 'L'$, $M \geq L \geq 0$, if $SIDE = 'R'$, $N \geq L \geq 0$.

* ***V (input)***

If $STOREV = 'C'$, $NV = K$; if $STOREV = 'R'$, $NV = L$.

* ***LDV (input)***

The leading dimension of the array V . If $STOREV = 'C'$, $LDV \geq L$; if $STOREV = 'R'$, $LDV \geq K$.

* ***T (input)***

The triangular K -by- K matrix T in the representation of the block reflector.

* ***LDT (input)***

The leading dimension of the array T . $LDT \geq K$.

* ***C (input/output)***

On entry, the M -by- N matrix C . On exit, C is overwritten by H^*C or H^*C or C^*H or C^*H .

* ***LDC (input)***

The leading dimension of the array C . $LDC \geq \max(1, M)$.

* ***WORK (workspace)***

$\text{dimension}(\max(M, N), K)$

* ***LDWORK (input)***

The leading dimension of the array $WORK$. If $SIDE = 'L'$, $LDWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LDWORK \geq \max(1, M)$.

NAME

clarzt - form the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors

SYNOPSIS

```
SUBROUTINE CLARZT( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
CHARACTER * 1 DIRECT, STOREV
COMPLEX V(LDV,*), TAU(*), T(LDT,*)
INTEGER N, K, LDV, LDT
```

```
SUBROUTINE CLARZT_64( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
CHARACTER * 1 DIRECT, STOREV
COMPLEX V(LDV,*), TAU(*), T(LDT,*)
INTEGER*8 N, K, LDV, LDT
```

F95 INTERFACE

```
SUBROUTINE LARZT( DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
CHARACTER(LEN=1) :: DIRECT, STOREV
COMPLEX, DIMENSION(:) :: TAU
COMPLEX, DIMENSION(:,*) :: V, T
INTEGER :: N, K, LDV, LDT
```

```
SUBROUTINE LARZT_64( DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
CHARACTER(LEN=1) :: DIRECT, STOREV
COMPLEX, DIMENSION(:) :: TAU
COMPLEX, DIMENSION(:,*) :: V, T
INTEGER(8) :: N, K, LDV, LDT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void clarzt(char direct, char storev, int n, int k, complex *v, int ldv, complex *tau, complex *t, int ldt);
```

```
void clarzt_64(char direct, char storev, long n, long k, complex *v, long ldv, complex *tau, complex *t, long ldt);
```

PURPOSE

clarzt forms the triangular factor T of a complex block reflector H of order $> n$, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', $H = H(1) H(2) \dots H(k)$ and T is upper triangular;

If DIRECT = 'B', $H = H(k) \dots H(2) H(1)$ and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

$$H = I - V * T * V'$$

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

$$H = I - V' * T * V$$

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

*** DIRECT (input)**

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

*** STOREV (input)**

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):

*** N (input)**

The order of the block reflector H. $N \geq 0$.

*** K (input)**

The order of the triangular factor T (= the number of elementary reflectors). $K \geq 1$.

*** V (input)**

(LDV,K) if STOREV = 'C' (LDV,N) if STOREV = 'R' The matrix V. See further details.

*** LDV (input)**

The leading dimension of the array V. If STOREV = 'C', $LDV \geq \max(1,N)$; if STOREV = 'R', $LDV \geq K$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i).

*** T (input)**

The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq K$. .SH FURTHER DETAILS Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the H(i) is best illustrated by the following

example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and STOREV = 'R':

V =	<pre>(v1 v2 v3) (v1 v2 v3) 1 . . . 1 . . . 1</pre>	<pre> _____V_____ / \ (v1 v1 v1 v1 v1 1) (v2 v2 v2 v2 v2 1) (v3 v3 v3 v3 v3 . . 1 . .)</pre>
-----	---	--

DIRECT = 'B' and STOREV = 'C': DIRECT = 'B' and STOREV = 'R':

V =	<pre>1 . 1 . . 1 (v1 v2 v3) (v1 v2 v3)</pre>	<pre> _____V_____ / \ (1 v1 v1 v1 v1 v1) (. 1 v2 v2 v2 v2 v2) (. . 1 . . . v3 v3 v3 v3 v3)</pre>
-----	---	--

* [WORK])
CHARACTER(LEN=1) :: SIDE
COMPLEX :: TAU
COMPLEX, DIMENSION(:) :: V, WORK
COMPLEX, DIMENSION(:, :) :: C1, C2
INTEGER(8) :: M, N, INCV, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void clatzm(char side, int m, int n, complex *v, int incv, complex tau, complex *c1, complex *c2, int ldc);
```

```
void clatzm_64(char side, long m, long n, complex *v, long incv, complex tau, complex *c1, complex *c2, long ldc);
```

PURPOSE

clatzm routine is deprecated and has been replaced by routine CUNMRZ.

CLATZM applies a Householder matrix generated by CTZRQF to a matrix.

Let $P = I - \tau * u * u'$, $u = \begin{pmatrix} 1 \\ \vdots \\ 0 \end{pmatrix}$,

$$\begin{pmatrix} \vdots \\ v \\ \vdots \end{pmatrix}$$

where v is an $(m-1)$ vector if $SIDE = 'L'$, or a $(n-1)$ vector if $SIDE = 'R'$.

If $SIDE$ equals 'L', let

$$C = \begin{bmatrix} C1 & 1 \\ C2 & m-1 \\ & n \end{bmatrix}$$

Then C is overwritten by $P * C$.

If $SIDE$ equals 'R', let

$$C = \begin{bmatrix} C1, & C2 \\ 1 & n-1 \end{bmatrix} \begin{matrix} m \\ \end{matrix}$$

Then C is overwritten by $C * P$.

ARGUMENTS

* **SIDE** (*input*)

* **M** (*input*)

The number of rows of the matrix C .

* **N** (*input*)

The number of columns of the matrix C .

* **V** (*input*)

$(1 + (M-1) * \text{abs}(INCV))$ if $SIDE = 'L'$ $(1 + (N-1) * \text{abs}(INCV))$ if $SIDE = 'R'$ The vector v in the representation of P .
 V is not used if $TAU = 0$.

* **INCV** (*input*)

The increment between elements of v . $INCV <> 0$

* **TAU** (*input*)

The value τ in the representation of P .

* **C1** (*input/output*)

(LDC, N) if $SIDE = 'L'$ $(M, 1)$ if $SIDE = 'R'$ On entry, the n -vector $C1$ if $SIDE = 'L'$, or the m -vector $C1$ if $SIDE = 'R'$.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

* **C2 (input/output)**

(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

* **LDC (input)**

The leading dimension of the arrays C1 and C2. LDC \geq max(1,M).

* **WORK (workspace)**

(N) if SIDE = 'L' (M) if SIDE = 'R'

NAME

cosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE COSQB( N, X, WSAVE)
  INTEGER N
  REAL X(*), WSAVE(*)

SUBROUTINE COSQB_64( N, X, WSAVE)
  INTEGER*8 N
  REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB( [N], X, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE COSQB_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cosqb(int n, float *x, float *wsave);

void cosqb_64(long n, float *x, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave cosine synthesis of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$ that has been initialized by COSQI.

NAME

cosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE COSQF( N, X, WSAVE)
  INTEGER N
  REAL X(*), WSAVE(*)

SUBROUTINE COSQF_64( N, X, WSAVE)
  INTEGER*8 N
  REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQF( [N], X, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE COSQF_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cosqf(int n, float *x, float *wsave);

void cosqf_64(long n, float *x, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave cosine transform of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$ that has been initialized by COSQI.

NAME

cosqi - initialize the array WSAVE, which is used in both COSQF and COSQB.

SYNOPSIS

```
SUBROUTINE COSQI( N, WSAVE)
  INTEGER N
  REAL WSAVE(*)
```

```
SUBROUTINE COSQI_64( N, WSAVE)
  INTEGER*8 N
  REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQI( N, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE COSQI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cosqi(int n, float *wsave);
```

```
void cosqi_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

* *WSAVE (input)*

On entry, an array of dimension $(3 * N + 15)$ or greater. COSQI needs to be called only once to initialize WSAVE before calling COSQF and/or COSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

cost - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by $2 * (N-1)$.

SYNOPSIS

```
SUBROUTINE COST( N, X, WSAVE)
INTEGER N
REAL X(*), WSAVE(*)

SUBROUTINE COST_64( N, X, WSAVE)
INTEGER*8 N
REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COST( [N], X, WSAVE)
INTEGER :: N
REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE COST_64( [N], X, WSAVE)
INTEGER(8) :: N
REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cost(int n, float *x, float *wsave);

void cost_64(long n, float *x, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the cosine transform of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$, initialized by COST1.

NAME

costi - initialize the array WSAVE, which is used in COST.

SYNOPSIS

```
SUBROUTINE COSTI( N, WSAVE)
  INTEGER N
  REAL WSAVE(*)
```

```
SUBROUTINE COSTI_64( N, WSAVE)
  INTEGER*8 N
  REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSTI( N, WSAVE)
  INTEGER :: N
  REAL, DIMENSION(:) :: WSAVE
```

```
SUBROUTINE COSTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void costi(int n, float *wsave);
```

```
void costi_64(long n, float *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

* *WSAVE (input)*

On entry, an array of dimension $(3 * N + 15)$ or greater. *COSTI* is called once to initialize *WSAVE* before calling *COST* and need not be called again between calls to *COST* if *N* and *WSAVE* remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

cpbco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in banded storage. If the condition number is not needed then xPBFA is slightly faster. It is typical to follow a call to xPBCO with a call to xPBSL to solve $Ax = b$ or to xPBFI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE CPBCO( A, LDA, N, NDIAG, RCOND, WORK, INFO)
COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, NDIAG, INFO
REAL RCOND
```

```
SUBROUTINE CPBCO_64( A, LDA, N, NDIAG, RCOND, WORK, INFO)
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, NDIAG, INFO
REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbco(complex *a, int lda, int n, int ndiag, float *rcond, int *info);
```

```
void cpbco_64(complex *a, long lda, long n, long ndiag, float *rcond, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

*** N (input)**

Order of the matrix A. $N <> 0$.

*** NDIAG (input)**

Number of diagonals. $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

*** RCOND (output)**

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

cpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPBTRF

SYNOPSIS

```
SUBROUTINE CPBCON( UPLO, N, NDIAG, A, LDA, ANORM, RCOND, WORK,
*                WORK2, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), WORK(*)
INTEGER N, NDIAG, LDA, INFO
REAL ANORM, RCOND
REAL WORK2(*)

SUBROUTINE CPBCON_64( UPLO, N, NDIAG, A, LDA, ANORM, RCOND, WORK,
*                   WORK2, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, NDIAG, LDA, INFO
REAL ANORM, RCOND
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE PBCON( UPLO, [N], NDIAG, A, [LDA], ANORM, RCOND, [WORK],
*               [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2

SUBROUTINE PBCON_64( UPLO, [N], NDIAG, A, [LDA], ANORM, RCOND, [WORK],
*                   [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbcon(char uplo, int n, int ndiag, complex *a, int lda, float anorm, float *rcond, int *info);
```

```
void cpbcon_64(char uplo, long n, long ndiag, complex *a, long lda, float anorm, float *rcond, long *info);
```

PURPOSE

cpbcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'.
 $\text{NDIAG} \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ of the band matrix A, stored in the first $\text{NDIAG}+1$ rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(\text{kd}+1+i-j, j) = U(i, j)$ for $\max(1, j-\text{kd}) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = L(i, j)$ for $j \leq i \leq \min(n, j+\text{kd})$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \text{NDIAG}+1$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the Hermitian band matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cpbdi - (obsolete) compute the determinant of a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by CPBCO or CPBFA.

SYNOPSIS

```
SUBROUTINE CPBDI( A, LDA, N, NDIAG, DET)
COMPLEX A(LDA,*)
INTEGER LDA, N, NDIAG
REAL DET(*)
```

```
SUBROUTINE CPBDI_64( A, LDA, N, NDIAG, DET)
COMPLEX A(LDA,*)
INTEGER*8 LDA, N, NDIAG
REAL DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbdi(complex *a, int lda, int n, int ndiag, float *det);
```

```
void cpbdi_64(complex *a, long lda, long n, long ndiag, float *det);
```

ARGUMENTS

*** A (input)**

Cholesky factorization of the matrix A, as computed by CPBCO or CPBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA >= NDIAG + 1.

*** N (input)**

Order of the original matrix A. N >= 0.

*** NDIAG (input)**

Number of diagonals. N-1 >= NDIAG >= 0 but if N = 0 then NDIAG = 0.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$.

NAME

cpbequ - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE CPBEQU( UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER N, NDIAG, LDA, INFO
REAL SCOND, AMAX
REAL SCALE(*)
```

```
SUBROUTINE CPBEQU_64( UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX,
* INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER*8 N, NDIAG, LDA, INFO
REAL SCOND, AMAX
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU( UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: N, NDIAG, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE PBEQU_64( UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: N, NDIAG, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbequ(char uplo, int n, int ndiag, complex *a, int lda, float *scale, float *scond, float *amax, int *info);
```

```
void cpbequ_64(char uplo, long n, long ndiag, complex *a, long lda, float *scale, float *scond, float *amax, long *info);
```

PURPOSE

cpbequ computes row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* **A** (*input*)

The upper or lower triangle of the Hermitian band matrix A , stored in the first $NDIAG+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **SCALE** (*output*)

If $INFO = 0$, $SCALE$ contains the scale factors for A .

* **SCOND** (*output*)

If $INFO = 0$, $SCALE$ contains the ratio of the smallest $SCALE(i)$ to the largest $SCALE(i)$. If $SCOND \geq 0.1$ and $AMAX$ is neither too large nor too small, it is not worth scaling by $SCALE$.

* **AMAX** (*output*)

Absolute value of largest matrix element. If $AMAX$ is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO** (*output*)

NAME

cpbfa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A in banded storage. It is typical to follow a call to CPBFA with a call to CPBSL to solve $Ax = b$ or to CPBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE CPBFA( A, LDA, N, NDIAG, INFO)
COMPLEX A(LDA,*)
INTEGER LDA, N, NDIAG, INFO
```

```
SUBROUTINE CPBFA_64( A, LDA, N, NDIAG, INFO)
COMPLEX A(LDA,*)
INTEGER*8 LDA, N, NDIAG, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbfa(complex *a, int lda, int n, int ndiag, int *info);
```

```
void cpbfa_64(complex *a, long lda, long n, long ndiag, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** NDIAG (input)**

Number of diagonals. $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value of k if the leading minor of order k is not positive definite.

NAME

cpbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE CPBRFS( UPLO, N, NDIAG, NRHS, A, LDA, AF, LDAF, B, LDB,  
*      X, LDX, FERR, BERR, WORK, WORK2, INFO)  
CHARACTER * 1 UPLO  
COMPLEX A(LDA,*), AF(LDAF,*), B(LDB,*), X(LDX,*), WORK(*)  
INTEGER N, NDIAG, NRHS, LDA, LDAF, LDB, LDX, INFO  
REAL FERR(*), BERR(*), WORK2(*)
```

```
SUBROUTINE CPBRFS_64( UPLO, N, NDIAG, NRHS, A, LDA, AF, LDAF, B,  
*      LDB, X, LDX, FERR, BERR, WORK, WORK2, INFO)  
CHARACTER * 1 UPLO  
COMPLEX A(LDA,*), AF(LDAF,*), B(LDB,*), X(LDX,*), WORK(*)  
INTEGER*8 N, NDIAG, NRHS, LDA, LDAF, LDB, LDX, INFO  
REAL FERR(*), BERR(*), WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE PBRFS( UPLO, [N], NDIAG, [NRHS], A, [LDA], AF, [LDAF], B,  
*      [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A, AF, B, X  
INTEGER :: N, NDIAG, NRHS, LDA, LDAF, LDB, LDX, INFO  
REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

```
SUBROUTINE PBRFS_64( UPLO, [N], NDIAG, [NRHS], A, [LDA], AF, [LDAF],  
*      B, [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A, AF, B, X  
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDAF, LDB, LDX, INFO  
REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbrfs(char uplo, int n, int ndiag, int nrhs, complex *a, int lda, complex *af, int ldaf, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void cpbrfs_64(char uplo, long n, long ndiag, long nrhs, complex *a, long lda, complex *af, long ldaf, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS ≥ 0 .

* **A** (*input*)

The upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) < i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j < i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A. LDA \geq NDIAG+1.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ of the band matrix A as computed by CPBTRF, in the same storage format as A (see A).

* **LDAF** (*input*)

The leading dimension of the array AF. LDAF \geq NDIAG+1.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. LDB \geq max(1,N).

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CPBTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cpbsl - (obsolete) section solve the linear system $Ax = b$ for a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by CPBCO or CPBFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CPBSL( A, LDA, N, NDIAG, B)
COMPLEX A(LDA,*), B(*)
INTEGER LDA, N, NDIAG
```

```
SUBROUTINE CPBSL_64( A, LDA, N, NDIAG, B)
COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N, NDIAG
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbsl(complex *a, int lda, int n, int ndiag, complex *b);
```

```
void cpbsl_64(complex *a, long lda, long n, long ndiag, complex *b);
```

ARGUMENTS

* **A** (*input*)

Cholesky factorization of the matrix A , as computed by CPBCO or CPBFA.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

* **N** (*input*)

Order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

Number of diagonals of matrix A . $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

* **B** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

cpbstf - compute a split Cholesky factorization of a complex Hermitian positive definite band matrix A

SYNOPSIS

```
SUBROUTINE CPBSTF( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
COMPLEX AB(LDAB,*)
INTEGER N, KD, LDAB, INFO
```

```
SUBROUTINE CPBSTF_64( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO

```

```
void cpbstf_64(char uplo, long n, long kd, complex *ab, long ldab, long *info);
```

PURPOSE

cpbstf computes a split Cholesky factorization of a complex Hermitian positive definite band matrix A.

This routine is designed to be used in conjunction with CHBGST.

The factorization has the form $A = S^{**}H^*S$ where S is a band matrix of the same bandwidth as A and the following structure:

$$S = \begin{pmatrix} U & \\ & M & L \end{pmatrix}$$

where U is upper triangular of order $m = (n+kd)/2$, and L is lower triangular of order $n-m$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if INFO = 0, the factor S from the split Cholesky factorization $A = S^{**}H^*S$. See Further Details.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KD+1$.

* **INFO** (*output*)

NAME

cpbsv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE CPBSV( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NDIAG, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE CPBSV_64( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NDIAG, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE PBSV( UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, NDIAG, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE PBSV_64( UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbsv(char uplo, int n, int ndiag, int nrhs, complex *a, int lda, complex *b, int ldb, int *info);
```

```
void cpbsv_64(char uplo, long n, long ndiag, long nrhs, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

cpbsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{*H} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{*H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NDIAG (input)**

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $NDIAG+1$ rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(NDIAG+1+i-j,j) = A(i,j)$ for $\max(1,j-NDIAG) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(N,j+NDIAG)$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{*H}U$ or $A = L^{*H}L$ of the band matrix A, in the same storage format as A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq NDIAG+1$.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbsvx(char fact, char uplo, int n, int ndiag, int nrhs, complex *a, int lda, complex *af, int ldaf, char equed, float *scale, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void cpbsvx_64(char fact, char uplo, long n, long ndiag, long nrhs, complex *a, long lda, complex *af, long ldaf, char equed, float *scale, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

cpbsvx uses the Cholesky factorization $A = U^{**H}U$ or $A = L*L^{**H}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B  
Whether or not the system will be equilibrated depends on the  
scaling of the matrix A, but if equilibration is used, A is  
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as $A = U^{**H} * U$, if UPLO = 'U', or

```
A = L * L^{**H}, if UPLO = 'L',  
where U is an upper triangular band matrix, and L is a lower  
triangular band matrix.
```

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by diag(S) so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* *NDIAG* (input)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* *NRHS* (input)

The number of right-hand sides, i.e., the number of columns of the matrices B and X . $NRHS \geq 0$.

* *A* (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A , stored in the first $NDIAG+1$ rows of the array, except if $FACT = 'F'$ and $EQUED = 'Y'$, then A must contain the equilibrated matrix $\text{diag}(SCALE)*A*\text{diag}(SCALE)$. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(NDIAG+1+i-j,j) = A(i,j)$ for $\max(1,j-NDIAG) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(N,j+NDIAG)$. See below for further details.

On exit, if $FACT = 'E'$ and $EQUED = 'Y'$, A is overwritten by $\text{diag}(SCALE)*A*\text{diag}(SCALE)$.

* *LDA* (input)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* *AF* (input/output)

If $FACT = 'F'$, then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the band matrix A , in the same storage format as A (see A). If $EQUED = 'Y'$, then AF is the factored form of the equilibrated matrix A .

If $FACT = 'N'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$.

If $FACT = 'E'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *LDAF* (input)

The leading dimension of the array AF . $LDAF \geq NDIAG+1$.

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for A ; not accessed if $EQUED = 'N'$. $SCALE$ is an input argument if $FACT = 'F'$; otherwise, $SCALE$ is an output argument. If $FACT = 'F'$ and $EQUED = 'Y'$, each element of $SCALE$ must be positive.

* *B* (input/output)

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $EQUED = 'N'$, B is not modified; if $EQUED = 'Y'$, B is overwritten by $\text{diag}(SCALE) * B$.

* *LDB* (input)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* *X* (output)

If $INFO = 0$ or $INFO = N+1$, the N -by- $NRHS$ solution matrix X to the original system of equations. Note that if

EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

* **LDX** (*input*)

The leading dimension of the array X. $\text{LDX} \geq \max(1, N)$.

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if $\text{RCOND} = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $\text{INFO} > 0$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $\text{FERR}(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - \text{XTRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cpbtf2 - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

SYNOPSIS

```
SUBROUTINE CPBTF2( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
COMPLEX AB(LDAB,*)
INTEGER N, KD, LDAB, INFO
```

```
SUBROUTINE CPBTF2_64( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
COMPLEX AB(LDAB,*)
INTEGER*8 N, KD, LDAB, INFO
```

F95 INTERFACE

```
SUBROUTINE PBTF2( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: AB
INTEGER :: N, KD, LDAB, INFO
```

```
SUBROUTINE PBTF2_64( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: AB
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbtf2(char uplo, int n, int kd, complex *ab, int ldab, int *info);
```

```
void cpbtf2_64(char uplo, long n, long kd, complex *ab, long ldab, long *info);
```

PURPOSE

cpbtf2 computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

$$\begin{aligned} A &= U' * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L', & \text{if } UPLO = 'L', & \end{aligned}$$

where U is an upper triangular matrix, U' is the conjugate transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** KD (input)**

The number of super-diagonals of the matrix A if $UPLO = 'U'$, or the number of sub-diagonals if $UPLO = 'L'$. $KD \geq 0$.

*** AB (input/output)**

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if $INFO = 0$, the triangular factor U or L from the Cholesky factorization $A = U'U$ or $A = L'L$ of the band matrix A, in the same storage format as A.

*** LDAB (input)**

The leading dimension of the array AB. $LDAB \geq KD+1$.

*** INFO (output)**

NAME

cpbtrf - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

SYNOPSIS

```
SUBROUTINE CPBTRF( UPLO, N, NDIAG, A, LDA, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER N, NDIAG, LDA, INFO
```

```
SUBROUTINE CPBTRF_64( UPLO, N, NDIAG, A, LDA, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER*8 N, NDIAG, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE PBTRF( UPLO, [N], NDIAG, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: N, NDIAG, LDA, INFO
```

```
SUBROUTINE PBTRF_64( UPLO, [N], NDIAG, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: N, NDIAG, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbtrf(char uplo, int n, int ndiag, complex *a, int lda, int *info);
```

```
void cpbtrf_64(char uplo, long n, long ndiag, complex *a, long lda, long *info);
```

PURPOSE

cpbtrf computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

$$\begin{aligned} A &= U^{*H} * U, & \text{if } \text{UPLO} = 'U', & \text{ or} \\ A &= L * L^{*H}, & \text{if } \text{UPLO} = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{*H}U$ or $A = L^{*H}L$ of the band matrix A, in the same storage format as A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **INFO** (*output*)

NAME

cpbtrs - solve a system of linear equations $A \cdot X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U \cdot H \cdot U$ or $A = L \cdot L^H$ computed by CPBTRF

SYNOPSIS

```
SUBROUTINE CPBTRS( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)

```
SUBROUTINE PBTRS_64( UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB],
*               [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpbtrs(char uplo, int n, int ndiag, int nrhs, complex *a, int lda, complex *b, int ldb, int *info);
```

```
void cpbtrs_64(char uplo, long n, long ndiag, long nrhs, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

cpbtrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite band matrix A using the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ computed by CPBTRF.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ of the band matrix A , stored in the first $NDIAG+1$ rows of the array. The j -th column of U or L is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = U(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = L(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

epoco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A. If the condition number is not needed then xPOFA is slightly faster. It is typical to follow a call to xPOCO with a call to xPOSL to solve $Ax = b$ or to xPODI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE CPOCO( A, LDA, N, RCOND, WORK, INFO)
COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, INFO
REAL RCOND
```

```
SUBROUTINE CPOCO_64( A, LDA, N, RCOND, WORK, INFO)
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, INFO
REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpoco(complex *a, int lda, int n, float *rcond, int *info);
```

```
void cpoco_64(complex *a, long lda, long n, float *rcond, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** RCOND (output)**

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

*** WORK (workspace)**

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

epocon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^{**}H*U$ or $A = L*L^{**}H$ computed by CPOTRF

SYNOPSIS

```

```
void cpocon(char uplo, int n, complex *a, int lda, float anorm, float *rcond, int *info);
```

```
void cpocon_64(char uplo, long n, complex *a, long lda, float anorm, float *rcond, long *info);
```

PURPOSE

cpocon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$ computed by CPOTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$, as computed by CPOTRF.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the Hermitian matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cpodi - (obsolete) compute the determinant and inverse of a symmetric positive definite matrix A, which has been Cholesky-factored by CPOCO, CPOFA, or CQRDC.

SYNOPSIS

```
SUBROUTINE CPODI( A, LDA, N, DET, JOB)
  COMPLEX A(LDA,*)
  INTEGER LDA, N, JOB
  REAL DET(*)

SUBROUTINE CPODI_64( A, LDA, N, DET, JOB)
  COMPLEX A(LDA,*)
  INTEGER*8 LDA, N, JOB
  REAL DET(*)
```

C INTERFACE

```
#include <sunperf.h>

void cpodi(complex *a, int lda, int n, float *det, int job);

void cpodi_64(complex *a, long lda, long n, float *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the Cholesky factorization of the matrix A, as computed by CPOCO, CPOFA, or CQRDC. On exit, the inverse of the original matrix A if the inverse was requested, otherwise A is unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) = 0.0$.

*** JOB (input)**

Determines which operation the subroutine will perform:

- 11 both determinant and inverse
- 01 inverse only
- 10 determinant only

NAME

cpoequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE CPOEQU( N, A, LDA, SCALE, SCOND, AMAX, INFO)
COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
REAL SCOND, AMAX
REAL SCALE(*)
```

```
SUBROUTINE CPOEQU_64( N, A, LDA, SCALE, SCOND, AMAX, INFO)
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
REAL SCOND, AMAX
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU( [N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: N, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE POEQU_64( [N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: N, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpoequ(int n, complex *a, int lda, float *scale, float *scond, float *amax, int *info);
```

```
void cpoequ_64(long n, complex *a, long lda, float *scale, float *scond, float *amax, long *info);
```

PURPOSE

cpoequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** SCALE (output)**

If INFO = 0, SCALE contains the scale factors for A.

*** SCOND (output)**

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

cpofa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A. It is typical to follow a call to CPOFA with a call to CPOSL to solve $Ax = b$ or to CPODI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE CPOFA( A, LDA, N, INFO)
COMPLEX A(LDA,*)
INTEGER LDA, N, INFO
```

```
SUBROUTINE CPOFA_64( A, LDA, N, INFO)
COMPLEX A(LDA,*)
INTEGER*8 LDA, N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpofa(complex *a, int lda, int n, int *info);
```

```
void cpofa_64(complex *a, long lda, long n, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

cporfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite,

SYNOPSIS

```
SUBROUTINE CPORFS( UPLO, N, NRHS, A, LDA, AF, LDAF, B, LDB, X, LDX,

```

```
SUBROUTINE PORFS_64( UPLO, [N], [NRHS], A, [LDA], AF, [LDAF], B,  
*      [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:,:) :: A, AF, B, X  
INTEGER(8) :: N, NRHS, LDA, LDAF, LDB, LDX, INFO  
REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cporfs(char uplo, int n, int nrhs, complex *a, int lda, complex *af, int ldaf, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void cporfs_64(char uplo, long n, long nrhs, complex *a, long lda, complex *af, long ldaf, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cporfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$, as computed by CPOTRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CPOTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($2*N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

cposl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite matrix A , which has been Cholesky-factored by CPOCO or CPOFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CPOSL( A, LDA, N, B)
  COMPLEX A(LDA,*), B(*)
  INTEGER LDA, N
```

```
SUBROUTINE CPOSL_64( A, LDA, N, B)

```

```
void cposl(complex *a, int lda, int n, complex *b);
```

```
void cposl_64(complex *a, long lda, long n, complex *b);
```

ARGUMENTS

*** A (input)**

Cholesky factorization of the matrix A , as computed by CPOCO or CPOFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

cposv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE CPOSV( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE CPOSV_64( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE POSV( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE POSV_64( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cposv(char uplo, int n, int nrhs, complex *a, int lda, complex *b, int ldb, int *info);
```

```
void cposv_64(char uplo, long n, long nrhs, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

cposv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**H} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input/output*)

On entry, the Hermitian matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the factor U or L from the Cholesky factorization $A = U^{**H} * U$ or $A = L * L^{**H}$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input/output*)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

cposvx - use the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ to compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cposvx(char fact, char uplo, int n, int nrhs, complex *a, int lda, complex *af, int ldaf, char equed, float *scale, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void cposvx_64(char fact, char uplo, long n, long nrhs, complex *a, long lda, complex *af, long ldaf, char equed, float *scale, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

cposvx uses the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian positive definite matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If $FACT = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $FACT = 'E'$) as $A = U^{*}H^{*}U$, if $UPLO = 'U'$, or

```
A = L * L^{*}H, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A .

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $diag(S)$ so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A* (input/output)

On entry, the Hermitian matrix A, except if *FACT* = 'F' and *EQUED* = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. If *UPLO* = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If *UPLO* = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if *FACT* = 'F' or 'N', or if *FACT* = 'E' and *EQUED* = 'N' on exit.

On exit, if *FACT* = 'E' and *EQUED* = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *AF* (input/output)

If *FACT* = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U * U^H$ or $A = L * L^H$, in the same storage format as A. If *EQUED* = 'N', then AF is the factored form of the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

If *FACT* = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U^H$ or $A = L * L^H$ of the original matrix A.

If *FACT* = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U^H$ or $A = L * L^H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *LDAF* (input)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for A; not accessed if *EQUED* = 'N'. *SCALE* is an input argument if *FACT* = 'F'; otherwise, *SCALE* is an output argument. If *FACT* = 'F' and *EQUED* = 'Y', each element of *SCALE* must be positive.

* *B* (input/output)

On entry, the N-by-NRHS righthand side matrix B. On exit, if *EQUED* = 'N', B is not modified; if *EQUED* = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* *X* (output)

If *INFO* = 0 or *INFO* = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if *EQUED* = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

* *LDX* (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

cpotf2 - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

SYNOPSIS

```
SUBROUTINE CPOTF2( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
```

```
SUBROUTINE CPOTF2_64( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE POTF2( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: N, LDA, INFO
```

```
SUBROUTINE POTF2_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpotf2(char uplo, int n, complex *a, int lda, int *info);
```

```
void cpotf2_64(char uplo, long n, complex *a, long lda, long *info);
```

PURPOSE

cpotf2 computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

$$\begin{aligned} A &= U' * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L', & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** INFO (output)**

NAME

cpotrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

SYNOPSIS

```
SUBROUTINE CPOTRF( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
```

```
SUBROUTINE CPOTRF_64( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE POTRF( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,) :: A
INTEGER :: N, LDA, INFO
```

```
SUBROUTINE POTRF_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpotrf(char uplo, int n, complex *a, int lda, int *info);
```

```
void cpotrf_64(char uplo, long n, complex *a, long lda, long *info);
```

PURPOSE

cpotrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

$$\begin{aligned} A &= U^{**H} * U, & \text{if UPLO} = 'U', & \text{or} \\ A &= L * L^{**H}, & \text{if UPLO} = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A. $N \geq 0$.

* *A* (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U^{**H}U$ or $A = L * L^{**H}$.

* *LDA* (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (output)

NAME

cpotri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPOTRF

SYNOPSIS

```
SUBROUTINE CPOTRI( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
```

```
SUBROUTINE CPOTRI_64( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE POTRI( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: N, LDA, INFO
```

```
SUBROUTINE POTRI_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpotri(char uplo, int n, complex *a, int lda, int *info);
```

```
void cpotri_64(char uplo, long n, complex *a, long lda, long *info);
```

PURPOSE

cpotri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPOTRF.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$, as computed by CPOTRF. On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

cpotrs - solve a system of linear equations $A*X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ computed by CPOTRF

SYNOPSIS

```
SUBROUTINE CPOTRS( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE CPOTRS_64( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE POTRS( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, NRHS, LDA, LDB, INFO
```

```
SUBROUTINE POTRS_64( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpotrs(char uplo, int n, int nrhs, complex *a, int lda, complex *b, int ldb, int *info);
```

```
void cpotrs_64(char uplo, long n, long nrhs, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

cpotrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite matrix A using the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ computed by CPOTRF.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A . $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* *A* (input)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$, as computed by CPOTRF.

* *LDA* (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* *B* (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* *LDB* (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* *INFO* (output)

NAME

cppco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in packed storage. If the condition number is not needed then CPPFA is slightly faster. It is typical to follow a call to CPPCO with a call to CPPSL to solve $Ax = b$ or to CPPDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE CPPCO( A, N, RCOND, WORK, INFO)
  COMPLEX A(*), WORK(*)
  INTEGER N, INFO
  REAL RCOND
```

```
SUBROUTINE CPPCO_64( A, N, RCOND, WORK, INFO)
  COMPLEX A(*), WORK(*)
  INTEGER*8 N, INFO
  REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cppco(complex *a, int n, float *rcond, int *info);
```

```
void cppco_64(complex *a, long n, float *rcond, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

* **N** (*input*)

Order of the matrix A. $N <> 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

cppcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$ computed by CPPTRF

SYNOPSIS

```
SUBROUTINE CPPCON( UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), WORK(*)
INTEGER N, INFO
REAL ANORM, RCOND
REAL WORK2(*)
```

```
SUBROUTINE CPPCON_64( UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
REAL ANORM, RCOND
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE PPCON( UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE PPCON_64( UPLO, N, A, ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cppcon(char uplo, int n, complex *a, float anorm, float *rcond, int *info);
```

```
void cppcon_64(char uplo, long n, complex *a, float anorm, float *rcond, long *info);
```

PURPOSE

cppcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$ computed by CPPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $RCOND = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the Hermitian matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

$\text{dimension}(2*N)$

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cppdi - (obsolete) compute the determinant and inverse of a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by CPPCO or CPPFA.

SYNOPSIS

```
SUBROUTINE CPPDI( A, N, DET, JOB)
  COMPLEX A(*)
  INTEGER N, JOB
  REAL DET(*)
```

```
SUBROUTINE CPPDI_64( A, N, DET, JOB)
  COMPLEX A(*)
  INTEGER*8 N, JOB
  REAL DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cppdi(complex *a, int n, float *det, int job);
```

```
void cppdi_64(complex *a, long n, float *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the Cholesky factorization of the matrix A, as computed by CPPCO or CPPFA. On exit, the inverse of the original matrix A if the inverse was requested, otherwise A is unchanged. The strict lower triangle of A is not referenced.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$.

*** JOB (input)**

Determines which operation the subroutine will perform:

- o 11 both determinant and inverse
- o 01 inverse only

- 10 determinant only

NAME

cppequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE CPPEQU( UPLO, N, A, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*)
INTEGER N, INFO
REAL SCOND, AMAX
REAL SCALE(*)
```

```
SUBROUTINE CPPEQU_64( UPLO, N, A, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*)
INTEGER*8 N, INFO
REAL SCOND, AMAX
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PPEQU( UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE PPEQU_64( UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER(8) :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cppequ(char uplo, int n, complex *a, float *scale, float *scond, float *amax, int *info);
```

```
void cppequ_64(char uplo, long n, complex *a, float *scale, float *scond, float *amax, long *info);
```

PURPOSE

cppequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i)=1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j)=S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input*)

The upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **SCALE** (*output*)

If $INFO = 0$, $SCALE$ contains the scale factors for A .

* **SCOND** (*output*)

If $INFO = 0$, $SCALE$ contains the ratio of the smallest $SCALE(i)$ to the largest $SCALE(i)$. If $SCOND \geq 0.1$ and $AMAX$ is neither too large nor too small, it is not worth scaling by $SCALE$.

* **AMAX** (*output*)

Absolute value of largest matrix element. If $AMAX$ is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO** (*output*)

NAME

cppfa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A in packed storage. It is typical to follow a call to CPPFA with a call to CPPSL to solve $Ax = b$ or to CPPDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE CPPFA( A, N, INFO)
  COMPLEX A(*)
  INTEGER N, INFO
```

```
SUBROUTINE CPPFA_64( A, N, INFO)
  COMPLEX A(*)
  INTEGER*8 N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cppfa(complex *a, int n, int *info);
```

```
void cppfa_64(complex *a, long n, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that CPPSL will divide by zero if called.

NAME

cpprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE CPPRFS( UPLO, N, NRHS, A, AF, B, LDB, X, LDX, FERR, BERR,  
*      WORK, WORK2, INFO)  
CHARACTER * 1 UPLO  
COMPLEX A(*), AF(*), B(LDB,*), X(LDX,*), WORK(*)  
INTEGER N, NRHS, LDB, LDX, INFO  
REAL FERR(*), BERR(*), WORK2(*)

*      BERR, WORK, WORK2, INFO)  
CHARACTER * 1 UPLO  
COMPLEX A(*), AF(*), B(LDB,*), X(LDX,*), WORK(*)  
INTEGER*8 N, NRHS, LDB, LDX, INFO  
REAL FERR(*), BERR(*), WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE PPRFS( UPLO, N, [NRHS], A, AF, B, [LDB], X, [LDX], FERR,  
*      BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A, AF, WORK  
COMPLEX, DIMENSION(:, :) :: B, X  
INTEGER :: N, NRHS, LDB, LDX, INFO  
REAL, DIMENSION(:) :: FERR, BERR, WORK2  
  
SUBROUTINE PPRFS_64( UPLO, N, [NRHS], A, AF, B, [LDB], X, [LDX],  
*      FERR, BERR, [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: A, AF, WORK  
COMPLEX, DIMENSION(:, :) :: B, X  
INTEGER(8) :: N, NRHS, LDB, LDX, INFO  
REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cprfs(char uplo, int n, int nrhs, complex *a, complex *af, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void cprfs_64(char uplo, long n, long nrhs, complex *a, complex *af, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**}H^{*}U$ or $A = L^{*}L^{**}H$, as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see A).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CPPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

- * **WORK** (*workspace*)
dimension(2*N)
- * **WORK2** (*workspace*)
- * **INFO** (*output*)

NAME

cpsl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by CPPCO or CPPFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CPPSL( A, N, B)
COMPLEX A(*), B(*)
INTEGER N
```

```
SUBROUTINE CPPSL_64( A, N, B)
COMPLEX A(*), B(*)
INTEGER*8 N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpsl(complex *a, int n, complex *b);
```

```
void cpsl_64(complex *a, long n, complex *b);
```

ARGUMENTS

*** A (input)**

Cholesky factorization of the matrix A , as computed by CPPCO or CPPFA.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

cppsv - compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE CPPSV( UPLO, N, NRHS, A, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO
```

```
SUBROUTINE CPPSV_64( UPLO, N, NRHS, A, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), B(LDB,*)
INTEGER*8 N, NRHS, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE PPSV( UPLO, N, [NRHS], A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
```

```
SUBROUTINE PPSV_64( UPLO, N, [NRHS], A, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cppsv(char uplo, int n, int nrhs, complex *a, complex *b, int ldb, int *info);
```

```
void cppsv_64(char uplo, long n, long nrhs, complex *a, complex *b, long ldb, long *info);
```

PURPOSE

cppsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian positive definite matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**H} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** *UPLO* (input)**

*** *N* (input)**

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

*** *NRHS* (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** *A* (input/output)**

On entry, the upper or lower triangle of the Hermitian matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if $INFO = 0$, the factor U or L from the Cholesky factorization $A = U^{**H} * U$ or $A = L * L^{**H}$, in the same storage format as A .

*** *B* (input/output)**

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

*** *LDB* (input)**

The leading dimension of the array B . $LDB \geq \max(1, N)$.

*** *INFO* (output)**

NAME

cppsvx - use the Cholesky factorization $A = U^{*}H^{*}U$ or $A = L^{*}L^{*}H$ to compute the solution to a complex system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE CPPSVX( FACT, UPLO, N, NRHS, A, AF, EQUED, SCALE, B, LDB,

void cppsvox_64(char fact, char uplo, long n, long nrhs, complex *a, complex *af, char equed, float *scale, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

cppsvx uses the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^*H$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N Hermitian positive definite matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'E'$, real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
```

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(S)*A*diag(S)$ and B by $diag(S)*B$.

2. If $FACT = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $FACT = 'E'$) as $A = U^*U$, if $UPLO = 'U'$, or

```
A = L * L', if UPLO = 'L',
```

where U is an upper triangular matrix, L is a lower triangular matrix, and $'$ indicates conjugate transpose.

3. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A .

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $diag(S)$ so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A* (input/output)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array, except if $FACT = 'F'$ and $EQUED = 'Y'$, then A must contain the equilibrated matrix $diag(SCALE)*A*diag(SCALE)$. The j-th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details. A is not modified if $FACT = 'F'$ or $'N'$, or if $FACT = 'E'$ and $EQUED = 'N'$ on exit.

On exit, if $FACT = 'E'$ and $EQUED = 'Y'$, A is overwritten by $diag(SCALE)*A*diag(SCALE)$.

* *AF* (input/output)

If $FACT = 'F'$, then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$, in the same storage format as A. If $EQUED = 'N'$, then AF is the factored form of the equilibrated matrix A.

If $FACT = 'N'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the original matrix A.

If $FACT = 'E'$, then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U**H*U$ or $A = L*L**H$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (input/output)

The scale factors for A; not accessed if $EQUED = 'N'$. SCALE is an input argument if $FACT = 'F'$; otherwise, SCALE is an output argument. If $FACT = 'F'$ and $EQUED = 'Y'$, each element of SCALE must be positive.

* *B* (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if $EQUED = 'N'$, B is not modified; if $EQUED = 'Y'$, B is overwritten by $diag(SCALE) * B$.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* *X* (output)

If $INFO = 0$ or $INFO = N+1$, the N-by-NRHS solution matrix X to the original system of equations. Note that if $EQUED = 'Y'$, A and B are modified on exit, and the solution to the equilibrated system is $inv(diag(SCALE))*X$.

* *LDX* (input)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* *RCOND* (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

* *FERR* (output)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR (output)***

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK (workspace)***

dimension($2*N$)

* ***WORK2 (workspace)***

* ***INFO (output)***

NAME

cpptrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE CPPTRF( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*)
INTEGER N, INFO
```

```
SUBROUTINE CPPTRF_64( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*)
INTEGER*8 N, INFO
```

F95 INTERFACE

```
SUBROUTINE PPTRF( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER :: N, INFO
```

```
SUBROUTINE PPTRF_64( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER(8) :: N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpptrf(char uplo, int n, complex *a, int *info);
```

```
void cpptrf_64(char uplo, long n, complex *a, long *info);
```

PURPOSE

cpptrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format.

The factorization has the form

$$\begin{aligned} A &= U^{**H} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**H}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{**H}U$ or $A = L^{**H}L$, in the same storage format as A.

* *INFO* (*output*)

NAME

cpptri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPPTRF

SYNOPSIS

```
SUBROUTINE CPPTRI( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*)
INTEGER N, INFO

SUBROUTINE CPPTRI_64( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*)
INTEGER*8 N, INFO
```

F95 INTERFACE

```
SUBROUTINE PPTRI( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER :: N, INFO

SUBROUTINE PPTRI_64( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER(8) :: N, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cpptri(char uplo, int n, complex *a, int *info);

void cpptri_64(char uplo, long n, complex *a, long *info);
```

PURPOSE

cpptri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPPTRF.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$, packed columnwise as a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

* *INFO* (*output*)

NAME

cpptrs - solve a system of linear equations $A^*X = B$ with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U^*H^*U$ or $A = L^*L^{**}H$ computed by CPPTRF

SYNOPSIS

```
SUBROUTINE CPPTRS( UPLO, N, NRHS, A, B, LDB, INFO)

COMPLEX, DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpptrs(char uplo, int n, int nrhs, complex *a, complex *b, int ldb, int *info);
```

```
void cpptrs_64(char uplo, long n, long nrhs, complex *a, complex *b, long ldb, long *info);
```

PURPOSE

cpptrs solves a system of linear equations $A \cdot X = B$ with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$ computed by CPPTRF.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^H$ or $A = L \cdot L^H$, packed columnwise in a linear array. The j -th column of U or L is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1) \cdot j / 2) = U(i, j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1) \cdot (2n-j) / 2) = L(i, j)$ for $j \leq i \leq n$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

cptcon - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L^*D^*L^{**}H$ or $A = U^{**}H^*D^*U$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE CPTCON( N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
  COMPLEX OFFD(*)
  INTEGER N, INFO
  REAL ANORM, RCOND
  REAL DIAG(*), WORK(*)
```

```
SUBROUTINE CPTCON_64( N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
  COMPLEX OFFD(*)
  INTEGER*8 N, INFO
  REAL ANORM, RCOND
  REAL DIAG(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTCN( [N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
  COMPLEX, DIMENSION(:) :: OFFD
  INTEGER :: N, INFO
  REAL :: ANORM, RCOND
  REAL, DIMENSION(:) :: DIAG, WORK
```

```
SUBROUTINE PTCN_64( [N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
  COMPLEX, DIMENSION(:) :: OFFD
  INTEGER(8) :: N, INFO
  REAL :: ANORM, RCOND
  REAL, DIMENSION(:) :: DIAG, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cptcon(int n, float *diag, complex *offd, float anorm, float *rcond, int *info);
```

```
void cptcon_64(long n, float *diag, complex *offd, float anorm, float *rcond, long *info);
```

PURPOSE

cptcon computes the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization $A = L*D*L^*H$ or $A = U^*H*D*U$ computed by CPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

$$RCOND = 1 / (ANORM * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* *N (input)*

The order of the matrix A. $N \geq 0$.

* *DIAG (input)*

The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by CPTTRF.

* *OFFD (input)*

The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by CPTTRF.

* *ANORM (input)*

The 1-norm of the original matrix A.

* *RCOND (output)*

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is the 1-norm of inv(A) computed in this routine.

* *WORK (workspace)*

* *INFO (output)*

NAME

cpteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor

SYNOPSIS

```
SUBROUTINE CPTEQR( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
COMPLEX Z(LDZ,*)
INTEGER N, LDZ, INFO
REAL D(*), E(*), WORK(*)
```

```
SUBROUTINE CPTEQR_64( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
COMPLEX Z(LDZ,*)
INTEGER*8 N, LDZ, INFO
REAL D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTEQR( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
COMPLEX, DIMENSION(:,*) :: Z
INTEGER :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE PTEQR_64( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
COMPLEX, DIMENSION(:,*) :: Z
INTEGER(8) :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpteqr(char compz, int n, float *d, float *e, complex *z, int ldz, int *info);
```

```
void cpteqr_64(char compz, long n, float *d, float *e, complex *z, long ldz, long *info);
```

PURPOSE

cpeteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band positive definite Hermitian matrix can also be found if CHETRD, CHPTRD, or CHBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if COMPZ = 'V', the unitary matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original Hermitian matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if COMPZ = 'V' or 'I', $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension(4*N)

* **INFO** (*output*)

NAME

cptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE CPTRFS( UPLO, N, NRHS, DIAG, OFFD, DIAGF, OFFDF, B, LDB,

#include <sunperf.h>
```

```
void cptrfs(char uplo, int n, int nrhs, float *diag, complex *offd, float *diagf, complex *offdf, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void cptrfs_64(char uplo, long n, long nrhs, float *diag, complex *offd, float *diagf, complex *offdf, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cptrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

*** UPLO (input)**

Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** DIAG (input)**

The n real diagonal elements of the tridiagonal matrix A.

*** OFFD (input)**

The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

*** DIAGF (input)**

The n diagonal elements of the diagonal matrix DIAG from the factorization computed by CPTTRF.

*** OFFDF (input)**

The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by CPTTRF (see UPLO).

*** B (input)**

The right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** X (input/output)**

On entry, the solution matrix X, as computed by CPTTRS. On exit, the improved solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

*** FERR (output)**

The forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$.

* ***BERR (output)***

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK (workspace)***

dimension(N)

* ***WORK2 (workspace)***

* ***INFO (output)***

NAME

cptsl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite tridiagonal matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE CPTSL( N, DIAG, OFFD, B)
COMPLEX DIAG(*), OFFD(*), B(*)
INTEGER N
```

```
SUBROUTINE CPTSL_64( N, DIAG, OFFD, B)
COMPLEX DIAG(*), OFFD(*), B(*)
INTEGER*8 N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cptsl(int n, complex *diag, complex *offd, complex *b);
```

```
void cptsl_64(long n, complex *diag, complex *offd, complex *b);
```

ARGUMENTS

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *DIAG* (*input*)

Main diagonal elements of A .

* *OFFD* (*input*)

Off diagonal elements of A . $OFFD(1)$ through $OFFD(N*1)$ contains the off diagonal elements; $OFFD(N)$ is not referenced.

* *B* (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

cptsv - compute the solution to a complex system of linear equations $A*X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix, and X and B are N -by- $NRHS$ matrices.

C INTERFACE

```
#include <sunperf.h>
```

```
void cptsv(int n, int nrhs, float *diag, complex *sub, complex *b, int ldb, int *info);
```

```
void cptsv_64(long n, long nrhs, float *diag, complex *sub, complex *b, long ldb, long *info);
```

PURPOSE

cptsv computes the solution to a complex system of linear equations $A*X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix, and X and B are N -by- $NRHS$ matrices.

A is factored as $A = L*D*L^{**H}$, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** $NRHS$ (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** $DIAG$ (input/output)**

On entry, the n diagonal elements of the tridiagonal matrix A . On exit, the n diagonal elements of the diagonal matrix $DIAG$ from the factorization $A = L*DIAG*L^{**H}$.

*** SUB (input/output)**

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A . On exit, the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L*DIAG*L^{**H}$ factorization of A . SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the $U^{**H}*DIAG*U$ factorization of A .

*** B (input/output)**

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1, N)$.

*** $INFO$ (output)**

NAME

cptsvx - use the factorization $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

SYNOPSIS

```

REAL :: RCOND
REAL, DIMENSION(:) :: DIAG, DIAGF, FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cptsvx(char fact, int n, int nrhs, float *diag, complex *sub, float *diagf, complex *subf, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void cptsvx_64(char fact, long n, long nrhs, float *diag, complex *sub, float *diagf, complex *subf, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

cptsvx uses the factorization $A = L^*D^*L^{**}H$ to compute the solution to a complex system of linear equations $A^*X = B$, where A is an N -by- N Hermitian positive definite tridiagonal matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the matrix A is factored as $A = L^*D^*L^{**}H$, where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form

$$A = U^{**}H^*D^*U.$$

2. If the leading i -by- i principal minor is not positive definite, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

*** *FACT* (input)**

Specifies whether or not the factored form of the matrix A is supplied on entry.

*** *N* (input)**

The order of the matrix A . $N \geq 0$.

*** *NRHS* (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X . $NRHS \geq 0$.

*** *DIAG* (input)**

The n diagonal elements of the tridiagonal matrix A .

*** *SUB* (input)**

The $(n-1)$ subdiagonal elements of the tridiagonal matrix A .

*** *DIAGF* (input/output)**

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the diagonal matrix DIAG from the $L^*DIAG^*L^{**H}$ factorization of A. If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the diagonal matrix DIAG from the $L^*DIAG^*L^{**H}$ factorization of A.

*** *SUBF* (input/output)**

If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*DIAG^*L^{**H}$ factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*DIAG^*L^{**H}$ factorization of A.

*** *B* (input)**

The N-by-NRHS right hand side matrix B.

*** *LDB* (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** *X* (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** *LDX* (input)**

The leading dimension of the array X. $LDX \geq \max(1,N)$.

*** *RCOND* (output)**

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if $RCOND = 0$), the matrix is singular to working precision. This condition is indicated by a return code of $INFO > 0$.

*** *FERR* (output)**

The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j).

*** *BERR* (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** *WORK* (workspace)**

dimension(N)

*** *WORK2* (workspace)**

dimension(N)

*** *INFO* (output)**

NAME

cpttrf - compute the L^*D^*L' factorization of a complex Hermitian positive definite tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE CPTTRF( N, DIAG, OFFD, INFO)
  COMPLEX OFFD(*)
  INTEGER N, INFO
  REAL DIAG(*)

SUBROUTINE CPTTRF_64( N, DIAG, OFFD, INFO)
  COMPLEX OFFD(*)
  INTEGER*8 N, INFO
  REAL DIAG(*)
```

F95 INTERFACE

```
SUBROUTINE PTTRF( [N], DIAG, OFFD, [INFO])
  COMPLEX, DIMENSION(:) :: OFFD
  INTEGER :: N, INFO
  REAL, DIMENSION(:) :: DIAG

SUBROUTINE PTTRF_64( [N], DIAG, OFFD, [INFO])
  COMPLEX, DIMENSION(:) :: OFFD
  INTEGER(8) :: N, INFO
  REAL, DIMENSION(:) :: DIAG
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpttrf(int n, float *diag, complex *offd, int *info);
```

```
void cpttrf_64(long n, float *diag, complex *offd, long *info);
```

PURPOSE

cpttrf computes the L^*D^*L' factorization of a complex Hermitian positive definite tridiagonal matrix A . The factorization may also be regarded as having the form $A = U^*D^*U$.

ARGUMENTS

*** *N* (input)**

The order of the matrix A . $N \geq 0$.

*** *DIAG* (input/output)**

On entry, the n diagonal elements of the tridiagonal matrix A . On exit, the n diagonal elements of the diagonal matrix $DIAG$ from the L^*DIAG^*L' factorization of A .

*** *OFFD* (input/output)**

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix A . On exit, the $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the L^*DIAG^*L' factorization of A . *OFFD* can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^*DIAG^*U factorization of A .

*** *INFO* (output)**

NAME

cpttrs - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U * D * U$ or $A = L * D * L'$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE CPTTRS( UPLO, N, NRHS, DIAG, OFFD, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX OFFD(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO

```
SUBROUTINE PTTRS_64( UPLO, [N], [NRHS], DIAG, OFFD, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: OFFD
COMPLEX, DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: DIAG
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpttrs(char uplo, int n, int nrhs, float *diag, complex *offd, complex *b, int ldb, int *info);
```

```
void cpttrs_64(char uplo, long n, long nrhs, float *diag, complex *offd, complex *b, long ldb, long *info);
```

PURPOSE

cpttrs solves a tridiagonal system of the form $A * X = B$ using the factorization $A = U * D * U$ or $A = L * D * L'$ computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

* **UPLO** (*input*)

Specifies the form of the factorization and whether the vector OFFD is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L.

* **N** (*input*)

The order of the tridiagonal matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **DIAG** (*input*)

The n diagonal elements of the diagonal matrix DIAG from the factorization $A = U * DIAG * U$ or $A = L * DIAG * L'$.

* **OFFD** (*input/output*)

If UPLO = 'U', the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U * DIAG * U$. If UPLO = 'L', the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization $A = L * DIAG * L'$.

* **B** (*input/output*)

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

cptts2 - solve a tridiagonal system of the form $A * X = B$ using the factorization $A = U * D * U$ or $A = L * D * L'$ computed by CPTTRF

SYNOPSIS

```
SUBROUTINE CPTTS2( IUPLO, N, NRHS, D, E, B, LDB)
  COMPLEX E(*), B(LDB,*)
  INTEGER IUPLO, N, NRHS, LDB
  REAL D(*)
```

```
SUBROUTINE CPTTS2_64( IUPLO, N, NRHS, D, E, B, LDB)
  COMPLEX E(*), B(LDB,*)
  INTEGER*8 IUPLO, N, NRHS, LDB
  REAL D(*)
```

F95 INTERFACE

```
SUBROUTINE CPTTS2( IUPLO, N, NRHS, D, E, B, [LDB])
  COMPLEX, DIMENSION(:) :: E
  COMPLEX, DIMENSION(:, :) :: B
  INTEGER :: IUPLO, N, NRHS, LDB
  REAL, DIMENSION(:) :: D
```

```
SUBROUTINE CPTTS2_64( IUPLO, N, NRHS, D, E, B, [LDB])
  COMPLEX, DIMENSION(:) :: E
  COMPLEX, DIMENSION(:, :) :: B
  INTEGER(8) :: IUPLO, N, NRHS, LDB
  REAL, DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cptts2(int iuplo, int n, int nrhs, float *d, complex *e, complex *b, int ldb);
```

```
void cptts2_64(long iuplo, long n, long nrhs, float *d, complex *e, complex *b, long ldb);
```

PURPOSE

cpts2 solves a tridiagonal system of the form $A * X = B$ using the factorization $A = U * D * U$ or $A = L * D * L'$ computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

*** IUPLO (input)**

Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L.

*** N (input)**

The order of the tridiagonal matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** D (input)**

The n diagonal elements of the diagonal matrix D from the factorization $A = U * D * U$ or $A = L * D * L'$.

*** E (input)**

If IUPLO = 1, the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization $A = U * D * U$.
If IUPLO = 0, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization $A = L * D * L'$.

*** B (input/output)**

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

NAME

cqrdc - (obsolete) compute the QR factorization of a general matrix A. It is typical to follow a call to CQRDC with a call to CQRSL to solve $Ax = b$ or to CPODI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE CQRDC( A, LDA, N, P, QRAUX, IPIVOT, WORK, JOB)
COMPLEX A(LDA,*), QRAUX(*), WORK(*)
INTEGER LDA, N, P, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE CQRDC_64( A, LDA, N, P, QRAUX, IPIVOT, WORK, JOB)
COMPLEX A(LDA,*), QRAUX(*), WORK(*)
INTEGER*8 LDA, N, P, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cqrdc(complex *a, int lda, int n, int p, complex *qraux, int *ipivot, int job);
```

```
void cqrdc_64(complex *a, long lda, long n, long p, complex *qraux, long *ipivot, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, the upper triangle of A contains the matrix R and the strict lower triangle of A contains information that will allow construction of the matrix Q. If pivoting was requested, A contains the factorization of the original matrix A permuted by the requested pivots.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows in the matrix A. $N \geq 0$.

*** P (input)**

Number of columns in the matrix A. $P \geq 0$.

*** QRAUX (output)**

On exit, contains information required to construct the orthogonal matrix Q.

*** IPIVOT (input)**

If JOB selected no pivoting, then IPIVOT is not referenced. If JOB selected pivoting, then on entry to the subroutines, IPIVOT contains integers representing array indices that control the selection of pivot elements from the diagonal of A according to the system below:

```
IPIVOT(k) > 0   A(k,k) is an initial element.  
IPIVOT(k) = 0   A(k,k) is a free element.  
IPIVOT(k) < 0   A(k,k) is a final element.
```

Before the decomposition is computed, symmetric row and column interchanges are used to move initial elements to the beginning of A and final elements to the end of A. During the computation, symmetric row and column interchanges are used to move the largest remaining free diagonal element into the pivot position. On exit, IPIVOT(k) contains the index of the diagonal element of A that was moved into the kth position.

* **WORK** (*workspace*)

Scratch array with a dimension of N. WORK is not referenced if JOB = 0.

* **JOB** (*input*)

Determines how the factorization is done:

- o 0 with no pivoting

not 0 with pivoting

NAME

cqrs1 - (obsolete) solve the linear system $Ax = b$ for a general matrix A , which has been QR- factored by CQRDC, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CQRSL( A, LDA, N, K, QRAUX, Y, QY, QTY, B, RESID, AB,  
*      JOB, INFO)  
COMPLEX A(LDA,*), QRAUX(*), Y(*), QY(*), QTY(*), B(*), RESID(*), AB(*)  
INTEGER LDA, N, K, JOB, INFO
```

```
SUBROUTINE CQRSL_64( A, LDA, N, K, QRAUX, Y, QY, QTY, B, RESID, AB,  
*      JOB, INFO)  
COMPLEX A(LDA,*), QRAUX(*), Y(*), QY(*), QTY(*), B(*), RESID(*), AB(*)  
INTEGER*8 LDA, N, K, JOB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cqrs1(complex *a, int lda, int n, int k, complex *qraux, complex *y, complex *qy, complex *qty, complex *b, complex *resid, complex *ab, int job, int *info);
```

```
void cqrs1_64(complex *a, long lda, long n, long k, complex *qraux, complex *y, complex *qy, complex *qty, complex *b, complex *resid, complex *ab, long job, long *info);
```

ARGUMENTS

*** A (input)**

Part of the QR factorization of matrix A as computed by CQRDC.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows in the matrix AK where AK is described below. $N \geq 0$.

*** K (input)**

Number of columns in the matrix AK where AK is described below. $K \geq 0$.

*** QRAUX (input)**

Auxiliary output from CQRDC.

*** Y (input)**

Vector to be manipulated by CQRSL.

* **QY (output)**

On exit, QY contains $Q * Y$ if its computation has been requested in JOB; QY is not referenced if its computation is not requested.

* **QTY (output)**

On exit, QTY contains $QT * Y$ if its computation has been requested in JOB; QTY is not referenced if its computation is not requested.

* **B (input/output)**

On entry, the right-hand side vector b. On exit, the solution vector x. B is not referenced if its computation is not requested.

* **RESID (output)**

On exit, RESID contains the least squares residual $y - AK * b$ if its computation has been requested. RESID also is the orthogonal projection of y onto the orthogonal complement of the column space of AK. RESID is not referenced if its computation is not requested.

* **AB (output)**

On exit, AB contains the least squares approximation $AK * b$ if its computation has been requested. AB is the orthogonal projection of y onto the column space of x. AB is not referenced if its computation is not requested.

* **JOB (input)**

Integer in the form abcde; determines which operation or operations the subroutine will perform:

```
a <> 0  compute QY
b, c, d, or e <> 0      compute QTY
c <> 0  compute B
d <> 0  compute RESID
e <> 0  compute AB
```

* **INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the computation of B has been requested and R is singular; the value of k is then the index of the first zero element of R. The matrix AK is constructed from the factored orthogonal matrix Q and upper triangular matrix R from CQRDC.

NAME

crot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors CX and CY are complex

SYNOPSIS

```
SUBROUTINE CROT( N, X, INCX, Y, INCY, C, S)
  COMPLEX S
  COMPLEX X(*), Y(*)
  INTEGER N, INCX, INCY
  REAL C
```

```
SUBROUTINE CROT_64( N, X, INCX, Y, INCY, C, S)
  COMPLEX S
  COMPLEX X(*), Y(*)
  INTEGER*8 N, INCX, INCY
  REAL C
```

F95 INTERFACE

```
SUBROUTINE ROT( [N], X, [INCX], Y, [INCY], C, S)
  COMPLEX :: S
  COMPLEX, DIMENSION(:) :: X, Y
  INTEGER :: N, INCX, INCY
  REAL :: C
```

```
SUBROUTINE ROT_64( [N], X, [INCX], Y, [INCY], C, S)
  COMPLEX :: S
  COMPLEX, DIMENSION(:) :: X, Y
  INTEGER(8) :: N, INCX, INCY
  REAL :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void crot(int n, complex *x, int incx, complex *y, int incy, float c, complex s);
```

```
void crot_64(long n, complex *x, long incx, complex *y, long incy, float c, complex s);
```

PURPOSE

croT CROT applies a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors CX and CY are complex.

ARGUMENTS

* *N (input)*

The number of elements in the vectors X and Y.

* *X (output)*

On input, the vector X. On output, X is overwritten with $C*X + S*Y$.

* *INCX (input)*

The increment between successive values of Y. $INCX \neq 0$.

* *Y (output)*

On input, the vector Y. On output, Y is overwritten with $-\text{CONJG}(S)*X + C*Y$.

* *INCY (input)*

The increment between successive values of Y. $INCY \neq 0$.

* *C (input)*

* *S (input)*

$\forall \theta \in \mathbb{R}$ C and S define a rotation $\begin{bmatrix} C & S \\ -\text{conjg}(S) & C \end{bmatrix}$ where $C^2 + S^2 = 1$.

NAME

crotg - Construct a Given's plane rotation

SYNOPSIS

```
SUBROUTINE CROTG( A, B, C, S)
COMPLEX A, B, S
REAL C
```

```
SUBROUTINE CROTG_64( A, B, C, S)
COMPLEX A, B, S
REAL C
```

F95 INTERFACE

```
SUBROUTINE ROTG( A, B, C, S)
COMPLEX :: A, B, S
REAL :: C
```

```
SUBROUTINE ROTG_64( A, B, C, S)
COMPLEX :: A, B, S
REAL :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void crotg(complex *a, complex *b, float *c, complex *s);
```

```
void crotg_64(complex *a, complex *b, float *c, complex *s);
```

PURPOSE

crotd Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

* ***A*** (*input/output*)

On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

* ***B*** (*input/output*)

On entry, B contains the entry to be annihilated in the second vector. On exit, contains either S or 1/C depending on which of the input values of A and B is larger.

* ***C*** (*output*)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

* ***S*** (*output*)

On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

NAME

cscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE CSCAL( N, ALPHA, Y, INCY)
  COMPLEX ALPHA
  COMPLEX Y(*)
  INTEGER N, INCY
```

```
SUBROUTINE CSCAL_64( N, ALPHA, Y, INCY)
  COMPLEX ALPHA
  COMPLEX Y(*)
  INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE SCAL( [N], ALPHA, Y, [INCY])
  COMPLEX :: ALPHA
  COMPLEX, DIMENSION(:) :: Y
  INTEGER :: N, INCY
```

```
SUBROUTINE SCAL_64( [N], ALPHA, Y, [INCY])
  COMPLEX :: ALPHA
  COMPLEX, DIMENSION(:) :: Y
  INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cscal(int n, complex alpha, complex *y, int incy);
```

```
void cscal_64(long n, complex alpha, complex *y, long incy);
```

PURPOSE

cscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

* *Y (input/output)*

$(1 + (m - 1) * \text{abs}(INCY))$. On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

* *INCY (input)*

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

NAME

csctr, dsctr, ssctr, zsctr - Scatters elements from x into y

SYNOPSIS

```
SUBROUTINE CSCTR( NZ, X, INDX, Y)
COMPLEX X(*), Y(*)
INTEGER NZ
INTEGER INDX(*)
```

```
SUBROUTINE CSCTR_64( NZ, X, INDX, Y)
COMPLEX X(*), Y(*)
INTEGER*8 NZ
INTEGER*8 INDX(*)
```

F95 INTERFACE

```
SUBROUTINE SCTR( [NZ], X, INDX, Y)
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX
```

```
SUBROUTINE SCTR_64( [NZ], X, INDX, Y)
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

csctr xSCTR - Scatters the components of a sparse vector x stored in compressed form into specified components of a vector y in full storage form.

```
      do 10, i = 1, n
         y(indx(i)) = x(i)
      10 continue
```

ARGUMENTS

* *NZ (input)*

- INTEGER

Number of elements in the compressed form. Unchanged on exit.

* *X (input)*

Vector containing the values to be scattered from compressed form into full storage form. Unchanged on exit.

* *INDX (input)*

- INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

* *Y (output)*

Vector whose elements specified by indx have been set to the corresponding entries of x. Only the elements corresponding to the indices in indx have been modified.

NAME

csico - (obsolete) compute the UDU factorization and condition number of a symmetric matrix A. If the condition number is not needed then CSIFA is slightly faster. It is typical to follow a call to CSICO with a call to CSISL to solve $Ax = b$ or to CSIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE CSICO( A, LDA, N, IPIVOT, RCOND, WORK)
  COMPLEX A(LDA,*), WORK(*)
  INTEGER LDA, N
  INTEGER IPIVOT(*)
  REAL RCOND
```

```
SUBROUTINE CSICO_64( A, LDA, N, IPIVOT, RCOND, WORK)
  COMPLEX A(LDA,*), WORK(*)
  INTEGER*8 LDA, N
  INTEGER*8 IPIVOT(*)
  REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csico(complex *a, int lda, int n, int *ipivot, float *rcond);
```

```
void csico_64(complex *a, long lda, long n, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq \text{RCOND} \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $\text{RCOND} + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

csidi - (obsolete) compute the determinant, inertia, and inverse of a symmetric matrix A, which has been UDU-factored by CSICO or CSIFA.

SYNOPSIS

```
SUBROUTINE CSIDI( A, LDA, N, IPIVOT, DET, WORK, JOB)
COMPLEX A(LDA,*), DET(*), WORK(*)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE CSIDI_64( A, LDA, N, IPIVOT, DET, WORK, JOB)
COMPLEX A(LDA,*), DET(*), WORK(*)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csidi(complex *a, int lda, int n, int *ipivot, complex *det, int job);
```

```
void csidi_64(complex *a, long lda, long n, long *ipivot, complex *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by CSICO or CSIFA. On exit, if the c digit of JOB $\neq 0$, then the upper triangle of A contains the upper triangle of the inverse of the original matrix A if the inverse was requested, otherwise unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CSICO or CSIFA.

*** DET (output)**

On exit, if the b digit of JOB $\neq 0$, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) =$

0.0. If the b digit of JOB = 0, DET is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form bc; determines operation the subroutine will perform:

```
b <> 0  Compute the determinant.  
c <> 0  Compute the inverse.
```

Note that the inverse should not be computed if CSICO has set RCOND = 0 or if CSIFA has set INFO >= 0.

NAME

csifa - (obsolete) compute the UDU factorization of a symmetric matrix A. It is typical to follow a call to CSIFA with a call to CSISL to solve $Ax = b$ or to CSIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE CSIFA( A, LDA, N, IPIVOT, INFO)
COMPLEX A(LDA,*)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CSIFA_64( A, LDA, N, IPIVOT, INFO)
COMPLEX A(LDA,*)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csifa(complex *a, int lda, int n, int *ipivot, int *info);
```

```
void csifa_64(complex *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that CSISL or CSIDI will divide by zero if called.

NAME

csisl - (obsolete) solve the linear system $Ax = b$ for a symmetric matrix A , which has been UDU-factored by CSICO or CSIFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE CSISL( A, LDA, N, IPIVOT, B)
COMPLEX A(LDA,*), B(*)
INTEGER LDA, N
INTEGER IPIVOT(*)
```

```
SUBROUTINE CSISL_64( A, LDA, N, IPIVOT, B)
COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csisl(complex *a, int lda, int n, int *ipivot, complex *b);
```

```
void csisl_64(complex *a, long lda, long n, long *ipivot, complex *b);
```

ARGUMENTS

*** A (input)**

UDU factorization of the matrix A , as computed by CSICO or CSIFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CSICO or CSIFA.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

cspco - (obsolete) compute the UDU factorization and condition number of a symmetric matrix A in packed storage. If the condition number is not needed then CSPFA is slightly faster. It is typical to follow a call to CSPCO with a call to CSPSL to solve $Ax = b$ or to CSPDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE CSPCO( A, N, IPIVOT, RCOND, WORK)
  COMPLEX A(*), WORK(*)
  INTEGER N
  INTEGER IPIVOT(*)
  REAL RCOND
```

```
SUBROUTINE CSPCO_64( A, N, IPIVOT, RCOND, WORK)
  COMPLEX A(*), WORK(*)
  INTEGER*8 N
  INTEGER*8 IPIVOT(*)
  REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cspco(complex *a, int n, int *ipivot, float *rcond);
```

```
void cspco_64(complex *a, long n, long *ipivot, float *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

cspcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by CSPTRF

SYNOPSIS

```
SUBROUTINE CSPCON( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), WORK(*)
INTEGER N, INFO
INTEGER IPIVOT(*)
REAL ANORM, RCOND

SUBROUTINE CSPCON_64( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
REAL ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE SPCON( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND

SUBROUTINE SPCON_64( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cspcon(char uplo, int n, complex *a, int *ipivot, float anorm, float *rcond, int *info);
```

```
void cspcon_64(char uplo, long n, complex *a, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

cspcon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by CSPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

*** UPLO (input)**

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

*** IPIVOT (input)**

Details of the interchanges and the block structure of D as determined by CSPTRF.

*** ANORM (input)**

The 1-norm of the original matrix A.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

*** WORK (workspace)**

$\text{dimension}(2*N)$

*** INFO (output)**

NAME

csmdi - (obsolete) compute the determinant, inertia, and inverse of a symmetric matrix A in packed storage, which has been UDU-factored by CSPCO or CSPFA.

SYNOPSIS

```
SUBROUTINE CSPDI( A, N, IPIVOT, DET, WORK, JOB)
COMPLEX A(*), DET(*), WORK(*)
INTEGER N, JOB
INTEGER IPIVOT(*)
```

```
SUBROUTINE CSPDI_64( A, N, IPIVOT, DET, WORK, JOB)
COMPLEX A(*), DET(*), WORK(*)
INTEGER*8 N, JOB
INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csmdi(complex *a, int n, int *ipivot, complex *det, int job);
```

```
void csmdi_64(complex *a, long n, long *ipivot, complex *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by CSPCO or CSPFA. On exit, if the c digit of JOB $\neq 0$, then A contains the upper triangle of the inverse of the original matrix A; otherwise unchanged.

*** N (input)**

Order of the original matrix A. $N \neq 0$.

*** IPIVOT (input)**

Pivot vector as computed by CSPCO or CSPFA.

*** DET (output)**

On exit, if the b digit of JOB $\neq 0$, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$. If the b digit of JOB = 0, DET is not referenced.

*** WORK (workspace)**

Scratch array with a dimension of N.

*** JOB (input)**

Integer in the form bc; determines operation the subroutine will perform:

b <> 0 Compute the determinant.
c <> 0 Compute the inverse.

Note that the inverse should not be computed if CSPCO has set RCOND = 0 or if CSPFA has set INFO <> 0.

NAME

csdfa - (obsolete) compute the UDU factorization of a symmetric matrix A in packed storage. It is typical to follow a call to CSPFA with a call to CSPSL to solve $Ax = b$ or to CSPDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE CSPFA( A, N, IPIVOT, INFO)
  COMPLEX A(*)
  INTEGER N, INFO
  INTEGER IPIVOT(*)

SUBROUTINE CSPFA_64( A, N, IPIVOT, INFO)
  COMPLEX A(*)
  INTEGER*8 N, INFO
  INTEGER*8 IPIVOT(*)
```

C INTERFACE

```
#include <sunperf.h>

void csdfa(complex *a, int n, int *ipivot, int *info);

void csdfa_64(complex *a, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that CSPSL or CSPDI will divide by zero if called.

NAME

csprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE CSPRFS( UPLO, N, NRHS, A, AF, IPIVOT, B, LDB, X, LDX,

SUBROUTINE SPRFS_64( UPLO, [N], [NRHS], A, AF, IPIVOT, B, [LDB], X,
*      [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, AF, WORK
COMPLEX, DIMENSION(:,*) :: B, X
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csprfs(char uplo, int n, int nrhs, complex *a, complex *af, int *ipivot, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void csprfs_64(char uplo, long n, long nrhs, complex *a, complex *af, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

csprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSPTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CSPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

cspsl - (obsolete) solve the linear system $Ax = b$ for a symmetric matrix A in packed storage, which has been UDU-factored by CSPCO or CSPFA, and vectors b and x .

SYNOPSIS

COMPLEX, DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE SPSV_64( UPLO, [N], [NRHS], A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cspsv(char uplo, int n, int nrhs, complex *a, int *ipivot, complex *b, int ldb, int *info);
```

```
void cspsv_64(char uplo, long n, long nrhs, complex *a, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cspsv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**T}, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * D * L^{**T}, & \text{if } UPLO = 'L', & \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by CSPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

cspsvx - use the diagonal pivoting factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cspsvx(char fact, char uplo, int n, int nrhs, complex *a, complex *af, int *ipivot, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void cspsvx_64(char fact, char uplo, long n, long nrhs, complex *a, complex *af, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

cspsvx uses the diagonal pivoting factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A as $A = U * D * U^{**T}$, if $UPLO = 'U'$, or

```
    A = L * D * L^{**T}, if UPLO = 'L',  
    where U (or L) is a product of permutation and unit upper (lower)  
    triangular matrices and D is symmetric and block diagonal with  
    1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

*** A (input)**

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CSPTRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1,N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

*** FERR (output)**

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

csptf - compute the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE CSPTRF( UPLO, N, A, IPIVOT, INFO)
CHARACTER * 1 UPLO

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE SPTRF_64( UPLO, [N], A, IPIVOT, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csptf(char uplo, int n, complex *a, int *ipivot, int *info);
```

```
void csptf_64(char uplo, long n, complex *a, long *ipivot, long *info);
```

PURPOSE

csptf computes the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A . $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L , stored as a packed triangular matrix overwriting A (see below for further details).

* *IPIVOT* (*output*)

Details of the interchanges and the block structure of D . If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

* *INFO* (*output*)

NAME

csptri - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

SYNOPSIS

```
SUBROUTINE CSPTRI( UPLO, N, A, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), WORK(*)
INTEGER N, INFO
INTEGER IPIVOT(*)

SUBROUTINE CSPTRI_64( UPLO, N, A, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE SPTRI( UPLO, [N], A, IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE SPTRI_64( UPLO, [N], A, IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void csptri(char uplo, int n, complex *a, int *ipivot, int *info);

void csptri_64(char uplo, long n, complex *a, long *ipivot, long *info);
```

PURPOSE

csptri computes the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization $A = U^*D*U^{**T}$ or $A = L^*D*L^{**T}$ computed by CSPTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of $\text{inv}(A)$ is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = \text{inv}(A)(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = \text{inv}(A)(i,j)$ for $j \leq i \leq n$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSPTRF.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

csptrs - solve a system of linear equations $A^*X = B$ with a complex symmetric matrix A stored in packed format using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSPTRF

SYNOPSIS

```
SUBROUTINE CSPTRS( UPLO, N, NRHS, A, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO
INTEGER IPIVOT(*)

SUBROUTINE CSPTRS_64( UPLO, N, NRHS, A, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
COMPLEX A(*), B(LDB,*)
INTEGER*8 N, NRHS, LDB, INFO
INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE SPTRS( UPLO, [N], [NRHS], A, IPIVOT, B, [LDB], [INFO])

COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:, :) :: B
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE SPTRS_64( UPLO, [N], [NRHS], A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:, :) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csptrs(char uplo, int n, int nrhs, complex *a, int *ipivot, complex *b, int ldb, int *info);
```

```
void csptrs_64(char uplo, long n, long nrhs, complex *a, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

csptrs solves a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by CSPTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSPTRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

csrot - Apply a plane rotation.

SYNOPSIS

```
SUBROUTINE CSROT( N, X, INCX, Y, INCY, C, S)
COMPLEX C, S
COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE CSROT_64( N, X, INCX, Y, INCY, C, S)
COMPLEX C, S
COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE ROT( [N], X, [INCX], Y, [INCY], C, S)
COMPLEX :: C, S
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE ROT_64( [N], X, [INCX], Y, [INCY], C, S)
COMPLEX :: C, S
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csrot(int n, complex *x, int incx, complex *y, int incy, complex c, complex s);
```

```
void csrot_64(long n, complex *x, long incx, complex *y, long incy, complex c, complex s);
```

PURPOSE

csrot Apply a plane rotation, where the cos and sin (c and s) are real and the vectors x and y are complex.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input)*

Before entry, the incremented array X must contain the vector x . Unchanged on exit.

* *INCX (input)*

On entry, $INCX$ specifies the increment for the elements of X . $INCX$ must not be zero. Unchanged on exit.

* *Y (output)*

On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

* *INCY (input)*

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

* *C (input)*

On entry, the cosine.

* *S (input)*

On entry, the sin.

NAME

csscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE CSSCAL( N, ALPHA, Y, INCY)
COMPLEX Y(*)
INTEGER N, INCY
REAL ALPHA
```

```
SUBROUTINE CSSCAL_64( N, ALPHA, Y, INCY)
COMPLEX Y(*)
INTEGER*8 N, INCY
REAL ALPHA
```

F95 INTERFACE

```
SUBROUTINE SCAL( [N], ALPHA, Y, [INCY])
COMPLEX, DIMENSION(:) :: Y
INTEGER :: N, INCY
REAL :: ALPHA
```

```
SUBROUTINE SCAL_64( [N], ALPHA, Y, [INCY])
COMPLEX, DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
REAL :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csscal(int n, float alpha, complex *y, int incy);
```

```
void csscal_64(long n, float alpha, complex *y, long incy);
```

PURPOSE

csscal Compute $y := \alpha * y$ where α is a scalar and y is an n -vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(INCY)$). On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

* *INCY (input)*

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

NAME

stedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

SYNOPSIS

SUBROUTINE STEDC_64( COMPZ, [N], D, E, Z, [LDZ], [WORK], [LWORK],  
*      [RWORK], [LRWORK], [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: COMPZ  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: Z  
INTEGER(8) :: N, LDZ, LWORK, LRWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL, DIMENSION(:) :: D, E, RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cstedc(char compz, int n, float *d, float *e, complex *z, int ldz, int *info);
```

```
void cstedc_64(char compz, long n, float *d, float *e, complex *z, long ldz, long *info);
```

PURPOSE

stedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The dimension of the symmetric tridiagonal matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if $COMPZ = 'V'$, then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if $INFO = 0$, then if $COMPZ = 'V'$, Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if $COMPZ = 'I'$, Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $COMPZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$. If eigenvectors are desired, then $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $COMPZ = 'N'$ or $'I'$, or $N \leq 1$, LWORK must be at least 1. If $COMPZ = 'V'$ and $N > 1$, LWORK must be at least $N*N$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **RWORK** (*workspace*)

dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

*** LRWORK (input)**

The dimension of the array RWORK. If COMPZ = 'N' or $N \leq 1$, LRWORK must be at least 1. If COMPZ = 'V' and $N > 1$, LRWORK must be at least $1 + 3*N + 2*N*\lg N + 3*N**2$, where $\lg(N)$ = smallest integer k such that $2**k \geq N$. If COMPZ = 'I' and $N > 1$, LRWORK must be at least $1 + 4*N + 2*N**2$.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. If COMPZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If COMPZ = 'V' or $N > 1$, LIWORK must be at least $6 + 6*N + 5*N*\lg N$. If COMPZ = 'I' or $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

NAME

```

```
void cstegr_64(char jobz, char range, long n, float *d, float *e, float vl, float vu, long il, long iu, float abstol, long *m, float *w, complex *z, long ldz, long *isuppz, long *info);
```

PURPOSE

cstegr b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,

- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently CSTEGR is only set up to find ALL the n eigenvalues and eigenvectors of T in $O(n^2)$ time

Note 2 : Currently the routine CSTEIN is called when an appropriate σ_i cannot be chosen in step (c) above. CSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : CSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix T . On exit, D is overwritten.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 1 to $N-1$ of E ; $E(N)$ need not be set. On exit, E is overwritten.

* **VL** (*input*)

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced

if RANGE = 'A' or 'I'.

*** VU (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $V_L < V_U$. Not referenced if RANGE = 'A' or 'I'.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** ABSTOL (input)**

The absolute error tolerance for the eigenvalues/eigenvectors. If JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than $N \cdot \text{EPS} \cdot |T|$, then $N \cdot \text{EPS} \cdot |T|$ will be used in its place, where EPS is the machine precision and $|T|$ is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of $\text{EPS} \cdot |T|$ irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

*** M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

*** W (output)**

The first M elements contain the selected eigenvalues in ascending order.

*** Z (input/output)**

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** ISUPPZ (output)**

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements $ISUPPZ(2 \cdot i - 1)$ through $ISUPPZ(2 \cdot i)$.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, 18 \cdot N)$

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** LIWORK (input)**

The dimension of the array IWORK. $LIWORK \geq \max(1, 10 \cdot N)$

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** INFO (output)**

NAME

cstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

SYNOPSIS

```
SUBROUTINE CSTEIN( N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,
*      IWORK, IFAIL, INFO)
COMPLEX Z(LDZ,*)
INTEGER N, M, LDZ, INFO
INTEGER IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
REAL D(*), E(*), W(*), WORK(*)

SUBROUTINE CSTEIN_64( N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,
*      IWORK, IFAIL, INFO)
COMPLEX Z(LDZ,*)
INTEGER*8 N, M, LDZ, INFO
INTEGER*8 IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
REAL D(*), E(*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEIN( [N], D, E, [M], W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],
*      [IWORK], IFAIL, [INFO])
COMPLEX, DIMENSION(:,*) :: Z
INTEGER :: N, M, LDZ, INFO
INTEGER, DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL, DIMENSION(:) :: D, E, W, WORK

SUBROUTINE STEIN_64( [N], D, E, [M], W, IBLOCK, ISPLIT, Z, [LDZ],
*      [WORK], [IWORK], IFAIL, [INFO])
COMPLEX, DIMENSION(:,*) :: Z
INTEGER(8) :: N, M, LDZ, INFO
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL, DIMENSION(:) :: D, E, W, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cstein(int n, float *d, float *e, int m, float *w, int *iblock, int *isplit, complex *z, int ldz, int *ifail, int *info);
```

```
void cstein_64(long n, float *d, float *e, long m, float *w, long *iblock, long *isplit, complex *z, long ldz, long *ifail, long
```

*info);

PURPOSE

cstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Although the eigenvectors are real, they are stored in a complex array, which may be passed to CUNMTR or CUPMTR for back

transformation to the eigenvectors of a complex Hermitian matrix which was reduced to tridiagonal form.

ARGUMENTS

*** N (input)**

The order of the matrix. $N \geq 0$.

*** D (input)**

The n diagonal elements of the tridiagonal matrix T.

*** E (input)**

The (n-1) subdiagonal elements of the tridiagonal matrix T, stored in elements 1 to N-1; E(N) need not be set.

*** M (input)**

The number of eigenvectors to be found. $0 \leq M \leq N$.

*** W (input)**

The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBSZ with ORDER = 'B' is expected here.)

*** IBLOCK (input)**

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBSZ is expected here.)

*** ISPLIT (input)**

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBSZ is expected here.)

*** Z (output)**

The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations. The imaginary parts of the eigenvectors are set to zero.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq \max(1,N)$.

*** WORK (workspace)**

dimension(5*N)

* ***IWORK*** (*workspace*)

dimension(N)

* ***IFAIL*** (*output*)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

* ***INFO*** (*output*)

NAME

csteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```
SUBROUTINE CSTEQR( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
COMPLEX Z(LDZ,*)
INTEGER N, LDZ, INFO
REAL D(*), E(*), WORK(*)
```

```
SUBROUTINE CSTEQR_64( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
COMPLEX Z(LDZ,*)
INTEGER*8 N, LDZ, INFO
REAL D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEQR( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
COMPLEX, DIMENSION(:,*) :: Z
INTEGER :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
```

```
SUBROUTINE STEQR_64( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
COMPLEX, DIMENSION(:,*) :: Z
INTEGER(8) :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csteqr(char compz, int n, float *d, float *e, complex *z, int ldz, int *info);
```

```
void csteqr_64(char compz, long n, float *d, float *e, complex *z, long ldz, long *info);
```

PURPOSE

csteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if $COMPZ = 'V'$, then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if $INFO = 0$, then if $COMPZ = 'V'$, Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if $COMPZ = 'I'$, Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $COMPZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if eigenvectors are desired, then $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

If $COMPZ = 'N'$, then WORK is not referenced.

* **INFO** (*output*)

NAME

cstsv - compute the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix

SYNOPSIS

```
SUBROUTINE CSTSV( N, NRHS, L, D, SUBL, B, LDB, IPIV, INFO)
COMPLEX L(*), D(*), SUBL(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO

```
void cstsv(int n, int nrhs, complex *l, complex *d, complex *subl, complex *b, int ldb, int *ipiv, int *info);
```

```
void cstsv_64(long n, long nrhs, complex *l, complex *d, complex *subl, complex *b, long ldb, long *ipiv, long *info);
```

PURPOSE

cstsv computes the solution to a complex system of linear equations $A * X = B$ where A is a Hermitian tridiagonal matrix.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides in B.

*** L (input/output)**

COMPLEX array, dimension (N)

On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

*** D (input/output)**

REAL array, dimension (N)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

*** SUBL (output)**

COMPLEX array, dimension (N)

On exit, part of the factorization of A.

*** B (input/output)**

The columns of B contain the right hand sides.

*** LDB (input)**

The leading dimension of B as specified in a type or DIMENSION statement.

*** IPIV (output)**

INTEGER array, dimension (N)

On exit, the pivot indices of the factorization.

*** INFO (output)**

INTEGER

NAME

csstrf - compute the factorization of a complex Hermitian tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE CSTTRF( N, L, D, SUBL, IPIV, INFO)
COMPLEX L(*), D(*), SUBL(*)
INTEGER N, INFO
INTEGER IPIV(*)
```

```
SUBROUTINE CSTTRF_64( N, L, D, SUBL, IPIV, INFO)

COMPLEX, DIMENSION(:) :: L, D, SUBL
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csstrf(int n, complex *l, complex *d, complex *subl, int *ipiv, int *info);
```

```
void csstrf_64(long n, complex *l, complex *d, complex *subl, long *ipiv, long *info);
```

PURPOSE

csttrf computes the $L^*D^*L^{**}H$ factorization of a complex Hermitian tridiagonal matrix A.

ARGUMENTS

*** *N* (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** *L* (input/output)**

COMPLEX array, dimension (N)

On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

*** *D* (input/output)**

REAL array, dimension (N)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

*** *SUBL* (output)**

COMPLEX array, dimension (N)

On exit, part of the factorization of A.

*** *IPIV* (output)**

INTEGER array, dimension (N)

On exit, the pivot indices of the factorization.

*** *INFO* (output)**

INTEGER

NAME

csstrs - computes the solution to a complex system of linear equations $A * X = B$

SYNOPSIS

```
SUBROUTINE CSTTRS( N, NRHS, L, D, SUBL, B, LDB, IPIV, INFO)
COMPLEX L(*), D(*), SUBL(*), B(LDB,*)
INTEGER N, NRHS, LDB, INFO

INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csstrs(int n, int nrhs, complex *l, complex *d, complex *subl, complex *b, int ldb, int *ipiv, int *info);
```

```
void csstrs_64(long n, long nrhs, complex *l, complex *d, complex *subl, complex *b, long ldb, long *ipiv, long *info);
```

PURPOSE

csttrs computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

*** N (input)**

INTEGER

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

INTEGER

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** L (input)**

COMPLEX array, dimension (N-1)

On entry, the subdiagonal elements of LL and DD.

*** D (input)**

COMPLEX array, dimension (N)

On entry, the diagonal elements of DD.

*** SUBL (input)**

COMPLEX array, dimension (N-2)

On entry, the second subdiagonal elements of LL.

*** B (input/output)**

COMPLEX array, dimension (LDB, NRHS)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

INTEGER

The leading dimension of the array B. $LDB \geq \max(1, N)$

*** IPIV (output)**

INTEGER array, dimension (N)

Details of the interchanges and block pivot. If IPIV(K) > 0, 1 by 1 pivot, and if IPIV(K) = K + 1 an interchange done; If IPIV(K) < 0, 2 by 2 pivot, no interchange required.

*** INFO (output)**

INTEGER

NAME

csvdc - (obsolete) compute the singular value decomposition of a general matrix A.

SYNOPSIS

```
SUBROUTINE CSVDC( A, LDA, N, P, SVALS, E, LSVEC, LDL, RSVEC, LDR,  
*   WORK, JOB, INFO)  
COMPLEX A(LDA,*), SVALS(*), E(*), LSVEC(LDL,*), RSVEC(LDR,*), WORK(*)  
INTEGER LDA, N, P, LDL, LDR, JOB, INFO
```

```
SUBROUTINE CSVDC_64( A, LDA, N, P, SVALS, E, LSVEC, LDL, RSVEC, LDR,  
*   WORK, JOB, INFO)  
COMPLEX A(LDA,*), SVALS(*), E(*), LSVEC(LDL,*), RSVEC(LDR,*), WORK(*)  
INTEGER*8 LDA, N, P, LDL, LDR, JOB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csvdc(complex *a, int lda, int n, int p, complex *svals, complex *e, complex *lsvec, int ldl, complex *rsvec, int ldr, int job, int *info);
```

```
void csvdc_64(complex *a, long lda, long n, long p, complex *svals, complex *e, complex *lsvec, long ldl, complex *rsvec, long ldr, long job, long *info);
```

ARGUMENTS

*** A (input/output)**

Matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows of the matrix A. $N \geq 0$.

*** P (input)**

Number of columns of the matrix A. $P \geq 0$.

*** SVALS (output)**

On exit, the singular values of A arranged in descending order of magnitude.

*** E (output)**

On exit, normally contains zero, but see INFO below.

*** LSVEC (input/output)**

On exit, the matrix of left singular vectors; not referenced if the a digit of JOB = 0.

*** LDL (input)**

Leading dimension of LSVEC as specified in a dimension or type statement. $LDL \geq \max(1, N)$.

*** RSVEC (input/output)**

On exit, the matrix of right singular vectors; not referenced if the b digit of JOB = 0.

*** LDR (input)**

Leading dimension of RSVEC as specified in a dimension or type statement. $LDR \geq \max(1, P)$.

*** WORK (workspace)**

Scratch array with a dimension of N.

*** JOB (input)**

Integer in the form ab; determines operation subroutine will perform:

a = 0	do not compute the left singular vectors
a = 1	return the n left singular vectors in LSVEC
a * 2	return the first min(N,P) singular vectors in LSVEC
b = 0	do not compute the right singular vectors
b = 1	return the right singular vectors in RSVEC

*** INFO (output)**

On exit, the singular values and their corresponding singular vectors $SVALS(INFO+1)$, $SVALS(INFO+2), \dots, SVALS(\min(N, P))$ are correct. If $INFO = 0$ then all singular values and singular vectors are correct. The matrix B defined as $LSVECT * A * RSVEC$ is the bidiagonal matrix with S on its diagonal and E on its superdiagonal. Therefore the singular values of A and B are the same.

NAME

cswap - Exchange vectors x and y.

SYNOPSIS

```
SUBROUTINE CSWAP( N, X, INCX, Y, INCY)
COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
```

```
SUBROUTINE CSWAP_64( N, X, INCX, Y, INCY)
COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE SWAP( [N], X, [INCX], Y, [INCY])
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
```

```
SUBROUTINE SWAP_64( [N], X, [INCX], Y, [INCY])
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cswap(int n, complex *x, int incx, complex *y, int incy);
```

```
void cswap_64(long n, complex *x, long incx, complex *y, long incy);
```

PURPOSE

cswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input/output)*

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, the y vector.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

(1 + (m - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

csycon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by CSYTRF

SYNOPSIS

```
SUBROUTINE CSYCON( UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,
*                INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
INTEGER IPIVOT(*)
REAL ANORM, RCOND

SUBROUTINE CSYCON_64( UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,
*                   INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIVOT(*)
REAL ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE SYCON( UPLO, [N], A, [LDA], IPIVOT, ANORM, RCOND, [WORK],
*               [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND

SUBROUTINE SYCON_64( UPLO, [N], A, [LDA], IPIVOT, ANORM, RCOND,
*                  [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csycon(char uplo, int n, complex *a, int lda, int *ipivot, float anorm, float *rcond, int *info);
```

```
void csycon_64(char uplo, long n, complex *a, long lda, long *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

csycon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by CSYTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSYTRF.

* **ANORM** (*input*)

The 1-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **INFO** (*output*)

NAME

csymm - perform one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$

SYNOPSIS

```
SUBROUTINE CSYMM( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
*             LDC)
CHARACTER * 1 SIDE, UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER M, N, LDA, LDB, LDC

SUBROUTINE CSYMM_64( SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA,
*             C, LDC)
CHARACTER * 1 SIDE, UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 M, N, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE SYMM( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*             BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER :: M, N, LDA, LDB, LDC

SUBROUTINE SYMM_64( SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
*             BETA, C, [LDC])
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER(8) :: M, N, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csymm(char side, char uplo, int m, int n, complex alpha, complex *a, int lda, complex *b, int ldb, complex beta,
complex *c, int ldc);
```

```
void csymm_64(char side, char uplo, long m, long n, complex alpha, complex *a, long lda, complex *b, long ldb, complex
```

beta, complex *c, long ldc);

PURPOSE

csymm performs one of the matrix-matrix operations $C := \alpha * A * B + \beta * C$ or $C := \alpha * B * A + \beta * C$ where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

* *SIDE* (input)

On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l' $C := \alpha * A * B + \beta * C$,

SIDE = 'R' or 'r' $C := \alpha * B * A + \beta * C$,

Unchanged on exit.

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix C. $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix C. $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'I' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, n)$. Unchanged on exit.

*** B (input)**

Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. $LDB \geq \max(1, m)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

*** C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

NAME

csyr2k - perform one of the symmetric rank 2k operations $C := \alpha A B' + \alpha B A' + \beta C$ or $C := \alpha A' B + \alpha B' A + \beta C$

SYNOPSIS

```
SUBROUTINE CSYR2K( UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB, BETA,
*      C, LDC)
CHARACTER * 1 UPLO, TRANSA
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER N, K, LDA, LDB, LDC

SUBROUTINE CSYR2K_64( UPLO, TRANSA, N, K, ALPHA, A, LDA, B, LDB,
*      BETA, C, LDC)
CHARACTER * 1 UPLO, TRANSA
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 N, K, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE SYR2K( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B, [LDB],
*      BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER :: N, K, LDA, LDB, LDC

SUBROUTINE SYR2K_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,
*      [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER(8) :: N, K, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csyr2k(char uplo, char transa, int n, int k, complex alpha, complex *a, int lda, complex *b, int ldb, complex beta, complex *c, int ldc);
```

void csyr2k_64(char uplo, char transa, long n, long k, complex *a, long lda, complex *b, long ldb, complex beta, complex *c, long ldc);

PURPOSE

csyr2k K performs one of the symmetric rank 2k operations $C := \alpha * A * B' + \alpha * B * A' + \beta * C$ or $C := \alpha * A * B + \alpha * B' * A + \beta * C$ where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $C := \alpha * A * B' + \alpha * B * A' + \beta * C$.

TRANSA = 'T' or 't' $C := \alpha * A * B + \alpha * B' * A + \beta * C$.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *B* (input)

k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

* **LDB** (*input*)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least $\max(1, n)$, otherwise LDB must be at least $\max(1, k)$. Unchanged on exit.

* **BETA** (*input*)

On entry, BETA specifies the scalar beta. Unchanged on exit.

* **C** (*input/output*)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

* **LDC** (*input*)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

NAME

csyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE CSYRFS( UPLO, N, NRHS, A, LDA, AF, LDAF, IPIVOT, B, LDB,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void csyrfs(char uplo, int n, int nrhs, complex *a, int lda, complex *af, int ldaf, int *ipivot, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void csyrfs_64(char uplo, long n, long nrhs, complex *a, long lda, complex *af, long ldaf, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

csyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The symmetric matrix A. If **UPLO** = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If **UPLO** = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{*T}$ or $A = L * D * L^{*T}$ as computed by CSYTRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSYTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by CSYTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

csyrk - perform one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$

SYNOPSIS

```
SUBROUTINE SYRK_64( UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
* C, [LDC])
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,*) :: A, C
INTEGER(8) :: N, K, LDA, LDC
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csyrk(char uplo, char transa, int n, int k, complex alpha, complex *a, int lda, complex beta, complex *c, int ldc);
```

```
void csyrk_64(char uplo, char transa, long n, long k, complex alpha, complex *a, long lda, complex beta, complex *c, long ldc);
```

PURPOSE

csyrk performs one of the symmetric rank k operations $C := \alpha * A * A' + \beta * C$ or $C := \alpha * A' * A + \beta * C$ where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' $C := \alpha * A * A' + \beta * C$.

TRANS = 'T' or 't' $C := \alpha * A' * A + \beta * C$.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry with TRANS = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANS = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANS = 'N' or 'n', and is n otherwise. Before entry with TRANS = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANS = 'N' or 'n' then LDA must be at least $\max(1, n)$, otherwise LDA must be at least $\max(1, k)$. Unchanged on exit.

* *BETA* (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

* *C* (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

* **LDC** (*input*)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least $\max(1, n)$. Unchanged on exit.

CHARACTER(LEN=1) :: UPLO  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:,) :: A, B  
INTEGER(8) :: N, NRHS, LDA, LDB, LWORK, INFO  
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csysv(char uplo, int n, int nrhs, complex *a, int lda, int *ipiv, complex *b, int ldb, int *info);
```

```
void csysv_64(char uplo, long n, long nrhs, complex *a, long lda, long *ipiv, complex *b, long ldb, long *info);
```

PURPOSE

csysv computes the solution to a complex system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**T}, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * D * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by CSYTRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIV (output)**

Details of the interchanges and the block structure of D, as determined by CSYTRF. If $IPIV(k) > 0$, then rows and columns k and $IPIV(k)$ were interchanged, and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIV(k) = IPIV(k-1) < 0$, then rows and columns k-1 and $-IPIV(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIV(k) = IPIV(k+1) < 0$, then rows and columns k+1 and $-IPIV(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK** (*input*)

The length of WORK. LWORK ≥ 1 , and for best performance LWORK $\geq N \cdot NB$, where NB is the optimal blocksize for CSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void csysvx(char fact, char uplo, int n, int nrhs, complex *a, int lda, complex *af, int ldaf, int *ipivot, complex *b, int ldb, complex *x, int ldx, float *rcond, float *ferr, float *berr, int *info);
```

```
void csysvx_64(char fact, char uplo, long n, long nrhs, complex *a, long lda, complex *af, long ldaf, long *ipivot, complex *b, long ldb, complex *x, long ldx, float *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

csysvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations $A * X = B$, where A is an N -by- N symmetric matrix and X and B are N -by- $NRHS$ matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If $FACT = 'N'$, the diagonal pivoting method is used to factor A . The form of the factorization is

```
A = U * D * U**T,  if UPLO = 'U', or
A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices, and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with $INFO = i$. Otherwise, the factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, $INFO = N+1$ is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A .

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* ***FACT*** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* ***UPLO*** (*input*)

* ***N*** (*input*)

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* ***NRHS*** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS \geq 0.

*** A (input)**

The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

*** LDA (input)**

The leading dimension of the array A. LDA \geq max(1,N).

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ as computed by CSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$.

*** LDAF (input)**

The leading dimension of the array AF. LDAF \geq max(1,N).

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSYTRF. If IPIVOT(k) $>$ 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) $<$ 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) $<$ 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CSYTRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. LDB \geq max(1,N).

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. LDX \geq max(1,N).

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO $>$ 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The length of WORK. LDWORK $\geq 2*N$, and for best performance LDWORK $\geq N*NB$, where NB is the optimal blocksize for CSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

csytf2 - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```
SUBROUTINE CSYTF2( UPLO, N, A, LDA, IPIV, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER N, LDA, INFO

CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE SYTF2( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
```

```
SUBROUTINE SYTF2_64( UPLO, [N], A, [LDA], IPIV, [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,*) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csytf2(char uplo, int n, complex *a, int lda, int *ipiv, int *info);
```

```
void csytf2_64(char uplo, long n, complex *a, long lda, long *ipiv, long *info);
```

PURPOSE

csytf2 computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U' \quad \text{or} \quad A = L^*D^*L'$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIV (output)**

Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k, k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1, k:k+1) is a 2-by-2 diagonal block.

*** INFO (output)**

```

```
void csytrf_64(char uplo, long n, complex *a, long lda, long *ipivot, long *info);
```

PURPOSE

csytrf computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

$$A = U * D * U^{**T} \quad \text{or} \quad A = L * D * L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A . If $UPLO = 'U'$, the leading N -by- N upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N -by- N lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

*** LDA (input)**

The leading dimension of the array A . $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D . If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged and $D(k, k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns $k-1$ and $-IPIVOT(k)$ were interchanged and $D(k-1:k, k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns $k+1$ and $-IPIVOT(k)$ were interchanged and $D(k:k+1, k:k+1)$ is a 2-by-2 diagonal block.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

*** LDWORK (input)**

The length of $WORK$. $LDWORK \geq 1$. For best performance $LDWORK \geq N * NB$, where NB is the block size returned by $ILAENV$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

*** INFO (output)**

NAME

csytri - compute the inverse of a complex symmetric indefinite matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by CSYTRF

SYNOPSIS

```
SUBROUTINE CSYTRI( UPLO, N, A, LDA, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
INTEGER IPIVOT(*)
```

```
SUBROUTINE CSYTRI_64( UPLO, N, A, LDA, IPIVOT, WORK, INFO)

INTEGER*8 IPIVOT(*)
```

F95 INTERFACE

```
SUBROUTINE SYTRI( UPLO, [N], A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
SUBROUTINE SYTRI_64( UPLO, [N], A, [LDA], IPIVOT, [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csytri(char uplo, int n, complex *a, int lda, int *ipivot, int *info);
```

```
void csytri_64(char uplo, long n, complex *a, long lda, long *ipivot, long *info);
```

PURPOSE

csytri computes the inverse of a complex symmetric indefinite matrix A using the factorization $A = U^*D^*U^{**T}$ or $A = L^*D^*L^{**T}$ computed by CSYTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input/output*)

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if $INFO = 0$, the (symmetric) inverse of the original matrix. If $UPLO = 'U'$, the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if $UPLO = 'L'$ the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSYTRF.

* **WORK** (*workspace*)

dimension($2*N$)

* **INFO** (*output*)

NAME

csytrs - solve a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A using the factorization $A = U \cdot D \cdot U^* \cdot T$ or $A = L \cdot D \cdot L^* \cdot T$ computed by CSYTRF

SYNOPSIS

```
SUBROUTINE CSYTRS( UPLO, N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)

```
void csytrs(char uplo, int n, int nrhs, complex *a, int lda, int *ipivot, complex *b, int ldb, int *info);
```

```
void csytrs_64(char uplo, long n, long nrhs, complex *a, long lda, long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

csytrs solves a system of linear equations $A \cdot X = B$ with a complex symmetric matrix A using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by CSYTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by CSYTRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

ctbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE CTBCON( NORM, UPLO, DIAG, N, NDIAG, A, LDA, RCOND, WORK,  
*      WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
COMPLEX A(LDA,*), WORK(*)  
INTEGER N, NDIAG, LDA, INFO  
REAL RCOND  
REAL WORK2(*)
```

```
SUBROUTINE CTBCON_64( NORM, UPLO, DIAG, N, NDIAG, A, LDA, RCOND,  
*      WORK, WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, NDIAG, LDA, INFO  
REAL RCOND  
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TBCON( NORM, UPLO, DIAG, [N], NDIAG, A, [LDA], RCOND,  
*      [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, NDIAG, LDA, INFO  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE TBCON_64( NORM, UPLO, DIAG, [N], NDIAG, A, [LDA], RCOND,  
*      [WORK], [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, NDIAG, LDA, INFO  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctbcon(char norm, char uplo, char diag, int n, int ndiag, complex *a, int lda, float *rcond, int *info);
```

```
void ctbcon_64(char norm, char uplo, char diag, long n, long ndiag, complex *a, long lda, float *rcond, long *info);
```

PURPOSE

ctbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension($2*N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

ctbmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE CTBMV( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER N, NDIAG, LDA, INCY
```

```
SUBROUTINE CTBMV_64( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, NDIAG, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBMV( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INCY
```

```
SUBROUTINE TBMV_64( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctbmv(char uplo, char transa, char diag, int n, int ndiag, complex *a, int lda, complex *y, int incy);
```

```
void ctbmv_64(char uplo, char transa, char diag, long n, long ndiag, complex *a, long lda, complex *y, long incy);
```

PURPOSE

ctbmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the operation to be performed as follows:

TRANS = 'N' or 'n' $x := A*x$.

TRANS = 'T' or 't' $x := A'*x$.

TRANS = 'C' or 'c' $x := \text{conjg}(A')*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
DO 20, J = 1, N
  = NDIAG + 1 - J
O 10, I = MAX( 1, J - NDIAG ), J
  A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
    O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

ctbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

SYNOPSIS

```

```
void ctbrfs(char uplo, char transa, char diag, int n, int ndiag, int nrhs, complex *a, int lda, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void ctbrfs_64(char uplo, char transa, char diag, long n, long ndiag, long nrhs, complex *a, long lda, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

ctbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by CTBTRS or some other means before entering this routine. CTBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

ctbsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

SYNOPSIS

```
SUBROUTINE CTBSV( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER N, NDIAG, LDA, INCY
```

```
SUBROUTINE CTBSV_64( UPLO, TRANSA, DIAG, N, NDIAG, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, NDIAG, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBSV( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, NDIAG, LDA, INCY

```
SUBROUTINE TBSV_64( UPLO, [TRANSA], DIAG, [N], NDIAG, A, [LDA], Y,
*             [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, NDIAG, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctbsv(char uplo, char transa, char diag, int n, int ndiag, complex *a, int lda, complex *y, int incy);
```

```
void ctbsv_64(char uplo, char transa, char diag, long n, long ndiag, complex *a, long lda, complex *y, long incy);
```

PURPOSE

ctbsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with $(k + 1)$ diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' $A*x = b$.

TRANSA = 'T' or 't' $A'*x = b$.

TRANSA = 'C' or 'c' $\text{conjg}(A')*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry with UPLO = 'U' or 'u', NDIAG specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', NDIAG specifies the number of sub-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k , and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NDIAG + 1 - J
      O 10, I = MAX( 1, J - NDIAG ), J
```

```
A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N  
        = 1 - J  
      O 10, I = J, MIN( N, J + NDIAG )  
        A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA \geq (k + 1). Unchanged on exit.

*** Y (input/output)**

(1 + (n - 1) * abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

NAME

```

```
void ctbtrs_64(char uplo, char transa, char diag, long n, long ndiag, long nrhs, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

ctbtrs solves a triangular system of the form

where A is a triangular band matrix of order N , and B is an N -by- $NRHS$ matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals or subdiagonals of the triangular band matrix A . $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular band matrix A , stored in the first $kd+1$ rows of A . The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. If $DIAG = 'U'$, the diagonal elements of A are not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, if $INFO = 0$, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

ctgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B)

REAL, DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctgevc(char side, char howmny, logical *select, int n, complex *a, int lda, complex *b, int ldb, complex *vl, int ldvl, complex *vr, int ldvr, int mm, int *m, int *info);
```

```
void ctgevc_64(char side, char howmny, logical *select, long n, complex *a, long lda, complex *b, long ldb, complex *vl, long ldvl, complex *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

ctgevc computes some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

$$(A - wB) * x = 0 \quad \text{and} \quad y^{*H} * (A - wB) = 0$$

where y^{*H} denotes the conjugate transpose of y .

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products $Z*X$ and/or $Q*Y$, where Z and Q are input unitary matrices. If (A,B) was obtained from the generalized Schur factorization of an original pair of matrices

$$(A0, B0) = (Q*A*Z^{*H}, Q*B*Z^{*H}),$$

then $Z*X$ and $Q*Y$ are the matrices of right or left eigenvectors of A.

ARGUMENTS

* *SIDE* (input)

* *HOWMNY* (input)

* *SELECT* (input)

If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *A* (input)

The upper triangular matrix A.

* *LDA* (input)

The leading dimension of array A. $LDA \geq \max(1,N)$.

* ***B (input)***

The upper triangular matrix B. B must have real diagonal elements.

* ***LDB (input)***

The leading dimension of array B. $LDB \geq \max(1,N)$.

* ***VL (input/output)***

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of left Schur vectors returned by CHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q^*Y ; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

* ***LDVL (input)***

The leading dimension of array VL. $LDVL \geq \max(1,N)$ if SIDE = 'L' or 'B'; $LDVL \geq 1$ otherwise.

* ***VR (input/output)***

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Z of right Schur vectors returned by CHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z^*X ; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

* ***LDVR (input)***

The leading dimension of the array VR. $LDVR \geq \max(1,N)$ if SIDE = 'R' or 'B'; $LDVR \geq 1$ otherwise.

* ***MM (input)***

The number of columns in the arrays VL and/or VR. $MM \geq M$.

* ***M (output)***

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

* ***WORK (workspace)***

dimension($2*N$)

* ***RWORK (workspace)***

dimension($2*N$)

* ***INFO (output)***

NAME

ctgexc - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST

SYNOPSIS

```
SUBROUTINE CTGEXC( WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z, LDZ,
*   IFST, ILST, INFO)
COMPLEX A(LDA,*), B(LDB,*), Q(LDQ,*), Z(LDZ,*)
INTEGER N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL WANTQ, WANTZ
```

```
SUBROUTINE CTGEXC_64( WANTQ, WANTZ, N, A, LDA, B, LDB, Q, LDQ, Z,
*   LDZ, IFST, ILST, INFO)
COMPLEX A(LDA,*), B(LDB,*), Q(LDQ,*), Z(LDZ,*)
INTEGER*8 N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL*8 WANTQ, WANTZ
```

F95 INTERFACE

```
SUBROUTINE TGEXC( WANTQ, WANTZ, [N], A, [LDA], B, [LDB], Q, [LDQ],
*   Z, [LDZ], IFST, ILST, [INFO])
COMPLEX, DIMENSION(:,*) :: A, B, Q, Z
INTEGER :: N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL :: WANTQ, WANTZ
```

```
SUBROUTINE TGEXC_64( WANTQ, WANTZ, [N], A, [LDA], B, [LDB], Q, [LDQ],
*   Z, [LDZ], IFST, ILST, [INFO])
COMPLEX, DIMENSION(:,*) :: A, B, Q, Z
INTEGER(8) :: N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL(8) :: WANTQ, WANTZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctgexc(logical wantq, logical wantz, int n, complex *a, int lda, complex *b, int ldb, complex *q, int ldq, complex *z, int ldz, int *ifst, int *ilst, int *info);
```

```
void ctgexc_64(logical wantq, logical wantz, long n, complex *a, long lda, complex *b, long ldb, complex *q, long ldq, complex *z, long ldz, long *ifst, long *ilst, long *info);
```

PURPOSE

ctgexc reorders the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation $(A, B) := Q * (A, B) * Z'$, so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

$$\begin{aligned} Q(\text{in}) * A(\text{in}) * Z(\text{in})' &= Q(\text{out}) * A(\text{out}) * Z(\text{out})' \\ Q(\text{in}) * B(\text{in}) * Z(\text{in})' &= Q(\text{out}) * B(\text{out}) * Z(\text{out})' \end{aligned}$$

ARGUMENTS

*** WANTQ (input)**

.TRUE. : update the left transformation matrix Q;

.FALSE.: do not update Q.

*** WANTZ (input)**

.TRUE. : update the right transformation matrix Z;

.FALSE.: do not update Z.

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the upper triangular matrix A in the pair (A, B). On exit, the updated matrix A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** B (input/output)**

On entry, the upper triangular matrix B in the pair (A, B). On exit, the updated matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** Q (input/output)**

On entry, if WANTQ = .TRUE., the unitary matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$; If WANTQ = .TRUE., $LDQ \geq N$.

*** Z (input/output)**

On entry, if WANTZ = .TRUE., the unitary matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$; If WANTZ = .TRUE., $LDZ \geq N$.

*** IFST (input/output)**

Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks.

* ***ILST*** (*input/output*)

See the description of IFST.

* ***INFO*** (*output*)

NAME

ctgsen - reorder the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence transformation $Q^*(A, B)Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B)

SYNOPSIS

```

```

PURPOSE

ctgsen reorders the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of a unitary equivalence transformation $Q' * (A, B) * Z$), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B). The leading columns of Q and Z form unitary bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

CTGSEN also computes the generalized eigenvalues

$$w(j) = \text{ALPHA}(j) / \text{BETA}(j)$$

of the reordered matrix pair (A, B).

Optionally, the routine computes estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are $\text{Difu}[(A_{11}, B_{11}), (A_{22}, B_{22})]$ and $\text{Difl}[(A_{11}, B_{11}), (A_{22}, B_{22})]$, i.e. the separation(s) between the matrix pairs (A₁₁, B₁₁) and (A₂₂, B₂₂) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

* IJOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):

* WANTQ (input)

.TRUE. : update the left transformation matrix Q;

.FALSE.: do not update Q.

* **WANTZ (input)**

.TRUE. : update the right transformation matrix Z;

.FALSE.: do not update Z.

* **SELECT (input)**

SELECT specifies the eigenvalues in the selected cluster. To select an eigenvalue $w(j)$, SELECT(j) must be set to .TRUE..

* **N (input)**

The order of the matrices A and B. $N \geq 0$.

* **A (input/output)**

On entry, the upper triangular matrix A, in generalized Schur canonical form. On exit, A is overwritten by the reordered matrix A.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B (input/output)**

On entry, the upper triangular matrix B, in generalized Schur canonical form. On exit, B is overwritten by the reordered matrix B.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **ALPHA (output)**

The diagonal elements of A and B, respectively, when the pair (A,B) has been reduced to generalized Schur form. ALPHA(i)/BETA(i) $i=1, \dots, N$ are the generalized eigenvalues.

* **BETA (output)**

See the description of ALPHA.

* **Q (input/output)**

On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

* **LDQ (input)**

The leading dimension of the array Q. $LDQ \geq 1$. If WANTQ = .TRUE., $LDQ \geq N$.

* **Z (input/output)**

On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$. If WANTZ = .TRUE., $LDZ \geq N$.

* **M (output)**

The dimension of the specified pair of left and right eigenspaces, (deflating subspaces) $0 \leq M \leq N$.

* **PL (output)**

IF IJOB = 1, 4, or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspace with respect to the selected cluster.

$0 < PL, PR \leq 1$. If $M = 0$ or $M = N$, $PL = PR = 1$. If IJOB = 0, 2, or 3 PL, PR are not referenced.

* **PR (output)**

See the description of PL.

* **DIF (output)**

If IJOB ≥ 2 , DIF(1:2) store the estimates of Difu and Difl.

If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on

Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl, computed using reversed communication with CLACON. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

* **WORK (workspace)**

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK \geq 1. If IJOB = 1, 2 or 4, LWORK \geq $2 * M * (N - M)$. If IJOB = 3 or 5, LWORK \geq $4 * M * (N - M)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK (input)**

The dimension of the array IWORK. LIWORK \geq 1. If IJOB = 1, 2 or 4, LIWORK \geq N+2; If IJOB = 3 or 5, LIWORK \geq MAX(N+2, $2 * M * (N - M)$);

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

NAME

ctgsja - compute the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B

```

PURPOSE

ctgsja computes the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine CGGSVP from a general M-by-N matrix A and P-by-N matrix B:

$$\begin{aligned} A &= \begin{matrix} & \begin{matrix} N-K-L & K & L \end{matrix} \\ \begin{matrix} K \\ L \\ M-K-L \end{matrix} & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \\ 0 & 0 & 0 \end{pmatrix} \end{matrix} \text{ if } M-K-L \geq 0; \\ A &= \begin{matrix} & \begin{matrix} N-K-L & K & L \end{matrix} \\ \begin{matrix} K \\ M-K \end{matrix} & \begin{pmatrix} 0 & A12 & A13 \\ 0 & 0 & A23 \end{pmatrix} \end{matrix} \text{ if } M-K-L < 0; \\ B &= \begin{matrix} & \begin{matrix} N-K-L & K & L \end{matrix} \\ \begin{matrix} L \\ P-L \end{matrix} & \begin{pmatrix} 0 & 0 & B13 \\ 0 & 0 & 0 \end{pmatrix} \end{matrix} \end{aligned}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if $M-K-L \geq 0$, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

$$U' * A * Q = D1 * \begin{pmatrix} 0 & R \end{pmatrix}, \quad V' * B * Q = D2 * \begin{pmatrix} 0 & R \end{pmatrix},$$

where U, V and Q are unitary matrices, Z' denotes the conjugate transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are "diagonal" matrices, which are of the following structures:

If $M-K-L \geq 0$,

$$\begin{aligned} D1 &= \begin{matrix} & \begin{matrix} K & L \end{matrix} \\ \begin{matrix} K \\ L \\ M-K-L \end{matrix} & \begin{pmatrix} I & 0 \\ 0 & C \\ 0 & 0 \end{pmatrix} \end{matrix} \\ D2 &= \begin{matrix} & \begin{matrix} K & L \end{matrix} \\ \begin{matrix} L \\ P-L \end{matrix} & \begin{pmatrix} 0 & S \\ 0 & 0 \end{pmatrix} \end{matrix} \\ \begin{pmatrix} 0 & R \end{pmatrix} &= \begin{matrix} & \begin{matrix} N-K-L & K & L \end{matrix} \\ \begin{matrix} K \\ L \end{matrix} & \begin{pmatrix} 0 & R11 & R12 \\ 0 & 0 & R22 \end{pmatrix} \end{matrix} \begin{matrix} K \\ L \end{matrix} \end{aligned}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(K+L)),$
 $S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(K+L)),$
 $C^{**2} + S^{**2} = I.$
 R is stored in $A(1:K+L, N-K-L+1:N)$ on exit.

If $M-K-L < 0,$

$$\begin{array}{l}
 D1 = \begin{array}{cccc} & K & M-K & K+L-M \\ K & (I & 0 & 0) \\ M-K & (0 & C & 0) \end{array} \\
 D2 = \begin{array}{cccc} & K & M-K & K+L-M \\ M-K & (0 & S & 0) \\ K+L-M & (0 & 0 & I) \\ P-L & (0 & 0 & 0) \\ & N-K-L & K & M-K & K+L-M \\ M-K & (0 & 0 & R22 & R23) \\ K+L-M & (0 & 0 & 0 & R33) \end{array}
 \end{array}$$

where

$C = \text{diag}(\text{ALPHA}(K+1), \dots, \text{ALPHA}(M)),$

$S = \text{diag}(\text{BETA}(K+1), \dots, \text{BETA}(M)),$

$C^{**2} + S^{**2} = I.$

$R = (R11 \ R12 \ R13)$ is stored in $A(1:M, N-K-L+1:N)$ and $R33$ is stored $(0 \ R22 \ R23)$
 in $B(M-K+1:L, N+M-K-L+1:N)$ on exit.

The computation of the unitary transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices $U1, V1,$ or $Q1.$

CTGSJA essentially uses a variant of Kogbetliantz algorithm to reduce $\min(L, M-K)$ -by- L triangular (or trapezoidal) matrix $A23$ and L -by- L matrix $B13$ to the form:

$$U1' * A13 * Q1 = C1 * R1; \quad V1' * B13 * Q1 = S1 * R1,$$

where $U1, V1$ and $Q1$ are unitary matrix, and Z' is the conjugate transpose of $Z.$ $C1$ and $S1$ are diagonal matrices satisfying

$$C1^{**2} + S1^{**2} = I,$$

and $R1$ is an L -by- L nonsingular upper triangular matrix.

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **K** (*input*)

K and L specify the subblocks in the input matrices A and B:

$A_{23} = A(K+1:\min(K+L,M), N-L+1:N)$ and $B_{13} = B(1:L, N-L+1:N)$ of A and B, whose GSVD is going to be computed by CTGSJA. See the Further Details section below.

* **L** (*input*)

See the description of K.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, $A(N-K+1:N, 1:\min(K+L,M))$ contains the triangular matrix R or part of R. See Purpose for details.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the P-by-N matrix B. On exit, if necessary, $B(M-K+1:L, N+M-K-L+1:N)$ contains a part of R. See Purpose for details.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, P)$.

* **TOLA** (*input*)

TOLA and TOLB are the convergence criteria for the Jacobi-Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say $TOLA = \max(M, N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P, N) * \text{norm}(B) * \text{MACHEPS}$.

* **TOLB** (*input*)

See the description of TOLA.

* **ALPHA** (*output*)

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$,

$BETA(1:K) = 0$, and if $M-K-L \geq 0$, $ALPHA(K+1:K+L) = \text{diag}(C)$,

$BETA(K+1:K+L) = \text{diag}(S)$, or if $M-K-L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$

$BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$. Furthermore, if $K+L < N$, $ALPHA(K+L+1:N) = 0$

$BETA(K+L+1:N) = 0$.

* **BETA** (*output*)

See the description of ALPHA.

* **U** (*input*)

On entry, if `JOBV = 'U'`, `U` must contain a matrix `U1` (usually the unitary matrix returned by `CGGSVP`). On exit, if `JOBV = 'I'`, `U` contains the unitary matrix `U`; if `JOBV = 'U'`, `U` contains the product `U1*U`. If `JOBV = 'N'`, `U` is not referenced.

* ***LDU (input)***

The leading dimension of the array `U`. `LDU` \geq `max(1,M)` if `JOBV = 'U'`; `LDU` \geq 1 otherwise.

* ***V (input)***

On entry, if `JOBV = 'V'`, `V` must contain a matrix `V1` (usually the unitary matrix returned by `CGGSVP`). On exit, if `JOBV = 'I'`, `V` contains the unitary matrix `V`; if `JOBV = 'V'`, `V` contains the product `V1*V`. If `JOBV = 'N'`, `V` is not referenced.

* ***LDV (input)***

The leading dimension of the array `V`. `LDV` \geq `max(1,P)` if `JOBV = 'V'`; `LDV` \geq 1 otherwise.

* ***Q (input)***

On entry, if `JOBQ = 'Q'`, `Q` must contain a matrix `Q1` (usually the unitary matrix returned by `CGGSVP`). On exit, if `JOBQ = 'I'`, `Q` contains the unitary matrix `Q`; if `JOBQ = 'Q'`, `Q` contains the product `Q1*Q`. If `JOBQ = 'N'`, `Q` is not referenced.

* ***LDQ (input)***

The leading dimension of the array `Q`. `LDQ` \geq `max(1,N)` if `JOBQ = 'Q'`; `LDQ` \geq 1 otherwise.

* ***WORK (workspace)***

`dimension(2*N)`

* ***NCYCLE (output)***

The number of cycles required for convergence.

* ***INFO (output)***

```

PURPOSE

ctgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B).

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):

*** HOWMNT (input)**

*** SELECT (input)**

If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the corresponding j-th eigenvalue and/or eigenvector, SELECT(j) must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

*** N (input)**

The order of the square matrix pair (A, B). $N \geq 0$.

*** A (input)**

The upper triangular matrix A in the pair (A,B).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input)**

The upper triangular matrix B in the pair (A, B).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** VL (input)**

If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CTGEVC. If JOB = 'V', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. $LDVL \geq 1$; and If JOB = 'E' or 'B', $LDVL \geq N$.

* **VR** (*input*)

If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CTGEVC. If JOB = 'V', VR is not referenced.

* **LDVR** (*input*)

The leading dimension of the array VR. LDVR ≥ 1 ; If JOB = 'E' or 'B', LDVR $\geq N$.

* **S** (*output*)

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If JOB = 'V', S is not referenced.

* **DIF** (*output*)

If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of Difl . If JOB = 'E', DIF is not referenced.

* **MM** (*input*)

The number of elements in the arrays S and DIF. MM $\geq M$.

* **M** (*output*)

The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected eigenvalue one element is used. If HOWMNT = 'A', M is set to N.

* **WORK** (*workspace*)

If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. LWORK ≥ 1 . If JOB = 'V' or 'B', LWORK $\geq 2*N*N$.

* **IWORK** (*workspace*)

If JOB = 'E', IWORK is not referenced.

* **INFO** (*output*)

```

```
void ctgsyl(char trans, int ijob, int m, int n, complex *a, int lda, complex *b, int ldb, complex *c, int ldc, complex *d, int ldd, complex *e, int lde, complex *f, int ldf, float *scale, float *dif, int *info);
```

```
void ctgsyl_64(char trans, long ijob, long m, long n, complex *a, long lda, complex *b, long ldb, complex *c, long ldc, complex *d, long ldd, complex *e, long lde, complex *f, long ldf, float *scale, float *dif, long *info);
```

PURPOSE

ctgsyl solves the generalized Sylvester equation:

$$\begin{aligned} A * R - L * B &= \text{scale} * C \\ D * R - L * E &= \text{scale} * F \end{aligned} \quad (1)$$

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with complex entries. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). $0 \leq \text{SCALE} \leq 1$

is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve $Zx = \text{scale} * b$, where Z is defined as

$$Z = \begin{bmatrix} \text{kron}(I_n, A) & -\text{kron}(B', I_m) \\ \text{kron}(I_n, D) & -\text{kron}(E', I_m) \end{bmatrix}, \quad (2)$$

Here I_x is the identity matrix of size x and X' is the conjugate transpose of X. $\text{Kron}(X, Y)$ is the Kronecker product between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system $Z' * y = \text{scale} * b$ is solved for, which is equivalent to solve for R and L in

$$\begin{aligned} A' * R + D' * L &= \text{scale} * C \\ R * B' + L * E' &= \text{scale} * -F \end{aligned} \quad (3)$$

This case (TRANS = 'C') is used to compute an one-norm-based estimate of $\text{Dif}[(A,D), (B,E)]$, the separation between the matrix pairs (A,D) and (B,E), using CLACON.

If IJOB ≥ 1 , CTGSYL computes a Frobenius norm-based estimate of $\text{Dif}[(A,D), (B,E)]$. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z.

This is a level-3 BLAS algorithm.

ARGUMENTS

* **TRANS** (*input*)

* **IJOB** (*input*)

Specifies what kind of functionality to be performed.

* **M** (*input*)

The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

* **N** (*input*)

The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

* **A** (*input*)

The upper triangular matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input*)

The upper triangular matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **C** (*input/output*)

On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **D** (*input*)

The upper triangular matrix D.

* **LDD** (*input*)

The leading dimension of the array D. $LDD \geq \max(1, M)$.

* **E** (*input*)

The upper triangular matrix E.

* **LDE** (*input*)

The leading dimension of the array E. $LDE \geq \max(1, N)$.

* **F** (*input/output*)

On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

* **LDF** (*input*)

The leading dimension of the array F. $LDF \geq \max(1, M)$.

* **SCALE** (*output*)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma\text{-min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

* **DIF** (*output*)

On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of $\text{Dif}[(A,D), (B,E)] = \sigma\text{-min}(Z)$, where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

* **WORK** (*workspace*)

If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO=0 then WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. LWORK >= 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

If IJOB = 0, IWORK is not referenced.

* **INFO** (*output*)

NAME

ctpccon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE CTPCON( NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM, UPLO, DIAG
COMPLEX A(*), WORK(*)
INTEGER N, INFO
REAL RCOND
REAL WORK2(*)
```

```
SUBROUTINE CTPCON_64( NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 NORM, UPLO, DIAG
COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
REAL RCOND
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON( NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
REAL :: RCOND
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE TPCON_64( NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
REAL :: RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctpcon(char norm, char uplo, char diag, int n, complex *a, float *rcond, int *info);
```

```
void ctpcon_64(char norm, char uplo, char diag, long n, complex *a, float *rcond, long *info);
```

PURPOSE

ctpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **UPLO** (*input*)

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

ctpmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$

SYNOPSIS

```
SUBROUTINE CTPMV( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(*), Y(*)
INTEGER N, INCY
```

```
SUBROUTINE CTPMV_64( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(*), Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPMV( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, Y
INTEGER :: N, INCY
```

```
SUBROUTINE TPMV_64( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctpmv(char uplo, char transa, char diag, int n, complex *a, complex *y, int incy);
```

```
void ctpmv_64(char uplo, char transa, char diag, long n, complex *a, complex *y, long incy);
```

PURPOSE

ctpmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A')*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A')*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(2,1)$ and $a(3,1)$ respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

* *Y* (input/output)

$(1 + (n-1)*\text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

ctprfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

SYNOPSIS

```
SUBROUTINE CTPRFS( UPLO, TRANSA, DIAG, N, NRHS, A, B, LDB, X, LDX,

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(*), B(LDB,*), X(LDX,*), WORK(*)
INTEGER*8 N, NRHS, LDB, LDX, INFO
REAL FERR(*), BERR(*), WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TPRFS( UPLO, [TRANSA], DIAG, N, [NRHS], A, B, [LDB], X,
*      [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, WORK
COMPLEX, DIMENSION(:, :) :: B, X
INTEGER :: N, NRHS, LDB, LDX, INFO
REAL, DIMENSION(:) :: FERR, BERR, WORK2

SUBROUTINE TPRFS_64( UPLO, [TRANSA], DIAG, N, [NRHS], A, B, [LDB],
*      X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, WORK
COMPLEX, DIMENSION(:, :) :: B, X
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctpfrs(char uplo, char transa, char diag, int n, int nrhs, complex *a, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void ctpfrs_64(char uplo, char transa, char diag, long n, long nrhs, complex *a, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

ctprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by CTPTRS or some other means before entering this routine. CTPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($2*N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

ctpsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$

SYNOPSIS

```
SUBROUTINE CTPSV( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(*), Y(*)
INTEGER N, INCY
```

```
SUBROUTINE CTPSV_64( UPLO, TRANSA, DIAG, N, A, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(*), Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPSV( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, Y
INTEGER :: N, INCY
```

```
SUBROUTINE TPSV_64( UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctpsv(char uplo, char transa, char diag, int n, complex *a, complex *y, int incy);
```

```
void ctpsv_64(char uplo, char transa, char diag, long n, complex *a, complex *y, long incy);
```

PURPOSE

ctpsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A)*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' $A*x = b$.

TRANS = 'T' or 't' $A'*x = b$.

TRANS = 'C' or 'c' $\text{conjg}(A)*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

$((n*(n+1))/2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(1,2)$ and $a(2,2)$ respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains $a(1,1)$, A(2) and A(3) contain $a(2,1)$ and $a(3,1)$ respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

* *Y* (input/output)

$(1 + (n-1)*\text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

ctptri - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE CTPTRI( UPLO, DIAG, N, A, INFO)
CHARACTER * 1 UPLO, DIAG
COMPLEX A(*)
INTEGER N, INFO
```

```
SUBROUTINE CTPTRI_64( UPLO, DIAG, N, A, INFO)
CHARACTER * 1 UPLO, DIAG
COMPLEX A(*)
INTEGER*8 N, INFO
```

F95 INTERFACE

```
SUBROUTINE TPTRI( UPLO, DIAG, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX, DIMENSION(:) :: A
INTEGER :: N, INFO
```

```
SUBROUTINE TPTRI_64( UPLO, DIAG, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX, DIMENSION(:) :: A
INTEGER(8) :: N, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctptri(char uplo, char diag, int n, complex *a, int *info);
```

```
void ctptri_64(char uplo, char diag, long n, complex *a, long *info);
```

PURPOSE

ctptri computes the inverse of a complex upper or lower triangular matrix A stored in packed format.

ARGUMENTS

* *UPLO* (*input*)

* *DIAG* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangular matrix A, stored columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*((2*n-j)/2)) = A(i,j)$ for $j \leq i \leq n$. See below for further details. On exit, the (triangular) inverse of the original matrix, in the same packed storage format.

* *INFO* (*output*)

NAME

ctptrs - solve a triangular system of the form $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

SYNOPSIS

```

```
void ctptrs_64(char uplo, char transa, char diag, long n, long nrhs, complex *a, complex *b, long ldb, long *info);
```

PURPOSE

ctptrs solves a triangular system of the form

where A is a triangular matrix of order N stored in packed format, and B is an N -by- $NRHS$ matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangular matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, if $INFO = 0$, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

ctrans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE CTRANS( PLACE, SCALE, SOURCE, M, N, DEST)
CHARACTER * 1 PLACE
COMPLEX SCALE
COMPLEX SOURCE(*), DEST(*)
INTEGER M, N
```

```
SUBROUTINE CTRANS_64( PLACE, SCALE, SOURCE, M, N, DEST)
CHARACTER * 1 PLACE
COMPLEX SCALE
COMPLEX SOURCE(*), DEST(*)
INTEGER*8 M, N
```

F95 INTERFACE

```
SUBROUTINE TRANS( [PLACE], SCALE, SOURCE, M, N, DEST)
CHARACTER(LEN=1) :: PLACE
COMPLEX :: SCALE
COMPLEX, DIMENSION(:) :: SOURCE, DEST
INTEGER :: M, N
```

```
SUBROUTINE TRANS_64( [PLACE], SCALE, SOURCE, M, N, DEST)
CHARACTER(LEN=1) :: PLACE
COMPLEX :: SCALE
COMPLEX, DIMENSION(:) :: SOURCE, DEST
INTEGER(8) :: M, N
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrans(char place, complex scale, complex *source, int m, int n, complex *dest);
```

```
void ctrans_64(char place, complex scale, complex *source, long m, long n, complex *dest);
```

PURPOSE

ctrans scales and transposes the source matrix. The $N_2 \times N_1$ result is written into SOURCE when PLACE = 'T' or 'i', and DEST when PLACE = 'O' or 'o'.

```
PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE '  
PLACE = 'O' or 'o': DEST = SCALE * SOURCE '
```

ARGUMENTS

* **PLACE** (*input*)

Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place.

* **SCALE** (*input*)

Scale factor on the SOURCE matrix.

* **SOURCE** (*input/output*)

on input. Array of (N, M) on output if in-place transpose.

* **M** (*input*)

Number of rows in the SOURCE matrix on input.

* **N** (*input*)

Number of columns in the SOURCE matrix on input.

* **DEST** (*output*)

Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

NAME

ctrco - (obsolete) estimate the condition number of a triangular matrix A. It is typical to follow a call to xTRCO with a call to xTRSL to solve $Ax = b$ or to xTRDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE CTRCO( A, LDA, N, RCOND, WORK, JOB)
COMPLEX A(LDA,*), WORK(*)
INTEGER LDA, N, JOB
REAL RCOND
```

```
SUBROUTINE CTRCO_64( A, LDA, N, RCOND, WORK, JOB)
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 LDA, N, JOB
REAL RCOND
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrco(complex *a, int lda, int n, float *rcond, int job);
```

```
void ctrco_64(complex *a, long lda, long n, float *rcond, long job);
```

ARGUMENTS

* **A** (*input/output*)

Matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

If $JOB = 0$, then A is lower triangular; otherwise A is upper triangular.

NAME

ctrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE CTRCON( NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,  
*      INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
COMPLEX A(LDA,*), WORK(*)  
INTEGER N, LDA, INFO  
REAL RCOND  
REAL WORK2(*)  
  
SUBROUTINE CTRCON_64( NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK,  
*      WORK2, INFO)  
CHARACTER * 1 NORM, UPLO, DIAG  
COMPLEX A(LDA,*), WORK(*)  
INTEGER*8 N, LDA, INFO  
REAL RCOND  
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON( NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER :: N, LDA, INFO  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK2  
  
SUBROUTINE TRCON_64( NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],  
*      [WORK2], [INFO])  
CHARACTER(LEN=1) :: NORM, UPLO, DIAG  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: A  
INTEGER(8) :: N, LDA, INFO  
REAL :: RCOND  
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrcon(char norm, char uplo, char diag, int n, complex *a, int lda, float *rcond, int *info);
```

```
void ctrcon_64(char norm, char uplo, char diag, long n, complex *a, long lda, float *rcond, long *info);
```

PURPOSE

ctrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for $\text{norm}(\text{inv}(A))$, then the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

*** NORM (input)**

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

*** UPLO (input)**

*** DIAG (input)**

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

dimension(N)

*** INFO (output)**

NAME

ctrdi - (obsolete) compute the determinant and inverse of a triangular matrix A.

SYNOPSIS

```
SUBROUTINE CTRDI( A, LDA, N, DET, JOB, INFO)
COMPLEX A(LDA,*), DET(*)
INTEGER LDA, N, JOB, INFO
```

```
SUBROUTINE CTRDI_64( A, LDA, N, DET, JOB, INFO)
COMPLEX A(LDA,*), DET(*)
INTEGER*8 LDA, N, JOB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrdi(complex *a, int lda, int n, complex *det, int job, int *info);
```

```
void ctrdi_64(complex *a, long lda, long n, complex *det, long job, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, the inverse of the original matrix A if the inverse was requested, otherwise unchanged.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10 ** \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) = 0.0$.

*** JOB (input)**

Determines which operation the subroutine will perform:

- o 010 no determinant, inverse of lower triangular A
- o 011 no determinant, inverse of upper triangular A
- o 100 determinant, no inverse

- 110 determinant, inverse of lower triangular A
- 111 determinant, inverse of upper triangular A

*** *INFO* (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Contains the index of a zero element of A if the inverse is requested and A is singular.

NAME

ctrevc - compute some or all of the right and/or left eigenvectors of a complex upper triangular matrix T

SYNOPSIS

```
SUBROUTINE CTREVC( SIDE, HOWMNY, SELECT, N, T, LDT, VL, LDVL, VR,  
* LDVR, MM, M, WORK, RWORK, INFO)

SUBROUTINE TREVC_64( SIDE, HOWMNY, SELECT, [N], T, [LDT], VL, [LDVL],  
* VR, [LDVR], MM, M, [WORK], [RWORK], [INFO])  
CHARACTER(LEN=1) :: SIDE, HOWMNY  
COMPLEX, DIMENSION(:) :: WORK  
COMPLEX, DIMENSION(:, :) :: T, VL, VR  
INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO  
LOGICAL(8), DIMENSION(:) :: SELECT  
REAL, DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrevc(char side, char howmny, logical *select, int n, complex *t, int ldt, complex *vl, int ldvl, complex *vr, int ldvr, int mm, int *m, int *info);
```

```
void ctrevc_64(char side, char howmny, logical *select, long n, complex *t, long ldt, complex *vl, long ldvl, complex *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

ctrevc computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

$$T*x = w*x, \quad y' * T = w*y'$$

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input unitary

matrix. If T was obtained from the Schur factorization of an original matrix $A = Q*T*Q'$, then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

ARGUMENTS

* *SIDE* (input)

* *HOWMNY* (input)

* *SELECT* (input/output)

If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

* *N* (input)

The order of the matrix T. $N \geq 0$.

* *T* (input/output)

The upper triangular matrix T. T is modified, but restored on exit.

* *LDT* (input)

The leading dimension of the array T. $LDT \geq \max(1, N)$.

* *VL* (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL is lower triangular. The i-th column VL(i) of VL is the eigenvector corresponding to $T(i, i)$. if HOWMNY = 'B', the matrix $Q*Y$; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

* **LDVL (input)**

The leading dimension of the array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

* **VR (input/output)**

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR is upper triangular. The i-th column VR(i) of VR is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

* **LDVR (input)**

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

* **MM (input)**

The number of columns in the arrays VL and/or VR. MM \geq M.

* **M (output)**

The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

* **WORK (workspace)**

dimension(2*N)

* **RWORK (workspace)**

dimension(N)

* **INFO (output)**

NAME

ctrexc - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that the diagonal element of T with row index IFST is moved to row ILST

SYNOPSIS

```
SUBROUTINE CTREXC( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)
CHARACTER * 1 COMPQ
COMPLEX T(LDT,*), Q(LDQ,*)
INTEGER N, LDT, LDQ, IFST, ILST, INFO
```

```
SUBROUTINE CTREXC_64( COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)
CHARACTER * 1 COMPQ
COMPLEX T(LDT,*), Q(LDQ,*)
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
```

F95 INTERFACE

```
SUBROUTINE TREXC( COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])
CHARACTER(LEN=1) :: COMPQ
COMPLEX, DIMENSION(:,*) :: T, Q
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO
```

```
SUBROUTINE TREXC_64( COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST,
* [INFO])
CHARACTER(LEN=1) :: COMPQ
COMPLEX, DIMENSION(:,*) :: T, Q
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrexc(char compq, int n, complex *t, int ldt, complex *q, int ldq, int ifst, int ilst, int *info);
```

```
void ctrexc_64(char compq, long n, complex *t, long ldt, complex *q, long ldq, long ifst, long ilst, long *info);
```

PURPOSE

ctrexc reorders the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that the diagonal element of T with row index $IFST$ is moved to row $ILST$.

The Schur form T is reordered by a unitary similarity transformation $Z^{**}H^*T^*Z$, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z .

ARGUMENTS

* *COMPQ (input)*

* *N (input)*

The order of the matrix T . $N \geq 0$.

* *T (input/output)*

On entry, the upper triangular matrix T . On exit, the reordered upper triangular matrix.

* *LDT (input)*

The leading dimension of the array T . $LDT \geq \max(1, N)$.

* *Q (input)*

On entry, if $COMPQ = 'V'$, the matrix Q of Schur vectors. On exit, if $COMPQ = 'V'$, Q has been postmultiplied by the unitary transformation matrix Z which reorders T . If $COMPQ = 'N'$, Q is not referenced.

* *LDQ (input)*

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

* *IFST (input)*

Specify the reordering of the diagonal elements of T : The element with row index $IFST$ is moved to row $ILST$ by a sequence of transpositions between adjacent elements. $1 \leq IFST \leq N$; $1 \leq ILST \leq N$.

* *ILST (input)*

See the description of $IFST$.

* *INFO (output)*

NAME

ctrmm - perform one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

SYNOPSIS

```
SUBROUTINE CTRMM( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
*              LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
COMPLEX ALPHA
COMPLEX A(LDA,*), B(LDB,*)
INTEGER M, N, LDA, LDB

SUBROUTINE CTRMM_64( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA,
*              B, LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
COMPLEX ALPHA
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 M, N, LDA, LDB
```

F95 INTERFACE

```
SUBROUTINE TRMM( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*              [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: M, N, LDA, LDB

SUBROUTINE TRMM_64( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*              [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrmm(char side, char uplo, char transa, char diag, int m, int n, complex alpha, complex *a, int lda, complex *b, int ldb);
```

```
void ctrmm_64(char side, char uplo, char transa, char diag, long m, long n, complex alpha, complex *a, long lda, complex *b, long ldb);
```

PURPOSE

ctrmm performs one of the matrix-matrix operations $B := \alpha * \text{op}(A) * B$, or $B := \alpha * B * \text{op}(A)$ where α is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of $\text{op}(A) = A$ or $\text{op}(A) = A'$ or $\text{op}(A) = \text{conjg}(A')$

ARGUMENTS

* *SIDE* (input)

On entry, *SIDE* specifies whether $\text{op}(A)$ multiplies B from the left or right as follows:

SIDE = 'L' or 'l' $B := \alpha * \text{op}(A) * B$.

SIDE = 'R' or 'r' $B := \alpha * B * \text{op}(A)$.

Unchanged on exit.

* *UPLO* (input)

On entry, *UPLO* specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, *TRANSA* specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' $\text{op}(A) = A$.

TRANSA = 'T' or 't' $\text{op}(A) = A'$.

TRANSA = 'C' or 'c' $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

* *DIAG* (input)

On entry, *DIAG* specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *M* (input)

On entry, *M* specifies the number of rows of B . $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of B. $N \geq 0$. Unchanged on exit.

* **ALPHA (input)**

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

* **A (input)**

when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

* **LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, M)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, N)$. Unchanged on exit.

* **B (input/output)**

Before entry, the leading M by N part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

* **LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB must be at least $\max(1, M)$. Unchanged on exit.

NAME

ctrmv - perform one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A)*x$

SYNOPSIS

```
SUBROUTINE CTRMV( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER N, LDA, INCY
```

```
SUBROUTINE CTRMV_64( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRMV( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, INCY
```

```
SUBROUTINE TRMV_64( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrmv(char uplo, char transa, char diag, int n, complex *a, int lda, complex *y, int incy);
```

```
void ctrmv_64(char uplo, char transa, char diag, long n, complex *a, long lda, complex *y, long incy);
```

PURPOSE

ctrmv performs one of the matrix-vector operations $x := A*x$, or $x := A'*x$, or $x := \text{conjg}(A)*x$ where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $x := A*x$.

TRANSA = 'T' or 't' $x := A'*x$.

TRANSA = 'C' or 'c' $x := \text{conjg}(A)*x$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$.

Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector x . On exit, Y is overwritten with the transformed vector x .

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

ctrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

SYNOPSIS

```
SUBROUTINE CTRRFS( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB, X,  
*      LDX, FERR, BERR, WORK, WORK2, INFO)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrrfs(char uplo, char transa, char diag, int n, int nrhs, complex *a, int lda, complex *b, int ldb, complex *x, int ldx, float *ferr, float *berr, int *info);
```

```
void ctrrfs_64(char uplo, char transa, char diag, long n, long nrhs, complex *a, long lda, complex *b, long ldb, complex *x, long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

ctrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by CTRTRS or some other means before entering this routine. CTRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input*)

The solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension($2*N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

ctrsen - reorder the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace

SYNOPSIS

```
SUBROUTINE CTRSEN( JOB, COMPQ, SELECT, N, T, LDT, Q, LDQ, W, M, S,  
*      SEP, WORK, LWORK, INFO)  
CHARACTER * 1 JOB, COMPQ

```
SUBROUTINE TRSEN_64( JOB, COMPQ, SELECT, [N], T, [LDT], Q, [LDQ], W,  
*      M, S, SEP, [WORK], [LWORK], [INFO])  
CHARACTER(LEN=1) :: JOB, COMPQ  
COMPLEX, DIMENSION(:) :: W, WORK  
COMPLEX, DIMENSION(:, :) :: T, Q  
INTEGER(8) :: N, LDT, LDQ, M, LWORK, INFO  
LOGICAL(8), DIMENSION(:) :: SELECT  
REAL :: S, SEP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsen(char job, char compq, logical *select, int n, complex *t, int ldt, complex *q, int ldq, complex *w, int *m, float *s, float *sep, int *info);
```

```
void ctrsen_64(char job, char compq, logical *select, long n, complex *t, long ldt, complex *q, long ldq, complex *w, long *m, float *s, float *sep, long *info);
```

PURPOSE

ctrsen reorders the Schur factorization of a complex matrix $A = Q^*T^*Q^{**}H$, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):

*** COMPQ (input)**

*** SELECT (input)**

SELECT specifies the eigenvalues in the selected cluster. To select the j -th eigenvalue, SELECT(j) must be set to .TRUE..

*** N (input)**

The order of the matrix T . $N \geq 0$.

*** T (input/output)**

On entry, the upper triangular matrix T . On exit, T is overwritten by the reordered matrix T , with the selected eigenvalues as the leading diagonal elements.

*** LDT (input)**

The leading dimension of the array T . $LDT \geq \max(1, N)$.

*** Q (input)**

On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix which reorders T ; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q . $LDQ \geq 1$; and if COMPQ = 'V', $LDQ \geq N$.

*** W (output)**

The reordered eigenvalues of T , in the same order as they appear on the diagonal of T .

*** M (output)**

The dimension of the specified invariant subspace. $0 \leq M \leq N$.

* ***S*** (*output*)

If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of \sqrt{N} . If M = 0 or N, S = 1. If JOB = 'N' or 'V', S is not referenced.

* ***SEP*** (*output*)

If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

* ***WORK*** (*workspace*)

If JOB = 'N', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* ***LWORK*** (*input*)

The dimension of the array WORK. If JOB = 'N', LWORK \geq 1; if JOB = 'E', LWORK = $M*(N-M)$; if JOB = 'V' or 'B', LWORK \geq $2*M*(N-M)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

ctrsl - (obsolete) solve the linear system $Ax = b$ for a triangular matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE CTRSL( A, LDA, N, B, JOB, INFO)
COMPLEX A(LDA,*), B(*)
INTEGER LDA, N, JOB, INFO
```

```
SUBROUTINE CTRSL_64( A, LDA, N, B, JOB, INFO)
COMPLEX A(LDA,*), B(*)
INTEGER*8 LDA, N, JOB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsl(complex *a, int lda, int n, complex *b, int job, int *info);
```

```
void ctrsl_64(complex *a, long lda, long n, complex *b, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

Matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **B** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* **JOB** (*input*)

Determines which operation the subroutine will perform:

- o 00 Solve $Ax = b$, A lower triangular.
- o 01 Solve $Ax = b$, A upper triangular.
- o 10 Solve $AHx = b$, A lower triangular.
- o 11 Solve $AHx = b$, A upper triangular.

- Note that $ATx = AHx$ for real matrices.

* ***INFO (output)***

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns the index of the first zero diagonal element of A.

NAME

ctrsm - solve one of the matrix equations $op(A)X = \alpha B$, or $Xop(A) = \alpha B$

SYNOPSIS

```
SUBROUTINE CTRSM( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
*               LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
COMPLEX ALPHA
COMPLEX A(LDA,*), B(LDB,*)
INTEGER M, N, LDA, LDB

SUBROUTINE CTRSM_64( SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA,
*                  B, LDB)
CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
COMPLEX ALPHA
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 M, N, LDA, LDB
```

F95 INTERFACE

```
SUBROUTINE TRSM( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*               [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: M, N, LDA, LDB

SUBROUTINE TRSM_64( SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
*                  [LDA], B, [LDB])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsm(char side, char uplo, char transa, char diag, int m, int n, complex alpha, complex *a, int lda, complex *b, int ldb);
```

```
void ctrsm_64(char side, char uplo, char transa, char diag, long m, long n, complex alpha, complex *a, long lda, complex *b, long ldb);
```

PURPOSE

ctrsm solves one of the matrix equations $\text{op}(A) * X = \alpha * B$, or $X * \text{op}(A) = \alpha * B$ where α is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and $\text{op}(A)$ is one of

$$\text{op}(A) = A \quad \text{or} \quad \text{op}(A) = A' \quad \text{or} \quad \text{op}(A) = \text{conjg}(A').$$

The matrix X is overwritten on B .

ARGUMENTS

* *SIDE* (input)

On entry, *SIDE* specifies whether $\text{op}(A)$ appears on the left or right of X as follows:

SIDE = 'L' or 'l' $\text{op}(A) * X = \alpha * B$.

SIDE = 'R' or 'r' $X * \text{op}(A) = \alpha * B$.

Unchanged on exit.

* *UPLO* (input)

On entry, *UPLO* specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, *TRANS* specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANS = 'N' or 'n' $\text{op}(A) = A$.

TRANS = 'T' or 't' $\text{op}(A) = A'$.

TRANS = 'C' or 'c' $\text{op}(A) = \text{conjg}(A')$.

Unchanged on exit.

* *DIAG* (input)

On entry, *DIAG* specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *M* (input)

On entry, *M* specifies the number of rows of B . $M \geq 0$. Unchanged on exit.

*** *N (input)***

On entry, N specifies the number of columns of B. $N \geq 0$. Unchanged on exit.

*** *ALPHA (input)***

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

*** *A (input)***

when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

*** *LDA (input)***

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then $LDA \geq \max(1, M)$, when SIDE = 'R' or 'r' then $LDA \geq \max(1, N)$. Unchanged on exit.

*** *B (input/output)***

Before entry, the leading M by N part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

*** *LDB (input)***

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. $LDB \geq \max(1, M)$. Unchanged on exit.

NAME

ctrсна - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q^*T^*Q^{**}H$ with Q unitary)

SYNOPSIS

LOGICAL(8), DIMENSION(:) :: SELECT  
REAL, DIMENSION(:) :: S, SEP, WORK1
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsna(char job, char howmny, logical *select, int n, complex *t, int ldt, complex *vl, int ldvl, complex *vr, int ldvr, float *s, float *sep, int mm, int *m, int ldwork, int *info);
```

```
void ctrsna_64(char job, char howmny, logical *select, long n, complex *t, long ldt, complex *vl, long ldvl, complex *vr, long ldvr, float *s, float *sep, long mm, long *m, long ldwork, long *info);
```

PURPOSE

ctrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix $Q^*T*Q^{**}H$ with Q unitary).

ARGUMENTS

*** JOB (input)**

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):

*** HOWMNY (input)**

*** SELECT (input)**

If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the j-th eigenpair, SELECT(j) must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

*** N (input)**

The order of the matrix T. $N \geq 0$.

*** T (input)**

The upper triangular matrix T.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq \max(1, N)$.

*** VL (input)**

If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any $Q^*T*Q^{**}H$ with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CHSEIN or CTREVC. If JOB = 'V', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. $LDVL \geq 1$; and if JOB = 'E' or 'B', $LDVL \geq N$.

*** VR (input)**

If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any $Q^*T*Q^{**}H$ with Q unitary), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CHSEIN or CTREVC. If JOB = 'V', VR is not referenced.

*** LDVR (input)**

The leading dimension of the array VR. $LDVR \geq 1$; and if JOB = 'E' or 'B', $LDVR \geq N$.

*** S (output)**

If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of

the array. Thus $S(j)$, $SEP(j)$, and the j -th columns of VL and VR all correspond to the same eigenpair (but not in general the j -th eigenpair, unless all eigenpairs are selected). If $JOB = 'V'$, S is not referenced.

* ***SEP (output)***

If $JOB = 'V'$ or $'B'$, the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If $JOB = 'E'$, SEP is not referenced.

* ***MM (input)***

The number of elements in the arrays S (if $JOB = 'E'$ or $'B'$) and/or SEP (if $JOB = 'V'$ or $'B'$). $MM \geq M$.

* ***M (output)***

The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If $HOWMNY = 'A'$, M is set to N .

* ***WORK (workspace)***

If $JOB = 'E'$, $WORK$ is not referenced.

* ***LDWORK (input)***

The leading dimension of the array $WORK$. $LDWORK \geq 1$; and if $JOB = 'V'$ or $'B'$, $LDWORK \geq N$.

* ***WORK1 (workspace)***

If $JOB = 'E'$, $WORK1$ is not referenced.

* ***INFO (output)***

NAME

ctrsv - solve one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conj}(A')*x = b$

SYNOPSIS

```
SUBROUTINE CTRSV( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER N, LDA, INCY
```

```
SUBROUTINE CTRSV_64( UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRSV( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, INCY
```

```
SUBROUTINE TRSV_64( UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsv(char uplo, char transa, char diag, int n, complex *a, int lda, complex *y, int incy);
```

```
void ctrsv_64(char uplo, char transa, char diag, long n, complex *a, long lda, complex *y, long incy);
```

PURPOSE

ctrsv solves one of the systems of equations $A*x = b$, or $A'*x = b$, or $\text{conjg}(A')*x = b$ where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

* *TRANS* (input)

On entry, TRANS specifies the equations to be solved as follows:

TRANS = 'N' or 'n' $A*x = b$.

TRANS = 'T' or 't' $A'*x = b$.

TRANS = 'C' or 'c' $\text{conjg}(A')*x = b$.

Unchanged on exit.

* *DIAG* (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

* *LDA* (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, n)$. Unchanged on exit.

* *Y* (input/output)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element right-hand side vector b . On exit, Y is overwritten with the solution vector x .

* *INCY* (*input*)

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

NAME

ctrsyl - solve the complex Sylvester matrix equation

SYNOPSIS

```
SUBROUTINE CTRSYL( TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC,
*   SCALE, INFO)

```

```
SUBROUTINE CTRSYL_64( TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C,
*   LDC, SCALE, INFO)
CHARACTER * 1 TRANA, TRANB
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 ISGN, M, N, LDA, LDB, LDC, INFO
REAL SCALE
```

F95 INTERFACE

```
SUBROUTINE TRSYL( TRANA, TRANB, ISGN, [M], [N], A, [LDA], B, [LDB],
*   C, [LDC], SCALE, [INFO])
CHARACTER(LEN=1) :: TRANA, TRANB
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL :: SCALE
```

```
SUBROUTINE TRSYL_64( TRANA, TRANB, ISGN, [M], [N], A, [LDA], B, [LDB],
*   C, [LDC], SCALE, [INFO])
CHARACTER(LEN=1) :: TRANA, TRANB
COMPLEX, DIMENSION(:,*) :: A, B, C
INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL :: SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrsyl(char trana, char tranb, int isgn, int m, int n, complex *a, int lda, complex *b, int ldb, complex *c, int ldc, float *scale, int *info);
```

```
void ctrsyl_64(char trana, char tranb, long isgn, long m, long n, complex *a, long lda, complex *b, long ldb, complex *c,
```

long ldc, float *scale, long *info);

PURPOSE

ctrsyl solves the complex Sylvester matrix equation:

$$\begin{aligned} \text{op}(A)*X + X*\text{op}(B) &= \text{scale}*C \text{ or} \\ \text{op}(A)*X - X*\text{op}(B) &= \text{scale}*C, \end{aligned}$$

where $\text{op}(A) = A$ or A^{**H} , and A and B are both upper triangular. A is M -by- M and B is N -by- N ; the right hand side C and the solution X are M -by- N ; and scale is an output scale factor, set ≤ 1 to avoid overflow in X .

ARGUMENTS

* **TRANA** (*input*)

Specifies the option $\text{op}(A)$:

* **TRANB** (*input*)

Specifies the option $\text{op}(B)$:

* **ISGN** (*input*)

Specifies the sign in the equation:

* **M** (*input*)

The order of the matrix A , and the number of rows in the matrices X and C . $M \geq 0$.

* **N** (*input*)

The order of the matrix B , and the number of columns in the matrices X and C . $N \geq 0$.

* **A** (*input*)

The upper triangular matrix A .

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, M)$.

* **B** (*input*)

The upper triangular matrix B .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **C** (*input/output*)

On entry, the M -by- N right hand side matrix C . On exit, C is overwritten by the solution matrix X .

* **LDC** (*input*)

The leading dimension of the array C . $LDC \geq \max(1, M)$

* **SCALE** (*output*)

The scale factor, scale , set ≤ 1 to avoid overflow in X .

* **INFO** (*output*)

NAME

ctrtri2 - compute the inverse of a complex upper or lower triangular matrix

SYNOPSIS

```
SUBROUTINE CTRTRI2( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
```

```
SUBROUTINE CTRTRI2_64( UPLO, DIAG, N, A, LDA, INFO)
CHARACTER * 1 UPLO, DIAG
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE TRTRI2( UPLO, DIAG, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX, DIMENSION(:,) :: A
INTEGER :: N, LDA, INFO
```

```
SUBROUTINE TRTRI2_64( UPLO, DIAG, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX, DIMENSION(:,) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrtri2(char uplo, char diag, int n, complex *a, int lda, int *info);
```

```
void ctrtri2_64(char uplo, char diag, long n, complex *a, long lda, long *info);
```

PURPOSE

ctrtri2 computes the inverse of a complex upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the matrix A is upper or lower triangular.

* **DIAG** (*input*)

Specifies whether or not the matrix A is unit triangular.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **INFO** (*output*)

NAME

```

```
void ctrtri_64(char uplo, char diag, long n, complex *a, long lda, long *info);
```

PURPOSE

ctrtri computes the inverse of a complex upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

* *UPLO* (*input*)

* *DIAG* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular matrix A. If *UPLO* = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If *UPLO* = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If *DIAG* = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

ctrtrs - solve a triangular system of the form $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

SYNOPSIS

```
SUBROUTINE CTRTRS( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,
*                INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NRHS, LDA, LDB, INFO

SUBROUTINE CTRTRS_64( UPLO, TRANSA, DIAG, N, NRHS, A, LDA, B, LDB,
*                   INFO)
CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE TRTRS( UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B,
*               [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER :: N, NRHS, LDA, LDB, INFO

SUBROUTINE TRTRS_64( UPLO, [TRANSA], DIAG, [N], [NRHS], A, [LDA], B,
*                  [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:,*) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrtrs(char uplo, char transa, char diag, int n, int nrhs, complex *a, int lda, complex *b, int ldb, int *info);
```

```
void ctrtrs_64(char uplo, char transa, char diag, long n, long nrhs, complex *a, long lda, complex *b, long ldb, long *info);
```

PURPOSE

ctrtrs solves a triangular system of the form

where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

* **UPLO** (*input*)

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **DIAG** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

ctzrqf - routine is deprecated and has been replaced by routine CTZRZF

SYNOPSIS

```
SUBROUTINE CTZRQF( M, N, A, LDA, TAU, INFO)
COMPLEX A(LDA,*), TAU(*)
INTEGER M, N, LDA, INFO
```

```
SUBROUTINE CTZRQF_64( M, N, A, LDA, TAU, INFO)
COMPLEX A(LDA,*), TAU(*)
INTEGER*8 M, N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE TZRQF( [M], [N], A, [LDA], TAU, [INFO])
COMPLEX, DIMENSION(:) :: TAU
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, INFO
```

```
SUBROUTINE TZRQF_64( [M], [N], A, [LDA], TAU, [INFO])
COMPLEX, DIMENSION(:) :: TAU
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctzrqf(int m, int n, complex *a, int lda, complex *tau, int *info);
```

```
void ctzrqf_64(long m, long n, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

ctzrqf routine is deprecated and has been replaced by routine CTZRZF.

CTZRQF reduces the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq M$.

*** A (input/output)**

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (output)**

The scalar factors of the elementary reflectors.

*** INFO (output)**

NAME

ctzrzf - reduce the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations

SYNOPSIS

```
SUBROUTINE CTZRZF( M, N, A, LDA, TAU, WORK, LWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LWORK, INFO
```

```
SUBROUTINE CTZRZF_64( M, N, A, LDA, TAU, WORK, LWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE TZRZF( [M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, LDA, LWORK, INFO
```

```
SUBROUTINE TZRZF_64( [M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctzrzf(int m, int n, complex *a, int lda, complex *tau, int *info);
```

```
void ctzrzf_64(long m, long n, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

ctzrzf reduces the M-by-N ($M \leq N$) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

$$A = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (output)**

The scalar factors of the elementary reflectors.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

cung2l - generate an m by n complex matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE CUNG2L( M, N, K, A, LDA, TAU, WORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, INFO
```

```

COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE UNG2L( M, [N], [K], A, [LDA], TAU, [WORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, INFO
```

```
SUBROUTINE UNG2L_64( M, [N], [K], A, [LDA], TAU, [WORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cung2l(int m, int n, int k, complex *a, int lda, complex *tau, int *info);
```

```
void cung2l_64(long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cg21 L generates an m by n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by CGEQLF.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix Q . $M \geq 0$.

* ***N (input)***

The number of columns of the matrix Q . $M \geq N \geq 0$.

* ***K (input)***

The number of elementary reflectors whose product defines the matrix Q . $N \geq K \geq 0$.

* ***A (input/output)***

On entry, the $(n-k+i)$ -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by CGEQLF in the last k columns of its array argument A . On exit, the m -by- n matrix Q .

* ***LDA (input)***

The first dimension of the array A . $LDA \geq \max(1, M)$.

* ***TAU (input)***

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by CGEQLF.

* ***WORK (workspace)***

dimension(N)

* ***INFO (output)***

NAME

NAME

cungbr - generate one of the complex unitary matrices Q or P**H determined by CGEBRD when reducing a complex matrix A to bidiagonal form

SYNOPSIS

```
SUBROUTINE CUNGBR( VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 VECT
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE CUNGBR_64( VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 VECT
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGBR( VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
CHARACTER(LEN=1) :: VECT
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE UNGBR_64( VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
CHARACTER(LEN=1) :: VECT
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cungbr(char vect, int m, int n, int k, complex *a, int lda, complex *tau, int *info);
```

```
void cungbr_64(char vect, long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cungbr generates one of the complex unitary matrices Q or P**H determined by CGEBRD when reducing a complex matrix A to bidiagonal form: $A = Q * B * P^{**H}$. Q and P**H are defined as products of elementary reflectors H(i) or G(i) respectively.

If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q is of order M:

if $m \geq k$, $Q = H(1) H(2) \dots H(k)$ and CUNGBR returns the first n columns of Q, where $m \geq n \geq k$;

if $m < k$, $Q = H(1) H(2) \dots H(m-1)$ and CUNGBR returns Q as an M-by-M matrix.

If VECT = 'P', A is assumed to have been a K-by-N matrix, and P**H is of order N:

if $k < n$, $P^{**H} = G(k) \dots G(2) G(1)$ and CUNGBR returns the first m rows of P**H, where $n \geq m \geq k$;

if $k \geq n$, $P^{**H} = G(n-1) \dots G(2) G(1)$ and CUNGBR returns P**H as an N-by-N matrix.

ARGUMENTS

* VECT (input)

Specifies whether the matrix Q or the matrix P**H is required, as defined in the transformation applied by CGEBRD:

* M (input)

The number of rows of the matrix Q or P**H to be returned. $M \geq 0$.

* N (input)

The number of columns of the matrix Q or P**H to be returned. $N \geq 0$. If VECT = 'Q', $M \geq N \geq \min(M,K)$; if VECT = 'P', $N \geq M \geq \min(N,K)$.

* K (input)

If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by CGEBRD. $K \geq 0$.

* A (input/output)

On entry, the vectors which define the elementary reflectors, as returned by CGEBRD. On exit, the M-by-N matrix Q or P**H.

* LDA (input)

The leading dimension of the array A. $LDA \geq M$.

* TAU (input)

($\min(M,K)$) if VECT = 'Q' ($\min(N,K)$) if VECT = 'P' TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P**H, as returned by CGEBRD in its array argument TAUQ or TAUP.

* WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* LWORK (input)

The dimension of the array WORK. $LWORK \geq \max(1, \min(M,N))$. For optimum performance $LWORK \geq \min(M,N) * NB$, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

** INFO (output)*

NAME

cunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

SYNOPSIS

```
SUBROUTINE CUNGHR( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER N, ILO, IHI, LDA, LWORK, INFO
```

```
SUBROUTINE CUNGHR_64( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGHR( [N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO
```

```
SUBROUTINE UNGHR_64( [N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
*                  [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunghr(int n, int ilo, int ihi, complex *a, int lda, complex *tau, int *info);
```

```
void cunghr_64(long n, long ilo, long ihi, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cunghr generates a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by CGEHRD:

$$Q = H(i_0) H(i_0+1) \dots H(i_{hi}-1).$$

ARGUMENTS

* ***N*** (*input*)

The order of the matrix Q . $N \geq 0$.

* ***ILO*** (*input*)

ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix $Q(i_0+1:i_{hi}, i_0+1:i_{hi})$. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI*** (*input*)

See the description of IHI.

* ***A*** (*input/output*)

On entry, the vectors which define the elementary reflectors, as returned by CGEHRD. On exit, the N -by- N unitary matrix Q .

* ***LDA*** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* ***TAU*** (*input*)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by CGEHRD.

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* ***LWORK*** (*input*)

The dimension of the array $WORK$. $LWORK \geq IHI - ILO$. For optimum performance $LWORK \geq (IHI - ILO) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* ***INFO*** (*output*)

NAME

cungl2 - generate an m-by-n complex matrix Q with orthonormal rows,

SYNOPSIS

```
SUBROUTINE CUNGL2( M, N, K, A, LDA, TAU, WORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, INFO
```

```
SUBROUTINE CUNGL2_64( M, N, K, A, LDA, TAU, WORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGL2( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, INFO
```

```
SUBROUTINE UNGL2_64( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cungl2(int m, int n, int k, complex *a, int lda, complex *tau, int *info);
```

```
void cungl2_64(long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cungl2 generates an m-by-n complex matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k)' \cdot \dots \cdot H(2)' H(1)'$$

as returned by CGELQF.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix Q. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix Q. $N \geq M$.

* ***K (input)***

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

* ***A (input/output)***

On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGELQF in the first k rows of its array argument A. On exit, the m by n matrix Q.

* ***LDA (input)***

The first dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU (input)***

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

* ***WORK (workspace)***

dimension(M)

* ***INFO (output)***

NAME

cunglq - generate an M-by-N complex matrix Q with orthonormal rows,

SYNOPSIS

```
SUBROUTINE CUNGLQ( M, N, K, A, LDA, TAU, WORK, LWORK, INFO)
COMPLEX A(LDA,*), TAU(*), WORK(*)

SUBROUTINE UNGLQ( M, [N], [K], A, [LDA], TAU, [WORK], [LWORK], [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: M, N, K, LDA, LWORK, INFO
```

```
SUBROUTINE UNGLQ_64( M, [N], [K], A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunglq(int m, int n, int k, complex *a, int lda, complex *tau, int *info);
```

```
void cunglq_64(long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cunglq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

$$Q = H(k)' \cdot \dots \cdot H(2)' \cdot H(1)'$$

as returned by CGELQF.

ARGUMENTS

* **M** (*input*)

The number of rows of the matrix Q. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix Q. $N \geq M$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

* **A** (*input/output*)

On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

* **LDA** (*input*)

The first dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M \cdot NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

cungql - generate an M-by-N complex matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE CUNGQL( M, N, K, A, LDA, TAU, WORK, LWORK, INFO)

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cungql(int m, int n, int k, complex *a, int lda, complex *tau, int *info);
```

```
void cungql_64(long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cungql generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by CGEQLF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $M \geq N \geq 0$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

*** A (input/output)**

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, N)$. For optimum performance $LWORK \geq N * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

cungqr - generate an M-by-N complex matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE CUNGQR( M, N, K, A, LDA, TAU, WORKIN, LWORKIN, INFO)
COMPLEX A(LDA,*), TAU(*), WORKIN(*)
INTEGER M, N, K, LDA, LWORKIN, INFO
```

```
void cungqr(int m, int n, int k, complex *a, int lda, complex *tau, int *info);
```

```
void cungqr_64(long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cungqr generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

$$Q = H(1) H(2) \dots H(k)$$

as returned by CGEQRF.

ARGUMENTS

* **M** (*input*)

The number of rows of the matrix Q. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix Q. $M \geq N \geq 0$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

* **A** (*input/output*)

On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

* **LDA** (*input*)

The first dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

* **WORKIN** (*workspace*)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

* **LWORKIN** (*input*)

The dimension of the array WORKIN. $LWORKIN \geq \max(1, N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

* **INFO** (*output*)

NAME

```

```
void cungrq_64(long m, long n, long k, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cungrq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by CGERQF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $N \geq M$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

*** A (input/output)**

On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq M \cdot NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

cungtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

SYNOPSIS

```
SUBROUTINE CUNGTR( UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER N, LDA, LWORK, INFO
```

```
SUBROUTINE CUNGTR_64( UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 N, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGTR( UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER :: N, LDA, LWORK, INFO
```

```
SUBROUTINE UNGTR_64( UPLO, [N], A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A
INTEGER(8) :: N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cungtr(char uplo, int n, complex *a, int lda, complex *tau, int *info);
```

```
void cungtr_64(char uplo, long n, complex *a, long lda, complex *tau, long *info);
```

PURPOSE

cungtr generates a complex unitary matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by CHETRD:

if $UPLO = 'U'$, $Q = H(n-1) \dots H(2) H(1)$,

if $UPLO = 'L'$, $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix Q . $N \geq 0$.

* **A** (*input/output*)

On entry, the vectors which define the elementary reflectors, as returned by CHETRD. On exit, the N -by- N unitary matrix Q .

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq N$.

* **TAU** (*input*)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by CHETRD.

* **WORK** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK** (*input*)

The dimension of the array $WORK$. $LWORK \geq N-1$. For optimum performance $LWORK \geq (N-1)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* **INFO** (*output*)

NAME

cunmbr - VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

COMPLEX, DIMENSION(:, :) :: A, C  
INTEGER :: M, N, K, LDA, LDC, LWORK, INFO
```

```
SUBROUTINE UNMBR_64( VECT, SIDE, [TRANS], [M], [N], K, A, [LDA],  
*      TAU, C, [LDC], [WORK], [LWORK], [INFO])  
CHARACTER(LEN=1) :: VECT, SIDE, TRANS  
COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:, :) :: A, C  
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunmbr(char vect, char side, char trans, int m, int n, int k, complex *a, int lda, complex *tau, complex *c, int ldc, int *info);
```

```
void cunmbr_64(char vect, char side, char trans, long m, long n, long k, complex *a, long lda, complex *tau, complex *c, long ldc, long *info);
```

PURPOSE

cunmbr VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N':
 $Q * C * Q$ TRANS = 'C': $Q^{**H} * C * Q^{**H}$

If VECT = 'P', CUNMBR overwrites the general complex M-by-N matrix C with

SIDE = 'L' SIDE = 'R'

TRANS = 'N': $P * C * P$

TRANS = 'C': $P^{**H} * C * P^{**H}$

Here Q and P^{**H} are the unitary matrices determined by CGEBRD when reducing a complex matrix A to bidiagonal form:
 $A = Q * B * P^{**H}$. Q and P^{**H} are defined as products of elementary reflectors H(i) and G(i) respectively.

Let $nq = m$ if SIDE = 'L' and $nq = n$ if SIDE = 'R'. Thus nq is the order of the unitary matrix Q or P^{**H} that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix: if $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

if $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If VECT = 'P', A is assumed to have been a K-by-NQ matrix: if $k < nq$, $P = G(1) G(2) \dots G(k)$;

if $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

ARGUMENTS

* *VECT (input)*

* *SIDE (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *K (input)*

If VECT = 'Q', the number of columns in the original matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by CGEBRD. $K \geq 0$.

* *A (input)*

(LDA, min(nq, K)) if VECT = 'Q' (LDA, nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by CGEBRD.

* *LDA (input)*

The leading dimension of the array A. If VECT = 'Q', $LDA \geq \max(1, nq)$; if VECT = 'P', $LDA \geq \max(1, \min(nq, K))$.

* *TAU (input)*

TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned

by CGEBRD in the array argument TAUQ or TAUP.

* ***C*** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**H}C$ or C^*Q^{**H} or C^*Q or P^*C or $P^{**H}C$ or C^*P or C^*P^{**H} .

* ***LDC*** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* ***LWORK*** (*input*)

The dimension of the array WORK. If $SIDE = 'L'$, $LWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if $SIDE = 'L'$, and $LWORK \geq M * NB$ if $SIDE = 'R'$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO*** (*output*)

CHARACTER(LEN=1) :: SIDE, TRANS
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A, C
INTEGER :: M, N, ILO, IHI, LDA, LDC, LWORK, INFO

SUBROUTINE UNMHR_64( SIDE, [TRANS], [M], [N], ILO, IHI, A, [LDA],
*   TAU, C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: SIDE, TRANS
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:, :) :: A, C
INTEGER(8) :: M, N, ILO, IHI, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunmhr(char side, char trans, int m, int n, int ilo, int ihi, complex *a, int lda, complex *tau, complex *c, int ldc, int *info);
```

```
void cunmhr_64(char side, char trans, long m, long n, long ilo, long ihi, complex *a, long lda, complex *tau, complex *c, long ldc, long *info);
```

PURPOSE

cunmhr overwrites the general complex M-by-N matrix C with TRANS = 'C': $Q^{*H} * C * Q^{*H}$

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by CGEHRD:

$Q = H(i_{lo}) H(i_{lo}+1) \dots H(i_{hi}-1)$.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **ILO** (*input*)

ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix $Q(i_{lo}+1:i_{hi}, i_{lo}+1:i_{hi})$. If SIDE = 'L', then $1 \leq ILO \leq IHI \leq M$, if $M > 0$, and $ILO = 1$ and $IHI = 0$, if $M = 0$; if SIDE = 'R', then $1 \leq ILO \leq IHI \leq N$, if $N > 0$, and $ILO = 1$ and $IHI = 0$, if $N = 0$.

* **IHI** (*input*)

See the description of ILO.

* **A** (*input*)

(LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CGEHRD.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$ if SIDE = 'L'; $LDA \geq \max(1, N)$ if SIDE = 'R'.

* **TAU** (*input*)

(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK

array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO*** (*output*)

COMPLEX, DIMENSION(:) :: TAU, WORK  
COMPLEX, DIMENSION(:, :) :: A, C  
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunmrq(char side, char trans, int m, int n, int k, complex *a, int lda, complex *tau, complex *c, int ldc, int *info);
```

```
void cunmrq_64(char side, char trans, long m, long n, long k, complex *a, long lda, complex *tau, complex *c, long ldc, long *info);
```

PURPOSE

cunmrq overwrites the general complex M-by-N matrix C with TRANS = 'C': $Q^{*H} * C * Q^{*H}$

where Q is a complex unitary matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by CGERQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

* **SIDE (input)**

* **TRANS (input)**

* **M (input)**

The number of rows of the matrix C. $M \geq 0$.

* **N (input)**

The number of columns of the matrix C. $N \geq 0$.

* **K (input)**

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

* **A (input)**

(LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CGERQF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, K)$.

* **TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

* **C (input/output)**

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{*H}C$ or C^*Q^{*H} or C^*Q .

* **LDC (input)**

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

** INFO (output)*

NAME

cunmrz - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```
SUBROUTINE CUNMRZ( SIDE, TRANS, M, N, K, L, A, LDA, TAU, C, LDC,

```

PURPOSE

cunmrz overwrites the general complex M-by-N matrix C with TRANS = 'C': $Q^{*H} * C * Q^{*H}$

where Q is a complex unitary matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by CTZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

* **L** (*input*)

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

* **A** (*input*)

(LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by CTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CTZRZF.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{*H} * C$ or $C * Q^{*H}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If `LWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LWORK` is issued by `XERBLA`.

* ***INFO*** (*output*)

```

```
void cunmtr_64(char side, char uplo, char trans, long m, long n, complex *a, long lda, complex *tau, complex *c, long ldc, long *info);
```

PURPOSE

cunmtr overwrites the general complex M-by-N matrix C with $TRANS = 'C': Q^{**H} * C * Q^{**H}$

where Q is a complex unitary matrix of order nq, with nq = m if $SIDE = 'L'$ and nq = n if $SIDE = 'R'$. Q is defined as the product of nq-1 elementary reflectors, as returned by CHETRD:

if $UPLO = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

if $UPLO = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

* *SIDE (input)*

* *UPLO (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *A (input)*

(LDA,M) if $SIDE = 'L'$ (LDA,N) if $SIDE = 'R'$ The vectors which define the elementary reflectors, as returned by CHETRD.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1,M)$ if $SIDE = 'L'$; $LDA \geq \max(1,N)$ if $SIDE = 'R'$.

* *TAU (input)*

(M-1) if $SIDE = 'L'$ (N-1) if $SIDE = 'R'$ TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

* *C (input/output)*

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**H} * C$ or $C * Q^{**H}$ or $C * Q$.

* *LDC (input)*

The leading dimension of the array C. $LDC \geq \max(1,M)$.

* *WORK (workspace)*

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* *LWORK (input)*

The dimension of the array WORK. If $SIDE = 'L'$, $LWORK \geq \max(1,N)$; if $SIDE = 'R'$, $LWORK \geq \max(1,M)$. For optimum performance $LWORK \geq N * NB$ if $SIDE = 'L'$, and $LWORK \geq M * NB$ if $SIDE = 'R'$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* *INFO (output)*

NAME

cupgtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

SYNOPSIS

```

```

```
void cupgtr_64(char uplo, long n, complex *ap, complex *tau, complex *q, long ldq, long *info);
```

PURPOSE

cupgtr generates a complex unitary matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by CHPTRD using packed storage:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix Q . $N \geq 0$.

* **AP** (*input*)

The vectors which define the elementary reflectors, as returned by CHPTRD.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by CHPTRD.

* **Q** (*output*)

The N -by- N unitary matrix Q .

* **LDQ** (*input*)

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension($N-1$)

* **INFO** (*output*)

or $(N-1)$ if $SIDE = 'R'$ TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHPTRD.

* *C (input/output)*

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q*C$ or $Q^{*H}*C$ or $C*Q^{*H}$ or $C*Q$.

* *LDC (input)*

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* *WORK (workspace)*

(N) if $SIDE = 'L'$ (M) if $SIDE = 'R'$

* *INFO (output)*

NAME

cvmul - compute the scaled product of complex vectors

SYNOPSIS

```
SUBROUTINE CVMUL( N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)
COMPLEX ALPHA, BETA
COMPLEX X(*), Y(*), Z(*)
INTEGER N, INCX, INCY, INCZ
```

```
SUBROUTINE CVMUL_64( N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)
COMPLEX ALPHA, BETA
COMPLEX X(*), Y(*), Z(*)
INTEGER*8 N, INCX, INCY, INCZ
```

F95 INTERFACE

```
SUBROUTINE VMUL( [N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y, Z
INTEGER :: N, INCX, INCY, INCZ
```

```
SUBROUTINE VMUL_64( [N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y, Z
INTEGER(8) :: N, INCX, INCY, INCZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cvmul(int n, complex alpha, complex *x, int incx, complex *y, int incy, complex beta, complex *z, int incz);
```

```
void cvmul_64(long n, complex alpha, complex *x, long incx, complex *y, long incy, complex beta, complex *z, long incz);
```

PURPOSE

cvmul computes the scaled product of complex vectors:

$$z(i) = \text{ALPHA} * x(i) * y(i) + \text{BETA} * z(i)$$

for $1 \leq i \leq N$.

ARGUMENTS

*** *N (input)***

Length of the vectors. $N \geq 0$. Returns immediately if $N = 0$.

*** *ALPHA (input)***

Scale factor on the multiplicand vectors.

*** *X (input)***

dimension(*)

Multiplicand vector.

*** *INCX (input)***

Stride between elements of the multiplicand vector X. $INCX > 0$.

*** *Y (input)***

dimension(*)

Multiplicand vector.

*** *INCY (input)***

Stride between elements of the multiplicand vector Y. $INCY > 0$.

*** *BETA (input)***

Scale factor on the product vector.

*** *Z (input/output)***

dimension(*)

Product vector. On exit, $z(i) = \text{ALPHA} * x(i) * y(i) + \text{BETA} * z(i)$.

*** *INCZ (input)***

Stride between elements of Z. $INCZ > 0$.

NAME

dasum - Return the sum of the absolute values of a vector x.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DASUM( N, X, INCX)
INTEGER N, INCX
DOUBLE PRECISION X(*)
```

```
DOUBLE PRECISION FUNCTION DASUM_64( N, X, INCX)
INTEGER*8 N, INCX
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION ASUM( [N], X, [INCX])
INTEGER :: N, INCX
REAL(8), DIMENSION(:) :: X
```

```
REAL(8) FUNCTION ASUM_64( [N], X, [INCX])
INTEGER(8) :: N, INCX
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dasum(int n, double *x, int incx);
```

```
double dasum_64(long n, double *x, long incx);
```

PURPOSE

dasum Return the sum of the absolute values of x where x is an n-vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input/output)*

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array X must contain the vector x. On exit, X is overwritten by the updated vector x.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

NAME

daxpy - compute $y := \alpha * x + y$

SYNOPSIS

```
SUBROUTINE DAXPY( N, ALPHA, X, INCX, Y, INCY)
INTEGER N, INCX, INCY
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*)
```

```
SUBROUTINE DAXPY_64( N, ALPHA, X, INCX, Y, INCY)
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE AXPY( [N], ALPHA, X, [INCX], Y, [INCY])
INTEGER :: N, INCX, INCY
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y
```

```
SUBROUTINE AXPY_64( [N], ALPHA, X, [INCX], Y, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void daxpy(int n, double alpha, double *x, int incx, double *y, int incy);
```

```
void daxpy_64(long n, double alpha, double *x, long incx, double *y, long incy);
```

PURPOSE

daxpy compute $y := \alpha * x + y$ where α is a scalar and x and y are n -vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

* *X (input)*

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the vector x . Unchanged on exit.

* *INCX (input)*

On entry, $INCX$ specifies the increment for the elements of X . $INCX$ must not be zero. Unchanged on exit.

* *Y (input/output)*

$(1 + (m - 1) * \text{abs}(INCY))$. On entry, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

* *INCY (input)*

On entry, $INCY$ specifies the increment for the elements of Y . $INCY$ must not be zero. Unchanged on exit.

NAME

dbdsdc - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B

SYNOPSIS

```
SUBROUTINE DBSDC( UPLO, COMPQ, N, D, E, U, LDU, VT, LDVT, Q, IQ,
*   WORK, IWORK, INFO)
CHARACTER * 1 UPLO, COMPQ
INTEGER N, LDU, LDVT, INFO
INTEGER IQ(*), IWORK(*)
DOUBLE PRECISION D(*), E(*), U(LDU,*), VT(LDVT,*), Q(*), WORK(*)

SUBROUTINE DBSDC_64( UPLO, COMPQ, N, D, E, U, LDU, VT, LDVT, Q, IQ,
*   WORK, IWORK, INFO)
CHARACTER * 1 UPLO, COMPQ
INTEGER*8 N, LDU, LDVT, INFO
INTEGER*8 IQ(*), IWORK(*)
DOUBLE PRECISION D(*), E(*), U(LDU,*), VT(LDVT,*), Q(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE BDSDC( UPLO, COMPQ, [N], D, E, U, [LDU], VT, [LDVT], Q,
*   IQ, [WORK], [IWORK], [INFO])
CHARACTER(LEN=1) :: UPLO, COMPQ
INTEGER :: N, LDU, LDVT, INFO
INTEGER, DIMENSION(:) :: IQ, IWORK
REAL(8), DIMENSION(:) :: D, E, Q, WORK
REAL(8), DIMENSION(:, :) :: U, VT

SUBROUTINE BDSDC_64( UPLO, COMPQ, [N], D, E, U, [LDU], VT, [LDVT],
*   Q, IQ, [WORK], [IWORK], [INFO])
CHARACTER(LEN=1) :: UPLO, COMPQ
INTEGER(8) :: N, LDU, LDVT, INFO
INTEGER(8), DIMENSION(:) :: IQ, IWORK
REAL(8), DIMENSION(:) :: D, E, Q, WORK
REAL(8), DIMENSION(:, :) :: U, VT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dbdsdc(char uplo, char compq, int n, double *d, double *e, double *u, int ldu, double *vt, int ldvt, double *q, int *iq, int *info);
```

```
void dbdsdc_64(char uplo, char compq, long n, double *d, double *e, double *u, long ldu, double *vt, long ldvt, double *q, long *iq, long *info);
```

PURPOSE

dbdsdc computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = U * S * VT$, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. SBDSDC can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLASD3 for details.

The code currently call SLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

ARGUMENTS

* **UPLO** (*input*)

* **COMPQ** (*input*)

Specifies whether singular vectors are to be computed as follows:

* **N** (*input*)

The order of the matrix B. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

* **E** (*input/output*)

On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

* **U** (*output*)

If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other values of COMPQ, U is not referenced.

* **LDU** (*input*)

The leading dimension of the array U. $LDU \geq 1$. If singular vectors are desired, then $LDU \geq \max(1, N)$.

* **VT** (*output*)

If COMPQ = 'I', then: On exit, if INFO = 0, VT contains the right singular vectors of the bidiagonal matrix. For other values of COMPQ, VT is not referenced.

* **LDVT** (*input*)

The leading dimension of the array VT. $LDVT \geq 1$. If singular vectors are desired, then $LDVT \geq \max(1, N)$.

* **Q** (*input*)

If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring $O(N \log N)$ space instead of $2*N**2$. In particular, Q contains all the REAL data in $LDQ \geq N*(11 + 2*SMLSIZ + 8*INT(\log_2(N/(SMLSIZ+1))))$ words of memory, where SMLSIZ is returned by ILAENV and is

equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, Q is not referenced.

*** IQ (output)**

If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring $O(N \log N)$ space instead of $2 * N^2$. In particular, IQ contains all INTEGER data in LDIO $\geq N * (3 + 3 * \text{INT}(\text{LOG}_2(N / (\text{SMLSIZ} + 1))))$ words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, IQ is not referenced.

*** WORK (workspace)**

If COMPQ = 'N' then LWORK $\geq (2 * N)$. If COMPQ = 'P' then LWORK $\geq (6 * N)$. If COMPQ = 'I' then LWORK $\geq (3 * N^2 + 4 * N)$.

*** IWORK (workspace)**

dimension(8*N)

*** INFO (output)**

NAME

dbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

SYNOPSIS

```
SUBROUTINE DBDSQR( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U, LDU,
*      C, LDC, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
DOUBLE PRECISION D(*), E(*), VT(LDVT,*), U(LDU,*), C(LDC,*), WORK(*)

SUBROUTINE DBDSQR_64( UPLO, N, NCVT, NRU, NCC, D, E, VT, LDVT, U,
*      LDU, C, LDC, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
DOUBLE PRECISION D(*), E(*), VT(LDVT,*), U(LDU,*), C(LDC,*), WORK(*)
```

F95 INTERFACE

REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: VT, U, C

SUBROUTINE BDSQR_64( UPLO, [N], [NCVT], [NRU], [NCC], D, E, VT,
*      [LDVT], U, [LDU], C, [LDC], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NCVT, NRU, NCC, LDVT, LDU, LDC, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: VT, U, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dbdsqr(char uplo, int n, int ncv, int nru, int ncc, double *d, double *e, double *vt, int ldvt, double *u, int ldu, double *c, int ldc, int *info);
```

```
void dbdsqr_64(char uplo, long n, long ncv, long nru, long ncc, double *d, double *e, double *vt, long ldvt, double *u, long ldu, double *c, long ldc, long *info);
```

PURPOSE

dbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: $B = Q * S * P'$ (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes $U * Q$, $P' * VT$, or $Q' * C$, for given real input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and

"Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix B. $N \geq 0$.

* **NCVT** (*input*)

The number of columns of the matrix VT. $NCVT \geq 0$.

* **NRU** (*input*)

The number of rows of the matrix U. $NRU \geq 0$.

* **NCC** (*input*)

The number of columns of the matrix C. $NCC \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

* **E** (*input/output*)

On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit (INFO = 0), E is destroyed. If the algorithm does not converge (INFO > 0), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. E(N) is used for workspace.

* **VT** (*input/output*)

On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by $P' * VT$. VT is not referenced if $NCVT = 0$.

* **LDVT** (*input*)

The leading dimension of the array VT. $LDVT \geq \max(1, N)$ if $NCVT > 0$; $LDVT \geq 1$ if $NCVT = 0$.

* **U** (*input/output*)

On entry, an NRU-by-N matrix U. On exit, U is overwritten by $U * Q$. U is not referenced if $NRU = 0$.

* **LDU** (*input*)

The leading dimension of the array U. $LDU \geq \max(1, NRU)$.

* **C** (*input/output*)

On entry, an N-by-NCC matrix C. On exit, C is overwritten by $Q' * C$. C is not referenced if $NCC = 0$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, N)$ if $NCC > 0$; $LDC \geq 1$ if $NCC = 0$.

* **WORK** (*workspace*)

dimension(4*N)

* **INFO** (*output*)

NAME

dchdc - (obsolete) compute the Cholesky decomposition of a symmetric positive definite matrix A.

SYNOPSIS

```
SUBROUTINE DCHDC( A, LDA, N, WORK, IPIVOT, JOB, INFO)
INTEGER LDA, N, JOB, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DCHDC_64( A, LDA, N, WORK, IPIVOT, JOB, INFO)
INTEGER*8 LDA, N, JOB, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dchdc(double *a, int lda, int n, int *ipivot, int job, int *info);
```

```
void dchdc_64(double *a, long lda, long n, long *ipivot, long job, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of A. On exit, the upper triangle of the Cholesky factor, as permuted by pivoting if pivoting was selected. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

* **N** (*input*)

Order of the matrix A. N \geq 0.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **IPIVOT** (*input*)

If JOB selected no pivoting then IPIVOT is not referenced. On entry, if JOB selected pivoting, IPIVOT contains integers representing array indices that control the selection of pivot elements from the diagonal of A according to the system below:

$IPIVOT(k) > 0$ $A(k,k)$ is an initial element.

$IPIVOT(k) = 0$ $A(k,k)$ is a free element.

$IPIVOT(k) < 0$ $A(k,k)$ is a final element.

Before the decomposition is computed, symmetric row and column interchanges are used to move initial elements to the beginning of A and final elements to the end of A . During the computation, symmetric row and column interchanges are used to move the largest remaining free diagonal element into the pivot position. On exit, $IPIVOT(k)$ contains the index of the diagonal element of A that was moved into the k th position.

*** *JOB* (input)**

Determines how decomposition is done:

- 0 without pivoting

not 0 with pivoting

*** *INFO* (output)**

On exit: Returns the index of the last positive diagonal element of the Cholesky factor. The subroutine was successful if $INFO = N$.

NAME

dchdd - (obsolete) downdate an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

SYNOPSIS

```
SUBROUTINE DCHDD( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN, INFO)
INTEGER LDA, N, LDZ, NZ, INFO
DOUBLE PRECISION A(LDA,*), X(*), Z(LDZ,*), Y(*), RHO(*), COS(*), SIN(*)
```

```
SUBROUTINE DCHDD_64( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN,
* INFO)
INTEGER*8 LDA, N, LDZ, NZ, INFO
DOUBLE PRECISION A(LDA,*), X(*), Z(LDZ,*), Y(*), RHO(*), COS(*), SIN(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dchdd(double *a, int lda, int n, double *x, double *z, int ldz, int nz, double *y, double *rho, double *cos, double *sin, int *info);
```

```
void dchdd_64(double *a, long lda, long n, double *x, double *z, long ldz, long nz, double *y, double *rho, double *cos, double *sin, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangular matrix A. On exit, A has been downdated. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

*** N (input)**

Order of the matrix A. N \geq 0.

*** X (input)**

Row to be added to A.

*** Z (input/output)**

Vectors to be downdated with A.

*** LDZ (input)**

Leading dimension on the array Z as specified in a dimension or type statement. $LDZ \geq \max(1, N)$.

* ***NZ (input)***

Number of vectors to be downdated with A. $NZ \geq 0$. If $NZ = 0$ then Z, Y, and RHO are not used.

* ***Y (input)***

Scalars for downdating the vectors in Z.

* ***RHO (input/output)***

On entry, the norms of the residual vectors that are to be downdated. On exit, RHO has been downdated. If $RHO(i)$ is negative on entry then it is not changed.

* ***COS (input/output)***

Cosines of the transforming rotations.

* ***SIN (output)***

Sines of the transforming rotations.

* ***INFO (output)***

On exit:

INFO = 0 Subroutine completed normally.

INFO = -1 A could not be downdated; all values are left unchanged.

INFO = 1 Some RHOs could not be downdated; all RHOs that could not be downdated are changed to -1.

NAME

dchex - (obsolete) compute the Cholesky decomposition of a symmetric positive definite matrix A.

SYNOPSIS

```
SUBROUTINE DCHEX( A, LDA, N, K, L, Z, LDZ, NZ, COS, SIN, JOB)
INTEGER LDA, N, K, L, LDZ, NZ, JOB
DOUBLE PRECISION A(LDA,*), Z(LDZ,*), COS(*), SIN(*)
```

```
SUBROUTINE DCHEX_64( A, LDA, N, K, L, Z, LDZ, NZ, COS, SIN, JOB)
INTEGER*8 LDA, N, K, L, LDZ, NZ, JOB
DOUBLE PRECISION A(LDA,*), Z(LDZ,*), COS(*), SIN(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dchex(double *a, int lda, int n, int k, int l, double *z, int ldz, int nz, double *cos, double *sin, int job);
```

```
void dchex_64(double *a, long lda, long n, long k, long l, double *z, long ldz, long nz, double *cos, double *sin, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, the upper triangle of A contains the upper triangle of the updated factor. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** K (input)**

First column to be permuted. $1 \leq K \leq L$.

*** L (input)**

Last column to be permuted; must be strictly greater than K. $K \leq L \leq N$.

*** Z (input/output)**

Array of vectors into which the transformation U is multiplied. Not used if $NZ = 0$.

*** LDZ (input)**

Leading dimension of the array Z as specified in a dimension or type statement. $LDZ \geq \max(1,N)$.

* ***NZ (input)***

Number of columns in the matrix Z. $NZ \geq 0$.

* ***COS (input)***

Cosines of the transforming rotations.

* ***SIN (output)***

Sines of the transforming rotations.

* ***JOB (input)***

Determines the type of permutation:

- 1 right circular shift
- 2 left circular shift

NAME

dchud - (obsolete) update an augmented Cholesky decomposition of the triangular part of an augmented QR decomposition.

SYNOPSIS

```
SUBROUTINE DCHUD( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN)
INTEGER LDA, N, LDZ, NZ
DOUBLE PRECISION A(LDA,*), X(*), Z(LDZ,*), Y(*), RHO(*), COS(*), SIN(*)
```

```
SUBROUTINE DCHUD_64( A, LDA, N, X, Z, LDZ, NZ, Y, RHO, COS, SIN)
INTEGER*8 LDA, N, LDZ, NZ
DOUBLE PRECISION A(LDA,*), X(*), Z(LDZ,*), Y(*), RHO(*), COS(*), SIN(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dchud(double *a, int lda, int n, double *x, double *z, int ldz, int nz, double *y, double *rho, double *cos, double *sin);
```

```
void dchud_64(double *a, long lda, long n, double *x, double *z, long ldz, long nz, double *y, double *rho, double *cos, double *sin);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangular matrix A. On exit, A has been updated. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA \geq max(1,N).

*** N (input)**

Order of the matrix A. N \geq 0.

*** X (input)**

Row to be added to A.

*** Z (input/output)**

Vectors to be updated with A.

*** LDZ (input)**

Leading dimension on the array Z as specified in a dimension or type statement. LDZ \geq max(1,N).

*** NZ (input)**

Number of vectors to be updated with A. $NZ \geq 0$. If $NZ = 0$ then Z, Y, and RHO are not used.

* ***Y (input)***

Scalars for updating the vectors in Z.

* ***RHO (input/output)***

On entry, the norms of the residual vectors that are to be updated. On exit, RHO has been updated. If $RHO(i)$ is negative on entry then it is not changed.

* ***COS (input)***

Cosines of the transforming rotations.

* ***SIN (input)***

Sines of the transforming rotations.

NAME

dcnvcor - compute the convolution or correlation of real vectors

SYNOPSIS

```
SUBROUTINE DCNVCOR( CNVCOR, FOUR, NX, X, IFX, INCX, NY, NPRE, M, Y,  
*      IFY, INC1Y, INC2Y, NZ, K, Z, IFZ, INC1Z, INC2Z, WORK, LWORK)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dcnvcor(char cnvcor, char four, int nx, double *x, int ifx, int incx, int ny, int npre, int m, double *y, int ify, int inc1y, int inc2y, int nz, int k, double *z, int ifz, int inc1z, int inc2z, double *work, int lwork);
```

```
void dcnvcor_64(char cnvcor, char four, long nx, double *x, long ifx, long incx, long ny, long npre, long m, double *y, long ify, long inc1y, long inc2y, long nz, long k, double *z, long ifz, long inc1z, long inc2z, double *work, long lwork);
```

PURPOSE

dcnvcor computes the convolution or correlation of real vectors.

ARGUMENTS

* **CNVCOR** (*input*)

'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

* **FOUR** (*input*)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

* **NX** (*input*)

Length of the filter vector. $NX \geq 0$. DCNVCOR will return immediately if $NX = 0$.

* **X** (*input*)

Filter vector.

* **IFX** (*input*)

Index of the first element of X. $NX \geq IFX \geq 1$.

* **INCX** (*input*)

Stride between elements of the filter vector in X. $INCX > 0$.

* **NY** (*input*)

Length of the input vectors. $NY \geq 0$. DCNVCOR will return immediately if $NY = 0$.

* **NPRE** (*input*)

The number of implicit zeros prepended to the Y vectors. $NPRE \geq 0$.

* **M** (*input*)

Number of input vectors. $M \geq 0$. DCNVCOR will return immediately if $M = 0$.

* **Y** (*input*)

Input vectors.

* **IFY** (*input*)

Index of the first element of Y. $NY \geq IFY \geq 1$.

* **INC1Y** (*input*)

Stride between elements of the input vectors in Y. $INC1Y > 0$.

* **INC2Y** (*input*)

Stride between the input vectors in Y. $INC2Y > 0$.

* **NZ** (*input*)

Length of the output vectors. $NZ \geq 0$. DCNVCOR will return immediately if $NZ = 0$. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

* **K** (*input*)

Number of Z vectors. $K \geq 0$. If $K = 0$ then DCNVCOR will return immediately. If $K < M$ then only the first K input vectors will be processed. If $K > M$ then M input vectors will be processed.

* **Z** (*output*)

Result vectors.

* **IFZ** (*input*)

Index of the first element of Z. $NZ \geq IFZ \geq 1$.

* **INC1Z** (*input*)

Stride between elements of the output vectors in Z. $INC1Z > 0$.

* **INC2Z** (*input*)

Stride between the output vectors in Z. INC2Z > 0.

* **WORK** (*input/output*)

Scratch space. Before the first call to DCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to DCNVCOR or if DCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make DCNVCOR run faster.

* **LWORK** (*input*)

Length of WORK. LWORK >= 4*MAX(NX,NY,NZ)+15. .SH NOTES If any vector overlaps a writable vector, either because of argument aliasing or ill-chosen values of the various INC arguments, the results are undefined and may vary from one run to the next.

The most common form of the computation, and the case that executes fastest, is applying a filter vector X to a series of vectors stored in the columns of Y with the result placed into the columns of Z. In that case, INCX = 1, INC1Y = 1, INC2Y >= NY, INC1Z = 1, INC2Z >= NZ. Another common form is applying a filter vector X to a series of vectors stored in the rows of Y and store the result in the row of Z, in which case INCX = 1, INC1Y >= NY, INC2Y = 1, INC1Z >= NZ, and INC2Z = 1.

A common use of convolution is to compute the products of polynomials. The following code uses DCNVCOR to compute the product of $1 + 2x + 3x^2$ and $4 + 5x + 6x^2$:

NAME

dcnvcor2 - compute the convolution or correlation of real matrices

SYNOPSIS

```
SUBROUTINE DCNVCOR2( CNVCOR, METHOD, TRANSX, SCRATCHX, TRANSY,  
*   SCRATCHY, MX, NX, X, LDX, MY, NY, MPRE, NPRES, Y, LDY, MZ, NZ, Z,  
*   LDZ, WORKIN, LWORK)

```

PURPOSE

dcnvcor2 computes the convolution or correlation of real matrices.

ARGUMENTS

* **CNVCOR** (*input*)

'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

* **METHOD** (*input*)

'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

* **TRANSX** (*input*)

'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

* **SCRATCHX** (*input*)

'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

* **TRANSY** (*input*)

'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

* **SCRATCHY** (*input*)

'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

* **MX** (*input*)

Number of rows in the filter matrix. $MX \geq 0$.

* **NX** (*input*)

Number of columns in the filter matrix. $NX \geq 0$.

* **X** (*input*)

dimension(LDX, NX)

On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

* **LDX** (*input*)

Leading dimension of the array that contains the filter matrix.

* **MY (input)**

Number of rows in the input matrix. $MY \geq 0$.

* **NY (input)**

Number of columns in the input matrix. $NY \geq 0$.

* **MPRE (input)**

Number of implicit zeros to prepend to each row of the input matrix. $MPRE \geq 0$.

* **NPRE (input)**

Number of implicit zeros to prepend to each column of the input matrix. $NPRE \geq 0$.

* **Y (input)**

```
dimension(LDY, *)
```

Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

* **LDY (input)**

Leading dimension of the array that contains the input matrix.

* **MZ (input)**

Number of rows in the output matrix. $MZ \geq 0$. DCNVCOR2 will return immediately if $MZ = 0$.

* **NZ (input)**

Number of columns in the output matrix. $NZ \geq 0$. DCNVCOR2 will return immediately if $NZ = 0$.

* **Z (output)**

```
dimension(LDZ, *)
```

Result matrix.

* **LDZ (input)**

Leading dimension of the array that contains the result matrix. $LDZ \geq \text{MAX}(1, MZ)$.

* **WORKIN (input/output)**

(input/scratch) dimension(LWORK)

On entry for the first call to DCNVCOR2, WORKIN(1) must contain 0.0. After the first call, WORKIN(1) must be set to 0.0 iff WORKIN has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

* **LWORK (input)**

Length of the work vector. If the FFT is to be used then for best performance LWORK should be at least 30 words longer than the amount of memory needed to hold the trig tables. If the FFT is not used, the value of LWORK is unimportant.

NAME

dcopy - Copy x to y

SYNOPSIS

```
SUBROUTINE DCOPY( N, X, INCX, Y, INCY)
INTEGER N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)

SUBROUTINE DCOPY_64( N, X, INCX, Y, INCY)
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE COPY( [N], X, [INCX], Y, [INCY])
INTEGER :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y

SUBROUTINE COPY_64( [N], X, [INCX], Y, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>

void dcopy(int n, double *x, int incx, double *y, int incy);

void dcopy_64(long n, double *x, long incx, double *y, long incy);
```

PURPOSE

dcopy Copy x to y where x and y are n-vectors.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** *X (input)***

(1 + (n - 1) * abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** *Y (input/output)***

(1 + (m - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.

*** *INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

dcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE DCOSQB( N, X, WSAVE)
  INTEGER N
  DOUBLE PRECISION X(*), WSAVE(*)
```

```
SUBROUTINE DCOSQB_64( N, X, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB( [N], X, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE COSQB_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dcosqb(int n, double *x, double *wsave);
```

```
void dcosqb_64(long n, double *x, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave cosine synthesis of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$ that has been initialized by DCOSQI.

NAME

dcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE DCOSQF( N, X, WSAVE)
  INTEGER N
  DOUBLE PRECISION X(*), WSAVE(*)
```

```
SUBROUTINE DCOSQF_64( N, X, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQF( [N], X, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE COSQF_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dcosqf(int n, double *x, double *wsave);
```

```
void dcosqf_64(long n, double *x, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave cosine transform of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$ that has been initialized by DCOSQI.

NAME

dcosqi - initialize the array WSAVE, which is used in both COSQF and COSQB.

SYNOPSIS

```
SUBROUTINE DCOSQI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE DCOSQI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE COSQI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcosqi(int n, double *wsave);

void dcosqi_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

* *WSAVE (input)*

On entry, an array of dimension $(3 * N + 15)$ or greater. DCOSQI needs to be called only once to initialize WSAVE before calling DCOSQF and/or DCOSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

dcost - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by $2 * (N-1)$.

SYNOPSIS

```
SUBROUTINE DCOST( N, X, WSAVE)
  INTEGER N
  DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DCOST_64( N, X, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COST( [N], X, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE COST_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcost(int n, double *x, double *wsave);

void dcost_64(long n, double *x, double *wsave);
```

ARGUMENTS

*** *N* (input)**

Length of the sequence to be transformed. These subroutines are most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

*** *X* (input/output)**

On entry, an array of length N containing the sequence to be transformed. On exit, the cosine transform of the input.

*** *WSAVE* (input)**

On entry, an array with dimension of at least $(3 * N + 15)$, initialized by DCOST1.

NAME

dcosti - initialize the array WSAVE, which is used in COST.

SYNOPSIS

```
SUBROUTINE DCOSTI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE DCOSTI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSTI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE COSTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcosti(int n, double *wsave);

void dcosti_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when $N - 1$ is a product of small primes. $N \geq 2$.

* *WSAVE (input)*

On entry, an array of dimension $(3 * N + 15)$ or greater. DCOSTI is called once to initialize WSAVE before calling DCOST and need not be called again between calls to DCOST if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

ddisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

SYNOPSIS

```
SUBROUTINE DDISNA( JOB, M, N, D, SEP, INFO)
CHARACTER * 1 JOB
INTEGER M, N, INFO
DOUBLE PRECISION D(*), SEP(*)
```

```
SUBROUTINE DDISNA_64( JOB, M, N, D, SEP, INFO)
CHARACTER * 1 JOB
INTEGER*8 M, N, INFO
DOUBLE PRECISION D(*), SEP(*)
```

F95 INTERFACE

```
SUBROUTINE DISNA( JOB, M, N, D, SEP, [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER :: M, N, INFO
REAL(8), DIMENSION(:) :: D, SEP
```

```
SUBROUTINE DISNA_64( JOB, M, N, D, SEP, [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER(8) :: M, N, INFO
REAL(8), DIMENSION(:) :: D, SEP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ddisna(char job, int m, int n, double *d, double *sep, int *info);
```

```
void ddisna_64(char job, long m, long n, double *d, double *sep, long *info);
```

PURPOSE

ddisna computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix. The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the I-th computed vector is given by

$$\text{SLAMCH}('E') * (\text{ANORM} / \text{SEP}(I))$$

where $\text{ANORM} = 2\text{-norm}(A) = \max(\text{abs}(D(j)))$. $\text{SEP}(I)$ is not allowed to be smaller than $\text{SLAMCH}('E') * \text{ANORM}$ in order to limit the size of the error bound.

SDISNA may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

ARGUMENTS

*** JOB (input)**

Specifies for which problem the reciprocal condition numbers should be computed:

*** M (input)**

The number of rows of the matrix. $M \geq 0$.

*** N (input)**

If $\text{JOB} = 'L'$ or $'R'$, the number of columns of the matrix, in which case $N \geq 0$. Ignored if $\text{JOB} = 'E'$.

*** D (input)**

dimension ($\min(M,N)$) if $\text{JOB} = 'L'$ or $'R'$ The eigenvalues (if $\text{JOB} = 'E'$) or singular values (if $\text{JOB} = 'L'$ or $'R'$) of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

*** SEP (output)**

dimension ($\min(M,N)$) if $\text{JOB} = 'L'$ or $'R'$ The reciprocal condition numbers of the vectors.

*** INFO (output)**

NAME

ddot - compute the dot product of two vectors x and y.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DDOT( N, X, INCX, Y, INCY)
INTEGER N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)
```

```
DOUBLE PRECISION FUNCTION DDOT_64( N, X, INCX, Y, INCY)
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DOT( [N], X, [INCX], Y, [INCY])
INTEGER :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y
```

```
REAL(8) FUNCTION DOT_64( [N], X, [INCX], Y, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
double ddot(int n, double *x, int incx, double *y, int incy);
```

```
double ddot_64(long n, double *x, long incx, double *y, long incy);
```

PURPOSE

ddot compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

*** *X (input)***

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** *Y (input)***

(1 + (m - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

*** *INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

dezftb - computes a periodic sequence from its Fourier coefficients. DEZFTB is a simplified but slower version of DFFTB.

SYNOPSIS

```
SUBROUTINE DEZFTB( N, R, AZERO, A, B, WSAVE)
INTEGER N
DOUBLE PRECISION AZERO
DOUBLE PRECISION R(*), A(*), B(*), WSAVE(*)
```

```
SUBROUTINE DEZFTB_64( N, R, AZERO, A, B, WSAVE)
INTEGER*8 N
DOUBLE PRECISION AZERO
DOUBLE PRECISION R(*), A(*), B(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE DEZFTB( [N], R, AZERO, A, B, WSAVE)
INTEGER :: N
REAL(8) :: AZERO
REAL(8), DIMENSION(:) :: R, A, B, WSAVE
```

```
SUBROUTINE DEZFTB_64( [N], R, AZERO, A, B, WSAVE)
INTEGER(8) :: N
REAL(8) :: AZERO
REAL(8), DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dezftb(int n, double *r, double azero, double *a, double *b, double *wsave);
```

```
void dezftb_64(long n, double *r, double azero, double *a, double *b, double *wsave);
```

ARGUMENTS

* ***N (input)***

Length of the sequence to be synthesized. The method is most efficient when N is the product of small primes. $N \geq 0$.

* ***R (output)***

On exit, the Fourier synthesis of the inputs.

* ***AZERO (input)***

On entry, the constant Fourier coefficient A0. Unchanged on exit.

* ***A (input/output)***

On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

* ***B (input/output)***

On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

* ***WSAVE (input)***

On entry, an array with dimension of at least $(3 * N + 15)$, initialized by DEZFTI.

NAME

dezftf - computes the Fourier coefficients of a periodic sequence. DEZFTF is a simplified but slower version of DFFTF.

SYNOPSIS

```
SUBROUTINE DEZFTF( N, R, AZERO, A, B, WSAVE)
INTEGER N
DOUBLE PRECISION AZERO
DOUBLE PRECISION R(*), A(*), B(*), WSAVE(*)
```

```
SUBROUTINE DEZFTF_64( N, R, AZERO, A, B, WSAVE)
INTEGER*8 N
DOUBLE PRECISION AZERO
DOUBLE PRECISION R(*), A(*), B(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE DEZFTF( [N], R, AZERO, A, B, WSAVE)
INTEGER :: N
REAL(8) :: AZERO
REAL(8), DIMENSION(:) :: R, A, B, WSAVE
```

```
SUBROUTINE DEZFTF_64( [N], R, AZERO, A, B, WSAVE)
INTEGER(8) :: N
REAL(8) :: AZERO
REAL(8), DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dezftf(int n, double *r, double azero, double *a, double *b, double *wsave);
```

```
void dezftf_64(long n, double *r, double azero, double *a, double *b, double *wsave);
```

ARGUMENTS

* ***N (input)***

Length of the sequence to be transformed. The method is most efficient when N is the product of small primes. $N \geq 0$.

* ***R (input/output)***

On entry, a real array of length N containing the sequence to be transformed. On exit, R is unchanged.

* ***AZERO (output)***

On exit, the sum from $i=1$ to $i=n$ of $r(i)/n$.

* ***A (input/output)***

On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

* ***B (input/output)***

On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

* ***WSAVE (input)***

On entry, an array with dimension of at least $(3 * N + 15)$, initialized by DEZFTI.

NAME

dezfti - initializes the array WSAVE, which is used in both DEZFTF and DEZFTB.

SYNOPSIS

```
SUBROUTINE DEZFTI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE DEZFTI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE DEZFTI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE DEZFTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dezfti(int n, double *wsave);

void dezfti_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array with a dimension of at least $(3 * N + 15)$. The same work array can be used for both DEZFTF and DEZFTB as long as N remains unchanged. Different *WSAVE* arrays are required for different values of N . This initialization does not have to be repeated between calls to DEZFTF or DEZFTB as long as N and *WSAVE* remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

dfft2b - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFT2F followed by a call of DFFT2B will multiply the input sequence by $M*N$.

SYNOPSIS

```
SUBROUTINE DFFT2B( PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE
INTEGER M, N, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)

SUBROUTINE DFFT2B_64( PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE
INTEGER*8 M, N, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B( PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)
CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A, B

SUBROUTINE FFT2B_64( PLACE, [M], [N], A, [LDA], B, [LDB], WORK,
*                   LWORK)
CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dfft2b(char place, int m, int n, double *a, int lda, double *b, int ldb, double *work, int lwork);
```

```
void dfft2b_64(char place, long m, long n, double *a, long lda, double *b, long ldb, double *work, long lwork);
```

ARGUMENTS

* **PLACE** (*input*)

Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

* **M** (*input*)

Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

* **N** (*input*)

Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

* **A** (*input/output*)

Real array of dimension (LDA,N). On entry, the two-dimensional array A(LDA,N) contains the input data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N).

* **LDA** (*input*)

Integer specifying the leading dimension of A. If an out-of-place transform is desired $LDA \geq M$. Else if an in-place transform is desired $LDA \geq 2 * (M/2 + 1)$.

* **B** (*input/output*)

Real array of dimension ($2 * LDB$, N). On entry, if an out-of-place transform is requested B contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

* **LDB** (*input*)

Integer. If an out-of-place transform is desired, $2 * LDB$ is the leading dimension of the array B which contains the data to be transformed and $2 * LDB \geq 2 * (M/2 + 1)$. Otherwise it is not referenced.

* **WORK** (*input/output*)

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by DFFT2I.

* **LWORK** (*input*)

Integer. $LWORK \geq (M + 2 * N + \text{MAX}(M, 2 * N) + 30)$

NAME

dfft2f - compute the Fourier coefficients of a periodic sequence. The DFFT operations are unnormalized, so a call of DFFT2F followed by a call of DFFT2B will multiply the input sequence by $M \cdot N$.

SYNOPSIS

```
SUBROUTINE DFFT2F( PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE, FULL
INTEGER M, N, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

```
SUBROUTINE DFFT2F_64( PLACE, FULL, M, N, A, LDA, B, LDB, WORK,
* LWORK)
CHARACTER * 1 PLACE, FULL
INTEGER*8 M, N, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2F( PLACE, FULL, [M], [N], A, [LDA], B, [LDB], WORK,
* LWORK)
CHARACTER(LEN=1) :: PLACE, FULL
INTEGER :: M, N, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A, B
```

```
SUBROUTINE FFT2F_64( PLACE, FULL, [M], [N], A, [LDA], B, [LDB],
* WORK, LWORK)
CHARACTER(LEN=1) :: PLACE, FULL
INTEGER(8) :: M, N, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dfft2f(char place, char full, int m, int n, double *a, int lda, double *b, int ldb, double *work, int lwork);
```

```
void dfft2f_64(char place, char full, long m, long n, double *a, long lda, double *b, long ldb, double *work, long lwork);
```

ARGUMENTS

* *PLACE* (input)

Character. If *PLACE* = 'I' or 'i' (for in-place), the input and output data are stored in array A. If *PLACE* = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

* *FULL* (input)

Indicates whether or not to generate the full result matrix. 'F' or 'f' will cause DFFT2F to generate the full result matrix. Otherwise only a partial matrix that takes advantage of symmetry will be generated.

* *M* (input)

Integer specifying the number of rows to be transformed. It is most efficient when *M* is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

* *N* (input)

Integer specifying the number of columns to be transformed. It is most most efficient when *N* is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

* *A* (input/output)

On entry, a two-dimensional array $A(LDA,N)$ that contains the data to be transformed. Upon exit, *A* is unchanged if an out-of-place transform is done. If an in-place transform with partial result is requested, $A(1:(M/2+1)*2,1:N)$ will contain the transformed results. If an in-place transform with full result is requested, $A(1:2*M,1:N)$ will contain complete transformed results.

* *LDA* (input)

Leading dimension of the array containing the data to be transformed. *LDA* must be even if the transformed sequences are to be stored in *A*.

If *PLACE* = ('O' or 'o') $LDA \geq M$

If *PLACE* = ('I' or 'i') *LDA* must be even. If

FULL = ('F' or 'f'), $LDA \geq 2*M$

FULL is not ('F' or 'f'), $LDA \geq (M/2+1)*2$

* *B* (input/output)

Upon exit, a two-dimensional array $B(2*LDB,N)$ that contains the transformed results if an out-of-place transform is done. Otherwise, *B* is not used.

If an out-of-place transform is done and *FULL* is not 'F' or 'f', $B(1:(M/2+1)*2,1:N)$ will contain the partial transformed results. If *FULL* = 'F' or 'f', $B(1:2*M,1:N)$ will contain the complete transformed results.

* *LDB* (input)

$2*LDB$ is the leading dimension of the array *B*. If an in-place transform is desired *LDB* is ignored.

If *PLACE* is ('O' or 'o') and

FULL is ('F' or 'f'), $LDB \geq M$

FULL is not ('F' or 'f') and *M* is even, $LDB \geq M/2+1$

Note that even though *LDB* is used in the argument list, $2*LDB$ is the actual leading dimension of *B*.

* *WORK* (input/output)

One-dimensional real array of length at least *LWORK*. On input, *WORK* must have been initialized by DFFT2I.

* *LWORK* (input)

Integer. $LWORK \geq (M + 2*N + \text{MAX}(M, 2*N) + 30)$

NAME

dfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

SYNOPSIS

```
SUBROUTINE DFFT2I( M, N, WORK)
INTEGER M, N
DOUBLE PRECISION WORK(*)

SUBROUTINE DFFT2I_64( M, N, WORK)
INTEGER*8 M, N
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2I( M, N, WORK)
INTEGER :: M, N
REAL(8), DIMENSION(:) :: WORK

SUBROUTINE FFT2I_64( M, N, WORK)
INTEGER(8) :: M, N
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void dfft2i(int m, int n, double *work);

void dfft2i_64(long m, long n, double *work);
```

ARGUMENTS

* ***M*** (*input*)

Number of rows to be transformed. $M \geq 0$.

* ***N*** (*input*)

Number of columns to be transformed. $N \geq 0$.

* ***WORK*** (*input/output*)

On entry, an array of dimension $(M + 2*N + \text{MAX}(M, 2*N) + 30)$ or greater. DFFT2I needs to be called only once to initialize array WORK before calling DFFT2F and/or DFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

dfft3b - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFT3F followed by a call of DFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE DFFT3B( PLACE, M, N, K, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE
INTEGER M, N, K, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,N,*), B(LDB,N,*), WORK(*)

SUBROUTINE DFFT3B_64( PLACE, M, N, K, A, LDA, B, LDB, WORK, LWORK)
CHARACTER * 1 PLACE
INTEGER*8 M, N, K, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,N,*), B(LDB,N,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3B( PLACE, [M], [N], [K], A, [LDA], B, [LDB], WORK,
*              LWORK)
CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N, K, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:,:) :: A, B

SUBROUTINE FFT3B_64( PLACE, [M], [N], [K], A, [LDA], B, [LDB], WORK,
*              LWORK)
CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N, K, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dfft3b(char place, int m, int n, int k, double *a, int lda, double *b, int ldb, double *work, int lwork);
```

```
void dfft3b_64(char place, long m, long n, long k, double *a, long lda, double *b, long ldb, double *work, long lwork);
```

ARGUMENTS

*** PLACE (input)**

Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

*** M (input)**

Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

*** N (input)**

Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

*** K (input)**

Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. $K \geq 0$; when $K = 0$, the subroutine returns immediately without changing any data.

*** A (input/output)**

On entry, the three-dimensional array $A(LDA,N,K)$ contains the data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in $A(1:M,1:N,1:K)$.

*** LDA (input)**

Integer specifying the leading dimension of A. If an out-of-place transform is desired $LDA \geq M$. Else if an in-place transform is desired $LDA \geq 2*(M/2+1)$.

*** B (input/output)**

Real array of dimension $B(2*LDB,N,K)$. On entry, if an out-of-place transform is requested $B(1:2*(M/2+1),1:N,1:K)$ contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

*** LDB (input)**

If an out-of-place transform is desired, $2*LDB$ is the leading dimension of the array B which contains the data to be transformed and $2*LDB \geq 2*(M/2+1)$. Otherwise it is not referenced.

*** WORK (input/output)**

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by DFFT3I.

*** LWORK (input)**

Integer. $LWORK \geq (M + 2*(N + K) + 4*K + 45)$.

NAME

dfft3f - compute the Fourier coefficients of a real periodic sequence. The DFFT operations are unnormalized, so a call of DFFT3F followed by a call of DFFT3B will multiply the input sequence by $M*N*K$.

SYNOPSIS

```
SUBROUTINE DFFT3F( PLACE, FULL, M, N, K, A, LDA, B, LDB, WORK,
*                LWORK)
CHARACTER * 1 PLACE, FULL
INTEGER M, N, K, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,N,*), B(LDB,N,*), WORK(*)

SUBROUTINE DFFT3F_64( PLACE, FULL, M, N, K, A, LDA, B, LDB, WORK,
*                   LWORK)
CHARACTER * 1 PLACE, FULL
INTEGER*8 M, N, K, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,N,*), B(LDB,N,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3F( PLACE, FULL, [M], [N], [K], A, [LDA], B, [LDB],
*              WORK, LWORK)
CHARACTER(LEN=1) :: PLACE, FULL
INTEGER :: M, N, K, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:,:) :: A, B

SUBROUTINE FFT3F_64( PLACE, FULL, [M], [N], [K], A, [LDA], B, [LDB],
*                  WORK, LWORK)
CHARACTER(LEN=1) :: PLACE, FULL
INTEGER(8) :: M, N, K, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dfft3f(char place, char full, int m, int n, int k, double *a, int lda, double *b, int ldb, double *work, int lwork);
```

```
void dfft3f_64(char place, char full, long m, long n, long k, double *a, long lda, double *b, long ldb, double *work, long lwork);
```

ARGUMENTS

* *PLACE* (input)

Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

* *FULL* (input)

Select a full ('F' or 'f') or partial (' ') representation of the results. If the caller selects full representation then an $M \times N \times K$ real array will transform to produce an $M \times N \times K$ complex array. If the caller does not select full representation then an $M \times N \times K$ real array will transform to a $(M/2+1) \times N \times K$ complex array that takes advantage of the symmetry properties of a transformed real sequence.

* *M* (input)

Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. $M \geq 0$; when $M = 0$, the subroutine returns immediately without changing any data.

* *N* (input)

Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. $N \geq 0$; when $N = 0$, the subroutine returns immediately without changing any data.

* *K* (input)

Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. $K \geq 0$; when $K = 0$, the subroutine returns immediately without changing any data.

* *A* (input/output)

On entry, a three-dimensional array $A(LDA, N, K)$ that contains input data to be transformed. On exit, if an in-place transform is done and *FULL* is not 'F' or 'f', $A(1:2*(M/2+1), 1:N, 1:K)$ will contain the partial transformed results. If *FULL* = 'F' or 'f', $A(1:2*M, 1:N, 1:K)$ will contain the complete transformed results.

* *LDA* (input)

Leading dimension of the array containing the data to be transformed. *LDA* must be even if the transformed sequences are to be stored in *A*.

If *PLACE* = ('O' or 'o') $LDA \geq M$

If *PLACE* = ('I' or 'i') *LDA* must be even. If

FULL = ('F' or 'f'), $LDA \geq 2*M$

FULL is not ('F' or 'f'), $LDA \geq 2*(M/2+1)$

* *B* (input/output)

Upon exit, a three-dimensional array $B(2*LDB, N, K)$ that contains the transformed results if an out-of-place transform is done. Otherwise, *B* is not used.

If an out-of-place transform is done and *FULL* is not 'F' or 'f', $B(1:2*(M/2+1), 1:N, 1:K)$ will contain the partial transformed results. If *FULL* = 'F' or 'f', $B(1:2*M, 1:N, 1:K)$ will contain the complete transformed results.

* *LDB* (input)

$2*LDB$ is the leading dimension of the array *B*. If an in-place transform is desired *LDB* is ignored.

If *PLACE* is ('O' or 'o') and

FULL is ('F' or 'f'), then $LDB \geq M$

FULL is not ('F' or 'f'), then $LDB \geq M/2 + 1$

Note that even though *LDB* is used in the argument list, $2*LDB$ is the actual leading dimension of *B*.

* *WORK* (input/output)

One-dimensional real array of length at least LWORK. WORK must have been initialized by DFFT3I.

* **LWORK** (*input*)

Integer. LWORK $\geq (M + 2*(N + K) + 4*K + 45)$.

NAME

dfft3i - initialize the array WSAVE, which is used in both DFFT3F and DFFT3B.

SYNOPSIS

```
SUBROUTINE DFFT3I( M, N, K, WORK)
  INTEGER M, N, K
  DOUBLE PRECISION WORK(*)

SUBROUTINE DFFT3I_64( M, N, K, WORK)
  INTEGER*8 M, N, K
  DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3I( M, N, K, WORK)
  INTEGER :: M, N, K
  REAL(8), DIMENSION(:) :: WORK

SUBROUTINE FFT3I_64( M, N, K, WORK)
  INTEGER(8) :: M, N, K
  REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void dfft3i(int m, int n, int k, double *work);

void dfft3i_64(long m, long n, long k, double *work);
```

ARGUMENTS

* ***M*** (*input*)

Number of rows to be transformed. $M \geq 0$.

* ***N*** (*input*)

Number of columns to be transformed. $N \geq 0$.

* ***K*** (*input*)

Number of planes to be transformed. $K \geq 0$.

* ***WORK*** (*input/output*)

On entry, an array of dimension $(M + 2*(N + K) + 30)$ or greater. DFFT3I needs to be called only once to initialize array *WORK* before calling DFFT3F and/or DFFT3B if *M*, *N*, *K* and *WORK* remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

dfftb - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFTF followed by a call of DFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE DFFTB( N, X, WSAVE)
INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DFFTB_64( N, X, WSAVE)
INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB( [N], X, WSAVE)
INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE FFTB_64( [N], X, WSAVE)
INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dfftb(int n, double *x, double *wsave);

void dfftb_64(long n, double *x, double *wsave);
```

ARGUMENTS

*** *N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
 $N \geq 0$.

*** *X (input)***

On entry, an array of length N containing the sequence to be transformed.

*** *WSAVE (input)***

On entry, *WSAVE* must be an array of dimension $(2 * N + 15)$ or greater and must have been initialized by *DFFTI*.

NAME

dfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of DFFTF followed by a call of DFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE DFFTF( N, X, WSAVE)
INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DFFTF_64( N, X, WSAVE)
INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF( [N], X, WSAVE)
INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE FFTF_64( [N], X, WSAVE)
INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dfftf(int n, double *x, double *wsave);

void dfftf_64(long n, double *x, double *wsave);
```

ARGUMENTS

*** *N (input)***

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

*** *X (input)***

On entry, an array of length N containing the sequence to be transformed.

*** *WSAVE (input)***

On entry, WSAVE must be an array of dimension (2 * N + 15) or greater and must have been initialized by DFFTI.

NAME

dffti - initialize the array WSAVE, which is used in both DFFTF and DFFTB.

SYNOPSIS

```
SUBROUTINE DFFTI( N, WSAVE)
INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE DFFTI_64( N, WSAVE)
INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTI( N, WSAVE)
INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE FFTI_64( N, WSAVE)
INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dffti(int n, double *wsave);

void dffti_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input)*

On entry, an array of dimension $(2 * N + 15)$ or greater. DFFTI needs to be called only once to initialize array WORK before calling DFFTF and/or DFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

dfftopt - compute the length of the closest fast FFT

SYNOPSIS

```
INTEGER FUNCTION DFFTOPT( LEN )
INTEGER LEN
```

```
INTEGER*8 FUNCTION DFFTOPT_64( LEN )
INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION DFFTOPT( LEN )
INTEGER :: LEN
```

```
INTEGER(8) FUNCTION DFFTOPT_64( LEN )
INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>

int dfftopt(int len);

long dfftopt_64(long len);
```

PURPOSE

dfftopt computes the length of the closest fast FFT. Fast Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length $32=2*2*5$ will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

DFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. DFFTOPT will return 16 for an input of N=16 and return $18=2*3*3$ for an input of N=17.

Note that the length computed here is not guaranteed to be optimal, only to be a product of small primes. Also, the value

returned may change as the underlying FFTs become capable of handling larger primes. For example, passing in $N=51$ today will return $52=2*2*13$ rather than $51=3*17$ because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added and then $N=51$ will return 51.

ARGUMENTS

NAME

dgbbird - reduce a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation

SYNOPSIS

```
SUBROUTINE DGBBRD( VECT, M, N, NCC, KL, KU, AB, LDAB, D, E, Q, LDQ,

REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: AB, Q, PT, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbbird(char vect, int m, int n, int ncc, int kl, int ku, double *ab, int ldab, double *d, double *e, double *q, int ldq,
double *pt, int ldpt, double *c, int ldc, int *info);
```

```
void dgbbird_64(char vect, long m, long n, long ncc, long kl, long ku, double *ab, long ldab, double *d, double *e, double *q,
long ldq, double *pt, long ldpt, double *c, long ldc, long *info);
```

PURPOSE

dgbbdd reduces a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation: $Q' * A * P = B$.

The routine computes B, and optionally forms Q or P', or computes $Q'*C$ for a given matrix C.

ARGUMENTS

* **VECT** (*input*)

Specifies whether or not the matrices Q and P' are to be formed.

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* **NCC** (*input*)

The number of columns of the matrix C. $NCC \geq 0$.

* **KL** (*input*)

The number of subdiagonals of the matrix A. $KL \geq 0$.

* **KU** (*input*)

The number of superdiagonals of the matrix A. $KU \geq 0$.

* **AB** (*input/output*)

On entry, the m-by-n band matrix A, stored in rows 1 to $KL+KU+1$. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$. On exit, A is overwritten by values generated during the reduction.

* **LDAB** (*input*)

The leading dimension of the array A. $LDAB \geq KL+KU+1$.

* **D** (*output*)

The diagonal elements of the bidiagonal matrix B.

* **E** (*output*)

The superdiagonal elements of the bidiagonal matrix B.

* **Q** (*output*)

If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. $LDQ \geq \max(1,M)$ if VECT = 'Q' or 'B'; $LDQ \geq 1$ otherwise.

* **PT** (*output*)

If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

* **LDPT** (*input*)

The leading dimension of the array PT. $LDPT \geq \max(1,N)$ if VECT = 'P' or 'B'; $LDPT \geq 1$ otherwise.

* **C** (*input/output*)

On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q^*C . C is not referenced if $NCC = 0$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$ if $NCC > 0$; $LDC \geq 1$ if $NCC = 0$.

* **WORK** (*workspace*)

dimension($\text{MAX}(M, N)$)

* **INFO** (*output*)

NAME

dgbc - (obsolete) compute the LU factorization and condition number of a general matrix A in banded storage. If the condition number is not needed then SGBFA is slightly faster. It is typical to follow a call to SGBCO with a call to SGBSL to solve $Ax = b$ or to SGBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE DGBCO( A, LDA, N, NSUB, NSUPER, IPIVOT, RCOND, WORK)
INTEGER LDA, N, NSUB, NSUPER
INTEGER IPIVOT(*)
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DGBCO_64( A, LDA, N, NSUB, NSUPER, IPIVOT, RCOND, WORK)
INTEGER*8 LDA, N, NSUB, NSUPER
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbc(double *a, int lda, int n, int nsub, int nsuper, int *ipivot, double *rcond);
```

```
void dgbc_64(double *a, long lda, long n, long nsub, long nsuper, long *ipivot, double *rcond);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, an LU factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq \text{NSUPER} \geq 0$ but if $N = 0$ then $\text{NSUPER} = 0$.

* ***IPIVOT*** (*output*)

On exit, a vector of pivot indices.

* ***RCOND*** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq \text{RCOND} \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $\text{RCOND} + 1.0 = 1.0$ then A may be singular to working precision.

* ***WORK*** (*workspace*)

Scratch array with a dimension of N.

NAME

dgbcon - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

SYNOPSIS

```
SUBROUTINE DGBCON( NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,
*      RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM
INTEGER N, NSUB, NSUPER, LDA, INFO
INTEGER IPIVOT(*), WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)

SUBROUTINE DGBCON_64( NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,
*      RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM
INTEGER*8 N, NSUB, NSUPER, LDA, INFO
INTEGER*8 IPIVOT(*), WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GBCON( NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT, ANORM,
*      RCOND, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: NORM
INTEGER :: N, NSUB, NSUPER, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT, WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A

SUBROUTINE GBCON_64( NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT,
*      ANORM, RCOND, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, NSUB, NSUPER, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbcon(char norm, int n, int nsub, int nsuper, double *a, int lda, int *ipivot, double anorm, double *rcond, int *info);
```

```
void dgbcon_64(char norm, long n, long nsub, long nsuper, double *a, long lda, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

dgbcon estimates the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $\text{NSUB} \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $\text{NSUPER} \geq 0$.

* **A** (*input*)

Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with $\text{NSUB} + \text{NSUPER}$ superdiagonals in rows 1 to $\text{NSUB} + \text{NSUPER} + 1$, and the multipliers used during the factorization are stored in rows $\text{NSUB} + \text{NSUPER} + 2$ to $2 * \text{NSUB} + \text{NSUPER} + 1$.

* **LDA** (*input*)

The leading dimension of the array A. $\text{LDA} \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **ANORM** (*input*)

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

* **WORK** (*workspace*)

dimension($2 * N$)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dgbdI - (obsolete) compute the determinant of a general matrix A in banded storage, which has been LU-factored by SGBCO or SGBFA.

SYNOPSIS

```
SUBROUTINE DGBDI( A, LDA, N, NSUB, NSUPER, IPIVOT, DET)
INTEGER LDA, N, NSUB, NSUPER
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), DET(*)
```

```
SUBROUTINE DGBDI_64( A, LDA, N, NSUB, NSUPER, IPIVOT, DET)
INTEGER*8 LDA, N, NSUB, NSUPER
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbdI(double *a, int lda, int n, int nsub, int nsuper, int *ipivot, double *det);
```

```
void dgbdI_64(double *a, long lda, long n, long nsub, long nsuper, long *ipivot, double *det);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A, as computed by SGBCO or SGBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (input)**

Pivot vector as computed by SGBCO or SGBFA.

*** *DET* (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**}expon)$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) = 0.0$.

NAME

dgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE DGBEQU( M, N, NSUB, NSUPER, A, LDA, ROWSC, COLSC, ROWCN,  
* COLCN, AMAX, INFO)  
INTEGER M, N, NSUB, NSUPER, LDA, INFO  
DOUBLE PRECISION ROWCN, COLCN, AMAX  
DOUBLE PRECISION A(LDA,*), ROWSC(*), COLSC(*)
```

```
SUBROUTINE DGBEQU_64( M, N, NSUB, NSUPER, A, LDA, ROWSC, COLSC,  
* ROWCN, COLCN, AMAX, INFO)  
INTEGER*8 M, N, NSUB, NSUPER, LDA, INFO  
DOUBLE PRECISION ROWCN, COLCN, AMAX  
DOUBLE PRECISION A(LDA,*), ROWSC(*), COLSC(*)
```

F95 INTERFACE

```
SUBROUTINE GBEQU( [M], [N], NSUB, NSUPER, A, [LDA], ROWSC, COLSC,  
* ROWCN, COLCN, AMAX, [INFO])  
INTEGER :: M, N, NSUB, NSUPER, LDA, INFO  
REAL(8) :: ROWCN, COLCN, AMAX  
REAL(8), DIMENSION(:) :: ROWSC, COLSC  
REAL(8), DIMENSION(:,) :: A
```

```
SUBROUTINE GBEQU_64( [M], [N], NSUB, NSUPER, A, [LDA], ROWSC, COLSC,  
* ROWCN, COLCN, AMAX, [INFO])  
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INFO  
REAL(8) :: ROWCN, COLCN, AMAX  
REAL(8), DIMENSION(:) :: ROWSC, COLSC  
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbequ(int m, int n, int nsub, int nsuper, double *a, int lda, double *rowsc, double *colsc, double *rowcn, double *colcn, double *amax, int *info);
```

```
void dgbequ_64(long m, long n, long nsub, long nsuper, double *a, long lda, double *rowsc, double *colsc, double *rowcn, double *colcn, double *amax, long *info);
```

PURPOSE

dgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

* **M (input)**

The number of rows of the matrix A. $M \geq 0$.

* **N (input)**

The number of columns of the matrix A. $N \geq 0$.

* **NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **A (input)**

The band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

* **ROWSC (output)**

If $INFO = 0$, or $INFO > M$, ROWSC contains the row scale factors for A.

* **COLSC (output)**

If $INFO = 0$, COLSC contains the column scale factors for A.

* **ROWCN (output)**

If $INFO = 0$ or $INFO > M$, ROWCN contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If $ROWCN \geq 0.1$ and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

* **COLCN (output)**

If $INFO = 0$, COLCN contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If $COLCN \geq 0.1$, it is not worth scaling by COLSC.

* **AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO (output)**

NAME

dgbfa - (obsolete) compute the LU factorization of a matrix A in banded storage. It is typical to follow a call to SGBFA with a call to SGBSL to solve $Ax = b$ or to SGBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE DGBFA( A, LDA, N, NSUB, NSUPER, IPIVOT, INFO)
INTEGER LDA, N, NSUB, NSUPER, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DGBFA_64( A, LDA, N, NSUB, NSUPER, IPIVOT, INFO)
INTEGER*8 LDA, N, NSUB, NSUPER, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbfa(double *a, int lda, int n, int nsup, int *ipivot, int *info);
```

```
void dgbfa_64(double *a, long lda, long n, long nsup, long *ipivot, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, an LU factorization of the matrix A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

Number of subdiagonals of A. $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

* **NSUPER** (*input*)

Number of superdiagonals of A. $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that SGBSL will divide by zero if called.

NAME

dgbmv - perform one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A^T * x + \beta * y$

SYNOPSIS

```
SUBROUTINE DGBMV( TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,
*      INCX, BETA, Y, INCY)
CHARACTER * 1 TRANSA
INTEGER M, N, NSUB, NSUPER, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)

SUBROUTINE DGBMV_64( TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,
*      INCX, BETA, Y, INCY)
CHARACTER * 1 TRANSA
INTEGER*8 M, N, NSUB, NSUPER, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GBMV( [TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],
*      X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:, :) :: A

SUBROUTINE GBMV_64( [TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],
*      X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbmv(char transa, int m, int n, int nsub, int nsuper, double alpha, double *a, int lda, double *x, int incx, double beta, double *y, int incy);
```

void dgbmv_64(char transa, long m, long n, long nsub, long nsuper, double alpha, double *a, long lda, double *x, long incx, double beta, double *y, long incy);

PURPOSE

dgbmv performs one of the matrix-vector operations $y := \alpha * A * x + \beta * y$ or $y := \alpha * A' * x + \beta * y$, where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with kl sub-diagonals and ku super-diagonals.

ARGUMENTS

* *TRANSA* (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha * A * x + \beta * y$.

TRANSA = 'T' or 't' $y := \alpha * A' * x + \beta * y$.

TRANSA = 'C' or 'c' $y := \alpha * A' * x + \beta * y$.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

* *NSUB* (input)

On entry, NSUB specifies the number of sub-diagonals of the matrix A. $NSUB \geq 0$. Unchanged on exit.

* *NSUPER* (input)

On entry, NSUPER specifies the number of super-diagonals of the matrix A. $NSUPER \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry, the leading $(kl + ku + 1)$ by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row $(ku + 1)$ of the array, the first super-diagonal starting at position 2 in row ku, the first sub-diagonal starting at position 1 in row $(ku + 2)$, and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left ku by ku triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
DO 20, J = 1, N
  = NSUPER + 1 - J
O 10, I = MAX( 1, J - NSUPER ), MIN( M, J + NSUB )
  A( K + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Unchanged on exit.

* **LDA** (*input*)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (kl + ku + 1)$. Unchanged on exit.

* **X** (*input*)

$(1 + (n - 1) * \text{abs}(INCX))$ when TRANS = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(INCX))$ otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* **INCX** (*input*)

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

* **BETA** (*input*)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* **Y** (*input/output*)

$(1 + (m - 1) * \text{abs}(INCY))$ when TRANS = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(INCY))$ otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* **INCY** (*input*)

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

dgbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE DGBRFS( TRANSA, N, NSUB, NSUPER, NRHS, A, LDA, AF, LDAF,

REAL(8), DIMENSION(:,:) :: A, AF, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbrfs(char transa, int n, int nsub, int nsuper, int nrhs, double *a, int lda, double *af, int ldaf, int *ipivot, double *b, int ldb, double *x, int ldx, double *ferr, double *berr, int *info);
```

```
void dgbrfs_64(char transa, long n, long nsub, long nsuper, long nrhs, double *a, long lda, double *af, long ldaf, long *ipivot, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The original band matrix A, stored in rows 1 to $NSUB+NSUPER+1$. The j-th column of A is stored in the j-th column of the array A as follows: $A(ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(n,j+ku)$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NSUB+NSUPER+1$.

* **AF** (*input*)

Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq 2*NSUB*NSUPER+1$.

* **IPIVOT** (*input*)

The pivot indices from SGBTRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* ***X*** (*input/output*)

On entry, the solution matrix X, as computed by SGBTRS. On exit, the improved solution matrix X.

* ***LDX*** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* ***FERR*** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* ***WORK*** (*workspace*)

dimension(2*N)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

dgbsl - (obsolete) solve the linear system $Ax = b$ for a matrix A in banded storage, which has been LU-factored by SGBCO or SGBFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE DGBSL( A, LDA, N, NSUB, NSUPER, IPIVOT, B, JOB)
INTEGER LDA, N, NSUB, NSUPER, JOB
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), B(*)
```

```
SUBROUTINE DGBSL_64( A, LDA, N, NSUB, NSUPER, IPIVOT, B, JOB)
INTEGER*8 LDA, N, NSUB, NSUPER, JOB
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbsl(double *a, int lda, int n, int nsub, int nsuper, int *ipivot, double *b, int job);
```

```
void dgbsl_64(double *a, long lda, long n, long nsub, long nsuper, long *ipivot, double *b, long job);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A , as computed by SGBCO or SGBFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq 2 * NSUB + NSUPER + 1$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** NSUB (input)**

Number of subdiagonals of A . $N-1 \geq NSUB \geq 0$ but if $N = 0$ then $NSUB = 0$.

*** NSUPER (input)**

Number of superdiagonals of A . $N-1 \geq NSUPER \geq 0$ but if $N = 0$ then $NSUPER = 0$.

*** IPIVOT (input)**

Pivot vector as computed by SGBCO or SGBFA.

*** *B* (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

*** *JOB* (input)**

Determines which operation this subroutine will perform:

○ 0 solve the system $Ax = b$

not 0 solve the linear system $AHx = b$
Note that $ATx = AHx$ for real matrices.

NAME

dgbsv - compute the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

SYNOPSIS

```

```

```
void dgbsv_64(long n, long nsub, long nsuper, long nrhs, double *a, long lda, long *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dgbsv computes the solution to a real system of linear equations $A * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N -by- $NRHS$ matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as $A = L * U$, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with $KL+KU$ superdiagonals. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** N (input)**

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

*** $NSUB$ (input)**

The number of subdiagonals within the band of A . $NSUB \geq 0$.

*** $NSUPER$ (input)**

The number of superdiagonals within the band of A . $NSUPER \geq 0$.

*** $NRHS$ (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** A (input/output)**

On entry, the matrix A in band storage, in rows $NSUB+1$ to $2*NSUB+NSUPER+1$; rows 1 to $NSUB$ of the array need not be set. The j -th column of A is stored in the j -th column of the array A as follows:
 $A(NSUB+NSUPER+1+i-j,j) = A(i,j)$ for $\max(1,j-NSUPER) \leq i \leq \min(N,j+NSUB)$ On exit, details of the factorization: U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. See below for further details.

*** LDA (input)**

The leading dimension of the array A . $LDA \geq 2*NSUB+NSUPER+1$.

*** $IPIVOT$ (output)**

The pivot indices that define the permutation matrix P ; row i of the matrix was interchanged with row $IPIVOT(i)$.

*** B (input/output)**

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1,N)$.

*** $INFO$ (output)**

NAME

dgbsvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$,

SYNOPSIS

```
SUBROUTINE DGBSVX( FACT, TRANSA, N, NSUB, NSUPER, NRHS, A, LDA, AF,

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbsvx(char fact, char transa, int n, int nsub, int nsuper, int nrhs, double *a, int lda, double *af, int ldaf, int *ipivot, char equed, double *rowsc, double *colsc, double *b, int ldb, double *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void dgbsvx_64(char fact, char transa, long n, long nsub, long nsuper, long nrhs, double *a, long lda, double *af, long ldaf, long *ipivot, char equed, double *rowsc, double *colsc, double *b, long ldb, double *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

dgbsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$, $A^{**T} * X = B$, or $A^{**H} * X = B$, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
TRANS = 'T':  (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
TRANS = 'C':  (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

```
A = L * U,
where L is a product of permutation and unit lower triangular
matrices with KL subdiagonals, and U is upper triangular with
KL+KU superdiagonals.
```

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so that it solves the original system before equilibration.

ARGUMENTS

*** FACT (input)**

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

*** TRANS (input)**

Specifies the form of the system of equations.

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

*** NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the matrix A in band storage, in rows 1 to NSUB+NSUPER+1. The j-th column of A is stored in the j-th column of the array A as follows: $A(NSUPER+1+i-j,j) = A(i,j)$ for $\max(1,j-NSUPER) \leq i \leq \min(N,j+KL)$

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in ROWSC and/or COLSC. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'ROWSC': $A := \text{diag}(\text{ROWSC}) * A$

EQUED = 'COLSC': $A := A * \text{diag}(\text{COLSC})$

EQUED = 'B': $A := \text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \text{NSUB} + \text{NSUPER} + 1$.

* **AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to $2 * \text{NSUB} + \text{NSUPER} + 1$. If EQUED = 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* **LDAF (input)**

The leading dimension of the array AF. $LDAF \geq 2 * \text{NSUB} + \text{NSUPER} + 1$.

* **IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = L * U$ as computed by SGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L * U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = L * U$ of the equilibrated matrix A.

* **EQUED (input)**

Specifies the form of equilibration that was done.

* **ROWSC (input/output)**

The row scale factors for A. If EQUED = 'ROWSC' or 'B', A is multiplied on the left by $\text{diag}(\text{ROWSC})$; if EQUED = 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT = 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

* **COLSC (input/output)**

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

* **B (input/output)**

On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC}) * B$; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC}) * B$.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED = 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC})) * X$ if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC})) * X$ if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

* **LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK (workspace)**

On exit, WORK(1) contains the reciprocal pivot growth factor $\text{norm}(A) / \text{norm}(U)$. The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

* **WORK2 (workspace)**

* **INFO (output)**

NAME

dgbtf2 - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE DGBTF2( M, N, KL, KU, AB, LDAB, IPIV, INFO)
INTEGER M, N, KL, KU, LDAB, INFO
INTEGER IPIV(*)
DOUBLE PRECISION AB(LDAB,*)
```

```
SUBROUTINE DGBTF2_64( M, N, KL, KU, AB, LDAB, IPIV, INFO)
INTEGER*8 M, N, KL, KU, LDAB, INFO
INTEGER*8 IPIV(*)
DOUBLE PRECISION AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE GBTF2( [M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
INTEGER :: M, N, KL, KU, LDAB, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:,:) :: AB
```

```
SUBROUTINE GBTF2_64( [M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])
INTEGER(8) :: M, N, KL, KU, LDAB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:,:) :: AB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgbtf2(int m, int n, int kl, int ku, double *ab, int ldab, int *ipiv, int *info);
```

```
void dgbtf2_64(long m, long n, long kl, long ku, double *ab, long ldab, long *ipiv, long *info);
```

PURPOSE

dgbt2 computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** KL (input)**

The number of subdiagonals within the band of A. $KL \geq 0$.

*** KU (input)**

The number of superdiagonals within the band of A. $KU \geq 0$.

*** AB (input/output)**

On entry, the matrix A in band storage, in rows $KL+1$ to $2*KL+KU+1$; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: $AB(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1, j-ku) \leq i \leq \min(m, j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with $KL+KU$ superdiagonals in rows 1 to $KL+KU+1$, and the multipliers used during the factorization are stored in rows $KL+KU+2$ to $2*KL+KU+1$. See below for further details.

*** LDAB (input)**

The leading dimension of the array AB. $LDAB \geq 2*KL+KU+1$.

*** IPIV (output)**

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row $IPIV(i)$.

*** INFO (output)**

NAME

```

```
void dgbtrf_64(long m, long n, long nsub, long nsuper, double *a, long lda, long *ipivot, long *info);
```

PURPOSE

dgbrtf computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NSUB (input)**

The number of subdiagonals within the band of A. $NSUB \geq 0$.

*** NSUPER (input)**

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

*** A (input/output)**

On entry, the matrix A in band storage, in rows $NSUB+1$ to $2*NSUB+NSUPER+1$; rows 1 to $NSUB$ of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: $A(kl+ku+1+i-j,j) = A(i,j)$ for $\max(1,j-ku) \leq i \leq \min(m,j+kl)$

On exit, details of the factorization: U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$. See below for further details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq \min(M,N)$, row i of the matrix was interchanged with row $IPIVOT(i)$.

*** INFO (output)**

```
void dgbtrs_64(char transa, long n, long nsub, long nsuper, long nrhs, double *a, long lda, long *ipivot, double *b, long ldb,
```

long *info);

PURPOSE

dgbrs solves a system of linear equations $A * X = B$ or $A' * X = B$ with a general band matrix A using the LU factorization computed by SGBTRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NSUB** (*input*)

The number of subdiagonals within the band of A. $NSUB \geq 0$.

* **NSUPER** (*input*)

The number of superdiagonals within the band of A. $NSUPER \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with $NSUB+NSUPER$ superdiagonals in rows 1 to $NSUB+NSUPER+1$, and the multipliers used during the factorization are stored in rows $NSUB+NSUPER+2$ to $2*NSUB+NSUPER+1$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq 2*NSUB+NSUPER+1$.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

dgebak - form the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL

SYNOPSIS

```
SUBROUTINE DGEBAK( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)
CHARACTER * 1 JOB, SIDE
INTEGER N, ILO, IHI, M, LDV, INFO
DOUBLE PRECISION SCALE(*), V(LDV,*)
```

```
SUBROUTINE DGEBAK_64( JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV,
* INFO)
CHARACTER * 1 JOB, SIDE
INTEGER*8 N, ILO, IHI, M, LDV, INFO
DOUBLE PRECISION SCALE(*), V(LDV,*)
```

F95 INTERFACE

```
SUBROUTINE GEBAK( JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
* [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
INTEGER :: N, ILO, IHI, M, LDV, INFO
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: V

SUBROUTINE GEBAK_64( JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
* [INFO])
CHARACTER(LEN=1) :: JOB, SIDE
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: V
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgebak(char job, char side, int n, int ilo, int ihi, double *scale, int m, double *v, int ldv, int *info);
```

```
void dgebak_64(char job, char side, long n, long ilo, long ihi, double *scale, long m, double *v, long ldv, long *info);
```

PURPOSE

dgebak forms the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL.

ARGUMENTS

* ***JOB*** (*input*)

Specifies the type of backward transformation required:

* ***SIDE*** (*input*)

* ***N*** (*input*)

The number of rows of the matrix V . $N \geq 0$.

* ***ILO*** (*input*)

The integers ILO and IHI determined by SGEBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI*** (*input*)

See the description for ILO .

* ***SCALE*** (*input*)

Details of the permutation and scaling factors, as returned by SGEBAL.

* ***M*** (*input*)

The number of columns of the matrix V . $M \geq 0$.

* ***V*** (*input/output*)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by SHSEIN or STREVC. On exit, V is overwritten by the transformed eigenvectors.

* ***LDV*** (*input*)

The leading dimension of the array V . $LDV \geq \max(1, N)$.

* ***INFO*** (*output*)

NAME

dgebal - balance a general real matrix A

SYNOPSIS

CHARACTER * 1 JOB
INTEGER N, LDA, ILO, IHI, INFO
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

```
SUBROUTINE DGEBAL_64( JOB, N, A, LDA, ILO, IHI, SCALE, INFO)
CHARACTER * 1 JOB
INTEGER*8 N, LDA, ILO, IHI, INFO
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL( JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER :: N, LDA, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEBAL_64( JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER(8) :: N, LDA, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgebal(char job, int n, double *a, int lda, int *ilo, int *ihi, double *scale, int *info);
```

```
void dgebal_64(char job, long n, double *a, long lda, long *ilo, long *ihi, double *scale, long *info);
```

PURPOSE

dgebal balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

*** JOB (input)**

Specifies the operations to be performed on A:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** ILO (output)**

ILO and IHI are set to integers such that on exit $A(i, j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

*** IHI (output)**

See the description for ILO.

*** SCALE (output)**

Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then $SCALE(j) = P(j)$ for $j = 1, \dots, ILO-1$

*** INFO (output)**

NAME

dgebrd - reduce a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation

SYNOPSIS

```
SUBROUTINE DGEBRD( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,  
*                INFO)  
  INTEGER M, N, LDA, LWORK, INFO  
  DOUBLE PRECISION A(LDA,*), D(*), E(*), TAUQ(*), TAUP(*), WORK(*)  
  
SUBROUTINE DGEBRD_64( M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,  
*                   INFO)  
  INTEGER*8 M, N, LDA, LWORK, INFO  
  DOUBLE PRECISION A(LDA,*), D(*), E(*), TAUQ(*), TAUP(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEBRD( [M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],  
*               [LWORK], [INFO])  
  INTEGER :: M, N, LDA, LWORK, INFO  
  REAL(8), DIMENSION(:) :: D, E, TAUQ, TAUP, WORK  
  REAL(8), DIMENSION(:, :) :: A  
  
SUBROUTINE GEBRD_64( [M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],  
*                  [LWORK], [INFO])  
  INTEGER(8) :: M, N, LDA, LWORK, INFO  
  REAL(8), DIMENSION(:) :: D, E, TAUQ, TAUP, WORK  
  REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgebrd(int m, int n, double *a, int lda, double *d, double *e, double *tauq, double *taup, int *info);
```

```
void dgebrd_64(long m, long n, double *a, long lda, double *d, double *e, double *tauq, double *taup, long *info);
```

PURPOSE

dgebrd reduces a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation: $Q^*A = B$.

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

ARGUMENTS

*** M (input)**

The number of rows in the matrix A. $M \geq 0$.

*** N (input)**

The number of columns in the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N general matrix to be reduced. On exit, if $m \geq n$, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** D (output)**

The diagonal elements of the bidiagonal matrix B: $D(i) = A(i, i)$.

*** E (output)**

The off-diagonal elements of the bidiagonal matrix B: if $m \geq n$, $E(i) = A(i, i+1)$ for $i = 1, 2, \dots, n-1$; if $m < n$, $E(i) = A(i+1, i)$ for $i = 1, 2, \dots, m-1$.

*** TAUQ (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

*** TAUP (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

*** LWORK (input)**

The length of the array WORK. $LWORK \geq \max(1, M, N)$. For optimum performance $LWORK \geq (M+N)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

dgeco - (obsolete) compute the LU factorization and estimate the condition number of a general matrix A. If the condition number is not needed then SGEFA is slightly faster. It is typical to follow a call to SGECO with a call to SGESL to solve $Ax = b$ or to SGEDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE DGECO( A, LDA, N, IPIVOT, RCOND, WORK)
INTEGER LDA, N
INTEGER IPIVOT(*)
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DGECO_64( A, LDA, N, IPIVOT, RCOND, WORK)
INTEGER*8 LDA, N
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeco(double *a, int lda, int n, int *ipivot, double *rcond);
```

```
void dgeco_64(double *a, long lda, long n, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, an LU factorization of A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets

smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

dgecon - estimate the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF

SYNOPSIS

```
SUBROUTINE DGECON( NORM, N, A, LDA, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 NORM
INTEGER N, LDA, INFO
INTEGER WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DGECON_64( NORM, N, A, LDA, ANORM, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 NORM
INTEGER*8 N, LDA, INFO
INTEGER*8 WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GECON( NORM, [N], A, [LDA], ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: NORM
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GECON_64( NORM, [N], A, [LDA], ANORM, RCOND, [WORK],
* [WORK2], [INFO])
CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgecon(char norm, int n, double *a, int lda, double anorm, double *rcond, int *info);
```

```
void dgecon_64(char norm, long n, double *a, long lda, double anorm, double *rcond, long *info);
```

PURPOSE

dgecon estimates the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as

$$\text{RCOND} = 1 / (\text{norm}(A) * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

*** NORM (input)**

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The factors L and U from the factorization $A = P * L * U$ as computed by SGETRF.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** ANORM (input)**

If $\text{NORM} = '1'$ or $'O'$, the 1-norm of the original matrix A. If $\text{NORM} = 'I'$, the infinity-norm of the original matrix A.

*** RCOND (output)**

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{norm}(A) * \text{norm}(\text{inv}(A)))$.

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

dgedi - (obsolete) compute the determinant and inverse of a general matrix A, which has been LU-factored by SGECO or SGEFA.

SYNOPSIS

```
SUBROUTINE DGEDI( A, LDA, N, IPIVOT, DET, WORK, JOB)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), DET(*), WORK(*)
```

```
SUBROUTINE DGEDI_64( A, LDA, N, IPIVOT, DET, WORK, JOB)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), DET(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgedi(double *a, int lda, int n, int *ipivot, double *det, int job);
```

```
void dgedi_64(double *a, long lda, long n, long *ipivot, double *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the LU factorization of the matrix A, as computed by SGECO or SGEFA. On exit, the inverse of the original matrix A if the inverse was requested, otherwise it is unchanged.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by SGECO or SGEFA.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**}expon)$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \geq |DET(1)| \geq 10.0$ or $DET(1) = 0.0$.

*** WORK (workspace)**

Scratch array with a dimension of N.

* ***JOB*** (*input*)

Determines which operation the subroutine will perform:

- 11 both determinant and inverse
- 01 inverse only
- 10 determinant only

NAME

dgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE DGEEQU( M, N, A, LDA, ROWSC, COLSC, ROWCN, COLCN, AMAX,
*                INFO)
  INTEGER M, N, LDA, INFO
  DOUBLE PRECISION ROWCN, COLCN, AMAX
  DOUBLE PRECISION A(LDA,*), ROWSC(*), COLSC(*)

SUBROUTINE DGEEQU_64( M, N, A, LDA, ROWSC, COLSC, ROWCN, COLCN,
*                   AMAX, INFO)
  INTEGER*8 M, N, LDA, INFO
  DOUBLE PRECISION ROWCN, COLCN, AMAX
  DOUBLE PRECISION A(LDA,*), ROWSC(*), COLSC(*)
```

F95 INTERFACE

```
SUBROUTINE GEEQU( [M], [N], A, [LDA], ROWSC, COLSC, ROWCN, COLCN,
*               AMAX, [INFO])
  INTEGER :: M, N, LDA, INFO
  REAL(8) :: ROWCN, COLCN, AMAX
  REAL(8), DIMENSION(:) :: ROWSC, COLSC
  REAL(8), DIMENSION(:, :) :: A

SUBROUTINE GEEQU_64( [M], [N], A, [LDA], ROWSC, COLSC, ROWCN, COLCN,
*                  AMAX, [INFO])
  INTEGER(8) :: M, N, LDA, INFO
  REAL(8) :: ROWCN, COLCN, AMAX
  REAL(8), DIMENSION(:) :: ROWSC, COLSC
  REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeequ(int m, int n, double *a, int lda, double *rowsc, double *colsc, double *rowcn, double *colcn, double *amax, int *info);
```

```
void dgeequ_64(long m, long n, double *a, long lda, double *rowsc, double *colsc, double *rowcn, double *colcn, double *amax, long *info);
```

PURPOSE

dgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements $B(i,j)=R(i)*A(i,j)*C(j)$ have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input)**

The M-by-N matrix whose equilibration factors are to be computed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** ROWSC (output)**

If INFO = 0 or INFO > M, ROWSC contains the row scale factors for A.

*** COLSC (output)**

If INFO = 0, COLSC contains the column scale factors for A.

*** ROWCN (output)**

If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest ROWSC(i) to the largest ROWSC(i). If ROWCN ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by ROWSC.

*** COLCN (output)**

If INFO = 0, COLCN contains the ratio of the smallest COLSC(i) to the largest COLSC(i). If COLCN ≥ 0.1 , it is not worth scaling by COLSC.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

dgees - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

SYNOPSIS

```
SUBROUTINE DGEES( JOBZ, SORTEV, SELECT, N, A, LDA, NOUT, WR, WI, Z,  
*      LDZ, WORK, LDWORK, WORK3, INFO)

LOGICAL(8), DIMENSION(:) :: WORK3  
REAL(8), DIMENSION(:) :: WR, WI, WORK  
REAL(8), DIMENSION(:, :) :: A, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgees(char jobz, char sortev, logical(*select)(double,double), int n, double *a, int lda, int *nout, double *wr, double *wi, double *z, int ldz, int *info);
```

```
void dgees_64(char jobz, char sortev, logical(*select)(double,double), long n, double *a, long lda, long *nout, double *wr, double *wi, double *z, long ldz, long *info);
```

PURPOSE

dgees computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}T)$.

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ c & a \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$.

ARGUMENTS

* **JOBZ** (*input*)

* **SORTEV** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

* **SELECT** (*input*)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue $WR(j) + \sqrt{-1} * WI(j)$ is selected if $SELECT(WR(j), WI(j))$ is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy $SELECT(WR(j), WI(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO is set to N+2 (see INFO below).

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten by its real Schur form T.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **NOU**T (*output*)

If `SORTEV = 'N'`, `NOUT = 0`. If `SORTEV = 'S'`, `NOUT =` number of eigenvalues (after sorting) for which `SELECT` is true. (Complex conjugate pairs for which `SELECT` is true for either eigenvalue count as 2.)

* ***WR (output)***

`WR` and `WI` contain the real and imaginary parts, respectively, of the computed eigenvalues in the same order that they appear on the diagonal of the output Schur form `T`. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

* ***WI (output)***

See the description for `WR`.

* ***Z (output)***

If `JOBZ = 'V'`, `Z` contains the orthogonal matrix `Z` of Schur vectors. If `JOBZ = 'N'`, `Z` is not referenced.

* ***LDZ (input)***

The leading dimension of the array `Z`. `LDZ >= 1`; if `JOBZ = 'V'`, `LDZ >= N`.

* ***WORK (workspace)***

On exit, if `INFO = 0`, `WORK(1)` contains the optimal `LDWORK`.

* ***LDWORK (input)***

The dimension of the array `WORK`. `LDWORK >= max(1,3*N)`. For good performance, `LDWORK` must generally be larger.

If `LDWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LDWORK` is issued by `XERBLA`.

* ***WORK3 (workspace)***

Not referenced if `SORTEV = 'N'`.

* ***INFO (output)***

```

PURPOSE

dgeesx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization $A = Z^*T^*(Z^{**}T)$.

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A real matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

$$\begin{bmatrix} a & b \\ c & a \end{bmatrix}$$

where $b*c < 0$. The eigenvalues of such a block are $a \pm \sqrt{bc}$.

ARGUMENTS

* **JOBZ** (*input*)

* **SORTEV** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the Schur form.

* **SELECT** (*input*)

SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue $WR(j) + \sqrt{-1} * WI(j)$ is selected if $SELECT(WR(j), WI(j))$ is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both are. Note that a selected complex eigenvalue may no longer satisfy $SELECT(WR(j), WI(j)) = .TRUE.$ after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO may be set to N+3 (see INFO below).

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A is overwritten by its real Schur form T.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **NOUT** (*output*)

If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

* **WR** (*output*)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

* **WI** (*output*)

See the description for WR.

* **Z** (*output*)

If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

* **SRCONE** (*output*)

If SENSE = 'E' or 'B', SRCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

* **RCONV** (*output*)

If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, 3 * N)$. Also, if SENSE = 'E' or 'V' or 'B', $LDWORK \geq N + 2 * NOUT * (N - NOUT)$, where NOUT is the number of selected eigenvalues computed by this routine. Note that $N + 2 * NOUT * (N - NOUT) \leq N + N * N / 2$. For good performance, LDWORK must generally be larger.

* **IWORK2** (*workspace*)

Not referenced if SENSE = 'N' or 'E'. On exit, if INFO = 0, IWORK2(1) returns the optimal LDWRK2.

* **LDWRK2** (*input*)

The dimension of the array IWORK2. LDWRK2 \geq 1; if SENSE = 'V' or 'B', LDWRK2 \geq NOUT*(N-NOUT).

* **BWORK3** (*workspace*)

Not referenced if SORTEV = 'N'.

* **INFO** (*output*)

NAME

dgeev - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

SYNOPSIS

```

```

F95 INTERFACE

```
SUBROUTINE GEEV( JOBVL, JOBVR, [N], A, [LDA], WR, WI, VL, [LDVL],
*   VR, [LDVR], [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: JOBVL, JOBVR
INTEGER :: N, LDA, LDVL, LDVR, LDWORK, INFO
REAL(8), DIMENSION(:) :: WR, WI, WORK
REAL(8), DIMENSION(:, :) :: A, VL, VR

SUBROUTINE GEEV_64( JOBVL, JOBVR, [N], A, [LDA], WR, WI, VL, [LDVL],
*   VR, [LDVR], [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: JOBVL, JOBVR
INTEGER(8) :: N, LDA, LDVL, LDVR, LDWORK, INFO
REAL(8), DIMENSION(:) :: WR, WI, WORK
REAL(8), DIMENSION(:, :) :: A, VL, VR
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeev(char jobvl, char jobvr, int n, double *a, int lda, double *wr, double *wi, double *vl, int ldvl, double *vr, int ldvr, int *info);
```

```
void dgeev_64(char jobvl, char jobvr, long n, double *a, long lda, double *wr, double *wi, double *vl, long ldvl, double *vr, long ldvr, long *info);
```

PURPOSE

dgeev computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **WR** (*output*)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

* **WI** (*output*)

See the description for WR.

* **VL** (*output*)

If **JOBVL** = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If **JOBVL** = 'N', VL is not referenced. If the j-th eigenvalue is real, then $u(j) = VL(:,j)$, the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then $u(j) = VL(:,j) + i*VL(:,j+1)$ and

$$u(j+1) = VL(:,j) - i*VL(:,j+1).$$

* **LDVL** (*input*)

The leading dimension of the array VL. $LDVL \geq 1$; if **JOBVL** = 'V', $LDVL \geq N$.

* **VR** (*input*)

If JOBVR = 'V', the right eigenvectors $v(j)$ are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j -th eigenvalue is real, then $v(j) = VR(:,j)$, the j -th column of VR. If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j) + i*VR(:,j+1)$ and

$$v(j+1) = VR(:,j) - i*VR(:,j+1).$$

* **LDVR** (*input*)

The leading dimension of the array VR. LDVR ≥ 1 ; if JOBVR = 'V', LDVR $\geq N$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, 3*N)$, and if JOBVL = 'V' or JOBVR = 'V', LDWORK $\geq 4*N$. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

```

PURPOSE

dgeevx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

The right eigenvector $v(j)$ of A satisfies

$$A * v(j) = \text{lambda}(j) * v(j)$$

where $\text{lambda}(j)$ is its eigenvalue.

The left eigenvector $u(j)$ of A satisfies

$$u(j)**H * A = \text{lambda}(j) * u(j)**H$$

where $u(j)**H$ denotes the conjugate transpose of $u(j)$.

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation $D * A * D^{**(-1)}$, where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

* **BALANC** (*input*)

Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues.

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the N-by-N matrix A. On exit, A has been overwritten. If **JOBVL** = 'V' or **JOBVR** = 'V', A contains the real Schur form of the balanced version of the input matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **WR** (*output*)

WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

* **WI** (*output*)

See the description for WR.

* **VL** (*output*)

If **JOBVL** = 'V', the left eigenvectors $u(j)$ are stored one after another in the columns of VL, in the same order as their eigenvalues. If **JOBVL** = 'N', VL is not referenced. If the j-th eigenvalue is real, then $u(j) = VL(:,j)$, the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then $u(j) = VL(:,j) + i*VL(:,j+1)$ and

$$u(j+1) = VL(:,j) - i*VL(:,j+1).$$

* **LDVL** (*input*)

The leading dimension of the array VL. $LDVL \geq 1$; if **JOBVL** = 'V', $LDVL \geq N$.

* **VR** (*output*)

If $JOBV = 'V'$, the right eigenvectors $v(j)$ are stored one after another in the columns of VR , in the same order as their eigenvalues. If $JOBV = 'N'$, VR is not referenced. If the j -th eigenvalue is real, then $v(j) = VR(:,j)$, the j -th column of VR . If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then $v(j) = VR(:,j) + i*VR(:,j+1)$ and

$$v(j+1) = VR(:,j) - i*VR(:,j+1).$$

* ***LDVR (input)***

The leading dimension of the array VR . $LDVR \geq 1$, and if $JOBV = 'V'$, $LDVR \geq N$.

* ***ILO (output)***

ILO and IHI are integer values determined when A was balanced. The balanced $A(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$.

* ***IHI (output)***

See the description of ILO .

* ***SCALE (output)***

Details of the permutations and scaling factors applied when balancing A . If $P(j)$ is the index of the row and column interchanged with row and column j , and $D(j)$ is the scaling factor applied to row and column j , then $SCALE(j) = P(j)$, for $j = 1, \dots, ILO-1$

* ***ABNRM (output)***

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

* ***RCONE (output)***

$RCONE(j)$ is the reciprocal condition number of the j -th eigenvalue.

* ***RCONV (output)***

$RCONV(j)$ is the reciprocal condition number of the j -th right eigenvector.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LDWORK$.

* ***LDWORK (input)***

The dimension of the array $WORK$. If $SENSE = 'N'$ or $'E'$, $LDWORK \geq \max(1, 2*N)$, and if $JOBVL = 'V'$ or $JOBVR = 'V'$, $LDWORK \geq 3*N$. If $SENSE = 'V'$ or $'B'$, $LDWORK \geq N*(N+6)$. For good performance, $LDWORK$ must generally be larger.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LDWORK$ is issued by $XERBLA$.

* ***IWORK2 (workspace)***

If $SENSE = 'N'$ or $'E'$, not referenced.

* ***INFO (output)***

NAME

dgefa - (obsolete) compute the LU factorization of a general matrix A. It is typical to follow a call to SGEFA with a call to SGESL to solve $Ax = b$ or to SGEDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE DGEFA( A, LDA, N, IPIVOT, INFO)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*)

SUBROUTINE DGEFA_64( A, LDA, N, IPIVOT, INFO)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>

void dgefa(double *a, int lda, int n, int *ipivot, int *info);

void dgefa_64(double *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the matrix A. On exit, an LU factorization of A.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that SGESL will divide by zero if called.

```

PURPOSE

dgegs routine is deprecated and has been replaced by routine SGGES.

SGGES computes for a pair of N-by-N real nonsymmetric matrices A, B: the generalized eigenvalues (alpha +/- alpha*i, beta), the real Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver SGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually

represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one orthogonal matrix and both on the right by another orthogonal matrix, these two orthogonal matrices being chosen so as to bring the pair of matrices into (real) Schur form.

A pair of matrices A, B is in generalized real Schur form if B is upper triangular with non-negative diagonal and A is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of A will be "standardized" by making the corresponding elements of B have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in A and B will have a complex conjugate pair of generalized eigenvalues.

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the orthogonal matrices which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**T A (VSR), (VSL)**T B (VSR))

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. N >= 0.

* **A** (*input/output*)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A. Note: to avoid overflow, the Frobenius norm of the matrix A should be less than the overflow threshold.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B. Note: to avoid overflow, the Frobenius norm of the matrix B should be less than the overflow threshold.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **ALPHAR** (*output*)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **ALPHAI** (*output*)

See the description for ALPHAR.

* **BETA** (*output*)

See the description for ALPHAR.

* **VSL** (*input*)

If JOBVSL = 'V', VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if JOBVSL = 'N'.

* **LDVSL** (*input*)

The leading dimension of the matrix VSL. LDVSL >= 1, and if JOBVSL = 'V', LDVSL >= N.

* **VSR** (*input*)

If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

* **LDVSR** (*input*)

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1, 4 * N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: $NB \leftarrow \text{MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR}$ The optimal LDWORK is $2 * N + N * (NB + 1)$.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgegv(char jobvl, char jobvr, int n, double *a, int lda, double *b, int ldb, double *alphar, double *alphai, double *beta, double *vl, int ldvl, double *vr, int ldvr, int *info);
```

```
void dgegv_64(char jobvl, char jobvr, long n, double *a, long lda, double *b, long ldb, double *alphar, double *alphai, double *beta, double *vl, long ldvl, double *vr, long ldvr, long *info);
```

PURPOSE

dgegv routine is deprecated and has been replaced by routine SGGEV.

SGEGV computes for a pair of n-by-n real nonsymmetric matrices A and B, the generalized eigenvalues ($\alpha \pm i\beta$), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio $\alpha/\beta = w$, such that $A - wB$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta=0$, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that $(A - wB)r = 0$. A left generalized eigenvector is a vector l such that $l^*H^*(A - wB) = 0$, where l^*H is the

conjugate-transpose of l .

Note: this routine performs "full balancing" on A and B -- see "Further Details", below.

ARGUMENTS

* **JOBVL** (input)

* **JOBVR** (input)

* **N** (input)

The order of the matrices A, B, VL, and VR. $N \geq 0$.

* **A** (input/output)

On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

* **LDA** (input)

The leading dimension of A. $LDA \geq \max(1, N)$.

* **B** (input/output)

On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

* **LDB** (input)

The leading dimension of B. $LDB \geq \max(1, N)$.

* **ALPHAR** (output)

On exit, $(ALPHAR(j) + ALPHAI(j)*i)/BETA(j)$, $j=1, \dots, N$, will be the generalized eigenvalues. If $ALPHAI(j)$ is zero, then the j -th eigenvalue is real; if positive, then the j -th and $(j+1)$ -st eigenvalues are a complex conjugate pair, with $ALPHAI(j+1)$ negative.

Note: the quotients $ALPHAR(j)/BETA(j)$ and $ALPHAI(j)/BETA(j)$ may easily over- or underflow, and $BETA(j)$ may even be zero. Thus, the user should avoid naively computing the ratio α/β . However, $ALPHAR$ and $ALPHAI$ will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and $BETA$ always less than and usually comparable with $\text{norm}(B)$.

* **ALPHAI** (output)

See the description of $ALPHAR$.

* **BETA** (output)

See the description of $ALPHAR$.

* **VL** (output)

If $JOBVL = 'V'$, the left generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $JOBVL = 'N'$.

* **LDVL** (input)

The leading dimension of the matrix VL. $LDVL \geq 1$, and if $JOBVL = 'V'$, $LDVL \geq N$.

* **VR** (output)

If $JOBVR = 'V'$, the right generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have $\text{abs}(\text{real part}) + \text{abs}(\text{imag. part}) = 1$, *except* that for eigenvalues with $\alpha=\beta=0$, a zero vector will be returned as the corresponding eigenvector. Not referenced if $JOBVR = 'N'$.

* **LDVR** (*input*)

The leading dimension of the matrix VR. LDVR ≥ 1 , and if JOBVR = 'V', LDVR $\geq N$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, 8 * N)$. For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: NB -- MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR; The optimal LDWORK is: $2 * N + \text{MAX}(6 * N, N * (NB + 1))$.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dgehrd - reduce a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE DGEHRD( N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)
INTEGER N, ILO, IHI, LDA, LWORKIN, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORKIN(*)
```

```
SUBROUTINE DGEHRD_64( N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN,
* INFO)
INTEGER*8 N, ILO, IHI, LDA, LWORKIN, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORKIN(*)
```

F95 INTERFACE

```
SUBROUTINE GEHRD( [N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
* [INFO])
INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO
REAL(8), DIMENSION(:) :: TAU, WORKIN
REAL(8), DIMENSION(:,:) :: A
```

```
SUBROUTINE GEHRD_64( [N], ILO, IHI, A, [LDA], TAU, [WORKIN],
* [LWORKIN], [INFO])
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
REAL(8), DIMENSION(:) :: TAU, WORKIN
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgehrd(int n, int ilo, int ihi, double *a, int lda, double *tau, int *info);
```

```
void dgehrd_64(long n, long ilo, long ihi, double *a, long lda, double *tau, long *info);
```

PURPOSE

dgehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: $Q' * A * Q = H$.

ARGUMENTS

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** ILO (input)**

It is assumed that A is already upper triangular in rows and columns $1:ILO-1$ and $IHI+1:N$. ILO and IHI are normally set by a previous call to `SGBAL`; otherwise they should be set to 1 and N respectively. See Further Details.

*** IHI (input)**

See the description of ILO .

*** A (input/output)**

On entry, the N -by- N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H , and the elements below the first subdiagonal, with the array TAU , represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

*** LDA (input)**

The leading dimension of the array A . $LDA \geq \max(1,N)$.

*** TAU (output)**

The scalar factors of the elementary reflectors (see Further Details). Elements $1:ILO-1$ and $IHI:N-1$ of TAU are set to zero.

*** $WORKIN$ (workspace)**

On exit, if $INFO = 0$, $WORKIN(1)$ returns the optimal $LWORKIN$.

*** $LWORKIN$ (input)**

The length of the array $WORKIN$. $LWORKIN \geq \max(1,N)$. For optimum performance $LWORKIN \geq N * NB$, where NB is the optimal blocksize.

If $LWORKIN = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORKIN$ array, returns this value as the first entry of the $WORKIN$ array, and no error message related to $LWORKIN$ is issued by `XERBLA`.

*** $INFO$ (output)**

NAME

dgelqf - compute an LQ factorization of a real M-by-N matrix A

SYNOPSIS

```
SUBROUTINE DGELQF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGELQF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GELQF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
INTEGER :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GELQF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
INTEGER(8) :: M, N, LDA, LDWORK, INFO

#include <sunperf.h>
```

```
void dgelqf(int m, int n, double *a, int lda, double *tau, int *info);
```

```
void dgelqf_64(long m, long n, double *a, long lda, double *tau, long *info);
```

PURPOSE

dgelqf computes an LQ factorization of a real M-by-N matrix A: $A = L * Q$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if $m \leq n$); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

NAME

dgels - solve overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A

SYNOPSIS

```
SUBROUTINE DGELS( TRANSA, M, N, NRHS, A, LDA, B, LDB, WORK, LDWORK,
*              INFO)
CHARACTER * 1 TRANSA
INTEGER M, N, NRHS, LDA, LDB, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)

SUBROUTINE DGELS_64( TRANSA, M, N, NRHS, A, LDA, B, LDB, WORK,
*              LDWORK, INFO)
CHARACTER * 1 TRANSA
INTEGER*8 M, N, NRHS, LDA, LDB, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GELS( [TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
*              [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, NRHS, LDA, LDB, LDWORK, INFO
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A, B

SUBROUTINE GELS_64( [TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
*              [WORK], [LDWORK], [INFO])
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgels(char transa, int m, int n, int nrhs, double *a, int lda, double *b, int ldb, int *info);
```

```
void dgels_64(char transa, long m, long n, long nrhs, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dgels solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and $m \geq n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize $\| B - A * X \|^2$.
2. If TRANS = 'N' and $m < n$: find the minimum norm solution of an underdetermined system $A * X = B$.
3. If TRANS = 'T' and $m \geq n$: find the minimum norm solution of an undetermined system $A^{**T} * X = B$.
4. If TRANS = 'T' and $m < n$: find the least squares solution of an overdetermined system, i.e., solve the least squares problem minimize $\| B - A^{**T} * X \|^2$.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

* **TRANSA** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $M \geq N$, A is overwritten by details of its QR factorization as returned by SGEQRF; if $M < N$, A is overwritten by details of its LQ factorization as returned by SGELQF.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANSA = 'N', or N-by-NRHS if TRANSA = 'T'. On exit, B is overwritten by the solution vectors, stored columnwise: if TRANSA = 'N' and $m \geq n$, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANSA = 'N' and $m < n$, rows 1 to N of B contain the minimum norm solution vectors; if TRANSA = 'T' and $m \geq n$, rows 1 to M of B contain the minimum norm solution vectors; if TRANSA = 'T' and $m < n$, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, MN + \max(MN, NRHS))$. For optimal performance, $LDWORK \geq \max(1, MN + \max(MN, NRHS) * NB)$. where $MN = \min(M, N)$ and NB is the optimum block size.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

INTEGER(8) :: M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: S, WORK
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgelsd(int m, int n, int nrhs, double *a, int lda, double *b, int ldb, double *s, double rcond, int *rank, int *info);
```

```
void dgelsd_64(long m, long n, long nrhs, double *a, long lda, double *b, long ldb, double *s, double rcond, long *rank, long *info);
```

PURPOSE

dgelsd computes the minimum-norm solution to a real linear least squares problem: minimize 2-norm($| b - A*x |$)

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:

- (1) Reduce the coefficient matrix A to bidiagonal form with Householder transformations, reducing the original problem into a "bidiagonal least squares problem" (BLS)
- (2) Solve the BLS using a divide and conquer approach.
- (3) Apply back all the Householder transformations to solve the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** M (input)**

The number of rows of A. $M \geq 0$.

*** N (input)**

The number of columns of A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A has been destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $RANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, \max(M, N))$.

*** *S (output)***

The singular values of A in decreasing order. The condition number of A in the 2-norm = $S(1)/S(\min(m,n))$.

*** *RCOND (input)***

RCOND is used to determine the effective rank of A. Singular values $S(i) \leq RCOND * S(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

*** *RANK (output)***

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * S(1)$.

*** *WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

*** *LWORK (input)***

The dimension of the array WORK. $LWORK \geq 1$. The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least $12 * N + 2 * N * SMLSIZ + 8 * N * NLVL + N * NRHS * (SMLSIZ + 1) ** 2$, if M is greater than or equal to N or $12 * M + 2 * M * SMLSIZ + 8 * M * NLVL + M * NRHS * (SMLSIZ + 1) ** 2$, if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and $NLVL = \text{INT}(\text{LOG}_2(\text{MIN}(M, N) / (SMLSIZ + 1))) + 1$. For good performance, LWORK should generally be larger.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** *IWORK (workspace)***

$LIWORK \geq 3 * \text{MINMN} * NLVL + 11 * \text{MINMN}$, where $\text{MINMN} = \text{MIN}(M, N)$.

*** *INFO (output)***

NAME

dgelss - compute the minimum norm solution to a real linear least squares problem

SYNOPSIS

```

#include <sunperf.h>
```

```
void dgelss(int m, int n, int nrhs, double *a, int lda, double *b, int ldb, double *sing, double rcond, int *irank, int *info);
```

```
void dgelss_64(long m, long n, long nrhs, double *a, long lda, double *b, long ldb, double *sing, double rcond, long *irank, long *info);
```

PURPOSE

dgelss computes the minimum norm solution to a real linear least squares problem:

Minimize 2-norm($\| b - A*x \|$).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, the first $\min(m,n)$ rows of A are overwritten with its right singular vectors, stored rowwise.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,M)$.

*** B (input/output)**

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements $n+1:m$ in that column.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,\max(M,N))$.

*** SING (output)**

The singular values of A in decreasing order. The condition number of A in the 2-norm = $SING(1)/SING(\min(m,n))$.

*** RCOND (input)**

RCOND is used to determine the effective rank of A. Singular values $SING(i) \leq RCOND * SING(1)$ are treated as zero. If $RCOND < 0$, machine precision is used instead.

*** IRANK (output)**

The effective rank of A, i.e., the number of singular values which are greater than $RCOND * SING(1)$.

*** WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq 1$, and also: $LDWORK \geq 3 * \min(M,N) + \max(2 * \min(M,N),$

$\max(M,N)$, NRHS) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* *INFO* (output)

NAME

dgelsx - routine is deprecated and has been replaced by routine SGELSY

SYNOPSIS

```

```

```
void dgelsx_64(long m, long n, long nrhs, double *a, long lda, double *b, long ldb, long *jpivot, double rcond, long *irank, long *info);
```

PURPOSE

dgelsx routine is deprecated and has been replaced by routine SGELSY.

SGELSX computes the minimum-norm solution to a real linear least squares problem:

$$\text{minimize } || A * X - B ||$$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting: $A * P = Q * [R11 \ R12]$

$$[\ 0 \ R22 \]$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. M >= 0.

*** N (input)**

The number of columns of the matrix A. N >= 0.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* **B** (*input/output*)

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X. If $m \geq n$ and $IRANK = n$, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements N+1:M in that column.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* **JPIVOT** (*input*)

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if $JPIVOT(i) = k$, then the i-th column of A^*P was the k-th column of A.

* **RCOND** (*input*)

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

* **IRANK** (*output*)

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

* **WORK** (*workspace*)

$(\max(\min(M, N) + 3 * N, 2 * \min(M, N) + NRHS))$,

* **INFO** (*output*)

NAME

dgelsy - compute the minimum-norm solution to a real linear least squares problem

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgelsy(int m, int n, int nrhs, double *a, int lda, double *b, int ldb, int *jpvt, double rcond, int *rank, int *info);
```

```
void dgelsy_64(long m, long n, long nrhs, double *a, long lda, double *b, long ldb, long *jpvt, double rcond, long *rank, long *info);
```

PURPOSE

dgelsy computes the minimum-norm solution to a real linear least squares problem: minimize $\|A * X - B\|$

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting: $A * P = Q * [R11 \ R12]$

$$\begin{bmatrix} & 0 & R22 \end{bmatrix}$$

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

$$A * P = Q * \begin{bmatrix} T11 & 0 \\ 0 & 0 \end{bmatrix} * Z$$

The minimum-norm solution is then

$$X = P * Z' \begin{bmatrix} \text{inv}(T11) * Q1' * B \\ 0 \end{bmatrix}$$

where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:

- o The call to the subroutine xGEQPF has been substituted by the the call to the subroutine xGEQP3. This subroutine is a Blas-3 version of the QR factorization with column pivoting.
 - o Matrix B (the right hand side) is updated with Blas-3.
 - o The permutation of matrix B (the right hand side) is faster and more simple.
-

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***NRHS (input)***

The number of right hand sides, i.e., the number of columns of matrices B and X. $NRHS \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***B (input/output)***

On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

* ***LDB (input)***

The leading dimension of the array B. $LDB \geq \max(1, M, N)$.

* ***JPVT (input/output)***

On entry, if $JPVT(i) \neq 0$, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if $JPVT(i) = k$, then the i-th column of AP was the k-th column of A.

* ***RCOND (input)***

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number $< 1/RCOND$.

* ***RANK (output)***

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. The unblocked strategy requires that: $LWORK \geq \max(MN + 3 \cdot N + 1, 2 \cdot MN + NRHS)$, where $MN = \min(M, N)$. The block algorithm requires that: $LWORK \geq \max(MN + 2 \cdot N + NB \cdot (N + 1), 2 \cdot MN + NB \cdot NRHS)$, where NB is an upper bound on the blocksize returned by ILAENV for the routines SGEQP3, STZRZF, STZRQF, SORMQR, and SORMRZ.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO (output)***

NAME

dgemm - perform one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$

SYNOPSIS

```
SUBROUTINE DGEMM( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
*      BETA, C, LDC)
CHARACTER * 1 TRANSA, TRANSB

DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE DGEMM_64( TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
*      BETA, C, LDC)
CHARACTER * 1 TRANSA, TRANSB
INTEGER*8 M, N, K, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE GEMM( [TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],
*      B, [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: TRANSA, TRANSB
INTEGER :: M, N, K, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:, :) :: A, B, C

SUBROUTINE GEMM_64( [TRANSA], [TRANSB], [M], [N], [K], ALPHA, A,
*      [LDA], B, [LDB], BETA, C, [LDC])
CHARACTER(LEN=1) :: TRANSA, TRANSB
INTEGER(8) :: M, N, K, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:, :) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgemm(char transa, char transb, int m, int n, int k, double alpha, double *a, int lda, double *b, int ldb, double beta, double *c, int ldc);
```

```
void dgemm_64(char transa, char transb, long m, long n, long k, double alpha, double *a, long lda, double *b, long ldb,
```

double beta, double *c, long ldc);

PURPOSE

dgemm performs one of the matrix-matrix operations $C := \alpha * \text{op}(A) * \text{op}(B) + \beta * C$ where $\text{op}(X)$ is one of

$$\text{op}(X) = X \quad \text{or} \quad \text{op}(X) = X',$$

alpha and beta are scalars, and A, B and C are matrices, with $\text{op}(A)$ an m by k matrix, $\text{op}(B)$ a k by n matrix and C an m by n matrix.

ARGUMENTS

* *TRANSA* (input)

On entry, TRANSA specifies the form of $\text{op}(A)$ to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', $\text{op}(A) = A$.

TRANSA = 'T' or 't', $\text{op}(A) = A'$.

TRANSA = 'C' or 'c', $\text{op}(A) = A'$.

Unchanged on exit.

* *TRANSB* (input)

On entry, TRANSB specifies the form of $\text{op}(B)$ to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', $\text{op}(B) = B$.

TRANSB = 'T' or 't', $\text{op}(B) = B'$.

TRANSB = 'C' or 'c', $\text{op}(B) = B'$.

Unchanged on exit.

* *M* (input)

On entry, M specifies the number of rows of the matrix $\text{op}(A)$ and of the matrix C. M must be at least zero. Unchanged on exit.

* *N* (input)

On entry, N specifies the number of columns of the matrix $\text{op}(B)$ and the number of columns of the matrix C. N must be at least zero. Unchanged on exit.

* *K* (input)

On entry, K specifies the number of columns of the matrix $\text{op}(A)$ and the number of rows of the matrix $\text{op}(B)$. K must be at least zero. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

k when TRANSA = 'N' or 'n', and is m otherwise. Before entry with TRANSA = 'N' or 'n', the leading m by k part of

the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then $LDA \geq \max(1, m)$, otherwise $LDA \geq \max(1, k)$. Unchanged on exit.

*** B (input)**

n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

*** LDB (input)**

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then $LDB \geq \max(1, k)$, otherwise $LDB \geq \max(1, n)$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

*** C (input/output)**

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix $(\alpha * \text{op}(A) * \text{op}(B) + \text{beta} * C)$.

*** LDC (input)**

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. $LDC \geq \max(1, m)$. Unchanged on exit.

NAME

dgemv - perform one of the matrix-vector operations $y := \alpha A x + \beta y$ or $y := \alpha A' x + \beta y$

SYNOPSIS

```
SUBROUTINE DGEMV( TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,

DOUBLE PRECISION A(LDA,*), X(*), Y(*)

SUBROUTINE DGEMV_64( TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,
*              INCY)
CHARACTER * 1 TRANSA
INTEGER*8 M, N, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GEMV( [TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
*              BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:, :) :: A

SUBROUTINE GEMV_64( [TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
*              BETA, Y, [INCY])
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgemv(char transa, int m, int n, double alpha, double *a, int lda, double *x, int incx, double beta, double *y, int incy);
```

```
void dgemv_64(char transa, long m, long n, double alpha, double *a, long lda, double *x, long incx, double beta, double *y, long incy);
```

PURPOSE

dgemv performs one of the matrix-vector operations $y := \alpha A x + \beta y$, or $y := \alpha A^T x + \beta y$, where α and β are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

*** TRANSA (input)**

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' $y := \alpha A x + \beta y$.

TRANSA = 'T' or 't' $y := \alpha A^T x + \beta y$.

TRANSA = 'C' or 'c' $y := \alpha A^T x + \beta y$.

Unchanged on exit.

*** M (input)**

On entry, M specifies the number of rows of the matrix A. $M \geq 0$. Unchanged on exit.

*** N (input)**

On entry, N specifies the number of columns of the matrix A. $N \geq 0$. Unchanged on exit.

*** ALPHA (input)**

On entry, ALPHA specifies the scalar α . Unchanged on exit.

*** A (input)**

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

*** X (input)**

$(1 + (n - 1) * \text{abs}(INCX))$ when TRANSA = 'N' or 'n' and at least $(1 + (m - 1) * \text{abs}(INCX))$ otherwise. Before entry, the incremented array X must contain the vector x . Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar β . When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

*** Y (input/output)**

$(1 + (m - 1) * \text{abs}(INCY))$ when TRANSA = 'N' or 'n' and at least $(1 + (n - 1) * \text{abs}(INCY))$ otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y . On exit, Y is overwritten by the updated vector y .

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. INCY \neq 0. Unchanged on exit.

NAME

dgeqlf - compute a QL factorization of a real M-by-N matrix A

SYNOPSIS

```
SUBROUTINE DGEQLF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGEQLF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQLF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
INTEGER :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQLF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeqlf(int m, int n, double *a, int lda, double *tau, int *info);
```

```
void dgeqlf_64(long m, long n, double *a, long lda, double *tau, long *info);
```

PURPOSE

dgeqlf computes a QL factorization of a real M-by-N matrix A: $A = Q * L$.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* ***A*** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $m \geq n$, the lower triangle of the subarray $A(m-n+1:m, 1:n)$ contains the N-by-N lower triangular matrix L; if $m < n$, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

* ***TAU*** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

dgeqp3 - compute a QR factorization with column pivoting of a matrix A

SYNOPSIS

```
SUBROUTINE DGEQP3( M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)
INTEGER M, N, LDA, LWORK, INFO
INTEGER JPVT(*)
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGEQP3_64( M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)
INTEGER*8 M, N, LDA, LWORK, INFO
INTEGER*8 JPVT(*)
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQP3( [M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
*               [INFO])
INTEGER :: M, N, LDA, LWORK, INFO
INTEGER, DIMENSION(:) :: JPVT
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQP3_64( [M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
*               [INFO])
INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeqp3(int m, int n, double *a, int lda, int *jpvt, double *tau, int *info);
```

```
void dgeqp3_64(long m, long n, double *a, long lda, long *jpvt, double *tau, long *info);
```

PURPOSE

dgeqp3 computes a QR factorization with column pivoting of a matrix A: $A^*P = Q^*R$ using Level 3 BLAS.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of $\min(M,N)$ elementary reflectors.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***JPVT (input/output)***

On entry, if $JPVT(J) \neq 0$, the J-th column of A is permuted to the front of A^*P (a leading column); if $JPVT(J)=0$, the J-th column of A is a free column. On exit, if $JPVT(J)=K$, then the J-th column of A^*P was the K-th column of A.

* ***TAU (output)***

The scalar factors of the elementary reflectors.

* ***WORK (workspace)***

On exit, if $INFO=0$, $WORK(1)$ returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. $LWORK \geq 3*N+1$. For optimal performance $LWORK \geq 2*N+(N+1)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO (output)***

NAME

dgeqpf - routine is deprecated and has been replaced by routine SGEQP3

SYNOPSIS

```
SUBROUTINE DGEQPF( M, N, A, LDA, JPIVOT, TAU, WORK, INFO)
INTEGER M, N, LDA, INFO
INTEGER JPIVOT(*)
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGEQPF_64( M, N, A, LDA, JPIVOT, TAU, WORK, INFO)
INTEGER*8 M, N, LDA, INFO
INTEGER*8 JPIVOT(*)
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQPF( [M], [N], A, [LDA], JPIVOT, TAU, [WORK], [INFO])
INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: JPIVOT
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

```
SUBROUTINE GEQPF_64( [M], [N], A, [LDA], JPIVOT, TAU, [WORK], [INFO])
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: JPIVOT
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeqpf(int m, int n, double *a, int lda, int *jpivot, double *tau, int *info);
```

```
void dgeqpf_64(long m, long n, double *a, long lda, long *jpivot, double *tau, long *info);
```

PURPOSE

dgeqpf routine is deprecated and has been replaced by routine SGEQP3.

SGEQPF computes a QR factorization with column pivoting of a real M-by-N matrix A: $A * P = Q * R$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the $\min(M,N)$ -by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors.

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***JPIVOT (input)***

On entry, if $JPIVOT(i) \neq 0$, the i-th column of A is permuted to the front of $A * P$ (a leading column); if $JPIVOT(i) = 0$, the i-th column of A is a free column. On exit, if $JPIVOT(i) = k$, then the i-th column of $A * P$ was the k-th column of A.

* ***TAU (output)***

The scalar factors of the elementary reflectors.

* ***WORK (workspace)***

dimension(N)

* ***INFO (output)***

NAME

dgeqrf - compute a QR factorization of a real M-by-N matrix A

SYNOPSIS

```
SUBROUTINE DGEQRF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGEQRF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQRF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
INTEGER :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GEQRF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeqrf(int m, int n, double *a, int lda, double *tau, int *info);
```

```
void dgeqrf_64(long m, long n, double *a, long lda, double *tau, long *info);
```

PURPOSE

dgeqrf computes a QR factorization of a real M-by-N matrix A: $A = Q * R$.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix A. $M \geq 0$.

* ***N (input)***

The number of columns of the matrix A. $N \geq 0$.

* ***A (input/output)***

On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(M,N)$ -by-N upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

* ***LDA (input)***

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***TAU (output)***

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK (workspace)***

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK (input)***

The dimension of the array WORK. $LDWORK \geq \max(1,N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO (output)***

NAME

dger - perform the rank 1 operation $A := \alpha * x * y' + A$

SYNOPSIS

```
SUBROUTINE DGER( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
INTEGER M, N, INCX, INCY, LDA
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*), A(LDA,*)
```

```
SUBROUTINE DGER_64( M, N, ALPHA, X, INCX, Y, INCY, A, LDA)
INTEGER*8 M, N, INCX, INCY, LDA
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GER( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
INTEGER :: M, N, INCX, INCY, LDA
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GER_64( [M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])
INTEGER(8) :: M, N, INCX, INCY, LDA
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dger(int m, int n, double alpha, double *x, int incx, double *y, int incy, double *a, int lda);
```

```
void dger_64(long m, long n, double alpha, double *x, long incx, double *y, long incy, double *a, long lda);
```

PURPOSE

dger performs the rank 1 operation $A := \alpha * x * y' + A$, where α is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

*** *M (input)***

On entry, M specifies the number of rows of the matrix A . $M \geq 0$. Unchanged on exit.

*** *N (input)***

On entry, N specifies the number of columns of the matrix A . $N \geq 0$. Unchanged on exit.

*** *ALPHA (input)***

On entry, $ALPHA$ specifies the scalar α . Unchanged on exit.

*** *X (input)***

$(1 + (m - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the m element vector x . Unchanged on exit.

*** *INCX (input)***

On entry, $INCX$ specifies the increment for the elements of X . $INCX \neq 0$. Unchanged on exit.

*** *Y (input)***

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

*** *INCY (input)***

On entry, $INCY$ specifies the increment for the elements of Y . $INCY \neq 0$. Unchanged on exit.

*** *A (input/output)***

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

*** *LDA (input)***

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq \max(1, m)$. Unchanged on exit.

NAME

dgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE DGERFS( TRANSA, N, NRHS, A, LDA, AF, LDAF, IPIVOT, B,

REAL(8), DIMENSION(:, :) :: A, AF, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgerfs(char transa, int n, int nrhs, double *a, int lda, double *af, int ldaf, int *ipivot, double *b, int ldb, double *x, int ldx,  
double *ferr, double *berr, int *info);
```

```
void dgerfs_64(char transa, long n, long nrhs, double *a, long lda, double *af, long ldaf, long *ipivot, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The original N-by-N matrix A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The factors L and U from the factorization $A = P * L * U$ as computed by SGETRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **IPIVOT** (*input*)

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

- * **WORK** (*workspace*)
dimension(2*N)
- * **WORK2** (*workspace*)
- * **INFO** (*output*)

NAME

dgerqf - compute an RQ factorization of a real M-by-N matrix A

SYNOPSIS

```
SUBROUTINE DGERQF( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DGERQF_64( M, N, A, LDA, TAU, WORK, LDWORK, INFO)
INTEGER*8 M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GERQF( [M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])
INTEGER :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GERQF_64( [M], [N], A, [LDA], TAU, [WORK], [LDWORK],
* [INFO])
INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgerqf(int m, int n, double *a, int lda, double *tau, int *info);
```

```
void dgerqf_64(long m, long n, double *a, long lda, double *tau, long *info);
```

PURPOSE

dgerqf computes an RQ factorization of a real M-by-N matrix A: $A = R * Q$.

ARGUMENTS

* ***M*** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* ***N*** (*input*)

The number of columns of the matrix A. $N \geq 0$.

* ***A*** (*input/output*)

On entry, the M-by-N matrix A. On exit, if $m \leq n$, the upper triangle of the subarray $A(1:m, n-m+1:n)$ contains the M-by-M upper triangular matrix R; if $m \geq n$, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of $\min(m,n)$ elementary reflectors (see Further Details).

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* ***TAU*** (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1,M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

dgesdd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors

SYNOPSIS

```
SUBROUTINE DGESDD( JOBZ, M, N, A, LDA, S, U, LDU, VT, LDVT, WORK,  
*                LWORK, IWORK, INFO)

SUBROUTINE GESDD_64( JOBZ, [M], [N], A, [LDA], S, U, [LDU], VT,  
*                [LDVT], [WORK], [LWORK], [IWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ  
INTEGER(8) :: M, N, LDA, LDU, LDVT, LWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: S, WORK  
REAL(8), DIMENSION(:, :) :: A, U, VT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgesdd(char jobz, int m, int n, double *a, int lda, double *s, double *u, int ldu, double *vt, int ldvt, int *info);
```

```
void dgesdd_64(char jobz, long m, long n, double *a, long lda, double *s, double *u, long ldu, double *vt, long ldvt, long *info);
```

PURPOSE

dgesdd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm.

The SVD is written

$$= U * SIGMA * \text{transpose}(V)$$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns $VT = V^{**T}$, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** JOBZ (input)**

Specifies options for computing all or part of the matrix U:

*** M (input)**

The number of rows of the input matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the input matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if $M \geq N$; A is overwritten with the first M rows of V^{**T} (the right singular vectors, stored rowwise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** S (output)**

The singular values of A, sorted so that $S(i) \geq S(i+1)$.

*** U (output)**

UCOL = M if JOBZ = 'A' or JOBZ = 'O' and $M < N$; UCOL = $\min(M,N)$ if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and $M < N$, U contains the M-by-M orthogonal matrix U; if JOBZ = 'S', U contains the first $\min(M,N)$ columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and $M \geq N$, or JOBZ = 'N', U is not referenced.

*** LDU (input)**

The leading dimension of the array U. LDU ≥ 1 ; if JOBZ = 'S' or 'A' or JOBZ = 'O' and $M < N$, LDU $\geq M$.

*** VT (output)**

If JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, VT contains the N-by-N orthogonal matrix $V^{*}T$; if JOBZ = 'S', VT contains the first $\min(M,N)$ rows of $V^{*}T$ (the right singular vectors, stored rowwise); if JOBZ = 'O' and $M < N$, or JOBZ = 'N', VT is not referenced.

*** LDVT (input)**

The leading dimension of the array VT. LDVT ≥ 1 ; if JOBZ = 'A' or JOBZ = 'O' and $M \geq N$, LDVT $\geq N$; if JOBZ = 'S', LDVT $\geq \min(M,N)$.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

*** LWORK (input)**

The dimension of the array WORK. LWORK ≥ 1 . If JOBZ = 'N', LWORK $\geq 3 * \min(M,N) + \max(\max(M,N), 6 * \min(M,N))$. If JOBZ = 'O', LWORK $\geq 3 * \min(M,N) * \min(M,N) + \max(\max(M,N), 5 * \min(M,N)) * \min(M,N) + 4 * \min(M,N)$. If JOBZ = 'S' or 'A' LWORK $\geq 3 * \min(M,N) * \min(M,N) + \max(\max(M,N), 4 * \min(M,N)) * \min(M,N) + 4 * \min(M,N)$. For good performance, LWORK should generally be larger. If LWORK < 0 but other input arguments are legal, WORK(1) returns optimal LWORK.

*** IWORK (workspace)**

dimension(8*MIN(M,N))

*** INFO (output)**

NAME

dgesl - (obsolete) solve the linear system $Ax = b$ for a general matrix A , which has been LU- factored by SGECO or SGEFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE DGESL( A, LDA, N, IPIVOT, B, JOB)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), B(*)
```

```
SUBROUTINE DGESL_64( A, LDA, N, IPIVOT, B, JOB)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgesl(double *a, int lda, int n, int *ipivot, double *b, int job);
```

```
void dgesl_64(double *a, long lda, long n, long *ipivot, double *b, long job);
```

ARGUMENTS

*** A (input)**

LU factorization of the matrix A , as computed by SGECO or SGEFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (input)**

Pivot vector as computed by SGECO or SGEFA.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

*** JOB (input)**

Determines which operation the subroutine will perform:

o 0 Solve the system $Ax = b$.

not 0 Solve the linear system $A^T x = b$.
for real matrices.

NAME

dgesv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE DGESV( N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
INTEGER N, NRHS, LDA, LDB, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

```
SUBROUTINE DGESV_64( N, NRHS, A, LDA, IPIVOT, B, LDB, INFO)
INTEGER*8 N, NRHS, LDA, LDB, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE GESV( [N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
INTEGER :: N, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:, :) :: A, B
```

```
SUBROUTINE GESV_64( [N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgesv(int n, int nrhs, double *a, int lda, int *ipivot, double *b, int ldb, int *info);
```

```
void dgesv_64(long n, long nrhs, double *a, long lda, long *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dgesv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

$$A = P * L * U,$$

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** IPIVOT (output)**

The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

*** B (input/output)**

On entry, the N-by-NRHS matrix of right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

dgesvd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors

SYNOPSIS

```
SUBROUTINE DGESVD( JOBU, JOBVT, M, N, A, LDA, SING, U, LDU, VT,
*                LDVT, WORK, LDWORK, INFO)

C INTERFACE

```
#include <sunperf.h>
```

```
void dgesvd(char jobu, char jobvt, int m, int n, double *a, int lda, double *sing, double *u, int ldu, double *vt, int ldvt, int *info);
```

```
void dgesvd_64(char jobu, char jobvt, long m, long n, double *a, long lda, double *sing, double *u, long ldu, double *vt, long ldvt, long *info);
```

PURPOSE

dgesvd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written $A = U * SIGMA * transpose(V)$

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V^{**T} , not V.

ARGUMENTS

*** *JOBU* (input)**

Specifies options for computing all or part of the matrix U:

*** *JOBVT* (input)**

Specifies options for computing all or part of the matrix V^{**T} :

*** *M* (input)**

The number of rows of the input matrix A. $M \geq 0$.

*** *N* (input)**

The number of columns of the input matrix A. $N \geq 0$.

*** *A* (input/output)**

On entry, the M-by-N matrix A. On exit, if *JOBU* = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if *JOBVT* = 'O', A is overwritten with the first min(m,n) rows of V^{**T} (the right singular vectors, stored rowwise); if *JOBU* .ne. 'O' and *JOBVT* .ne. 'O', the contents of A are destroyed.

*** *LDA* (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** *SING* (output)**

The singular values of A, sorted so that $SING(i) \geq SING(i+1)$.

*** *U* (input)**

(LDU, M) if *JOBU* = 'A' or (LDU, min(M, N)) if *JOBU* = 'SING'. If *JOBU* = 'A', U contains the M-by-M orthogonal matrix U; if *JOBU* = 'SING', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if *JOBU* = 'N' or 'O', U is not referenced.

*** *LDU* (input)**

The leading dimension of the array U. $LDU \geq 1$; if *JOBU* = 'SING' or 'A', $LDU \geq M$.

*** *VT* (input)**

If *JOBVT* = 'A', VT contains the N-by-N orthogonal matrix V^{**T} ; if *JOBVT* = 'SING', VT contains the first min(m,n) rows of V^{**T} (the right singular vectors, stored rowwise); if *JOBVT* = 'N' or 'O', VT is not referenced.

*** *LDVT* (input)**

The leading dimension of the array VT. $LDVT \geq 1$; if *JOBVT* = 'A', $LDVT \geq N$; if *JOBVT* = 'SING', $LDVT \geq \min(M, N)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK; if INFO > 0, WORK(2:MIN(M,N)) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies $A = U * B * VT$, so it has the same singular values as A, and singular vectors related by U and VT.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK >= 1. LDWORK >= MAX(3*MIN(M,N)+MAX(M,N),5*MIN(M,N)). For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dgesvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$.

```

PURPOSE

dgesvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
TRANS = 'N':  diag(R)*A*diag(C)      *inv(diag(C))*X = diag(R)*B
TRANS = 'T':  (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
TRANS = 'C':  (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
or diag(C)*B (if TRANS = 'T' or 'C').
```

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

```
A = P * L * U,
where P is a permutation matrix, L is a unit lower triangular
matrix, and U is upper triangular.
```

3. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so that it solves the original system before equilibration.

ARGUMENTS

* **FACT (input)**

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* **TRANS (input)**

Specifies the form of the system of equations:

* **N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A (input/output)**

On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in ROWSC and/or COLSC. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'ROWSC': $A := \text{diag}(\text{ROWSC}) * A$

EQUED = 'COLSC': $A := A * \text{diag}(\text{COLSC})$

EQUED = 'B': $A := \text{diag}(\text{ROWSC}) * A * \text{diag}(\text{COLSC})$.

* **LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization $A = P * L * U$ as computed by SGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization $A = P * L * U$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* **LDAF (input)**

The leading dimension of the array AF. LDAF $\geq \max(1, N)$.

* **IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization $A = P * L * U$ as computed by SGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization $A = P * L * U$ of the equilibrated matrix A.

* **EQUED (input)**

Specifies the form of equilibration that was done.

* **ROWSC (input/output)**

The row scale factors for A. If EQUED = 'ROWSC' or 'B', A is multiplied on the left by $\text{diag}(\text{ROWSC})$; if EQUED = 'N' or 'COLSC', ROWSC is not accessed. ROWSC is an input argument if FACT = 'F'; otherwise, ROWSC is an output argument. If FACT = 'F' and EQUED = 'ROWSC' or 'B', each element of ROWSC must be positive.

* **COLSC (input/output)**

The column scale factors for A. If EQUED = 'COLSC' or 'B', A is multiplied on the right by $\text{diag}(\text{COLSC})$; if EQUED = 'N' or 'ROWSC', COLSC is not accessed. COLSC is an input argument if FACT = 'F'; otherwise, COLSC is an output argument. If FACT = 'F' and EQUED = 'COLSC' or 'B', each element of COLSC must be positive.

* **B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'ROWSC' or 'B', B is overwritten by $\text{diag}(\text{ROWSC}) * B$; if TRANSA = 'T' or 'COLSC' and EQUED = 'COLSC' or 'B', B is overwritten by $\text{diag}(\text{COLSC}) * B$.

* **LDB (input)**

The leading dimension of the array B. LDB $\geq \max(1, N)$.

* **X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED = 'N', and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{COLSC})) * X$ if TRANSA = 'N' and EQUED = 'COLSC' or 'B', or $\text{inv}(\text{diag}(\text{ROWSC})) * X$ if TRANSA = 'T' or 'COLSC' and EQUED = 'ROWSC' or 'B'.

* **LDX (input)**

The leading dimension of the array X. LDX $\geq \max(1, N)$.

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0 .

* **FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK (workspace)**

On exit, WORK(1) contains the reciprocal pivot growth factor $\text{norm}(A)/\text{norm}(U)$. The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \leq N$, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

* **WORK2 (workspace)**

* **INFO (output)**

NAME

dgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE DGETF2( M, N, A, LDA, IPIV, INFO)
INTEGER M, N, LDA, INFO
INTEGER IPIV(*)
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DGETF2_64( M, N, A, LDA, IPIV, INFO)
INTEGER*8 M, N, LDA, INFO
INTEGER*8 IPIV(*)
DOUBLE PRECISION A(LDA,*)
```

F95 INTERFACE

SUBROUTINE GETF2( [M], [N], A, [LDA], IPIV, [INFO])
INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GETF2_64( [M], [N], A, [LDA], IPIV, [INFO])
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgetf2(int m, int n, double *a, int lda, int *ipiv, int *info);
```

```
void dgetf2_64(long m, long n, double *a, long lda, long *ipiv, long *info);
```

PURPOSE

dgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** IPIV (output)**

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIV(i).

*** INFO (output)**

NAME

dgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

SYNOPSIS

```

```
void dgetrf_64(long m, long n, double *a, long lda, long *ipivot, long *info);
```

PURPOSE

dgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$), and U is upper triangular (upper trapezoidal if $m < n$).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization $A = P * L * U$; the unit diagonal elements of L are not stored.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** IPIVOT (output)**

The pivot indices; for $1 \leq i \leq \min(M, N)$, row i of the matrix was interchanged with row IPIVOT(i).

*** INFO (output)**

NAME

dgetri - compute the inverse of a matrix using the LU factorization computed by SGETRF

SYNOPSIS

```
SUBROUTINE DGETRI( N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DGETRI_64( N, A, LDA, IPIVOT, WORK, LDWORK, INFO)
INTEGER*8 N, LDA, LDWORK, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI( [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE GETRI_64( [N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgetri(int n, double *a, int lda, int *ipivot, int *info);
```

```
void dgetri_64(long n, double *a, long lda, long *ipivot, long *info);
```

PURPOSE

dgetri computes the inverse of a matrix using the LU factorization computed by SGETRF.

This method inverts U and then computes $\text{inv}(A)$ by solving the system $\text{inv}(A)*L = \text{inv}(U)$ for $\text{inv}(A)$.

ARGUMENTS

* ***N*** (*input*)

The order of the matrix A. $N \geq 0$.

* ***A*** (*input/output*)

On entry, the factors L and U from the factorization $A = P*L*U$ as computed by SGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

* ***LDA*** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* ***IPIVOT*** (*input*)

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* ***WORK*** (*workspace*)

On exit, if INFO=0, then WORK(1) returns the optimal LDWORK.

* ***LDWORK*** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimal performance $LDWORK \geq N*NB$, where NB is the optimal blocksize returned by ILAENV.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* ***INFO*** (*output*)

NAME

dgetrs - solve a system of linear equations $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A using the LU factorization computed by SGETRF

```

```
void dgetrs_64(char transa, long n, long nrhs, double *a, long lda, long *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dgetrs solves a system of linear equations $A * X = B$ or $A' * X = B$ with a general N-by-N matrix A using the LU factorization computed by SGETRF.

ARGUMENTS

* **TRANS** (*input*)

Specifies the form of the system of equations:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **A** (*input*)

The factors L and U from the factorization $A = P * L * U$ as computed by SGETRF.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **IPIVOT** (*input*)

The pivot indices from SGETRF; for $1 \leq i \leq N$, row i of the matrix was interchanged with row IPIVOT(i).

* **B** (*input/output*)

On entry, the right hand side matrix B. On exit, the solution matrix X.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

dggbak - form the right or left eigenvectors of a real generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL

SYNOPSIS

```
SUBROUTINE DGGBAK( JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V,
* LDV, INFO)
CHARACTER * 1 JOB, SIDE
INTEGER N, ILO, IHI, M, LDV, INFO
DOUBLE PRECISION LSCALE(*), RSCALE(*), V(LDV,*)

SUBROUTINE DGGBAK_64( JOB, SIDE, N, ILO, IHI, LSCALE, RSCALE, M, V,
* LDV, INFO)
CHARACTER * 1 JOB, SIDE

C INTERFACE

```
#include <sunperf.h>
```

```
void dggbak(char job, char side, int n, int ilo, int ihi, double *lscale, double *rscale, int m, double *v, int ldv, int *info);
```

```
void dggbak_64(char job, char side, long n, long ilo, long ihi, double *lscale, double *rscale, long m, double *v, long ldv, long *info);
```

PURPOSE

dggbak forms the right or left eigenvectors of a real generalized eigenvalue problem $A*x = \lambda*B*x$, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL.

ARGUMENTS

* **JOB** (*input*)

Specifies the type of backward transformation required:

* **SIDE** (*input*)

* **N** (*input*)

The number of rows of the matrix V. $N \geq 0$.

* **ILO** (*input*)

The integers ILO and IHI determined by SGGBAL. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* **IHI** (*input*)

See the description for ILO.

* **LSCALE** (*input*)

Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by SGGBAL.

* **RSCALE** (*input*)

Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by SGGBAL.

* **M** (*input*)

The number of columns of the matrix V. $M \geq 0$.

* **V** (*input/output*)

On entry, the matrix of right or left eigenvectors to be transformed, as returned by STGEVC. On exit, V is overwritten by the transformed eigenvectors.

* **LDV** (*input*)

The leading dimension of the matrix V. $LDV \geq \max(1,N)$.

* **INFO** (*output*)

NAME

dggbal - balance a pair of general real matrices (A,B)

SYNOPSIS

```
SUBROUTINE DGGBAL( JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE, RSCALE,
*   WORK, INFO)
CHARACTER * 1 JOB
INTEGER N, LDA, LDB, ILO, IHI, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*), LSCALE(*), RSCALE(*), WORK(*)

SUBROUTINE DGGBAL_64( JOB, N, A, LDA, B, LDB, ILO, IHI, LSCALE,
*   RSCALE, WORK, INFO)
CHARACTER * 1 JOB
INTEGER*8 N, LDA, LDB, ILO, IHI, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*), LSCALE(*), RSCALE(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GGBAL( JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
*   RSCALE, [WORK], [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER :: N, LDA, LDB, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: LSCALE, RSCALE, WORK
REAL(8), DIMENSION(:,) :: A, B

SUBROUTINE GGBAL_64( JOB, [N], A, [LDA], B, [LDB], ILO, IHI, LSCALE,
*   RSCALE, [WORK], [INFO])
CHARACTER(LEN=1) :: JOB
INTEGER(8) :: N, LDA, LDB, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: LSCALE, RSCALE, WORK
REAL(8), DIMENSION(:,) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dggbal(char job, int n, double *a, int lda, double *b, int ldb, int *ilo, int *ihi, double *lscale, double *rscale, int *info);
```

```
void dggbal_64(char job, long n, double *a, long lda, double *b, long ldb, long *ilo, long *ihi, double *lscale, double *rscale, long *info);
```

PURPOSE

dggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem $A*x = \lambda*B*x$.

ARGUMENTS

* **JOB** (*input*)

Specifies the operations to be performed on A and B:

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **A** (*input/output*)

On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* **B** (*input*)

On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **ILO** (*output*)

ILO and IHI are set to integers such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

* **IHI** (*output*)

See the description for ILO.

* **LSCALE** (*input*)

Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then $LSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$

* **RSCALE** (*input*)

Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then $RSCALE(j) = P(j)$ for $J = 1, \dots, ILO-1$

* **WORK** (*workspace*)

dimension(6*N)

* **INFO** (*output*)

C INTERFACE

```
#include <sunperf.h>
```

```
void dgges(char jobvsl, char jobvsr, char sort, logical(*delctg)(double,double,double), int n, double *a, int lda, double *b, int ldb, int *sdim, double *alphar, double *alphai, double *beta, double *vsl, int ldvsl, double *vsr, int ldvsr, int *info);
```

```
void dgges_64(char jobvsl, char jobvsr, char sort, logical(*delctg)(double,double,double), long n, double *a, long lda, double *b, long ldb, long *sdim, double *alphar, double *alphai, double *beta, double *vsl, long ldvsl, double *vsr, long ldvsr, long *info);
```

PURPOSE

dgges computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$(A, B) = ((VSL) * S * (VSR) ** T, (VSL) * T * (VSR) ** T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver SGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

* **JOBVSL** (*input*)

* **JOBVSR** (*input*)

* **SORT** (*input*)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

* **DELCTG** (*input*)

DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if DELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy DELCTG(ALPHAR(j),ALPHAI(j), BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2 in this case.

* **N** (*input*)

The order of the matrices A, B, VSL, and VSR. N >= 0.

* **A** (*input/output*)

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **SDIM** (*output*)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true. (Complex conjugate pairs for which DELCTG is true for either eigenvalue count as 2.)

* **ALPHAR** (*output*)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, and BETA(j), j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user

should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **ALPHAI (output)**

See the description for ALPHAR.

* **BETA (output)**

See the description for ALPHAR.

* **VSL (input)**

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

* **LDVSL (input)**

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if JOBVSL = 'V', LDVSL $\geq N$.

* **VSR (input)**

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

* **LDVSR (input)**

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if JOBVSR = 'V', LDVSR $\geq N$.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK $\geq 8*N+16$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **BWORK (workspace)**

Not referenced if SORT = 'N'.

* **INFO (output)**

NAME

```

PURPOSE

dggesx computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

$$A,B = ((VSL) S (VSR)**T, (VSL) T (VSR)**T)$$

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

$$\begin{bmatrix} a & 0 \\ 0 & b \end{bmatrix}$$

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

* **JOBVSL** (input)

* **JOBVSR** (input)

* **SORT** (input)

Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form.

* **DELCTG** (input)

DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if DELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy DELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

* **SENSE** (input)

Determines which reciprocal condition numbers are computed.

* **N** (input)

The order of the matrices A, B, VSL, and VSR. N >= 0.

* **A** (input/output)

On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

* **LDA** (input)

The leading dimension of A. LDA >= max(1,N).

* **B** (input/output)

On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

* **LDB** (input)

The leading dimension of B. LDB >= max(1,N).

* **SDIM** (output)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true. (Complex conjugate pairs for which DELCTG is true for either eigenvalue count as 2.)

* **ALPHAR** (output)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j), j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **ALPHAI** (output)

See the description for ALPHAR.

* **BETA** (output)

See the description for ALPHAR.

* **VSL** (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

* **LDVSL** (input)

The leading dimension of the matrix VSL. LDVSL ≥ 1 , and if JOBVSL = 'V', LDVSL $\geq N$.

* **VSR (input)**

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

* **LDVSR (input)**

The leading dimension of the matrix VSR. LDVSR ≥ 1 , and if JOBVSR = 'V', LDVSR $\geq N$.

* **RCONDE (output)**

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

* **RCONDV (output)**

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. LWORK $\geq 8*(N+1)+16$. If SENSE = 'E', 'V', or 'B', LWORK $\geq \text{MAX}(8*(N+1)+16, 2*SDIM*(N-SDIM))$.

* **IWORK (workspace)**

Not referenced if SENSE = 'N'.

* **LIWORK (input)**

The dimension of the array WORK. LIWORK $\geq N+6$.

* **BWORK (workspace)**

Not referenced if SORT = 'N'.

* **INFO (output)**

void dggev_64(char jobvl, char jobvr, long n, double *a, long lda, double *b, long ldb, double *alphar, double *alphai, double *beta, double *vl, long ldvl, double *vr, long ldvr, long *info);
```

PURPOSE

dggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j).$$

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B.$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **N** (*input*)

The order of the matrices A, B, VL, and VR. N >= 0.

* **A** (*input/output*)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **ALPHAR** (*output*)

On exit, (ALPHAR(j) + ALPHA I(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHA I(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHA I(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHA I(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHA I will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **ALPHA I** (*output*)

See the description for ALPHAR.

* **BETA** (*output*)

See the description for ALPHAR.

* **VL** (*input*)

If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part)+abs(imag. part)=1. Not referenced if JOBVL = 'N'.

* **LDVL** (*input*)

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

* **VR** (*input*)

If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector will be scaled so the largest component have abs(real

part)+abs(imag. part)=1. Not referenced if JOBVR = 'N'.

* **LDVR** (*input*)

The leading dimension of the matrix VR. LDVR \geq 1, and if JOBVR = 'V', LDVR \geq N.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. LWORK \geq max(1,8*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

```

PURPOSE

dggev_x computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$A * v(j) = lambda(j) * B * v(j) .$$

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

$$u(j)**H * A = lambda(j) * u(j)**H * B .$$

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

* **BALANC** (*input*)

Specifies the balance option to be performed.

* **JOBVL** (*input*)

* **JOBVR** (*input*)

* **SENSE** (*input*)

Determines which reciprocal condition numbers are computed.

* **N** (*input*)

The order of the matrices A, B, VL, and VR. N >= 0.

* **A** (*input/output*)

On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the real Schur form of the "balanced" versions of the input A and B.

* **LDA** (*input*)

The leading dimension of A. LDA >= max(1,N).

* **B** (*input/output*)

On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the real Schur form of the "balanced" versions of the input A and B.

* **LDB** (*input*)

The leading dimension of B. LDB >= max(1,N).

* **ALPHAR** (*output*)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

* **ALPHAI** (*output*)

See the description of ALPHAR.

* **BETA** (*output*)

See the description of ALPHAR.

* **VL** (*output*)

If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

* **LDVL** (*input*)

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

* **VR** (*output*)

If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) =

$VR(:,j)-i*VR(:,j+1)$. Each eigenvector will be scaled so the largest component have $abs(\text{real part}) + abs(\text{imag. part}) = 1$. Not referenced if $JOBVR = 'N'$.

* **LDVR (input)**

The leading dimension of the matrix VR. $LDVR \geq 1$, and if $JOBVR = 'V'$, $LDVR \geq N$.

* **ILO (output)**

ILO and IHI are integer values such that on exit $A(i,j) = 0$ and $B(i,j) = 0$ if $i > j$ and $j = 1, \dots, ILO-1$ or $i = IHI+1, \dots, N$. If $BALANC = 'N'$ or $'S'$, $ILO = 1$ and $IHI = N$.

* **IHI (output)**

See the description of ILO.

* **LSCALE (output)**

Details of the permutations and scaling factors applied to the left side of A and B. If $PL(j)$ is the index of the row interchanged with row j, and $DL(j)$ is the scaling factor applied to row j, then $LSCALE(j) = PL(j)$ for $j = 1, \dots, ILO-1$

* **RSCALE (output)**

Details of the permutations and scaling factors applied to the right side of A and B. If $PR(j)$ is the index of the column interchanged with column j, and $DR(j)$ is the scaling factor applied to column j, then $RSCALE(j) = PR(j)$ for $j = 1, \dots, ILO-1$

* **ABNRM (output)**

The one-norm of the balanced matrix A.

* **BBNRM (output)**

The one-norm of the balanced matrix B.

* **RCONDE (output)**

If $SENSE = 'E'$ or $'B'$, the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of RCONDE are set to the same value. Thus $RCONDE(j)$, $RCONDV(j)$, and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If $SENSE = 'V'$, RCONDE is not referenced.

* **RCONDV (output)**

If $SENSE = 'V'$ or $'B'$, the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of RCONDV are set to the same value. If the eigenvalues cannot be reordered to compute $RCONDV(j)$, $RCONDV(j)$ is set to 0; this can only occur when the true value would be very small anyway. If $SENSE = 'E'$, RCONDV is not referenced.

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, 6*N)$. If $SENSE = 'E'$, $LWORK \geq 12*N$. If $SENSE = 'V'$ or $'B'$, $LWORK \geq 2*N*N+12*N+16$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

If $SENSE = 'E'$, IWORK is not referenced.

* **BWORK (workspace)**

If $SENSE = 'N'$, BWORK is not referenced.

* **INFO (output)**

NAME

dggglm - solve a general Gauss-Markov linear model (GLM) problem

SYNOPSIS

```

F95 INTERFACE

```
SUBROUTINE GGGLM( [N], [M], [P], A, [LDA], B, [LDB], D, X, Y, [WORK],
*               [LDWORK], [INFO])
  INTEGER :: N, M, P, LDA, LDB, LDWORK, INFO
  REAL(8), DIMENSION(:) :: D, X, Y, WORK
  REAL(8), DIMENSION(:, :) :: A, B

SUBROUTINE GGGLM_64( [N], [M], [P], A, [LDA], B, [LDB], D, X, Y,
*                  [WORK], [LDWORK], [INFO])
  INTEGER(8) :: N, M, P, LDA, LDB, LDWORK, INFO
  REAL(8), DIMENSION(:) :: D, X, Y, WORK
  REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dggglm(int n, int m, int p, double *a, int lda, double *b, int ldb, double *d, double *x, double *y, int *info);
```

```
void dggglm_64(long n, long m, long p, double *a, long lda, double *b, long ldb, double *d, double *x, double *y, long *info);
```

PURPOSE

dggglm solves a general Gauss-Markov linear model (GLM) problem:

$$\underset{x}{\text{minimize}} \quad || y ||_2 \quad \text{subject to} \quad d = A*x + B*y$$

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that $M \leq N \leq M+P$, and

$$\text{rank}(A) = M \quad \text{and} \quad \text{rank}(A \ B) = N.$$

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

$$\underset{x}{\text{minimize}} \quad || \text{inv}(B)*(d-A*x) ||_2$$

where inv(B) denotes the inverse of B.

ARGUMENTS

*** N (input)**

The number of rows of the matrices A and B. $N \geq 0$.

*** M (input)**

The number of columns of the matrix A. $0 \leq M \leq N$.

*** P (input)**

The number of columns of the matrix B. $P \geq N-M$.

*** A (input/output)**

On entry, the N-by-M matrix A. On exit, A is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** B (input/output)**

On entry, the N-by-P matrix B. On exit, B is destroyed.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** D (input/output)**

On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

*** X (output)**

On exit, X and Y are the solutions of the GLM problem.

*** Y (output)**

See the description of X.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. LDWORK $\geq \max(1, N+M+P)$. For optimum performance, LDWORK $\geq M + \min(N, P) + \max(N, P) * NB$, where NB is an upper bound for the optimal block sizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dgghrd - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

SYNOPSIS

```
SUBROUTINE DGGHRD( COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q,  
* LDQ, Z, LDZ, INFO)

INTEGER :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO  
REAL(8), DIMENSION(:,:) :: A, B, Q, Z  
  
SUBROUTINE GGHRD_64( COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB],  
* Q, [LDQ], Z, [LDZ], [INFO])  
CHARACTER(LEN=1) :: COMPQ, COMPZ  
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO  
REAL(8), DIMENSION(:,:) :: A, B, Q, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgghrd(char compq, char compz, int n, int ilo, int ihi, double *a, int lda, double *b, int ldb, double *q, int ldq, double *z, int ldz, int *info);
```

```
void dgghrd_64(char compq, char compz, long n, long ilo, long ihi, double *a, long lda, double *b, long ldb, double *q, long ldq, double *z, long ldz, long *info);
```

PURPOSE

dgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular: $Q' * A * Z = H$ and $Q' * B * Z = T$, where H is upper Hessenberg, T is upper triangular, and Q and Z are orthogonal, and ' means transpose.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that

$$1 * A * Z1' = (Q1*Q) * H * (Z1*Z)' \quad 1 * B * Z1' = (Q1*Q) * T * (Z1*Z)'$$

ARGUMENTS

* *COMPQ (input)*

* *COMPZ (input)*

* *N (input)*

The order of the matrices A and B. $N \geq 0$.

* *ILO (input)*

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGGBAL; otherwise they should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

* *IHI (input)*

See the description of ILO.

* *A (input/output)*

On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

* *LDA (input)*

The leading dimension of the array A. $LDA \geq \max(1,N)$.

* *B (input/output)*

On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix $T = Q' B Z$. The elements below the diagonal are set to zero.

* *LDB (input)*

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* *Q (input/output)*

If COMPQ='N': Q is not referenced.

If COMPQ='I': on entry, Q need not be set, and on exit it contains the orthogonal matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain an orthogonal matrix Q1, and on exit this is overwritten by $Q1 * Q$.

* *LDQ (input)*

The leading dimension of the array Q. $LDQ \geq N$ if COMPQ='V' or 'I'; $LDQ \geq 1$ otherwise.

* *Z (input/output)*

If COMPZ='N': Z is not referenced.

If COMPZ='I': on entry, Z need not be set, and on exit it contains the orthogonal matrix Z, which is the product of

the Givens transformations which are applied to A and B on the right. If COMPZ='V': on entry, Z must contain an orthogonal matrix Z1, and on exit this is overwritten by Z1*Z.

* **LDZ** (*input*)

The leading dimension of the array Z. LDZ \geq N if COMPZ='V' or 'I'; LDZ \geq 1 otherwise.

* **INFO** (*output*)

NAME

dgglse - solve the linear equality-constrained least squares (LSE) problem

SYNOPSIS

```
SUBROUTINE DGGLSE( M, N, P, A, LDA, B, LDB, C, D, X, WORK, LDWORK,
*                INFO)
  INTEGER M, N, P, LDA, LDB, LDWORK, INFO

void dgglse(int m, int n, int p, double *a, int lda, double *b, int ldb, double *c, double *d, double *x, int *info);
```

```
void dgglse_64(long m, long n, long p, double *a, long lda, double *b, long ldb, double *c, double *d, double *x, long *info);
```

PURPOSE

dgglse solves the linear equality-constrained least squares (LSE) problem:

$$\text{minimize } || c - A*x ||_2 \quad \text{subject to} \quad B*x = d$$

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that $P \leq N \leq M+P$, and

$$\text{rank}(B) = P \quad \text{and} \quad \text{rank} \left(\begin{array}{c} A \\ B \end{array} \right) = N.$$

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** N (input)**

The number of columns of the matrices A and B. $N \geq 0$.

*** P (input)**

The number of rows of the matrix B. $0 \leq P \leq N \leq M+P$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, A is destroyed.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, B is destroyed.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** C (input/output)**

On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

*** D (input/output)**

On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

*** X (output)**

On exit, X is the solution of the LSE problem.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. LDWORK $\geq \max(1, M+N+P)$. For optimum performance LDWORK $\geq P + \min(M, N) + \max(M, N) * NB$, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (output)

NAME

dggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

SYNOPSIS

```

```
#include <sunperf.h>
```

```
void dggqrf(int n, int m, int p, double *a, int lda, double *tau, double *b, int ldb, double *taub, int *info);
```

```
void dggqrf_64(long n, long m, long p, double *a, long lda, double *tau, double *b, long ldb, double *taub, long *info);
```

PURPOSE

dggqrf computes a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B:

$$A = Q^*R, \quad B = Q^*T^*Z,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

if $N \geq M$, $R = \begin{pmatrix} R_{11} \\ 0 \end{pmatrix}$, or if $N < M$, $R = \begin{pmatrix} R_{11} & R_{12} \\ 0 \end{pmatrix}$, $\begin{pmatrix} 0 \\ 0 \end{pmatrix}$ N-M N M-N M

where R_{11} is upper triangular, and

if $N \leq P$, $T = \begin{pmatrix} 0 & T_{12} \\ 0 \end{pmatrix}$ N, or if $N > P$, $T = \begin{pmatrix} T_{11} \\ 0 \end{pmatrix}$ N-P, P-N N $\begin{pmatrix} T_{21} \\ 0 \end{pmatrix}$ P P

where T_{12} or T_{21} is upper triangular.

In particular, if B is square and nonsingular, the GQR factorization of A and B implicitly gives the QR factorization of $\text{inv}(B)^*A$:

$$\text{inv}(B)^*A = Z'^*(\text{inv}(T)^*R)$$

where $\text{inv}(B)$ denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

*** N (input)**

The number of rows of the matrices A and B. $N \geq 0$.

*** M (input)**

The number of columns of the matrix A. $M \geq 0$.

*** P (input)**

The number of columns of the matrix B. $P \geq 0$.

*** A (input/output)**

On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the $\min(N,M)$ -by-M upper trapezoidal matrix R (R is upper triangular if $N \geq M$); the elements below the diagonal, with the array TAUA, represent the orthogonal matrix Q as a product of $\min(N,M)$ elementary reflectors (see Further Details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** TAUA (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

*** B (input/output)**

On entry, the N-by-P matrix B. On exit, if $N \leq P$, the upper triangle of the subarray $B(1:N,P-N+1:P)$ contains the N-by-N upper triangular matrix T; if $N > P$, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **TAUB (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

* **WORK (workspace)**

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, N, M, P)$. For optimum performance $LWORK \geq \max(N, M, P) * \max(NB1, NB2, NB3)$, where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of SORMQR.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO (output)**

```
#include <sunperf.h>
```

```
void dggrqf(int m, int p, int n, double *a, int lda, double *tau, double *b, int ldb, double *taub, int *info);
```

```
void dggrqf_64(long m, long p, long n, double *a, long lda, double *tau, double *b, long ldb, double *taub, long *info);
```

PURPOSE

dggrqf computes a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B:

$$A = R*Q, \quad B = Z*T*Q,$$

where Q is an N-by-N orthogonal matrix, Z is a P-by-P orthogonal matrix, and R and T assume one of the forms:

if $M \leq N$, $R = \begin{pmatrix} 0 & R_{12} \end{pmatrix} M$, or if $M > N$, $R = \begin{pmatrix} R_{11} \\ \end{pmatrix} M-N, N-M \begin{pmatrix} R_{21} \end{pmatrix} N-N$

where R_{12} or R_{21} is upper triangular, and

if $P \geq N$, $T = \begin{pmatrix} T_{11} \end{pmatrix} N$, or if $P < N$, $T = \begin{pmatrix} T_{11} & T_{12} \\ \end{pmatrix} P, \begin{pmatrix} 0 \end{pmatrix} P-N \begin{pmatrix} T_{21} & T_{22} \end{pmatrix} P-N$

where T_{11} is upper triangular.

In particular, if B is square and nonsingular, the GRQ factorization of A and B implicitly gives the RQ factorization of $A*inv(B)$:

$$A*inv(B) = (R*inv(T))*Z'$$

where $inv(B)$ denotes the inverse of the matrix B, and Z' denotes the transpose of the matrix Z.

ARGUMENTS

*** M (input)**

The number of rows of the matrix A. $M \geq 0$.

*** P (input)**

The number of rows of the matrix B. $P \geq 0$.

*** N (input)**

The number of columns of the matrices A and B. $N \geq 0$.

*** A (input/output)**

On entry, the M-by-N matrix A. On exit, if $M \leq N$, the upper triangle of the subarray $A(1:M, N-M+1:N)$ contains the M-by-M upper triangular matrix R; if $M > N$, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** TAUA (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the $\min(P, N)$ -by-N upper trapezoidal matrix T (T is upper triangular if $P \geq N$); the elements below the diagonal, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, P)$.

*** TAUB (output)**

The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK \geq $\max(1, N, M, P)$. For optimum performance LWORK \geq $\max(N, M, P) * \max(NB1, NB2, NB3)$, where NB1 is the optimal blocksize for the RQ factorization of an M-by-N matrix, NB2 is the optimal blocksize for the QR factorization of a P-by-N matrix, and NB3 is the optimal blocksize for a call of SORMRQ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

NAME

dggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dggsvd(char job, char jobv, char jobq, int m, int n, int p, int *k, int *l, double *a, int lda, double *b, int ldb, double *alpha, double *beta, double *u, int ldu, double *v, int ldv, double *q, int ldq, int *iwork3, int *info);
```

```
void dggsvd_64(char job, char jobv, char jobq, long m, long n, long p, long *k, long *l, double *a, long lda, double *b, long ldb, double *alpha, double *beta, double *u, long ldu, double *v, long ldv, double *q, long ldq, long *iwork3, long *info);
```

If (A',B') has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem: $A^*A x = \lambda B^*B x$.

In some literature, the GSVD of A and B is presented in the form $U^*A^*X = (0 D1)$, $V^*B^*X = (0 D2)$

where U and V are orthogonal and X is nonsingular, D1 and D2 are "diagonal". The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

$$X = Q \begin{pmatrix} I & 0 \\ 0 & \text{inv}(R) \end{pmatrix}.$$

ARGUMENTS

* **JOBU** (input)

* **JOBV** (input)

* **JOBQ** (input)

* **M** (input)

The number of rows of the matrix A. $M \geq 0$.

* **N** (input)

The number of columns of the matrices A and B. $N \geq 0$.

* **P** (input)

The number of rows of the matrix B. $P \geq 0$.

* **K** (output)

On exit, K and L specify the dimension of the subblocks described in the Purpose section. $K + L =$ effective numerical rank of (A',B').

* **L** (output)

See the description of K.

* **A** (input/output)

On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

* **LDA** (input)

The leading dimension of the array A. $LDA \geq \max(1,M)$.

* **B** (input/output)

On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if $M-K-L < 0$. See Purpose for details.

* **LDB** (input)

The leading dimension of the array B. $LDB \geq \max(1,P)$.

* **ALPHA** (output)

On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; $ALPHA(1:K) = 1$,

$BETA(1:K) = 0$, and if $M-K-L \geq 0$, $ALPHA(K+1:K+L) = C$,

$BETA(K+1:K+L) = S$, or if $M-K-L < 0$, $ALPHA(K+1:M) = C$, $ALPHA(M+1:K+L) = 0$

$BETA(K+1:M) = S$, $BETA(M+1:K+L) = 1$ and $ALPHA(K+L+1:N) = 0$

$BETA(K+L+1:N) = 0$

* **BETA** (output)

See the description of ALPHA.

* **U** (output)

If **JOBU** = 'U', U contains the M-by-M orthogonal matrix U. If **JOBU** = 'N', U is not referenced.

* **LDU** (input)

The leading dimension of the array U. $LDU \geq \max(1,M)$ if **JOBU** = 'U'; $LDU \geq 1$ otherwise.

* ***V*** (*output*)

If `JOBV = 'V'`, `V` contains the `P`-by-`P` orthogonal matrix `V`. If `JOBV = 'N'`, `V` is not referenced.

* ***LDV*** (*input*)

The leading dimension of the array `V`. `LDV` \geq `max(1,P)` if `JOBV = 'V'`; `LDV` \geq 1 otherwise.

* ***Q*** (*output*)

If `JOBQ = 'Q'`, `Q` contains the `N`-by-`N` orthogonal matrix `Q`. If `JOBQ = 'N'`, `Q` is not referenced.

* ***LDQ*** (*input*)

The leading dimension of the array `Q`. `LDQ` \geq `max(1,N)` if `JOBQ = 'Q'`; `LDQ` \geq 1 otherwise.

* ***WORK*** (*workspace*)

dimension (`max(3*N,M,P)+N`)

* ***IWORK3*** (*output*)

On exit, `IWORK3` stores the sorting information. More precisely, the following loop will sort `ALPHA` for `I = K+1, min(M,K+L)`
swap `ALPHA(I)` and `ALPHA(IWORK3(I))` endfor such that `ALPHA(1) \geq ALPHA(2) \geq ... \geq ALPHA(N)`.

* ***INFO*** (*output*)

NAME

dggsvp - compute orthogonal matrices U, V and Q such that $N-K-L \text{ K L U}^*A^*Q = K \begin{pmatrix} 0 & A_{12} & A_{13} \end{pmatrix}$ if $M-K-L \geq 0$

```

PURPOSE

dggsvp computes orthogonal matrices U, V and Q such that $L \begin{pmatrix} 0 & 0 & A23 \end{pmatrix}$

$$V' * B * Q = \begin{matrix} & \begin{matrix} M-K-L & (& 0 & & 0 &) \\ & \begin{matrix} N-K-L & K & L \\ K & (& 0 & A12 & A13 &) \\ M-K & (& 0 & 0 & A23 &) \end{matrix} & \text{if } M-K-L < 0; \\ & \begin{matrix} N-K-L & K & L \\ L & (& 0 & 0 & B13 &) \\ P-L & (& 0 & 0 & 0 &) \end{matrix} \end{matrix}$$

where the K-by-K matrix A12 and L-by-L matrix B13 are nonsingular upper triangular; A23 is L-by-L upper triangular if $M-K-L \geq 0$, otherwise A23 is (M-K)-by-L upper trapezoidal. $K+L$ = the effective numerical rank of the (M+P)-by-N matrix (A',B'). Z' denotes the transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine SGGSD.

ARGUMENTS

* **JOBU** (*input*)

* **JOBV** (*input*)

* **JOBQ** (*input*)

* **M** (*input*)

The number of rows of the matrix A. $M \geq 0$.

* **P** (*input*)

The number of rows of the matrix B. $P \geq 0$.

* **N** (*input*)

The number of columns of the matrices A and B. $N \geq 0$.

* **A** (*input/output*)

On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, M)$.

*** B (input/output)**

On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,P)$.

*** TOLA (input)**

TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a subblock of A. Generally, they are set to $TOLA = \max(M,N) * \text{norm}(A) * \text{MACHEPS}$, $TOLB = \max(P,N) * \text{norm}(B) * \text{MACHEPS}$. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

*** TOLB (input)**

See the description of TOLA.

*** K (output)**

On exit, K and L specify the dimension of the subblocks described in Purpose. $K + L =$ effective numerical rank of $(A',B)'$.

*** L (output)**

See the description of K.

*** U (input)**

If $JOB_U = 'U'$, U contains the orthogonal matrix U. If $JOB_U = 'N'$, U is not referenced.

*** LDU (input)**

The leading dimension of the array U. $LDU \geq \max(1,M)$ if $JOB_U = 'U'$; $LDU \geq 1$ otherwise.

*** V (input)**

If $JOB_V = 'V'$, V contains the orthogonal matrix V. If $JOB_V = 'N'$, V is not referenced.

*** LDV (input)**

The leading dimension of the array V. $LDV \geq \max(1,P)$ if $JOB_V = 'V'$; $LDV \geq 1$ otherwise.

*** Q (input)**

If $JOB_Q = 'Q'$, Q contains the orthogonal matrix Q. If $JOB_Q = 'N'$, Q is not referenced.

*** LDQ (input)**

The leading dimension of the array Q. $LDQ \geq \max(1,N)$ if $JOB_Q = 'Q'$; $LDQ \geq 1$ otherwise.

*** IWORK (workspace)**

dimension(N)

*** TAU (workspace)**

NAME

dgssco - Condition number estimate.

SYNOPSIS

```
SUBROUTINE DGSSCO ( COND, HANDLE, IER )  
INTEGER          IER  
DOUBLE PRECISION COND  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSCO - Condition number estimate.

PARAMETERS

COND - DOUBLE PRECISION

On exit, an estimate of the condition number of the factored matrix. Must be called after the numerical factorization subroutine, *DGSSFA*().

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 700 : Invalid calling sequence - need to call DGSSFA first.
- 710 : Condition number estimate not available (not implemented for this HANDLE's matrix type).

NAME

dgssda - Deallocate working storage.

SYNOPSIS

```
SUBROUTINE DGSSDA ( HANDLE, IER )  
  INTEGER          IER  
  DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

none

NAME

dgssfa - Numeric factorization.

SYNOPSIS

```
SUBROUTINE DGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )
INTEGER           NEQNS, COLSTR(*), ROWIND(*), IER
DOUBLE PRECISION  VALUES(*)
DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

DGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

NEQNS - INTEGER

On entry, NEQNS specifies the number of equations in coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, COLSTR(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, ROWIND(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - DOUBLE PRECISION

On entry, VALUES(*) is an array of size COLSTR(NEQNS+1)-1, containing the numeric values of the sparse matrix to be factored. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 300 : Invalid calling sequence - need to call DGSSOR first.
- 301 : Failure to dynamically allocate memory.

-666 : Internal error.

NAME

dgssfs - One call interface.

SYNOPSIS

```
SUBROUTINE DGSSFS ( MTXTYP, PIVOT , NEQNS, COLSTR, ROWIND,
                   VALUES, NRHS , RHS , LDRHS , ORDMTHD,
                   OUTUNT, MSGLVL, HANDLE, IER )
CHARACTER*2      MTXTYP
CHARACTER*1      PIVOT
INTEGER          NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,
                OUTUNT, MSGLVL, IER
CHARACTER*3      ORDMTHD
DOUBLE PRECISION VALUES(*), RHS(*)
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSFS - Numeric factorization of a sparse matrix.

PARAMETERS

MTXTYP - CHARACTER*2

On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

```
'ss' or 'SS' - symmetric structure, symmetric values
'su' or 'SU' - symmetric structure, unsymmetric values
'uu' or 'UU' - unsymmetric structure, unsymmetric values
```

Unchanged on exit.

PIVOT - CHARACTER*1

On entry, pivot specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

```
'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).
```

Unchanged on exit.

NEQNS - INTEGER

On entry, NEQNS specifies the number of equations in coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, COLSTR(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, ROWIND(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

VALUES(*) - DOUBLE PRECISION array

On entry, VALUES(*) is an array of size COLSTR(NEQNS+1)-1, containing the non-zero numeric values of the sparse matrix to be factored. Unchanged on exit.

NRHS - INTEGER

On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(*) - DOUBLE PRECISION array

On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER

On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

ORDMTHD - CHARACTER*3

On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

```
'nat' or 'NAT' - natural ordering (no ordering)
'mmd' or 'MMD' - multiple minimum degree
'uso' or 'USO' - user specified ordering (see DGSSUO)
```

Unchanged on exit.

OUTUNT - INTEGER

Output unit. Unchanged on exit.

MSGVLV - INTEGER

Message level.

```
0 - no output from solver.
(No messages supported for this release.)
```

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array of containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

```
-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros is less than NEQNS.
-201 : Failure to dynamically allocate memory.
```

-301 : Failure to dynamically allocate memory.
-401 : Failure to dynamically allocate memory.
-402 : NRHS < 1
-403 : NEQNS > LDRHS
-666 : Internal error.

NAME

dgssin - Initialize the sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,
                   MSGLVL, HANDLE, IER )
CHARACTER*2       MTXTYP
CHARACTER*1       PIVOT
INTEGER           NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGLVL, IER
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

MTXTYP - CHARACTER*2

On entry, MTXTYP specifies the coefficient matrix type. Specifically, the valid options are:

```
'ss' or 'SS' - symmetric structure, symmetric values
'su' or 'SU' - symmetric structure, unsymmetric values
'uu' or 'UU' - unsymmetric structure, unsymmetric values
```

Unchanged on exit.

PIVOT - CHARACTER*1

On entry, PIVOT specifies whether or not pivoting is used in the course of the numeric factorization. The valid options are:

```
'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).
```

Unchanged on exit.

NEQNS - INTEGER

On entry, NEQNS specifies the number of equations in coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array

On entry, COLSTR(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array

On entry, ROWIND(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

OUTUNT - INTEGER

Output unit. Unchanged on exit.

MSGLVL - INTEGER

Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros less than NEQNS.

NAME

dgssor - Orders and symbolically factors.

SYNOPSIS

```
SUBROUTINE DGSSOR ( ORDMTHD, HANDLE, IER )
CHARACTER*3      ORDMTHD
INTEGER          IER
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

ORDMTHD - CHARACTER*3

On entry, ORDMTHD specifies the fill-reducing ordering to be used by the sparse solver. Specifically, the valid options are:

```
'nat' or 'NAT' - natural ordering (no ordering)
'mmd' or 'MMD' - multiple minimum degree
'uso' or 'USO' - user specified ordering (see DGSSUO)
```

Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

```
-200 : Invalid calling sequence - need to call DGSSIN first.
-201 : Failure to dynamically allocate memory.
-666 : Internal error.
```

NAME

dgssps - Print solver statics.

SYNOPSIS

```
SUBROUTINE DGSSPS ( HANDLE, IER )  
  INTEGER          IER  
  DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSPS - Print solver statistics.

PARAMETERS

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 800 : Invalid calling sequence - need to call DGSSSL first.
- 899 : Printed solver statistics not supported this release.

NAME

dgssrp - Return permutation.

SYNOPSIS

```
SUBROUTINE DGSSRP ( PERM, HANDLE, IER )  
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

PERM(NEQNS) - INTEGER array

Undefined on entry. PERM(NEQNS) is the permutation array used by the sparse solver for the fill-reducing ordering. Modified on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-600 : Invalid calling sequence - need to call DGSSOR first.

NAME

dgsssl - Solve.

SYNOPSIS

```
SUBROUTINE DGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )  
INTEGER           NRHS, LDRHS, IER  
DOUBLE PRECISION RHS(LDRHS,NRHS)  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

NRHS - INTEGER

On entry, NRHS specifies the number of right hand sides to solve for. Unchanged on exit.

RHS(LDRHS,*) - DOUBLE PRECISION array

On entry, RHS(LDRHS,NRHS) contains the NRHS right hand sides. On exit, it contains the solutions.

LDRHS - INTEGER

On entry, LDRHS specifies the leading dimension of the RHS array. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- 400 : Invalid calling sequence - need to call DGSSOR first.
- 401 : Failure to dynamically allocate memory.
- 402 : NRHS < 1
- 403 : NEQNS > LDRHS

NAME

dgssuo - User supplied permutation for ordering.

SYNOPSIS

```
SUBROUTINE DGSSUO ( PERM, HANDLE, IER )  
INTEGER          PERM(*), IER  
DOUBLE PRECISION HANDLE(150)
```

PURPOSE

DGSSUO - User supplied permutation for ordering. Must be called after DGSSIN (sparse solver initialization) and before DGSSOR (sparse solver ordering).

PARAMETERS

PERM(NEQNS) - INTEGER array

On entry, PERM(NEQNS) is a permutation array supplied by the user for the fill-reducing ordering. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array

On entry, HANDLE(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

IER - INTEGER

Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-500 : Invalid calling sequence - need to call DGSSIN first.

NAME

dgtcon - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF

SYNOPSIS

```
SUBROUTINE DGTCON( NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, WORK, IWORK2, INFO)  
CHARACTER * 1 NORM  
INTEGER N, INFO  
INTEGER IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)  
  
SUBROUTINE DGTCON_64( NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, WORK, IWORK2, INFO)  
CHARACTER * 1 NORM  
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GTCON( NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, [WORK], [IWORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK  
  
SUBROUTINE GTCON_64( NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,  
*      RCOND, [WORK], [IWORK2], [INFO])  
CHARACTER(LEN=1) :: NORM  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgtcon(char norm, int n, double *low, double *diag, double *up1, double *up2, int *ipivot, double anorm, double *rcond, int *info);
```

```
void dgtcon_64(char norm, long n, double *low, double *diag, double *up1, double *up2, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

dgtcon estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **NORM** (*input*)

Specifies whether the 1-norm condition number or the infinity-norm condition number is required:

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **LOW** (*input*)

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

* **DIAG** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UP1** (*input*)

The (n-1) elements of the first superdiagonal of U.

* **UP2** (*input*)

The (n-2) elements of the second superdiagonal of U.

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **ANORM** (*input*)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **IWORK2** (*workspace*)

* *INFO (output)*

NAME

dgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE DGTRFS( TRANSA, N, NRHS, LOW, DIAG, UP, LOWF, DIAGF,
*   UPF1, UPF2, IPIVOT, B, LDB, X, LDX, FERR, BERR, WORK, WORK2,

REAL(8), DIMENSION(:,:) :: B, X

SUBROUTINE GTRFS_64( [TRANSA], [N], [NRHS], LOW, DIAG, UP, LOWF,
*   DIAGF, UPF1, UPF2, IPIVOT, B, [LDB], X, [LDX], FERR, BERR, [WORK],
*   [WORK2], [INFO])
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, WORK2
REAL(8), DIMENSION(:) :: LOW, DIAG, UP, LOWF, DIAGF, UPF1, UPF2, FERR, BERR, WORK
REAL(8), DIMENSION(:,:) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgtrfs(char transa, int n, int nrhs, double *low, double *diag, double *up, double *lowf, double *diagf, double *upf1, double *upf2, int *ipivot, double *b, int ldb, double *x, int ldx, double *ferr, double *berr, int *info);
```

```
void dgtrfs_64(char transa, long n, long nrhs, double *low, double *diag, double *up, double *lowf, double *diagf, double *upf1, double *upf2, long *ipivot, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **TRANSA (input)**

Specifies the form of the system of equations:

* **N (input)**

The order of the matrix A. $N \geq 0$.

* **NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* **LOW (input)**

The (n-1) subdiagonal elements of A.

* **DIAG (input)**

The diagonal elements of A.

* **UP (input)**

The (n-1) superdiagonal elements of A.

* **LOWF (input)**

The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

* **DIAGF (input)**

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* **UPF1 (input)**

The (n-1) elements of the first superdiagonal of U.

* **UPF2 (input)**

The (n-2) elements of the second superdiagonal of U.

* **IPIVOT (input)**

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* **B (input)**

The right hand side matrix B.

* **LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X (input/output)**

On entry, the solution matrix X, as computed by SGTTRS. On exit, the improved solution matrix X.

* **LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR (output)**

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK (workspace)**

dimension(2*N)

* **WORK2 (workspace)**

* **INFO (output)**

NAME

dgtsl - (obsolete) solve the linear system $Ax = b$ for a tridiagonal matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE DGTSL( N, SUB, DIAG, SUPER, B, INFO)
INTEGER N, INFO
DOUBLE PRECISION SUB(*), DIAG(*), SUPER(*), B(*)

SUBROUTINE DGTSL_64( N, SUB, DIAG, SUPER, B, INFO)
INTEGER*8 N, INFO
DOUBLE PRECISION SUB(*), DIAG(*), SUPER(*), B(*)
```

C INTERFACE

```
#include <sunperf.h>

void dgtsl(int n, double *sub, double *diag, double *super, double *b, int *info);

void dgtsl_64(long n, double *sub, double *diag, double *super, double *b, long *info);
```

ARGUMENTS

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *SUB* (*input*)

Subdiagonal of A . $SUB(2)$ through $SUB(N)$ contain the subdiagonal and $SUB(1)$ is not referenced.

* *DIAG* (*input*)

Diagonal of A .

* *SUPER* (*input*)

Superdiagonal of A . $SUPER(1)$ through $SUPER(N-1)$ contain the superdiagonal and $SUPER(N)$ is not referenced.

* *B* (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

* *INFO* (*output*)

On exit:

$INFO = 0$ Subroutine completed normally.

INFO < 0 Returns a value k when the kth element of the diagonal becomes exactly zero.

NAME

dgtsv - solve the equation $A \cdot X = B$.

SYNOPSIS

```
SUBROUTINE DGTSV( N, NRHS, LOW, DIAG, UP, B, LDB, INFO)
INTEGER N, NRHS, LDB, INFO
DOUBLE PRECISION LOW(*), DIAG(*), UP(*), B(LDB,*)
```

```
SUBROUTINE DGTSV_64( N, NRHS, LOW, DIAG, UP, B, LDB, INFO)
INTEGER*8 N, NRHS, LDB, INFO
DOUBLE PRECISION LOW(*), DIAG(*), UP(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE GTSV( [N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
INTEGER :: N, NRHS, LDB, INFO
REAL(8), DIMENSION(:) :: LOW, DIAG, UP
REAL(8), DIMENSION(:, :) :: B
```

```
SUBROUTINE GTSV_64( [N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])
INTEGER(8) :: N, NRHS, LDB, INFO
REAL(8), DIMENSION(:) :: LOW, DIAG, UP
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgtsv(int n, int nrhs, double *low, double *diag, double *up, double *b, int ldb, int *info);
```

```
void dgtsv_64(long n, long nrhs, double *low, double *diag, double *up, double *b, long ldb, long *info);
```

PURPOSE

dgtsv solves the equation

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation $A^*X = B$ may be solved by interchanging the order of the arguments DU and DL .

ARGUMENTS

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** $NRHS$ (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** LOW (input/output)**

On entry, LOW must contain the $(n-1)$ sub-diagonal elements of A .

On exit, LOW is overwritten by the $(n-2)$ elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A , in $LOW(1), \dots, LOW(n-2)$.

*** $DIAG$ (input/output)**

On entry, $DIAG$ must contain the diagonal elements of A .

On exit, $DIAG$ is overwritten by the n diagonal elements of U .

*** UP (input/output)**

On entry, UP must contain the $(n-1)$ super-diagonal elements of A .

On exit, UP is overwritten by the $(n-1)$ elements of the first super-diagonal of U .

*** B (input/output)**

On entry, the N by $NRHS$ matrix of right hand side matrix B . On exit, if $INFO = 0$, the N by $NRHS$ solution matrix X .

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1, N)$.

*** $INFO$ (output)**

NAME

dgtsvx - use the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$.

SYNOPSIS

```
      SUBROUTINE DGTSVX( FACT, TRANSA, N, NRHS, LOW, DIAG, UP, LOWF,

C INTERFACE

```
#include <sunperf.h>
```

```
void dgtsvx(char fact, char transa, int n, int nrhs, double *low, double *diag, double *up, double *lowf, double *diagf, double *upf1, double *upf2, int *ipivot, double *b, int ldb, double *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void dgtsvx_64(char fact, char transa, long n, long nrhs, double *low, double *diag, double *up, double *lowf, double *diagf, double *upf1, double *upf2, long *ipivot, double *b, long ldb, double *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

dgtsvx uses the LU factorization to compute the solution to a real system of linear equations $A * X = B$ or $A^{**T} * X = B$, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A as $A = L * U$, where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.
 2. If some $U(i,i)=0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
 3. The system of equations is solved for X using the factored form of A.
 4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* FACT (input)

Specifies whether or not the factored form of A has been supplied on entry.

* TRANSA (input)

Specifies the form of the system of equations:

* N (input)

The order of the matrix A. $N \geq 0$.

* NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* LOW (input)

The (n-1) subdiagonal elements of A.

* DIAG (input)

The n diagonal elements of A.

* UP (input/output)

The (n-1) superdiagonal elements of A.

* LOWF (input/output)

If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

* DIAGF (input/output)

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

* UPF1 (input/output)

If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

* UPF2 (input/output)

If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

* IPIVOT (input/output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

* B (input)

The N-by-NRHS right hand side matrix B.

* LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

* LDX (input)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **RCOND** (*output*)

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK** (*workspace*)

dimension(2*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dgtrf - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

SYNOPSIS

```

```
SUBROUTINE GTTRF_64( [N], LOW, DIAG, UP1, UP2, IPIVOT, [INFO])
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgtrf(int n, double *low, double *diag, double *up1, double *up2, int *ipivot, int *info);
```

```
void dgtrf_64(long n, double *low, double *diag, double *up1, double *up2, long *ipivot, long *info);
```

PURPOSE

dgtrf computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

$$A = L * U$$

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

*** N (input)**

The order of the matrix A .

*** LOW (input/output)**

On entry, LOW must contain the $(n-1)$ sub-diagonal elements of A .

On exit, LOW is overwritten by the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .

*** $DIAG$ (input/output)**

On entry, $DIAG$ must contain the diagonal elements of A .

On exit, $DIAG$ is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A .

*** $UP1$ (input/output)**

On entry, $UP1$ must contain the $(n-1)$ super-diagonal elements of A .

On exit, $UP1$ is overwritten by the $(n-1)$ elements of the first super-diagonal of U .

*** $UP2$ (output)**

On exit, $UP2$ is overwritten by the $(n-2)$ elements of the second super-diagonal of U .

*** $IPIVOT$ (output)**

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row $IPIVOT(i)$. $IPIVOT(i)$ will always be either i or $i+1$; $IPIVOT(i) = i$ indicates a row interchange was not required.

*** $INFO$ (output)**

```
void dgtrrs_64(char transa, long n, long nrhs, double *low, double *diag, double *up1, double *up2, long *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dgtrrs solves one of the systems of equations $A*X = B$ or $A'*X = B$, with a tridiagonal matrix A using the LU factorization computed by SGTTRF.

ARGUMENTS

* **TRANSA** (*input*)

Specifies the form of the system of equations.

* **N** (*input*)

The order of the matrix A .

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **LOW** (*input*)

The $(n-1)$ multipliers that define the matrix L from the LU factorization of A .

* **DIAG** (*input*)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A .

* **UPI** (*input*)

The $(n-1)$ elements of the first super-diagonal of U .

* **UP2** (*input*)

The $(n-2)$ elements of the second super-diagonal of U .

* **IPIVOT** (*input*)

The pivot indices; for $1 \leq i \leq n$, row i of the matrix was interchanged with row $IPIVOT(i)$. $IPIVOT(i)$ will always be either i or $i+1$; $IPIVOT(i) = i$ indicates a row interchange was not required.

* **B** (*input/output*)

On entry, the matrix of right hand side vectors B . On exit, B is overwritten by the solution vectors X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

dhgeqz - implement a single-/double-shift version of the QZ method for finding the generalized eigenvalues $w(j)=(\text{ALPHAR}(j) + i*\text{ALPHAI}(j))/\text{BETAR}(j)$ of the equation $\det(A-w(i)B) = 0$ In addition, the pair A,B may be reduced to generalized Schur form

```

PURPOSE

dhgeqz implements a single-/double-shift version of the QZ method for finding the generalized eigenvalues B is upper triangular, and A is block upper triangular, where the diagonal blocks are either 1-by-1 or 2-by-2, the 2-by-2 blocks having complex generalized eigenvalues (see the description of the argument JOB.)

If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form by applying one orthogonal transformation (usually called Q) on the left and another (usually called Z) on the right. The 2-by-2 upper-triangular diagonal blocks of B corresponding to 2-by-2 blocks of A will be reduced to positive diagonal matrices. (I.e., if $A(j+1,j)$ is non-zero, then $B(j+1,j)=B(j,j+1)=0$ and $B(j,j)$ and $B(j+1,j+1)$ will be positive.)

If JOB='E', then at each iteration, the same transformations are computed, but they are only applied to those parts of A and B which are needed to compute ALPHAR, ALPHAI, and BETAR.

If JOB='S' and COMPQ and COMPZ are 'V' or 'T', then the orthogonal transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:

$$(in) A(in) Z(in)^* = Q(out) A(out) Z(out)^* \quad (in) B(in) Z(in)^* = Q(out) B(out) Z(out)^*$$

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrix Eigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

* JOB (input)

* COMPQ (input)

* COMPZ (input)

* N (input)

The order of the matrices A, B, Q, and Z. $N \geq 0$.

* ILO (input)

It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; ILO=1 and IHI=0, if $N=0$.

* IHI (input)

See the description of ILO.

* A (input)

On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to generalized Schur form. If JOB='E', then on exit A will have been destroyed. The diagonal blocks will be correct, but the off-diagonal portion will be meaningless.

* LDA (input)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* B (input)

On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. 2-by-2 blocks in B corresponding to 2-by-2 blocks in A will be reduced to positive diagonal form. (I.e., if $A(j+1,j)$ is non-zero, then $B(j+1,j)=B(j,j+1)=0$ and $B(j,j)$ and $B(j+1,j+1)$ will be positive.) If JOB='S', then on exit A and B will have been simultaneously reduced to Schur form. If JOB='E', then on exit B will have been destroyed. Elements corresponding to diagonal blocks of A will be correct, but the off-diagonal portion will be meaningless.

* LDB (input)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* ALPHAR (output)

ALPHAR(1:N) will be set to real parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if $A(j,j)$ is in a 1-by-1 block (i.e., $A(j+1,j)=A(j,j+1)=0$), then $ALPHAR(j)=A(j,j)$. Note that the (real or complex) values $(ALPHAR(j) + i*ALPHAI(j))/BETA(j)$, $j=1,\dots,N$, are the generalized eigenvalues of the matrix pencil $A - wB$.

* ALPHAI (output)

ALPHAI(1:N) will be set to imaginary parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if $A(j,j)$ is in a 1-by-1 block (i.e., $A(j+1,j)=A(j,j+1)=0$), then $ALPHAI(j)=0$. Note that the (real or complex) values $(ALPHAR(j) + i*ALPHAI(j))/BETA(j)$, $j=1,\dots,N$, are the generalized eigenvalues of the matrix pencil $A - wB$.

*** BETA (output)**

BETA(1:N) will be set to the (real) diagonal elements of B that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then BETA(j)=B(j,j). Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB. (Note that BETA(1:N) will always be non-negative, and no BETAI is necessary.)

*** Q (input/output)**

If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the transpose of the orthogonal transformations which are applied to A and B on the left will be applied to the array Q on the right.

*** LDQ (input)**

The leading dimension of the array Q. LDQ >= 1. If COMPQ='V' or 'I', then LDQ >= N.

*** Z (input/output)**

If COMPZ='N', then Z will not be referenced. If COMPZ='V' or 'I', then the orthogonal transformations which are applied to A and B on the right will be applied to the array Z on the right.

*** LDZ (input)**

The leading dimension of the array Z. LDZ >= 1. If COMPZ='V' or 'I', then LDZ >= N.

*** WORK (workspace)**

On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

*** LWORK (input)**

The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** INFO (output)**

```

PURPOSE

dhsein uses inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

$$H * x = w * x, \quad y^{*h} * H = w * y^{*h}$$

where y^{*h} denotes the conjugate transpose of the vector y.

ARGUMENTS

* *SIDE* (input)

* *EIGSRC* (input)

Specifies the source of eigenvalues supplied in (WR,WI):

* *INITV* (input)

* *SELECT* (input/output)

Specifies the eigenvectors to be computed. To select the real eigenvector corresponding to a real eigenvalue WR(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex eigenvalue (WR(j),WI(j)), with complex conjugate (WR(j+1),WI(j+1)), either SELECT(j) or SELECT(j+1) or both must be set to .TRUE.; then on exit SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

* *N* (input)

The order of the matrix H. N >= 0.

* *H* (input)

The upper Hessenberg matrix H.

* *LDH* (input)

The leading dimension of the array H. LDH >= max(1,N).

* *WR* (input/output)

On entry, the real and imaginary parts of the eigenvalues of H; a complex conjugate pair of eigenvalues must be stored in consecutive elements of WR and WI. On exit, WR may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

* *WI* (input)

See the description of WR.

*** VL (input/output)**

On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'R', VL is not referenced.

*** LDVL (input)**

The leading dimension of the array VL. LDVL \geq max(1,N) if SIDE = 'L' or 'B'; LDVL \geq 1 otherwise.

*** VR (input/output)**

On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

*** LDVR (input)**

The leading dimension of the array VR. LDVR \geq max(1,N) if SIDE = 'R' or 'B'; LDVR \geq 1 otherwise.

*** MM (input)**

The number of columns in the arrays VL and/or VR. MM \geq M.

*** M (output)**

The number of columns in the arrays VL and/or VR required to store the eigenvectors; each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

*** WORK (workspace)**

dimension((N+2)*N)

*** IFAILL (output)**

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VL hold a complex eigenvector, then IFAILL(i) and IFAILL(i+1) are set to the same value. If SIDE = 'R', IFAILL is not referenced.

*** IFAILR (output)**

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VR hold a complex eigenvector, then IFAILR(i) and IFAILR(i+1) are set to the same value. If SIDE = 'L', IFAILR is not referenced.

*** INFO (output)**

NAME

dhseqr - compute the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{*T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors

SYNOPSIS

```

REAL(8), DIMENSION(:, :) :: H, Z

SUBROUTINE HSEQR_64( JOB, COMPZ, N, ILO, IHI, H, [LDH], WR, WI, Z,
*      [LDZ], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: JOB, COMPZ
INTEGER(8) :: N, ILO, IHI, LDH, LDZ, LWORK, INFO
REAL(8), DIMENSION(:) :: WR, WI, WORK
REAL(8), DIMENSION(:, :) :: H, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dhseqr(char job, char compz, int n, int ilo, int ihi, double *h, int ldh, double *wr, double *wi, double *z, int ldz, int *info);
```

```
void dhseqr_64(char job, char compz, long n, long ilo, long ihi, double *h, long ldh, double *wr, double *wi, double *z, long
```

ldz, long *info);

PURPOSE

dhseqr computes the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z T Z^{**T}$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q , so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q : $A = Q^*H^*Q^{**T} = (QZ)^*T^*(QZ)^{**T}$.

ARGUMENTS

*** JOB (input)**

*** COMPZ (input)**

*** N (input)**

The order of the matrix H . $N \geq 0$.

*** ILO (input)**

It is assumed that H is already upper triangular in rows and columns $1:ILO-1$ and $IHI+1:N$. ILO and IHI are normally set by a previous call to SGEBAL, and then passed to SGEHRD when the matrix output by SGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

*** IHI (input)**

See the description of ILO .

*** H (input/output)**

On entry, the upper Hessenberg matrix H . On exit, if $JOB = 'S'$, H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i)*H(i,i+1) < 0$. If $JOB = 'E'$, the contents of H are unspecified on exit.

*** LDH (input)**

The leading dimension of the array H . $LDH \geq \max(1,N)$.

*** WR (output)**

The real and imaginary parts, respectively, of the computed eigenvalues. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI , say the i -th and $(i+1)$ th, with $WI(i) > 0$ and $WI(i+1) < 0$. If $JOB = 'S'$, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H , with $WR(i) = H(i,i)$ and, if $H(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $WI(i) = \sqrt{H(i+1,i)*H(i,i+1)}$ and $WI(i+1) = -WI(i)$.

*** WI (output)**

See the description of WR .

*** Z (input)**

If $COMPZ = 'N'$: Z is not referenced.

If $COMPZ = 'I'$: on entry, Z need not be set, and on exit, Z contains the orthogonal matrix Z of the Schur vectors of H . If $COMPZ = 'V'$: on entry Z must contain an N -by- N matrix Q , which is assumed to be equal to the unit matrix except for the submatrix $Z(ILO:IHI,ILO:IHI)$; on exit Z contains Q^*Z . Normally Q is the orthogonal matrix

generated by SORGHR after the call to SGEHRD which formed the Hessenberg matrix H.

* ***LDZ (input)***

The leading dimension of the array Z. LDZ \geq max(1,N) if COMPZ = 'I' or 'V'; LDZ \geq 1 otherwise.

* ***WORK (workspace)***

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* ***LWORK (input)***

The dimension of the array WORK. LWORK \geq max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* ***INFO (output)***

NAME

diamm, sdiamm, ddiamm - diagonal format matrix-matrix multiply

SYNOPSIS

```
SUBROUTINE SDIAMM( TRANSA, M, N, K, ALPHA, DESCRA,

```

DESCRIPTION

```
C <- alpha A B + beta C
C <- alpha A'B + beta C
```

(' indicates matrix transpose)

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
N	Number of columns in matrix C
K	Number of columns in matrix A
ALPHA	Scalar parameter
DESCRA()	Descriptor argument. Five element integer array DESCRA(1) matrix structure

0 : general
 1 : symmetric
 2 : Hermitian
 3 : Triangular
 4 : Skew(Anti)-Symmetric
 5 : Diagonal
 DESCRA(2) upper/lower triangular indicator (NOT IMPLEMENTED)
 1 : lower
 2 : upper
 DESCRA(3) main diagonal type (NOT IMPLEMENTED)
 0 : non-unit
 1 : unit
 DESCRA(4) Array base (NOT IMPLEMENTED)
 0 : C/C++ compatible
 1 : Fortran compatible
 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
 0 : unknown
 1 : no repeated indices
 VAL() two-dimensional LDA-by-NDIAG array such that VAL(:,I) consists of non-zero elements on diagonal IDIAG(I) of A. Diagonals in the lower triangular part of A are padded from the top, and those in the upper triangular part are padded from the bottom.
 LDA leading dimension of VAL, must be .GE. MIN(M,K)
 IDIAG() integer array of length NDIAG consisting of the corresponding diagonal offsets of the non-zero diagonals of A in VAL. Lower triangular diagonals have negative offsets, the main diagonal has offset 0, and upper triangular diagonals have positive offset.
 NDIAG number of non-zero diagonals in A.
 B() rectangular array with first dimension LDB.
 LDB leading dimension of B
 BETA Scalar parameter
 C() rectangular array with first dimension LDC.
 LDC leading dimension of C
 WORK() scratch array of length LWORK. LWORK should be at least MAX(M,N).
 LWORK length of WORK array

```

ARGUMENTS

TRANSA	Indicates how to operate with the sparse matrix 0 : operate with matrix 1 : operate with transpose matrix
M	Number of rows in matrix A
N	Number of columns in matrix C
UNITD	Type of scaling: 1 : Identity matrix (argument DV[] is ignored) 2 : Scale on left (row scaling) 3 : Scale on right (column scaling)

DV() Array containing the diagonal entries of the (block) diagonal matrix D.

ALPHA Scalar parameter

DESCRA() Descriptor argument. Five element integer array

DESCRA(1) matrix structure

- 0 : general
- 1 : symmetric
- 2 : Hermitian
- 3 : Triangular
- 4 : Skew(Anti-Symmetric)
- 5 : Diagonal

DESCRA(2) upper/lower triangular indicator

- 1 : lower
- 2 : upper

DESCRA(3) main diagonal type

- 0 : non-unit
- 1 : unit

DESCRA(4) Array base (NOT IMPLEMENTED)

- 0 : C/C++ compatible
- 1 : Fortran compatible

DESCRA(5) repeated indices? (NOT IMPLEMENTED)

- 0 : unknown
- 1 : no repeated indices

VAL() two-dimensional LDA-by-NDIAG array such that VAL(:,I) consists of non-zero elements on diagonal IDIAG(I) of A. Diagonals in the lower triangular part of A are padded from the top, and those in the upper triangular part are padded from the bottom.

LDA leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG() integer array of length NDIAG consisting of the corresponding diagonal offsets of the non-zero diagonals of A in VAL. Lower triangular diagonals have negative offsets, the main diagonal has offset 0, and upper triangular diagonals have positive offset.

NDIAG number of non-zero diagonals in A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. LWORK should be at least MAX(M,N).

LWORK length of WORK array

NAME

dlagtf - factorize the matrix $(T-\lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as $T-\lambda I = \text{PLU}$

SYNOPSIS

```
SUBROUTINE DLAGTF( N, A, LAMBDA, B, C, TOL, D, IN, INFO)
INTEGER N, INFO
INTEGER IN(*)
DOUBLE PRECISION LAMBDA, TOL
DOUBLE PRECISION A(*), B(*), C(*), D(*)
```

```
SUBROUTINE DLAGTF_64( N, A, LAMBDA, B, C, TOL, D, IN, INFO)
INTEGER*8 N, INFO
INTEGER*8 IN(*)
DOUBLE PRECISION LAMBDA, TOL
DOUBLE PRECISION A(*), B(*), C(*), D(*)
```

F95 INTERFACE

```
SUBROUTINE LAGTF( [N], A, LAMBDA, B, C, TOL, D, IN, [INFO])
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IN
REAL(8) :: LAMBDA, TOL
REAL(8), DIMENSION(:) :: A, B, C, D
```

```
SUBROUTINE LAGTF_64( [N], A, LAMBDA, B, C, TOL, D, IN, [INFO])
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IN
REAL(8) :: LAMBDA, TOL
REAL(8), DIMENSION(:) :: A, B, C, D
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dlagtf(int n, double *a, double lambda, double *b, double *c, double tol, double *d, int *in, int *info);
```

```
void dlagtf_64(long n, double *a, double lambda, double *b, double *c, double tol, double *d, long *in, long *info);
```

PURPOSE

dlagtf factorizes the matrix $(T - \lambda I)$, where T is an n by n tridiagonal matrix and λ is a scalar, as where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column.

The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling.

The parameter LAMBDA is included in the routine so that SLAGTF may be used, in conjunction with SLAGTS, to obtain eigenvectors of T by inverse iteration.

ARGUMENTS

*** N (input)**

The order of the matrix T .

*** A (input/output)**

On entry, A must contain the diagonal elements of T .

On exit, A is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T .

*** $LAMBDA$ (input)**

On entry, the scalar λ .

*** B (input/output)**

On entry, B must contain the $(n-1)$ super-diagonal elements of T .

On exit, B is overwritten by the $(n-1)$ super-diagonal elements of the matrix U of the factorization of T .

*** C (input/output)**

On entry, C must contain the $(n-1)$ sub-diagonal elements of T .

On exit, C is overwritten by the $(n-1)$ sub-diagonal elements of the matrix L of the factorization of T .

*** TOL (input/output)**

On entry, a relative tolerance used to indicate whether or not the matrix $(T - \lambda I)$ is nearly singular. TOL should normally be chosen as approximately the largest relative error in the elements of T . For example, if the elements of T are correct to about 4 significant figures, then TOL should be set to about 5×10^{-4} . If TOL is supplied as less than ϵ , where ϵ is the relative machine precision, then the value ϵ is used in place of TOL .

*** D (output)**

On exit, D is overwritten by the $(n-2)$ second super-diagonal elements of the matrix U of the factorization of T .

*** IN (output)**

On exit, IN contains details of the permutation matrix P . If an interchange occurred at the k th step of the elimination, then $IN(k) = 1$, otherwise $IN(k) = 0$. The element $IN(n)$ returns the smallest positive integer j such that

$$\text{abs}(u(j,j)) \leq \text{norm}((T - \lambda I)(j)) * TOL,$$

where $\text{norm}(A(j))$ denotes the sum of the absolute values of the j th row of the matrix A . If no such j exists then $IN(n)$ is returned as zero. If $IN(n)$ is returned as positive, then a diagonal element of U is small, indicating that $(T - \lambda I)$ is singular or nearly singular,

*** $INFO$ (output)**

NAME

dlamrg - will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order

SYNOPSIS

```
SUBROUTINE DLAMRG( N1, N2, A, TRD1, TRD2, INDEX)
INTEGER N1, N2, TRD1, TRD2
INTEGER INDEX(*)
DOUBLE PRECISION A(*)
```

```
SUBROUTINE DLAMRG_64( N1, N2, A, TRD1, TRD2, INDEX)
INTEGER*8 N1, N2, TRD1, TRD2
INTEGER*8 INDEX(*)
DOUBLE PRECISION A(*)
```

F95 INTERFACE

```
SUBROUTINE LAMRG( N1, N2, A, TRD1, TRD2, INDEX)
INTEGER :: N1, N2, TRD1, TRD2
INTEGER, DIMENSION(:) :: INDEX
REAL(8), DIMENSION(:) :: A
```

```
SUBROUTINE LAMRG_64( N1, N2, A, TRD1, TRD2, INDEX)
INTEGER(8) :: N1, N2, TRD1, TRD2
INTEGER(8), DIMENSION(:) :: INDEX
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dlamrg(int n1, int n2, double *a, int trd1, int trd2, int *index);
```

```
void dlamrg_64(long n1, long n2, double *a, long trd1, long trd2, long *index);
```

PURPOSE

dlamrg will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

ARGUMENTS

* *N1 (input)*

Length of the first sequence to be merged.

* *N2 (input)*

Length of the second sequence to be merged.

* *A (input)*

On entry, the first N1 elements of A contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final N2 elements.

* *TRD1 (input)*

Describes the stride to be taken through the array A for the first N1 elements.

* *TRD2 (input)*

Describes the stride to be taken through the array A for the first N1 elements.

* *INDEX (output)*

On exit this array will contain a permutation such that if $B(I) = A(\text{INDEX}(I))$ for $I=1, N1+N2$, then B will be sorted in ascending order.

NAME

dlarz - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right

SYNOPSIS

```
SUBROUTINE DLARZ( SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
CHARACTER * 1 SIDE
INTEGER M, N, L, INCV, LDC
DOUBLE PRECISION TAU
DOUBLE PRECISION V(*), C(LDC,*), WORK(*)

SUBROUTINE DLARZ_64( SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)
CHARACTER * 1 SIDE
INTEGER*8 M, N, L, INCV, LDC
DOUBLE PRECISION TAU
DOUBLE PRECISION V(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE LARZ( SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])
CHARACTER(LEN=1) :: SIDE
INTEGER :: M, N, L, INCV, LDC
REAL(8) :: TAU
REAL(8), DIMENSION(:) :: V, WORK
REAL(8), DIMENSION(:, :) :: C

SUBROUTINE LARZ_64( SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC],
* [WORK])
CHARACTER(LEN=1) :: SIDE
INTEGER(8) :: M, N, L, INCV, LDC
REAL(8) :: TAU
REAL(8), DIMENSION(:) :: V, WORK
REAL(8), DIMENSION(:, :) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dlarz(char side, int m, int n, int l, double *v, int incv, double tau, double *c, int ldc);
```

```
void dlarz_64(char side, long m, long n, long l, double *v, long incv, double tau, double *c, long ldc);
```

PURPOSE

dlarz applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right. H is represented in the form

$$H = I - \tau * v * v'$$

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

H is a product of k elementary reflectors as returned by STZRZF.

ARGUMENTS

* **SIDE** (*input*)

* **M** (*input*)

The number of rows of the matrix C.

* **N** (*input*)

The number of columns of the matrix C.

* **L** (*input*)

The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

* **V** (*input*)

The vector v in the representation of H as returned by STZRZF. V is not used if TAU = 0.

* **INCV** (*input*)

The increment between elements of v. INCV \neq 0.

* **TAU** (*input*)

The value tau in the representation of H.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

* **LDC** (*input*)

The leading dimension of the array C. LDC \geq max(1,M).

* **WORK** (*workspace*)

(N) if SIDE = 'L' or (M) if SIDE = 'R'. SH FURTHER DETAILS Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

*      [LDV], T, [LDT], C, [LDC], [WORK], [LDWORK])  
CHARACTER(LEN=1) :: SIDE, TRANS, DIRECT, STOREV  
INTEGER(8) :: M, N, K, L, LDV, LDT, LDC, LDWORK  
REAL(8), DIMENSION(:, :) :: V, T, C, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dlarzb(char side, char trans, char direct, char storev, int m, int n, int k, int l, double *v, int ldv, double *t, int ldt, double *c, int ldc, int ldwork);
```

```
void dlarzb_64(char side, char trans, char direct, char storev, long m, long n, long k, long l, double *v, long ldv, double *t, long ldt, double *c, long ldc, long ldwork);
```

PURPOSE

dlarzb applies a real block reflector H or its transpose H^*T to a real distributed M -by- N C from the left or the right.

Currently, only $STOREV = 'R'$ and $DIRECT = 'B'$ are supported.

ARGUMENTS

* *SIDE (input)*

* *TRANS (input)*

* *DIRECT (input)*

Indicates how H is formed from a product of elementary reflectors

* *STOREV (input)*

Indicates how the vectors which define the elementary reflectors are stored:

* *M (input)*

The number of rows of the matrix C .

* *N (input)*

The number of columns of the matrix C .

* *K (input)*

The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

* *L (input)*

The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If $SIDE = 'L'$, $M \geq L \geq 0$, if $SIDE = 'R'$, $N \geq L \geq 0$.

* *V (input)*

If $STOREV = 'C'$, $NV = K$; if $STOREV = 'R'$, $NV = L$.

* *LDV (input)*

The leading dimension of the array V . If $STOREV = 'C'$, $LDV \geq L$; if $STOREV = 'R'$, $LDV \geq K$.

* *T (input)*

The triangular K -by- K matrix T in the representation of the block reflector.

* *LDT (input)*

The leading dimension of the array T . $LDT \geq K$.

* *C (input/output)*

On entry, the M -by- N matrix C . On exit, C is overwritten by H^*C or H^*C or C^*H or C^*H .

* *LDC (input)*

The leading dimension of the array C . $LDC \geq \max(1,M)$.

* *WORK (workspace)*

$\text{dimension}(\text{MAX}(M,N),K)$

* *LDWORK (input)*

The leading dimension of the array $WORK$. If $SIDE = 'L'$, $LDWORK \geq \max(1,N)$; if $SIDE = 'R'$, $LDWORK \geq \max(1,M)$. .SH FURTHER DETAILS Based on contributions by

NAME

dlarzt - form the triangular factor T of a real block reflector H of order $> n$, which is defined as a product of k elementary reflectors

SYNOPSIS

```
SUBROUTINE DLARZT( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
CHARACTER * 1 DIRECT, STOREV
INTEGER N, K, LDV, LDT
DOUBLE PRECISION V(LDV,*), TAU(*), T(LDT,*)
```

```
SUBROUTINE DLARZT_64( DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)
CHARACTER * 1 DIRECT, STOREV
INTEGER*8 N, K, LDV, LDT
DOUBLE PRECISION V(LDV,*), TAU(*), T(LDT,*)
```

F95 INTERFACE

```
SUBROUTINE LARZT( DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
CHARACTER(LEN=1) :: DIRECT, STOREV
INTEGER :: N, K, LDV, LDT
REAL(8), DIMENSION(:) :: TAU
REAL(8), DIMENSION(:,:) :: V, T
```

```
SUBROUTINE LARZT_64( DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])
CHARACTER(LEN=1) :: DIRECT, STOREV
INTEGER(8) :: N, K, LDV, LDT
REAL(8), DIMENSION(:) :: TAU
REAL(8), DIMENSION(:,:) :: V, T
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dlarzt(char direct, char storev, int n, int k, double *v, int ldv, double *tau, double *t, int ldt);
```

```
void dlarzt_64(char direct, char storev, long n, long k, double *v, long ldv, double *tau, double *t, long ldt);
```

PURPOSE

dlarzt forms the triangular factor T of a real block reflector H of order $> n$, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', $H = H(1) H(2) \dots H(k)$ and T is upper triangular;

If DIRECT = 'B', $H = H(k) \dots H(2) H(1)$ and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

$$H = I - V * T * V'$$

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

$$H = I - V' * T * V$$

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

*** DIRECT (input)**

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

*** STOREV (input)**

Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):

*** N (input)**

The order of the block reflector H. $N \geq 0$.

*** K (input)**

The order of the triangular factor T (= the number of elementary reflectors). $K \geq 1$.

*** V (input)**

(LDV,K) if STOREV = 'C' (LDV,N) if STOREV = 'R' The matrix V. See further details.

*** LDV (input)**

The leading dimension of the array V. If STOREV = 'C', $LDV \geq \max(1,N)$; if STOREV = 'R', $LDV \geq K$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i).

*** T (input)**

The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

*** LDT (input)**

The leading dimension of the array T. $LDT \geq K$. .SH FURTHER DETAILS Based on contributions by

A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the H(i) is best illustrated by the following

example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and STOREV = 'R':

$V = \begin{pmatrix} (v1 & v2 & v3) \\ \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ 1 & \cdot & \cdot \\ & 1 & \cdot \\ & & 1 \end{pmatrix}$	$\begin{array}{c} \text{-----}V\text{-----} \\ / \qquad \qquad \qquad \backslash \\ (v1 \ v1 \ v1 \ v1 \ v1 \ \cdot \ \cdot \ \cdot \ \cdot \ 1) \\ (v2 \ v2 \ v2 \ v2 \ v2 \ \cdot \ \cdot \ \cdot \ 1) \\ (v3 \ v3 \ v3 \ v3 \ v3 \ \cdot \ \cdot \ 1) \end{array}$
---	---

DIRECT = 'B' and STOREV = 'C': DIRECT = 'B' and STOREV = 'R':

$V = \begin{pmatrix} 1 \\ \cdot & 1 \\ \cdot & \cdot & 1 \\ \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot \\ (v1 & v2 & v3) \end{pmatrix}$	$\begin{array}{c} \text{-----}V\text{-----} \\ / \qquad \qquad \qquad \backslash \\ (1 \ \cdot \ \cdot \ \cdot \ \cdot \ v1 \ v1 \ v1 \ v1 \ v1) \\ (\cdot \ 1 \ \cdot \ \cdot \ \cdot \ v2 \ v2 \ v2 \ v2 \ v2) \\ (\cdot \ \cdot \ 1 \ \cdot \ \cdot \ v3 \ v3 \ v3 \ v3 \ v3) \end{array}$
---	---

NAME

dlasrt - the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D')

SYNOPSIS

```
SUBROUTINE DLASRT( ID, N, D, INFO)
CHARACTER * 1 ID
INTEGER N, INFO
DOUBLE PRECISION D(*)

SUBROUTINE DLASRT_64( ID, N, D, INFO)
CHARACTER * 1 ID
INTEGER*8 N, INFO
DOUBLE PRECISION D(*)
```

F95 INTERFACE

```
SUBROUTINE LASRT( ID, [N], D, [INFO])
CHARACTER(LEN=1) :: ID
INTEGER :: N, INFO
REAL(8), DIMENSION(:) :: D

SUBROUTINE LASRT_64( ID, [N], D, [INFO])
CHARACTER(LEN=1) :: ID
INTEGER(8) :: N, INFO
REAL(8), DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>

void dlasrt(char id, int n, double *d, int *info);

void dlasrt_64(char id, long n, double *d, long *info);
```

PURPOSE

dlasrt the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D').

Use Quick Sort, reverting to Insertion sort on arrays of

size ≤ 20 . Dimension of STACK limits N to about 2^{32} .

ARGUMENTS

* *ID (input)*

* *N (input)*

The length of the array D.

* *D (input/output)*

On entry, the array to be sorted. On exit, D has been sorted into increasing order ($D(1) \leq \dots \leq D(N)$) or into decreasing order ($D(1) \geq \dots \geq D(N)$), depending on ID.

* *INFO (output)*

NAME

dlatzm - routine is deprecated and has been replaced by routine SORMRZ

SYNOPSIS

```
SUBROUTINE DLATZM( SIDE, M, N, V, INCV, TAU, C1, C2, LDC, WORK)
CHARACTER * 1 SIDE
INTEGER M, N, INCV, LDC
DOUBLE PRECISION TAU
DOUBLE PRECISION V(*), C1(LDC,*), C2(LDC,*), WORK(*)

SUBROUTINE DLATZM_64( SIDE, M, N, V, INCV, TAU, C1, C2, LDC, WORK)
CHARACTER * 1 SIDE

DOUBLE PRECISION TAU
DOUBLE PRECISION V(*), C1(LDC,*), C2(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE LATZM( SIDE, [M], [N], V, [INCV], TAU, C1, C2, [LDC],
* [WORK])
CHARACTER(LEN=1) :: SIDE
INTEGER :: M, N, INCV, LDC
REAL(8) :: TAU
REAL(8), DIMENSION(:) :: V, WORK
REAL(8), DIMENSION(:, :) :: C1, C2

SUBROUTINE LATZM_64( SIDE, [M], [N], V, [INCV], TAU, C1, C2, [LDC],
* [WORK])
CHARACTER(LEN=1) :: SIDE
INTEGER(8) :: M, N, INCV, LDC
REAL(8) :: TAU
REAL(8), DIMENSION(:) :: V, WORK
REAL(8), DIMENSION(:, :) :: C1, C2
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dlatzm(char side, int m, int n, double *v, int incv, double tau, double *c1, double *c2, int ldc);
```

```
void dlatzm_64(char side, long m, long n, double *v, long incv, double tau, double *c1, double *c2, long ldc);
```

PURPOSE

dlatzm routine is deprecated and has been replaced by routine SORMRZ.

SLATZM applies a Householder matrix generated by STZRQF to a matrix.

Let $P = I - \tau * u * u'$, $u = \begin{pmatrix} 1 \\ \vdots \\ 0 \end{pmatrix}$,

$$\begin{pmatrix} \vdots \\ v \end{pmatrix}$$

where v is an $(m-1)$ vector if $SIDE = 'L'$, or a $(n-1)$ vector if $SIDE = 'R'$.

If $SIDE$ equals 'L', let

$$C = \begin{bmatrix} C1 &] & 1 \\ C2 &] & m-1 \\ & & n \end{bmatrix}$$

Then C is overwritten by $P * C$.

If $SIDE$ equals 'R', let

$$C = \begin{bmatrix} C1, & C2 &] & m \\ & 1 & & n-1 \end{bmatrix}$$

Then C is overwritten by $C * P$.

ARGUMENTS

* **SIDE** (*input*)

* **M** (*input*)

The number of rows of the matrix C .

* **N** (*input*)

The number of columns of the matrix C .

* **V** (*input*)

$(1 + (M-1) * \text{abs}(INCV))$ if $SIDE = 'L'$ $(1 + (N-1) * \text{abs}(INCV))$ if $SIDE = 'R'$ The vector v in the representation of P .
 V is not used if $TAU = 0$.

* **INCV** (*input*)

The increment between elements of v . $INCV <> 0$

* **TAU** (*input*)

The value τ in the representation of P .

* **C1** (*input/output*)

(LDC, N) if $SIDE = 'L'$ $(M, 1)$ if $SIDE = 'R'$ On entry, the n -vector $C1$ if $SIDE = 'L'$, or the m -vector $C1$ if $SIDE = 'R'$.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

* **C2 (input/output)**

(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

* **LDC (input)**

The leading dimension of the arrays C1 and C2. LDC >= (1,M).

* **WORK (workspace)**

(N) if SIDE = 'L' (M) if SIDE = 'R'

NAME

dnrm2 - Return the Euclidian norm of a vector.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DNRM2( N, X, INCX)
INTEGER N, INCX
DOUBLE PRECISION X(*)
```

```
DOUBLE PRECISION FUNCTION DNRM2_64( N, X, INCX)
INTEGER*8 N, INCX
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION NRM2( [N], X, [INCX])
INTEGER :: N, INCX
REAL(8), DIMENSION(:) :: X
```

```
REAL(8) FUNCTION NRM2_64( [N], X, [INCX])
INTEGER(8) :: N, INCX
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dnrm2(int n, double *x, int incx);
```

```
double dnrm2_64(long n, double *x, long incx);
```

PURPOSE

dnrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input)*

(1 + (m - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NAME

dopgtr - generate a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by SSPTRD using packed storage

SYNOPSIS

```
SUBROUTINE DOPGTR( UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDQ, INFO
DOUBLE PRECISION AP(*), TAU(*), Q(LDQ,*), WORK(*)
```

```
SUBROUTINE DOPGTR_64( UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDQ, INFO
DOUBLE PRECISION AP(*), TAU(*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE OPGTR( UPLO, [N], AP, TAU, Q, [LDQ], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDQ, INFO
REAL(8), DIMENSION(:) :: AP, TAU, WORK
REAL(8), DIMENSION(:, :) :: Q
```

```
SUBROUTINE OPGTR_64( UPLO, [N], AP, TAU, Q, [LDQ], [WORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDQ, INFO
REAL(8), DIMENSION(:) :: AP, TAU, WORK
REAL(8), DIMENSION(:, :) :: Q
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dopgtr(char uplo, int n, double *ap, double *tau, double *q, int ldq, int *info);
```

```
void dopgtr_64(char uplo, long n, double *ap, double *tau, double *q, long ldq, long *info);
```

PURPOSE

dopgtr generates a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors $H(i)$ of order n , as returned by SSPTRD using packed storage:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix Q . $N \geq 0$.

* **AP** (*input*)

The vectors which define the elementary reflectors, as returned by SSPTRD.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SSPTRD.

* **Q** (*output*)

The N -by- N orthogonal matrix Q .

* **LDQ** (*input*)

The leading dimension of the array Q . $LDQ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension($N-1$)

* **INFO** (*output*)

NAME

dopmtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```
SUBROUTINE DOPMTR( SIDE, UPLO, TRANS, M, N, AP, TAU, C, LDC, WORK,
*                INFO)
CHARACTER * 1 SIDE, UPLO, TRANS
INTEGER M, N, LDC, INFO
DOUBLE PRECISION AP(*), TAU(*), C(LDC,*), WORK(*)

SUBROUTINE DOPMTR_64( SIDE, UPLO, TRANS, M, N, AP, TAU, C, LDC,
*                   WORK, INFO)
CHARACTER * 1 SIDE, UPLO, TRANS
INTEGER*8 M, N, LDC, INFO
DOUBLE PRECISION AP(*), TAU(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE OPMTTR( SIDE, UPLO, [TRANS], [M], [N], AP, TAU, C, [LDC],
*                [WORK], [INFO])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS
INTEGER :: M, N, LDC, INFO
REAL(8), DIMENSION(:) :: AP, TAU, WORK
REAL(8), DIMENSION(:, :) :: C

SUBROUTINE OPMTTR_64( SIDE, UPLO, [TRANS], [M], [N], AP, TAU, C, [LDC],
*                   [WORK], [INFO])
CHARACTER(LEN=1) :: SIDE, UPLO, TRANS
INTEGER(8) :: M, N, LDC, INFO
REAL(8), DIMENSION(:) :: AP, TAU, WORK
REAL(8), DIMENSION(:, :) :: C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dopmtr(char side, char uplo, char trans, int m, int n, double *ap, double *tau, double *c, int ldc, int *info);
```

```
void dopmtr_64(char side, char uplo, char trans, long m, long n, double *ap, double *tau, double *c, long ldc, long *info);
```

PURPOSE

dopmtr overwrites the general real M-by-N matrix C with TRANS = 'T': $Q^{**T} * C * Q^{**T}$

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by SSPTRD using packed storage:

if UPLO = 'U', $Q = H(nq-1) \dots H(2) H(1)$;

if UPLO = 'L', $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

* *SIDE (input)*

* *UPLO (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *AP (input)*

$(M*(M+1)/2)$ if SIDE = 'L' $(N*(N+1)/2)$ if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSPTRD. AP is modified by the routine but restored on exit.

* *TAU (input)*

or $(N-1)$ if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

* *C (input/output)*

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**T} * C$ or $C * Q^{**T}$ or $C * Q$.

* *LDC (input)*

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* *WORK (workspace)*

(N) if SIDE = 'L' (M) if SIDE = 'R'

* *INFO (output)*

NAME

dorg2l - generate an m by n real matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE DORG2L( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER M, N, K, LDA, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```

INTEGER :: M, N, K, LDA, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE ORG2L_64( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
INTEGER(8) :: M, N, K, LDA, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorg2l(int m, int n, int k, double *a, int lda, double *tau, int *info);
```

```
void dorg2l_64(long m, long n, long k, double *a, long lda, double *tau, long *info);
```

PURPOSE

dorg2l L generates an m by n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGEQLF.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix Q . $M \geq 0$.

* ***N (input)***

The number of columns of the matrix Q . $M \geq N \geq 0$.

* ***K (input)***

The number of elementary reflectors whose product defines the matrix Q . $N \geq K \geq 0$.

* ***A (input/output)***

On entry, the $(n-k+i)$ -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQLF in the last k columns of its array argument A . On exit, the m by n matrix Q .

* ***LDA (input)***

The first dimension of the array A . $LDA \geq \max(1, M)$.

* ***TAU (input)***

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEQLF.

* ***WORK (workspace)***

dimension(N)

* ***INFO (output)***

NAME

dorg2r - generate an m by n real matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE DORG2R( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER M, N, K, LDA, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DORG2R_64( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER*8 M, N, K, LDA, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORG2R( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
INTEGER :: M, N, K, LDA, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE ORG2R_64( [M], [N], [K], A, [LDA], TAU, [WORK], [INFO])
INTEGER(8) :: M, N, K, LDA, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorg2r(int m, int n, int k, double *a, int lda, double *tau, int *info);
```

```
void dorg2r_64(long m, long n, long k, double *a, long lda, double *tau, long *info);
```

PURPOSE

dorg2r R generates an m by n real matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) H(2) \dots H(k)$$

as returned by SGEQRF.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix Q . $M \geq 0$.

* ***N (input)***

The number of columns of the matrix Q . $M \geq N \geq 0$.

* ***K (input)***

The number of elementary reflectors whose product defines the matrix Q . $N \geq K \geq 0$.

* ***A (input/output)***

On entry, the i -th column must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGEQRF in the first k columns of its array argument A . On exit, the m -by- n matrix Q .

* ***LDA (input)***

The first dimension of the array A . $LDA \geq \max(1, M)$.

* ***TAU (input)***

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEQRF.

* ***WORK (workspace)***

dimension(N)

* ***INFO (output)***

NAME

dorgbr - generate one of the real orthogonal matrices Q or P**T determined by SGEBRD when reducing a real matrix A to bidiagonal form

SYNOPSIS

```

```

```
SUBROUTINE ORGBR_64( VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
CHARACTER(LEN=1) :: VECT
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorgbr(char vect, int m, int n, int k, double *a, int lda, double *tau, int *info);
```

```
void dorgbr_64(char vect, long m, long n, long k, double *a, long lda, double *tau, long *info);
```

PURPOSE

dorgbr generates one of the real orthogonal matrices Q or P^{**T} determined by SGEBRD when reducing a real matrix A to bidiagonal form: $A = Q * B * P^{**T}$. Q and P^{**T} are defined as products of elementary reflectors $H(i)$ or $G(i)$ respectively.

If $VECT = 'Q'$, A is assumed to have been an M -by- K matrix, and Q is of order M :

if $m \geq k$, $Q = H(1) H(2) \dots H(k)$ and SORGBR returns the first n columns of Q , where $m \geq n \geq k$;

if $m < k$, $Q = H(1) H(2) \dots H(m-1)$ and SORGBR returns Q as an M -by- M matrix.

If $VECT = 'P'$, A is assumed to have been a K -by- N matrix, and P^{**T} is of order N :

if $k < n$, $P^{**T} = G(k) \dots G(2) G(1)$ and SORGBR returns the first m rows of P^{**T} , where $n \geq m \geq k$;

if $k \geq n$, $P^{**T} = G(n-1) \dots G(2) G(1)$ and SORGBR returns P^{**T} as an N -by- N matrix.

ARGUMENTS

* *VECT* (input)

Specifies whether the matrix Q or the matrix P^{**T} is required, as defined in the transformation applied by SGEBRD:

* *M* (input)

The number of rows of the matrix Q or P^{**T} to be returned. $M \geq 0$.

* *N* (input)

The number of columns of the matrix Q or P^{**T} to be returned. $N \geq 0$. If $VECT = 'Q'$, $M \geq N \geq \min(M,K)$; if $VECT = 'P'$, $N \geq M \geq \min(N,K)$.

* *K* (input)

If $VECT = 'Q'$, the number of columns in the original M -by- K matrix reduced by SGEBRD. If $VECT = 'P'$, the number of rows in the original K -by- N matrix reduced by SGEBRD. $K \geq 0$.

* *A* (input/output)

On entry, the vectors which define the elementary reflectors, as returned by SGEBRD. On exit, the M -by- N matrix Q or P^{**T} .

* *LDA* (input)

The leading dimension of the array A . $LDA \geq \max(1,M)$.

* *TAU* (input)

$(\min(M,K))$ if $VECT = 'Q'$ ($\min(N,K)$) if $VECT = 'P'$ $TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$ or $G(i)$, which determines Q or P^{**T} , as returned by SGEBRD in its array argument $TAUQ$ or $TAUP$.

* *WORK* (workspace)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* *LWORK* (input)

The dimension of the array $WORK$. $LWORK \geq \max(1, \min(M,N))$. For optimum performance $LWORK \geq \min(M,N) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* *INFO* (output)

NAME

dorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD

SYNOPSIS

```
SUBROUTINE DORGHR( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
INTEGER N, ILO, IHI, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DORGHR_64( N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)
INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```

SUBROUTINE ORGHR( [N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
*               [INFO])
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

```

SUBROUTINE ORGHR_64( [N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
*                  [INFO])
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorghr(int n, int ilo, int ihi, double *a, int lda, double *tau, int *info);
```

```
void dorghr_64(long n, long ilo, long ihi, double *a, long lda, double *tau, long *info);
```

PURPOSE

dorghr generates a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N , as returned by SGEHRD:

$$Q = H(i_0) H(i_0+1) \dots H(i_{hi}-1).$$

ARGUMENTS

* ***N*** (*input*)

The order of the matrix Q . $N \geq 0$.

* ***ILO*** (*input*)

ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix $Q(i_0+1:i_{hi}, i_0+1:i_{hi})$. $1 \leq ILO \leq IHI \leq N$, if $N > 0$; $ILO=1$ and $IHI=0$, if $N=0$.

* ***IHI*** (*input*)

See the description of ILO.

* ***A*** (*input/output*)

On entry, the vectors which define the elementary reflectors, as returned by SGEHRD. On exit, the N -by- N orthogonal matrix Q .

* ***LDA*** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* ***TAU*** (*input*)

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGEHRD.

* ***WORK*** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* ***LWORK*** (*input*)

The dimension of the array $WORK$. $LWORK \geq IHI-ILO$. For optimum performance $LWORK \geq (IHI-ILO)*NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by XERBLA.

* ***INFO*** (*output*)

NAME

dorgl2 - generate an m by n real matrix Q with orthonormal rows,

SYNOPSIS

```
SUBROUTINE DORGL2( M, N, K, A, LDA, TAU, WORK, INFO)
INTEGER M, N, K, LDA, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```

#include <sunperf.h>
```

```
void dorgl2(int m, int n, int k, double *a, int lda, double *tau, int *info);
```

```
void dorgl2_64(long m, long n, long k, double *a, long lda, double *tau, long *info);
```

PURPOSE

dorgl2 generates an m by n real matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGELQF.

ARGUMENTS

* ***M (input)***

The number of rows of the matrix Q . $M \geq 0$.

* ***N (input)***

The number of columns of the matrix Q . $N \geq M$.

* ***K (input)***

The number of elementary reflectors whose product defines the matrix Q . $M \geq K \geq 0$.

* ***A (input/output)***

On entry, the i -th row must contain the vector which defines the elementary reflector $H(i)$, for $i = 1, 2, \dots, k$, as returned by SGELQF in the first k rows of its array argument A . On exit, the m -by- n matrix Q .

* ***LDA (input)***

The first dimension of the array A . $LDA \geq \max(1, M)$.

* ***TAU (input)***

$TAU(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by SGELQF.

* ***WORK (workspace)***

dimension(M)

* ***INFO (output)***

INTEGER(8) :: M, N, K, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorglq(int m, int n, int k, double *a, int lda, double *tau, int *info);
```

```
void dorglq_64(long m, long n, long k, double *a, long lda, double *tau, long *info);
```

PURPOSE

dorglq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGELQF.

ARGUMENTS

* **M** (*input*)

The number of rows of the matrix Q. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix Q. $N \geq M$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

* **A** (*input/output*)

On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

* **LDA** (*input*)

The first dimension of the array A. $LDA \geq \max(1, M)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

* **LDWORK** (*input*)

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dorgql - generate an M-by-N real matrix Q with orthonormal columns,

SYNOPSIS

```
SUBROUTINE DORGQL( M, N, K, A, LDA, TAU, WORK, LDWORK, INFO)

```

```
void dorgql_64(long m, long n, long k, double *a, long lda, double *tau, long *info);
```

PURPOSE

dorgql generates an M-by-N real matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGEQLF.

ARGUMENTS

*** M (input)**

The number of rows of the matrix Q. $M \geq 0$.

*** N (input)**

The number of columns of the matrix Q. $M \geq N \geq 0$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $N \geq K \geq 0$.

*** A (input/output)**

On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1, N)$. For optimum performance $LDWORK \geq N * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

The number of columns of the matrix Q. $N \geq M$.

*** K (input)**

The number of elementary reflectors whose product defines the matrix Q. $M \geq K \geq 0$.

*** A (input/output)**

On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

*** LDA (input)**

The first dimension of the array A. $LDA \geq \max(1, M)$.

*** TAU (input)**

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

*** WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

*** LDWORK (input)**

The dimension of the array WORK. $LDWORK \geq \max(1, M)$. For optimum performance $LDWORK \geq M * NB$, where NB is the optimal blocksize.

If $LDWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

*** INFO (output)**

NAME

dorgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD

SYNOPSIS

```
SUBROUTINE DORGTR( UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

```
SUBROUTINE DORGTR_64( UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGTR( UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE ORGTR_64( UPLO, [N], A, [LDA], TAU, [WORK], [LWORK],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorgtr(char uplo, int n, double *a, int lda, double *tau, int *info);
```

```
void dorgtr_64(char uplo, long n, double *a, long lda, double *tau, long *info);
```

PURPOSE

dorgtr generates a real orthogonal matrix Q which is defined as the product of $n-1$ elementary reflectors of order N , as returned by SSYTRD:

if UPLO = 'U', $Q = H(n-1) \dots H(2) H(1)$,

if UPLO = 'L', $Q = H(1) H(2) \dots H(n-1)$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix Q . $N \geq 0$.

* **A** (*input/output*)

On entry, the vectors which define the elementary reflectors, as returned by SSYTRD. On exit, the N -by- N orthogonal matrix Q .

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector $H(i)$, as returned by SSYTRD.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. $LWORK \geq \max(1, N-1)$. For optimum performance $LWORK \geq (N-1) * NB$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dormbr - VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```

SUBROUTINE ORMBR_64( VECT, SIDE, [TRANS], [M], [N], K, A, [LDA],
*   TAU, C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: VECT, SIDE, TRANS
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:, :) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dormbr(char vect, char side, char trans, int m, int n, int k, double *a, int lda, double *tau, double *c, int ldc, int *info);
```

```
void dormbr_64(char vect, char side, char trans, long m, long n, long k, double *a, long lda, double *tau, double *c, long ldc, long *info);
```

PURPOSE

dormbr VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N': $Q * C * Q^T$ TRANS = 'T': $Q^{**T} * C * Q^{**T}$

If VECT = 'P', SORMBR overwrites the general real M-by-N matrix C with

SIDE = 'L' SIDE = 'R'

TRANS = 'N': $P * C * P$

TRANS = 'T': $P^{**T} * C * P^{**T}$

Here Q and P^{**T} are the orthogonal matrices determined by SGEBRD when reducing a real matrix A to bidiagonal form: $A = Q * B * P^{**T}$. Q and P^{**T} are defined as products of elementary reflectors H(i) and G(i) respectively.

Let $nq = m$ if SIDE = 'L' and $nq = n$ if SIDE = 'R'. Thus nq is the order of the orthogonal matrix Q or P^{**T} that is applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K matrix: if $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

if $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If VECT = 'P', A is assumed to have been a K-by-NQ matrix: if $k < nq$, $P = G(1) G(2) \dots G(k)$;

if $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

ARGUMENTS

* *VECT (input)*

* *SIDE (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C. $M \geq 0$.

* *N (input)*

The number of columns of the matrix C. $N \geq 0$.

* *K (input)*

If VECT = 'Q', the number of columns in the original matrix reduced by SGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by SGEBRD. $K \geq 0$.

* *A (input)*

(LDA, min(nq, K)) if VECT = 'Q' (LDA, nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by SGEBRD.

* *LDA (input)*

The leading dimension of the array A. If VECT = 'Q', $LDA \geq \max(1, nq)$; if VECT = 'P', $LDA \geq \max(1, \min(nq, K))$.

* *TAU (input)*

TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by SGEBRD in the array argument TAUQ or TAUP.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by Q^*C or $Q^{**T}C$ or C^*Q^{**T} or C^*Q or P^*C or $P^{**T}C$ or C^*P or C^*P^{**T} .

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK** (*input*)

The dimension of the array WORK. If $SIDE = 'L'$, $LWORK \geq \max(1, N)$; if $SIDE = 'R'$, $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if $SIDE = 'L'$, and $LWORK \geq M * NB$ if $SIDE = 'R'$, where NB is the optimal blocksize.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $LWORK$ is issued by XERBLA.

* **INFO** (*output*)

NAME

dormhr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,) :: A, C

SUBROUTINE ORMHR_64( SIDE, [TRANS], [M], [N], ILO, IHI, A, [LDA],
*   TAU, C, [LDC], [WORK], [LWORK], [INFO])
CHARACTER(LEN=1) :: SIDE, TRANS
INTEGER(8) :: M, N, ILO, IHI, LDA, LDC, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dormhr(char side, char trans, int m, int n, int ilo, int ihi, double *a, int lda, double *tau, double *c, int ldc, int *info);
```

```
void dormhr_64(char side, char trans, long m, long n, long ilo, long ihi, double *a, long lda, double *tau, double *c, long ldc, long *info);
```

PURPOSE

dormhr overwrites the general real M-by-N matrix C with TRANS = 'T': $Q^{**T} * C * Q^{**T}$

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by SGEHRD:

$Q = H(i_{lo}) H(i_{lo}+1) \dots H(i_{hi}-1)$.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **ILO** (*input*)

ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix $Q(i_{lo}+1:i_{hi}, i_{lo}+1:i_{hi})$. If SIDE = 'L', then $1 \leq ILO \leq IHI \leq M$, if $M > 0$, and $ILO = 1$ and $IHI = 0$, if $M = 0$; if SIDE = 'R', then $1 \leq ILO \leq IHI \leq N$, if $N > 0$, and $ILO = 1$ and $IHI = 0$, if $N = 0$.

* **IHI** (*input*)

See the description of ILO.

* **A** (*input*)

(LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SGEHRD.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1,M)$ if SIDE = 'L'; $LDA \geq \max(1,N)$ if SIDE = 'R'.

* **TAU** (*input*)

(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**T} * C$ or $C * Q^{**T}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1,M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1,N)$; if SIDE = 'R', $LWORK \geq \max(1,M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by

XERBLA.

* *INFO (output)*

```

```
void dormlq_64(char side, char trans, long m, long n, long k, double *a, long lda, double *tau, double *c, long ldc, long *info);
```

PURPOSE

dormlq overwrites the general real M-by-N matrix C with TRANS = 'T': $Q^{**T} * C * Q^{**T}$

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

$$Q = H(k) \cdot \cdot \cdot H(2) H(1)$$

as returned by SGELQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

* **A** (*input*)

(LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGELQF in the first k rows of its array argument A. A is modified by the routine but restored on exit.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**T} * C$ or $C * Q^{**T}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

* **A** (*input*)

(LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by SGERQF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**T} * C$ or $C * Q^{**T}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

** INFO (output)*

NAME

dormrz - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```

REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A, C
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dormrz(char side, char trans, int m, int n, int k, int l, double *a, int lda, double *tau, double *c, int ldc, int *info);
```

```
void dormrz_64(char side, char trans, long m, long n, long k, long l, double *a, long lda, double *tau, double *c, long ldc, long *info);
```

PURPOSE

dormrz overwrites the general real M-by-N matrix C with TRANS = 'T': $Q^{**T} * C C * Q^{**T}$

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by STZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

* **SIDE** (*input*)

* **TRANS** (*input*)

* **M** (*input*)

The number of rows of the matrix C. $M \geq 0$.

* **N** (*input*)

The number of columns of the matrix C. $N \geq 0$.

* **K** (*input*)

The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', $M \geq K \geq 0$; if SIDE = 'R', $N \geq K \geq 0$.

* **L** (*input*)

The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', $M \geq L \geq 0$, if SIDE = 'R', $N \geq L \geq 0$.

* **A** (*input*)

(LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for $i = 1, 2, \dots, k$, as returned by STZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, K)$.

* **TAU** (*input*)

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by STZRZF.

* **C** (*input/output*)

On entry, the M-by-N matrix C. On exit, C is overwritten by $Q * C$ or $Q^{**H} * C$ or $C * Q^{**H}$ or $C * Q$.

* **LDC** (*input*)

The leading dimension of the array C. $LDC \geq \max(1, M)$.

* **WORK** (*workspace*)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If SIDE = 'L', $LWORK \geq \max(1, N)$; if SIDE = 'R', $LWORK \geq \max(1, M)$. For optimum performance $LWORK \geq N * NB$ if SIDE = 'L', and $LWORK \geq M * NB$ if SIDE = 'R', where NB is the optimal blocksize.

If `LWORK = -1`, then a workspace query is assumed; the routine only calculates the optimal size of the `WORK` array, returns this value as the first entry of the `WORK` array, and no error message related to `LWORK` is issued by `XERBLA`.

* ***INFO*** (*output*)

NAME

dormtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

SYNOPSIS

```
SUBROUTINE DORMTR( SIDE, UPLO, TRANS, M, N, A, LDA, TAU, C, LDC,

```

```
void dormtr_64(char side, char uplo, char trans, long m, long n, double *a, long lda, double *tau, double *c, long ldc, long *info);
```

PURPOSE

dormtr overwrites the general real M -by- N matrix C with $\text{TRANS} = 'T': Q^{**T} * C * Q^{**T}$

where Q is a real orthogonal matrix of order nq , with $nq = m$ if $\text{SIDE} = 'L'$ and $nq = n$ if $\text{SIDE} = 'R'$. Q is defined as the product of $nq-1$ elementary reflectors, as returned by `SSYTRD`:

if $\text{UPLO} = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

if $\text{UPLO} = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

ARGUMENTS

* *SIDE (input)*

* *UPLO (input)*

* *TRANS (input)*

* *M (input)*

The number of rows of the matrix C . $M \geq 0$.

* *N (input)*

The number of columns of the matrix C . $N \geq 0$.

* *A (input)*

(LDA, M) if $\text{SIDE} = 'L'$ (LDA, N) if $\text{SIDE} = 'R'$ The vectors which define the elementary reflectors, as returned by `SSYTRD`.

* *LDA (input)*

The leading dimension of the array A . $LDA \geq \max(1, M)$ if $\text{SIDE} = 'L'$; $LDA \geq \max(1, N)$ if $\text{SIDE} = 'R'$.

* *TAU (input)*

($M-1$) if $\text{SIDE} = 'L'$ ($N-1$) if $\text{SIDE} = 'R'$ $\text{TAU}(i)$ must contain the scalar factor of the elementary reflector $H(i)$, as returned by `SSYTRD`.

* *C (input/output)*

On entry, the M -by- N matrix C . On exit, C is overwritten by $Q * C$ or $Q^{**T} * C$ or $C * Q^{**T}$ or $C * Q$.

* *LDC (input)*

The leading dimension of the array C . $LDC \geq \max(1, M)$.

* *WORK (workspace)*

On exit, if $\text{INFO} = 0$, $\text{WORK}(1)$ returns the optimal $L\text{WORK}$.

* *LWORK (input)*

The dimension of the array WORK . If $\text{SIDE} = 'L'$, $L\text{WORK} \geq \max(1, N)$; if $\text{SIDE} = 'R'$, $L\text{WORK} \geq \max(1, M)$. For optimum performance $L\text{WORK} \geq N * \text{NB}$ if $\text{SIDE} = 'L'$, and $L\text{WORK} \geq M * \text{NB}$ if $\text{SIDE} = 'R'$, where NB is the optimal blocksize.

If $L\text{WORK} = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to $L\text{WORK}$ is issued by `XERBLA`.

* *INFO (output)*

NAME

dpbco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in banded storage. If the condition number is not needed then SPBFA is slightly faster. It is typical to follow a call to SPBCO with a call to SPBSL to solve $Ax = b$ or to SPBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE DPBCO( A, LDA, N, NDIAG, RCOND, WORK, INFO)
INTEGER LDA, N, NDIAG, INFO
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DPBCO_64( A, LDA, N, NDIAG, RCOND, WORK, INFO)
INTEGER*8 LDA, N, NDIAG, INFO
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbco(double *a, int lda, int n, int ndiag, double *rcond, int *info);
```

```
void dpbco_64(double *a, long lda, long n, long ndiag, double *rcond, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

*** N (input)**

Order of the matrix A. $N \neq 0$.

*** NDIAG (input)**

Number of diagonals. $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

*** RCOND (output)**

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO < 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

dpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPBTRF

SYNOPSIS

```
SUBROUTINE DPBCON( UPLO, N, NDIAG, A, LDA, ANORM, RCOND, WORK,  
*                WORK2, INFO)  
CHARACTER * 1 UPLO

DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)  
  
SUBROUTINE DPBCON_64( UPLO, N, NDIAG, A, LDA, ANORM, RCOND, WORK,  
*                   WORK2, INFO)  
CHARACTER * 1 UPLO  
INTEGER*8 N, NDIAG, LDA, INFO  
INTEGER*8 WORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PBCON( UPLO, [N], NDIAG, A, [LDA], ANORM, RCOND, [WORK],  
*               [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, NDIAG, LDA, INFO  
INTEGER, DIMENSION(:) :: WORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A  
  
SUBROUTINE PBCON_64( UPLO, [N], NDIAG, A, [LDA], ANORM, RCOND, [WORK],  
*                   [WORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, NDIAG, LDA, INFO  
INTEGER(8), DIMENSION(:) :: WORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: WORK  
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbcon(char uplo, int n, int ndiag, double *a, int lda, double anorm, double *rcond, int *info);
```

```
void dpbcon_64(char uplo, long n, long ndiag, double *a, long lda, double anorm, double *rcond, long *info);
```

PURPOSE

dpbcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPBTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ of the band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = U(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = L(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A. LDA \geq NDIAG+1.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the symmetric band matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dpbdi - (obsolete) compute the determinant of a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by SPBCO or SPBFA.

SYNOPSIS

```
SUBROUTINE DPBDI( A, LDA, N, NDIAG, DET)
  INTEGER LDA, N, NDIAG
  DOUBLE PRECISION A(LDA,*), DET(*)
```

```
SUBROUTINE DPBDI_64( A, LDA, N, NDIAG, DET)
  INTEGER*8 LDA, N, NDIAG
  DOUBLE PRECISION A(LDA,*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbdi(double *a, int lda, int n, int ndiag, double *det);
```

```
void dpbdi_64(double *a, long lda, long n, long ndiag, double *det);
```

ARGUMENTS

* *A* (*input*)

Cholesky factorization of the matrix A, as computed by SPBCO or SPBFA.

* *LDA* (*input*)

Leading dimension of the array A as specified in a dimension or type statement. LDA >= NDIAG + 1.

* *N* (*input*)

Order of the original matrix A. N >= 0.

* *NDIAG* (*input*)

Number of diagonals. N-1 >= NDIAG >= 0 but if N = 0 then NDIAG = 0.

* *DET* (*output*)

On exit, the determinant of the matrix A. The determinant is stored as b * (10 ** expon) where b is stored in DET(1) and expon is stored in DET(2). 1.0 <= |DET(1)| <= 10.0 or DET(1) = 0.0.

NAME

dpbequ - compute row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE DPBEQU( UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

```
SUBROUTINE DPBEQU_64( UPLO, N, NDIAG, A, LDA, SCALE, SCOND, AMAX,
* INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NDIAG, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU( UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NDIAG, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: A

SUBROUTINE PBEQU_64( UPLO, [N], NDIAG, A, [LDA], SCALE, SCOND, AMAX,
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NDIAG, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbequ(char uplo, int n, int ndiag, double *a, int lda, double *scale, double *scond, double *amax, int *info);
```

```
void dpbequ_64(char uplo, long n, long ndiag, double *a, long lda, double *scale, double *scond, double *amax, long *info);
```

PURPOSE

dpbequ computes row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric band matrix A , stored in the first $NDIAG+1$ rows of the array. The j -th column of A is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **SCALE** (*output*)

If $INFO = 0$, $SCALE$ contains the scale factors for A .

* **SCOND** (*output*)

If $INFO = 0$, $SCALE$ contains the ratio of the smallest $SCALE(i)$ to the largest $SCALE(i)$. If $SCOND \geq 0.1$ and $AMAX$ is neither too large nor too small, it is not worth scaling by $SCALE$.

* **AMAX** (*output*)

Absolute value of largest matrix element. If $AMAX$ is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO** (*output*)

NAME

dpbfa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A in banded storage. It is typical to follow a call to SPBFA with a call to SPBSL to solve $Ax = b$ or to SPBDI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE DPBFA( A, LDA, N, NDIAG, INFO)
INTEGER LDA, N, NDIAG, INFO
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DPBFA_64( A, LDA, N, NDIAG, INFO)
INTEGER*8 LDA, N, NDIAG, INFO
DOUBLE PRECISION A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbfa(double *a, int lda, int n, int ndiag, int *info);
```

```
void dpbfa_64(double *a, long lda, long n, long ndiag, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** NDIAG (input)**

Number of diagonals. $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value of k if the leading minor of order k is not positive definite.

NAME

dpbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE DPBRFS( UPLO, N, NDIAG, NRHS, A, LDA, AF, LDAF, B, LDB,
*      X, LDX, FERR, BERR, WORK, WORK2, INFO)

```

PURPOSE

dpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric band matrix A, stored in the first $NDIAG+1$ rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG+1$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^*U$ or $A = L^*L$ of the band matrix A as computed by SPBTRF, in the same storage format as A (see A).

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq NDIAG+1$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SPBTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

- * **WORK** (*workspace*)
dimension(2*N)
- * **WORK2** (*workspace*)
- * **INFO** (*output*)

NAME

dpbsl - (obsolete) section solve the linear system $Ax = b$ for a symmetric positive definite matrix A in banded storage, which has been Cholesky-factored by SPBCO or SPBFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE DPBSL( A, LDA, N, NDIAG, B)
INTEGER LDA, N, NDIAG
DOUBLE PRECISION A(LDA,*), B(*)
```

```
SUBROUTINE DPBSL_64( A, LDA, N, NDIAG, B)
INTEGER*8 LDA, N, NDIAG
DOUBLE PRECISION A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbsl(double *a, int lda, int n, int ndiag, double *b);
```

```
void dpbsl_64(double *a, long lda, long n, long ndiag, double *b);
```

ARGUMENTS

* **A** (*input*)

Cholesky factorization of the matrix A , as computed by SPBCO or SPBFA.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq NDIAG + 1$.

* **N** (*input*)

Order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

Number of diagonals of matrix A . $N-1 \geq NDIAG \geq 0$ but if $N = 0$ then $NDIAG = 0$.

* **B** (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

dpbstf - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE DPBSTF( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
INTEGER N, KD, LDAB, INFO
DOUBLE PRECISION AB(LDAB,*)
```

```
SUBROUTINE DPBSTF_64( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, KD, LDAB, INFO
DOUBLE PRECISION AB(LDAB,*)
```

F95 INTERFACE

```

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, KD, LDAB, INFO
REAL(8), DIMENSION(:, :) :: AB
```

```
SUBROUTINE PBSTF_64( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDAB, INFO
REAL(8), DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbstf(char uplo, int n, int kd, double *ab, int ldab, int *info);
```

```
void dpbstf_64(char uplo, long n, long kd, double *ab, long ldab, long *info);
```

PURPOSE

dpbstf computes a split Cholesky factorization of a real symmetric positive definite band matrix A.

This routine is designed to be used in conjunction with SSBGST.

The factorization has the form $A = S^{**T}S$ where S is a band matrix of the same bandwidth as A and the following structure:

$$S = \begin{pmatrix} U & \\ & M & L \end{pmatrix}$$

where U is upper triangular of order $m = (n+kd)/2$, and L is lower triangular of order $n-m$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $kd+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if INFO = 0, the factor S from the split Cholesky factorization $A = S^{**T}S$. See Further Details.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq kd+1$.

* **INFO** (*output*)

NAME

dpbsv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE DPBSV( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

```
SUBROUTINE DPBSV_64( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NDIAG, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PBSV( UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NDIAG, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:,*) :: A, B
```

```
SUBROUTINE PBSV_64( UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:,*) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbsv(char uplo, int n, int ndiag, int nrhs, double *a, int lda, double *b, int ldb, int *info);
```

```
void dpbsv_64(char uplo, long n, long ndiag, long nrhs, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dpbsv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**T} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NDIAG (input)**

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $NDIAG+1$ rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(NDIAG+1+i-j,j) = A(i,j)$ for $\max(1,j-NDIAG) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(N,j+NDIAG)$. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L * L^{**T}$ of the band matrix A, in the same storage format as A.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq NDIAG+1$.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

dpbsvx - use the Cholesky factorization $A = U^{*}T^{*}U$ or $A = L^{*}L^{*}T^{*}$ to compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbsvx(char fact, char uplo, int n, int ndiag, int nrhs, double *a, int lda, double *af, int ldaf, char equed, double *scale, double *b, int ldb, double *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

void dpbsvx_64(char fact, char uplo, long n, long ndiag, long nrhs, double *a, long lda, double *af, long ldaf, char equed, double *scale, double *b, long ldb, double *x, long ldx, double *rcond, double *ferr, double *berr, long *info);

PURPOSE

dpbsvx uses the Cholesky factorization $A = U^{**T}U$ or $A = L^{**T}L$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$
Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as $A = U^{**T} * U$, if UPLO = 'U', or

$$A = L * L^{**T}, \text{ if UPLO} = \text{'L'},$$
where U is an upper triangular band matrix, and L is a lower triangular band matrix.

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before

equilibration.

ARGUMENTS

* **FACT** (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* **UPLO** (input)

* **N** (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NDIAG** (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

* **NRHS** (input)

The number of right-hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array, except if FACT

= 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(\text{NDIAG}+1+i-j, j) = A(i, j)$ for $\max(1, j-\text{NDIAG}) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(N, j+\text{NDIAG})$. See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

*** LDA (input)**

The leading dimension of the array A. $\text{LDA} \geq \text{NDIAG}+1$.

*** AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ of the band matrix A, in the same storage format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

*** LDAF (input)**

The leading dimension of the array AF. $\text{LDAF} \geq \text{NDIAG}+1$.

*** EQUED (input)**

Specifies the form of equilibration that was done.

*** SCALE (input/output)**

The scale factors for A; not accessed if EQUED = 'N'. SCALE is an input argument if FACT = 'F'; otherwise, SCALE is an output argument. If FACT = 'F' and EQUED = 'Y', each element of SCALE must be positive.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

*** LDB (input)**

The leading dimension of the array B. $\text{LDB} \geq \max(1, N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

*** LDX (input)**

The leading dimension of the array X. $\text{LDX} \geq \max(1, N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

dimension(2*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

dpbtf2 - compute the Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE DPBTF2( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
INTEGER N, KD, LDAB, INFO
DOUBLE PRECISION AB(LDAB,*)
```

```
SUBROUTINE DPBTF2_64( UPLO, N, KD, AB, LDAB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, KD, LDAB, INFO
DOUBLE PRECISION AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE PBTf2( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, KD, LDAB, INFO
REAL(8), DIMENSION(:, :) :: AB
```

```
SUBROUTINE PBTf2_64( UPLO, [N], KD, AB, [LDAB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDAB, INFO
REAL(8), DIMENSION(:, :) :: AB
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbtf2(char uplo, int n, int kd, double *ab, int ldab, int *info);
```

```
void dpbtf2_64(char uplo, long n, long kd, double *ab, long ldab, long *info);
```

PURPOSE

dpbtf2 computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

$$\begin{aligned} A &= U' * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L', & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix, U' is the transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** KD (input)**

The number of super-diagonals of the matrix A if $UPLO = 'U'$, or the number of sub-diagonals if $UPLO = 'L'$. $KD \geq 0$.

*** AB (input/output)**

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if $INFO = 0$, the triangular factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$ of the band matrix A, in the same storage format as A.

*** LDAB (input)**

The leading dimension of the array AB. $LDAB \geq KD+1$.

*** INFO (output)**

NAME

dpbtrf - compute the Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE DPBTRF( UPLO, N, NDIAG, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DPBTRF_64( UPLO, N, NDIAG, A, LDA, INFO)

REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE PBTRF_64( UPLO, [N], NDIAG, A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NDIAG, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpbtrf(char uplo, int n, int ndiag, double *a, int lda, int *info);
```

```
void dpbtrf_64(char uplo, long n, long ndiag, double *a, long lda, long *info);
```

PURPOSE

dpbtrf computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

$$\begin{aligned} A &= U^{**T} * U, & \text{if UPLO} = 'U', & \text{or} \\ A &= L * L^{**T}, & \text{if UPLO} = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L * L^{**T}$ of the band matrix A, in the same storage format as A.

* **LDA** (*input*)

The leading dimension of the array A. LDA \geq NDIAG+1.

* **INFO** (*output*)

NAME

dpbtrs - solve a system of linear equations $A \cdot X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPBTRF

SYNOPSIS

```
SUBROUTINE DPBTRS( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NDIAG, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

```
SUBROUTINE DPBTRS_64( UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)

void dpbtrs(char uplo, int n, int ndiag, int nrhs, double *a, int lda, double *b, int ldb, int *info);
```

```
void dpbtrs_64(char uplo, long n, long ndiag, long nrhs, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dpbtrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite band matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPBTRF.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $NDIAG \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ of the band matrix A , stored in the first $NDIAG+1$ rows of the array. The j -th column of U or L is stored in the j -th column of the array A as follows: if $UPLO = 'U'$, $A(kd+1+i-j,j) = U(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $A(1+i-j,j) = L(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

* **LDA** (*input*)

The leading dimension of the array A . $LDA \geq NDIAG+1$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1,N)$.

* **INFO** (*output*)

NAME

dpoco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A. If the condition number is not needed then SPOFA is slightly faster. It is typical to follow a call to SPOCO with a call to SPOSL to solve $Ax = b$ or to SPODI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE DPOCO( A, LDA, N, RCOND, WORK, INFO)
INTEGER LDA, N, INFO
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DPOCO_64( A, LDA, N, RCOND, WORK, INFO)
INTEGER*8 LDA, N, INFO
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpoco(double *a, int lda, int n, double *rcond, int *info);
```

```
void dpoco_64(double *a, long lda, long n, double *rcond, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** RCOND (output)**

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

*** WORK (workspace)**

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO < 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

dpocon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPOTRF

SYNOPSIS

```
SUBROUTINE DPOCON( UPLO, N, A, LDA, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
INTEGER WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DPOCON_64( UPLO, N, A, LDA, ANORM, RCOND, WORK, WORK2,
* INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
INTEGER*8 WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE POCON( UPLO, [N], A, [LDA], ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A
```

```
SUBROUTINE POCON_64( UPLO, [N], A, [LDA], ANORM, RCOND, [WORK],
* [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpocon(char uplo, int n, double *a, int lda, double anorm, double *rcond, int *info);
```

```
void dpocon_64(char uplo, long n, double *a, long lda, double anorm, double *rcond, long *info);
```

PURPOSE

dpocon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization $A = U^{*}T^{*}U$ or $A = L^{*}L^{*}T^{*}$ computed by SPOTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A. $N \geq 0$.

* *A* (input)

The triangular factor U or L from the Cholesky factorization $A = U^{*}T^{*}U$ or $A = L^{*}L^{*}T^{*}$, as computed by SPOTRF.

* *LDA* (input)

The leading dimension of the array A. $\text{LDA} \geq \max(1, N)$.

* *ANORM* (input)

The 1-norm (or infinity-norm) of the symmetric matrix A.

* *RCOND* (output)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* *WORK* (workspace)

dimension(3*N)

* *WORK2* (workspace)

* *INFO* (output)

NAME

dpodi - (obsolete) compute the determinant and inverse of a symmetric positive definite matrix A, which has been Cholesky-factored by SPOCO, SPOFA, or SQRDC.

SYNOPSIS

```
SUBROUTINE DPODI( A, LDA, N, DET, JOB)
INTEGER LDA, N, JOB
DOUBLE PRECISION A(LDA,*), DET(*)

SUBROUTINE DPODI_64( A, LDA, N, DET, JOB)
INTEGER*8 LDA, N, JOB
DOUBLE PRECISION A(LDA,*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>

void dpodi(double *a, int lda, int n, double *det, int job);

void dpodi_64(double *a, long lda, long n, double *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the Cholesky factorization of the matrix A, as computed by SPOCO, SPOFA, or SQRDC. On exit, the inverse of the original matrix A if the inverse was requested, otherwise A is unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |DET(1)| \leq 10.0$ or $DET(1) = 0.0$.

*** JOB (input)**

Determines which operation the subroutine will perform:

- o 11 both determinant and inverse

- 01 inverse only
- 10 determinant only

NAME

dpoequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE DPOEQU( N, A, LDA, SCALE, SCOND, AMAX, INFO)
INTEGER N, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

```
SUBROUTINE DPOEQU_64( N, A, LDA, SCALE, SCOND, AMAX, INFO)
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU( [N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
INTEGER :: N, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE POEQU_64( [N], A, [LDA], SCALE, SCOND, AMAX, [INFO])
INTEGER(8) :: N, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpoequ(int n, double *a, int lda, double *scale, double *scond, double *amax, int *info);
```

```
void dpoequ_64(long n, double *a, long lda, double *scale, double *scond, double *amax, long *info);
```

PURPOSE

dpoequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i) = 1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j) = S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input)**

The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1,N)$.

*** SCALE (output)**

If INFO = 0, SCALE contains the scale factors for A.

*** SCOND (output)**

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

*** AMAX (output)**

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

*** INFO (output)**

NAME

dpofa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A. It is typical to follow a call to SPOFA with a call to SPOSL to solve $Ax = b$ or to SPODI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE DPOFA( A, LDA, N, INFO)
  INTEGER LDA, N, INFO
  DOUBLE PRECISION A(LDA,*)

SUBROUTINE DPOFA_64( A, LDA, N, INFO)
  INTEGER*8 LDA, N, INFO
  DOUBLE PRECISION A(LDA,*)
```

C INTERFACE

```

REAL(8), DIMENSION(:,) :: A, AF, B, X

SUBROUTINE PORFS_64( UPLO, [N], [NRHS], A, [LDA], AF, [LDAF], B,
*      [LDB], X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDAF, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8), DIMENSION(:) :: FERR, BERR, WORK
REAL(8), DIMENSION(:,) :: A, AF, B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dporfs(char uplo, int n, int nrhs, double *a, int lda, double *af, int ldaf, double *b, int ldb, double *x, int ldx, double *ferr, double *berr, int *info);
```

```
void dporfs_64(char uplo, long n, long nrhs, double *a, long lda, double *af, long ldaf, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dporfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The symmetric matrix A. If **UPLO** = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If **UPLO** = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$, as computed by SPOTRF.

* **LDAF** (*input*)

The leading dimension of the array AF. $LDAF \geq \max(1, N)$.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SPOTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If **XTRUE** is the true solution corresponding to $X(j)$, **FERR(j)** is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for **RCOND**, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* **WORK** (*workspace*)

dimension(3*N)

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dposl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite matrix A , which has been Cholesky-factored by SPOCO or SPOFA, and vectors b and x .

SYNOPSIS

```

ARGUMENTS

*** A (input)**

Cholesky factorization of the matrix A , as computed by SPOCO or SPOFA.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** B (input/output)**

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

dposv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE DPOSV( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

```
SUBROUTINE DPOSV_64( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE POSV( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:, :) :: A, B
```

```
SUBROUTINE POSV_64( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dposv(char uplo, int n, int nrhs, double *a, int lda, double *b, int ldb, int *info);
```

```
void dposv_64(char uplo, long n, long nrhs, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dposv computes the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric positive definite matrix and X and B are N -by- $NRHS$ matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**T} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

* *UPLO (input)*

* *N (input)*

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

* *NRHS (input)*

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* *A (input/output)*

On entry, the symmetric matrix A . If $UPLO = 'U'$, the leading N -by- N upper triangular part of A contains the upper triangular part of the matrix A , and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N -by- N lower triangular part of A contains the lower triangular part of the matrix A , and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$.

* *LDA (input)*

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* *B (input/output)*

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

* *LDB (input)*

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* *INFO (output)*

NAME

dposvx - use the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^*T^*$ to compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dposvx(char fact, char uplo, int n, int nrhs, double *a, int lda, double *af, int ldaf, char equed, double *scale, double *b, int ldb, double *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void dposvx_64(char fact, char uplo, long n, long nrhs, double *a, long lda, double *af, long ldaf, char equed, double *scale, double *b, long
```

ldb, double *x, long ldx, double *rcond, double *ferr, double *berr, long *info);

PURPOSE

dposvx uses the Cholesky factorization $A = U^{*T}U$ or $A = L^{*L}L^{*T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

$$\text{diag}(S) * A * \text{diag}(S) * \text{inv}(\text{diag}(S)) * X = \text{diag}(S) * B$$

Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by $\text{diag}(S)*A*\text{diag}(S)$ and B by $\text{diag}(S)*B$.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as $A = U^{*T}U$, if UPLO = 'U', or

$$A = L * L^{*T}, \text{ if UPLO} = \text{'L'},$$

where U is an upper triangular matrix and L is a lower triangular matrix.

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(S)$ so that it solves the original system before

equilibration.

ARGUMENTS

* FACT (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* UPLO (input)

* N (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* A (input/output)

On entry, the symmetric matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

* **LDA (input)**

The leading dimension of the array A. LDA \geq max(1,N).

* **AF (input/output)**

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U * U^T$ or $A = L * L^T$, in the same storage format as A. If EQUED = 'N', then AF is the factored form of the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U^T$ or $A = L * L^T$ of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U^T$ or $A = L * L^T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* **LDAF (input)**

The leading dimension of the array AF. LDAF \geq max(1,N).

* **EQUED (input)**

Specifies the form of equilibration that was done.

* **SCALE (input/output)**

The scale factors for A; not accessed if EQUED = 'N'. SCALE is an input argument if FACT = 'F'; otherwise, SCALE is an output argument. If FACT = 'F' and EQUED = 'Y', each element of SCALE must be positive.

* **B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

* **LDB (input)**

The leading dimension of the array B. LDB \geq max(1,N).

* **X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

* **LDX (input)**

The leading dimension of the array X. LDX \geq max(1,N).

* **RCOND (output)**

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* **FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

* **WORK (workspace)**

dimension(2*N)

* **WORK2 (workspace)**

dimension(N)

* **INFO (output)**

NAME

dpotf2 - compute the Cholesky factorization of a real symmetric positive definite matrix A

SYNOPSIS

```
SUBROUTINE DPOTF2( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DPOTF2_64( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE POTF2( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE POTF2_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpotf2(char uplo, int n, double *a, int lda, int *info);
```

```
void dpotf2_64(char uplo, long n, double *a, long lda, long *info);
```

PURPOSE

dpotf2 computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

$$\begin{aligned} A &= U' * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L', & \text{if } UPLO = 'L', & \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

*** UPLO (input)**

Specifies whether the upper or lower triangular part of the symmetric matrix A is stored.

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization $A = U' * U$ or $A = L * L'$.

*** LDA (input)**

The leading dimension of the array A. $LDA \geq \max(1, N)$.

*** INFO (output)**

NAME

dpotrf - compute the Cholesky factorization of a real symmetric positive definite matrix A

SYNOPSIS

```
SUBROUTINE DPOTRF( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DPOTRF_64( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE POTRF( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE POTRF_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpotrf(char uplo, int n, double *a, int lda, int *info);
```

```
void dpotrf_64(char uplo, long n, double *a, long lda, long *info);
```

PURPOSE

dpotrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

$$\begin{aligned} A &= U^{**T} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the symmetric matrix A. If $UPLO = 'U'$, the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $UPLO = 'L'$, the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if $INFO = 0$, the factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L * L^{**T}$.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

dpotri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{*}T^{*}U$ or $A = L^{*}L^{*}T^{*}$ computed by SPOTRF

SYNOPSIS

```
SUBROUTINE DPOTRI( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

```
SUBROUTINE DPOTRI_64( UPLO, N, A, LDA, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE POTRI( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

```
SUBROUTINE POTRI_64( UPLO, [N], A, [LDA], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL(8), DIMENSION(:, :) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpotri(char uplo, int n, double *a, int lda, int *info);
```

```
void dpotri_64(char uplo, long n, double *a, long lda, long *info);
```

PURPOSE

dpotri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^{**}T$ computed by SPOTRF.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^*T^*U$ or $A = L^*L^{**}T$, as computed by SPOTRF. On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

* *LDA* (*input*)

The leading dimension of the array A. $LDA \geq \max(1, N)$.

* *INFO* (*output*)

NAME

dpotrs - solve a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPOTRF

SYNOPSIS

```
SUBROUTINE DPOTRS( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

```
SUBROUTINE DPOTRS_64( UPLO, N, NRHS, A, LDA, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDA, LDB, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE POTRS( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:, :) :: A, B
```

```
SUBROUTINE POTRS_64( UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:, :) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpotrs(char uplo, int n, int nrhs, double *a, int lda, double *b, int ldb, int *info);
```

```
void dpotrs_64(char uplo, long n, long nrhs, double *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dpotrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPOTRF.

ARGUMENTS

* *UPLO* (input)

* *N* (input)

The order of the matrix A . $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* *A* (input)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$, as computed by SPOTRF.

* *LDA* (input)

The leading dimension of the array A . $LDA \geq \max(1, N)$.

* *B* (input/output)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* *LDB* (input)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* *INFO* (output)

NAME

dppco - (obsolete) compute a Cholesky factorization and condition number of a symmetric positive definite matrix A in packed storage. If the condition number is not needed then SPPFA is slightly faster. It is typical to follow a call to SPPCO with a call to SPPSL to solve $Ax = b$ or to SPPDI to compute the determinant and inverse of A.

SYNOPSIS

```
SUBROUTINE DPPCO( A, N, RCOND, WORK, INFO)
  INTEGER N, INFO
  DOUBLE PRECISION RCOND
  DOUBLE PRECISION A(*), WORK(*)
```

```
SUBROUTINE DPPCO_64( A, N, RCOND, WORK, INFO)
  INTEGER*8 N, INFO
  DOUBLE PRECISION RCOND
  DOUBLE PRECISION A(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dppco(double *a, int n, double *rcond, int *info);
```

```
void dppco_64(double *a, long n, double *rcond, long *info);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a Cholesky factorization of the matrix A.

* **N** (*input*)

Order of the matrix A. $N <> 0$.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **INFO** (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO < 0 Returns a value k if the leading minor of order k is not positive definite.

NAME

dppcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPSTRF

SYNOPSIS

```
SUBROUTINE DPPCON( UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
INTEGER WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(*), WORK(*)

SUBROUTINE DPPCON_64( UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
INTEGER*8 WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PPCON( UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: A, WORK

SUBROUTINE PPCON_64( UPLO, N, A, ANORM, RCOND, [WORK], [WORK2],
* [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dppcon(char uplo, int n, double *a, double anorm, double *rcond, int *info);
```

```
void dppcon_64(char uplo, long n, double *a, double anorm, double *rcond, long *info);
```

PURPOSE

dppcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPSTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

* **ANORM** (*input*)

The 1-norm (or infinity-norm) of the symmetric matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

$\text{dimension}(2*N)$

* **WORK2** (*workspace*)

* **INFO** (*output*)

NAME

dppdi - (obsolete) compute the determinant and inverse of a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by SPPCO or SPPFA.

SYNOPSIS

```
SUBROUTINE DPPDI( A, N, DET, JOB)
INTEGER N, JOB
DOUBLE PRECISION A(*), DET(*)
```

```
SUBROUTINE DPPDI_64( A, N, DET, JOB)
INTEGER*8 N, JOB
DOUBLE PRECISION A(*), DET(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dppdi(double *a, int n, double *det, int job);
```

```
void dppdi_64(double *a, long n, double *det, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the Cholesky factorization of the matrix A, as computed by SPPCO or SPPFA. On exit, the inverse of the original matrix A if the inverse was requested, otherwise A is unchanged. The strict lower triangle of A is not referenced.

*** N (input)**

Order of the original matrix A. $N \geq 0$.

*** DET (output)**

On exit, the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$.

*** JOB (input)**

Determines which operation the subroutine will perform:

- o 11 both determinant and inverse
- o 01 inverse only
- o 10 determinant only

NAME

dppequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE DPPEQU( UPLO, N, A, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION A(*), SCALE(*)
```

```
SUBROUTINE DPPEQU_64( UPLO, N, A, SCALE, SCOND, AMAX, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION A(*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PPEQU( UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: A, SCALE
```

```
SUBROUTINE PPEQU_64( UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: A, SCALE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dppequ(char uplo, int n, double *a, double *scale, double *scond, double *amax, int *info);
```

```
void dppequ_64(char uplo, long n, double *a, double *scale, double *scond, double *amax, long *info);
```

PURPOSE

dpequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, $S(i)=1/\sqrt{A(i,i)}$, chosen so that the scaled matrix B with elements $B(i,j)=S(i)*A(i,j)*S(j)$ has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **SCALE** (*output*)

If INFO = 0, SCALE contains the scale factors for A.

* **SCOND** (*output*)

If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND ≥ 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

* **AMAX** (*output*)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

* **INFO** (*output*)

NAME

dppfa - (obsolete) compute a Cholesky factorization of a symmetric positive definite matrix A in packed storage. It is typical to follow a call to SPPFA with a call to SPPSL to solve $Ax = b$ or to SPPDI to compute the determinant and inverse of A .

SYNOPSIS

```
SUBROUTINE DPPFA( A, N, INFO)
INTEGER N, INFO
DOUBLE PRECISION A(*)
```

```
SUBROUTINE DPPFA_64( A, N, INFO)
INTEGER*8 N, INFO
DOUBLE PRECISION A(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dppfa(double *a, int n, int *info);
```

```
void dppfa_64(double *a, long n, long *info);
```

ARGUMENTS

* *A* (*input/output*)

On entry, the upper triangle of the matrix A . On exit, a Cholesky factorization of the matrix A .

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *INFO* (*output*)

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if $U(k,k) = 0$ to indicate that SPPSL will divide by zero if called.

NAME

dpprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE DPPRFS( UPLO, N, NRHS, A, AF, B, LDB, X, LDX, FERR, BERR,
*      WORK, WORK2, INFO)

INTEGER*8 WORK2(*)
DOUBLE PRECISION A(*), AF(*), B(LDB,*), X(LDX,*), FERR(*), BERR(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PPRFS( UPLO, N, [NRHS], A, AF, B, [LDB], X, [LDX], FERR,
*      BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDB, LDX, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8), DIMENSION(:) :: A, AF, FERR, BERR, WORK
REAL(8), DIMENSION(:, :) :: B, X

SUBROUTINE PPRFS_64( UPLO, N, [NRHS], A, AF, B, [LDB], X, [LDX],
*      FERR, BERR, [WORK], [WORK2], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8), DIMENSION(:) :: A, AF, FERR, BERR, WORK
REAL(8), DIMENSION(:, :) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpprfs(char uplo, int n, int nrhs, double *a, double *af, double *b, int ldb, double *x, int ldx, double *ferr, double *berr, int *info);
```

```
void dpprfs_64(char uplo, long n, long nrhs, double *a, double *af, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dpprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L^*L^{**T}$, as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see A).

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SPPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

* **BERR** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

- * **WORK** (*workspace*)
dimension(2*N)
- * **WORK2** (*workspace*)
- * **INFO** (*output*)

NAME

dpsl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite matrix A in packed storage, which has been Cholesky-factored by SPPCO or SPPFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE DPPSL( A, N, B )
INTEGER N
DOUBLE PRECISION A( * ), B( * )

SUBROUTINE DPPSL_64( A, N, B )
INTEGER*8 N
DOUBLE PRECISION A( * ), B( * )
```

C INTERFACE

```
#include <sunperf.h>

void dpsl(double *a, int n, double *b);

void dpsl_64(double *a, long n, double *b);
```

ARGUMENTS

- * **A** (*input*)
Cholesky factorization of the matrix A , as computed by SPPCO or SPPFA.
- * **N** (*input*)
Order of the matrix A . $N \geq 0$.
- * **B** (*input/output*)
On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

dppsv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```

REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dppsv(char uplo, int n, int nrhs, double *a, double *b, int ldb, int *info);
```

```
void dppsv_64(char uplo, long n, long nrhs, double *a, double *b, long ldb, long *info);
```

PURPOSE

dppsv computes the solution to a real system of linear equations $A * X = B$, where A is an N -by- N symmetric positive definite matrix stored in packed format and X and B are N -by- $NRHS$ matrices.

The Cholesky decomposition is used to factor A as

$$\begin{aligned} A &= U^{**T} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** *UPLO* (input)**

*** *N* (input)**

The number of linear equations, i.e., the order of the matrix A . $N \geq 0$.

*** *NRHS* (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** *A* (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if $INFO = 0$, the factor U or L from the Cholesky factorization $A = U^{**T} * U$ or $A = L * L^{**T}$, in the same storage format as A .

*** *B* (input/output)**

On entry, the N -by- $NRHS$ right hand side matrix B . On exit, if $INFO = 0$, the N -by- $NRHS$ solution matrix X .

*** *LDB* (input)**

The leading dimension of the array B . $LDB \geq \max(1, N)$.

*** *INFO* (output)**

NAME

dppsvx - use the Cholesky factorization $A = U^{**T}U$ or $A = L^{**T}L$ to compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE DPPSVX( FACT, UPLO, N, NRHS, A, AF, EQUED, SCALE, B, LDB,

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dppsvx(char fact, char uplo, int n, int nrhs, double *a, double *af, char equed, double *scale, double *b, int ldb, double *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void dppsvx_64(char fact, char uplo, long n, long nrhs, double *a, double *af, char equed, double *scale, double *b, long ldb, double *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

dppsvx uses the Cholesky factorization $A = U^{*}T^{*}U$ or $A = L^{*}L^{*}T$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

```
diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.
```

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as $A = U^{*}T^{*}U$, if UPLO = 'U', or

```
A = L * L^{*}T, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.
```

3. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the factored form of A.

5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

6. If equilibration was used, the matrix X is premultiplied by diag(S) so that it solves the original system before

```
equilibration.
```

ARGUMENTS

* *FACT* (input)

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

* *UPLO* (input)

* *N* (input)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* *NRHS* (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* *A* (input/output)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array, except if *FACT* = 'F' and *EQUED* = 'Y', then A must contain the equilibrated matrix $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$. The j-th column of A is stored in the array A as follows: if *UPLO* = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if *UPLO* = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details. A is not modified if *FACT* = 'F' or 'N', or if *FACT* = 'E' and *EQUED* = 'N' on exit.

On exit, if *FACT* = 'E' and *EQUED* = 'Y', A is overwritten by $\text{diag}(\text{SCALE}) * A * \text{diag}(\text{SCALE})$.

* *AF* (input/output)

$(N*(N+1)/2)$ If *FACT* = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U * U$ or $A = L * L'$, in the same storage format as A. If *EQUED* = 'N', then AF is the factored form of the equilibrated matrix A.

If *FACT* = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U$ or $A = L * L'$ of the original matrix A.

If *FACT* = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U * U$ or $A = L * L'$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

* *EQUED* (input)

Specifies the form of equilibration that was done.

* *SCALE* (output)

The scale factors for A; not accessed if *EQUED* = 'N'. *SCALE* is an input argument if *FACT* = 'F'; otherwise, *SCALE* is an output argument. If *FACT* = 'F' and *EQUED* = 'Y', each element of *SCALE* must be positive.

* *B* (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if *EQUED* = 'N', B is not modified; if *EQUED* = 'Y', B is overwritten by $\text{diag}(\text{SCALE}) * B$.

* *LDB* (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* *X* (output)

If *INFO* = 0 or *INFO* = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if *EQUED* = 'Y', A and B are modified on exit, and the solution to the equilibrated system is $\text{inv}(\text{diag}(\text{SCALE})) * X$.

* *LDX* (input)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* *RCOND* (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If *RCOND* is less than the machine precision (in particular, if *RCOND* = 0), the matrix is singular to working precision. This condition is indicated by a return code of *INFO* > 0.

* *FERR* (output)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If *XTRUE* is

the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension($3 \cdot N$)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

dpptrf - compute the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE DPPTRF( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
DOUBLE PRECISION A(*)
```

```
SUBROUTINE DPPTRF_64( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
DOUBLE PRECISION A(*)
```

F95 INTERFACE

```
SUBROUTINE PPTRF( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL(8), DIMENSION(:) :: A
```

```
SUBROUTINE PPTRF_64( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpptrf(char uplo, int n, double *a, int *info);
```

```
void dpptrf_64(char uplo, long n, double *a, long *info);
```

PURPOSE

dpptf computes the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format.

The factorization has the form

$$\begin{aligned} A &= U^{**T} * U, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, if $INFO = 0$, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$, in the same storage format as A.

* *INFO* (*output*)

NAME

dpptri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^*T*U$ or $A = L*L^*T$ computed by SPTRF

SYNOPSIS

```
SUBROUTINE DPPTRI( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
DOUBLE PRECISION A(*)

SUBROUTINE DPPTRI_64( UPLO, N, A, INFO)
CHARACTER * 1 UPLO
INTEGER*8 N, INFO
DOUBLE PRECISION A(*)
```

F95 INTERFACE

```
SUBROUTINE PPTRI( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL(8), DIMENSION(:) :: A

SUBROUTINE PPTRI_64( UPLO, N, A, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dpptri(char uplo, int n, double *a, int *info);

void dpptri_64(char uplo, long n, double *a, long *info);
```

PURPOSE

dpptri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$ computed by SPPTRF.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *A* (*input/output*)

On entry, the triangular factor U or L from the Cholesky factorization $A = U^{**T}U$ or $A = L*L^{**T}$, packed columnwise as a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = U(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

* *INFO* (*output*)

NAME

dpptrs - solve a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPTRF

SYNOPSIS

```
SUBROUTINE DPPTRS( UPLO, N, NRHS, A, B, LDB, INFO)

#include <sunperf.h>

void dpptrs(char uplo, int n, int nrhs, double *a, double *b, int ldb, int *info);

void dpptrs_64(char uplo, long n, long nrhs, double *a, double *b, long ldb, long *info);
```

PURPOSE

dppttrs solves a system of linear equations $A \cdot X = B$ with a symmetric positive definite matrix A in packed storage using the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$ computed by SPPTRF.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The triangular factor U or L from the Cholesky factorization $A = U \cdot U^T$ or $A = L \cdot L^T$, packed columnwise in a linear array. The j -th column of U or L is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1) \cdot j/2) = U(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1) \cdot (2n-j)/2) = L(i,j)$ for $j \leq i \leq n$.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

dptcon - compute the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L^*D*L^{**T}$ or $A = U^{**T}*D*U$ computed by SPTTRF

SYNOPSIS

```
SUBROUTINE DPTCON( N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
INTEGER N, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION DIAG(*), OFFD(*), WORK(*)

SUBROUTINE DPTCON_64( N, DIAG, OFFD, ANORM, RCOND, WORK, INFO)
INTEGER*8 N, INFO
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION DIAG(*), OFFD(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTCON( [N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
INTEGER :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: DIAG, OFFD, WORK

SUBROUTINE PTCON_64( [N], DIAG, OFFD, ANORM, RCOND, [WORK], [INFO])
INTEGER(8) :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: DIAG, OFFD, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dptcon(int n, double *diag, double *offd, double anorm, double *rcond, int *info);
```

```
void dptcon_64(long n, double *diag, double *offd, double anorm, double *rcond, long *info);
```

PURPOSE

dptcon computes the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization $A = L*D*L**T$ or $A = U**T*D*U$ computed by SPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

$$RCOND = 1 / (ANORM * \text{norm}(\text{inv}(A))).$$

ARGUMENTS

* *N (input)*

The order of the matrix A. $N \geq 0$.

* *DIAG (input)*

The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by SPTTRF.

* *OFFD (input)*

The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by SPTTRF.

* *ANORM (input)*

The 1-norm of the original matrix A.

* *RCOND (output)*

The reciprocal of the condition number of the matrix A, computed as $RCOND = 1/(ANORM * AINVNM)$, where AINVNM is the 1-norm of inv(A) computed in this routine.

* *WORK (workspace)*

dimension(N)

* *INFO (output)*

NAME

dpqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor

SYNOPSIS

```
SUBROUTINE DPTEQR( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
INTEGER N, LDZ, INFO
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE DPTEQR_64( COMPZ, N, D, E, Z, LDZ, WORK, INFO)
CHARACTER * 1 COMPZ
INTEGER*8 N, LDZ, INFO
DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PTEQR( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
INTEGER :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: Z
```

```
SUBROUTINE PTEQR_64( COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpqr(char compz, int n, double *d, double *e, double *z, int ldz, int *info);
```

```
void dpqr_64(char compz, long n, double *d, double *e, double *z, long ldz, long *info);
```

PURPOSE

dpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band symmetric positive definite matrix can also be found if SSYTRD, SSPTRD, or SSBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if COMPZ = 'V', the orthogonal matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original symmetric matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if COMPZ = 'V' or 'I', $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension(4*N)

* **INFO** (*output*)

NAME

dptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

SYNOPSIS

```
SUBROUTINE DPTRFS( N, NRHS, DIAG, OFFD, DIAGF, OFFDF, B, LDB, X,
*      LDX, FERR, BERR, WORK, INFO)

```

PURPOSE

dptrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* ***N (input)***

The order of the matrix A. $N \geq 0$.

* ***NRHS (input)***

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

* ***DIAG (input)***

The n diagonal elements of the tridiagonal matrix A.

* ***OFFD (input)***

The (n-1) subdiagonal elements of the tridiagonal matrix A.

* ***DIAGF (input)***

The n diagonal elements of the diagonal matrix DIAG from the factorization computed by SPTTRF.

* ***OFFDF (input)***

The (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization computed by SPTTRF.

* ***B (input)***

The right hand side matrix B.

* ***LDB (input)***

The leading dimension of the array B. $LDB \geq \max(1, N)$.

* ***X (input/output)***

On entry, the solution matrix X, as computed by SPTTRS. On exit, the improved solution matrix X.

* ***LDX (input)***

The leading dimension of the array X. $LDX \geq \max(1, N)$.

* ***FERR (output)***

The forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in $X(j)$.

* ***BERR (output)***

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK (workspace)***

dimension(N)

* ***INFO (output)***

NAME

dptsl - (obsolete) solve the linear system $Ax = b$ for a symmetric positive definite tridiagonal matrix A and vectors b and x .

SYNOPSIS

```
SUBROUTINE DPTSL( N, DIAG, OFFD, B)
  INTEGER N
  DOUBLE PRECISION DIAG(*), OFFD(*), B(*)
```

```
SUBROUTINE DPTSL_64( N, DIAG, OFFD, B)
  INTEGER*8 N
  DOUBLE PRECISION DIAG(*), OFFD(*), B(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dptsl(int n, double *diag, double *offd, double *b);
```

```
void dptsl_64(long n, double *diag, double *offd, double *b);
```

ARGUMENTS

* *N* (*input*)

Order of the matrix A . $N \geq 0$.

* *DIAG* (*input*)

Main diagonal elements of A .

* *OFFD* (*input*)

Off diagonal elements of A . $OFFD(1)$ through $OFFD(N*1)$ contains the off diagonal elements; $OFFD(N)$ is not referenced.

* *B* (*input/output*)

On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

dptsv - compute the solution to a real system of linear equations $A \cdot X = B$, where A is an N -by- N symmetric positive definite tridiagonal matrix, and X and B are N -by- $NRHS$ matrices.

SYNOPSIS

```
SUBROUTINE DPTSV( N, NRHS, DIAG, SUB, B, LDB, INFO)
  INTEGER N, NRHS, LDB, INFO
  DOUBLE PRECISION DIAG(*), SUB(*), B(LDB,*)
```

```
SUBROUTINE DPTSV_64( N, NRHS, DIAG, SUB, B, LDB, INFO)
  INTEGER*8 N, NRHS, LDB, INFO
  DOUBLE PRECISION DIAG(*), SUB(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PTVS( [N], [NRHS], DIAG, SUB, B, [LDB], [INFO])
  INTEGER :: N, NRHS, LDB, INFO
  REAL(8), DIMENSION(:) :: DIAG, SUB
  REAL(8), DIMENSION(:, :) :: B
```

```
SUBROUTINE PTVS_64( [N], [NRHS], DIAG, SUB, B, [LDB], [INFO])
  INTEGER(8) :: N, NRHS, LDB, INFO
  REAL(8), DIMENSION(:) :: DIAG, SUB
  REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dptsv(int n, int nrhs, double *diag, double *sub, double *b, int ldb, int *info);
```

```
void dptsv_64(long n, long nrhs, double *diag, double *sub, double *b, long ldb, long *info);
```

PURPOSE

dptsv computes the solution to a real system of linear equations $A \cdot X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as $A = L \cdot D \cdot L^T$, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** DIAG (input/output)**

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the factorization $A = L \cdot \text{DIAG} \cdot L^T$.

*** SUB (input/output)**

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L \cdot \text{DIAG} \cdot L^T$ factorization of A. (SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the $U^T \cdot \text{DIAG} \cdot U$ factorization of A.)

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

*** INFO (output)**

NAME

dptsvx - use the factorization $A = L^*D^*L^{**T}$ to compute the solution to a real system of linear equations $A^*X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

SYNOPSIS

```
SUBROUTINE DPTSVX( FACT, N, NRHS, DIAG, SUB, DIAGF, SUBF, B, LDB, X,
*   LDX, RCOND, FERR, BERR, WORK, INFO)
CHARACTER * 1 FACT

REAL(8), DIMENSION(:) :: DIAG, SUB, DIAGF, SUBF, FERR, BERR, WORK
REAL(8), DIMENSION(:,:) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dptsvx(char fact, int n, int nrhs, double *diag, double *sub, double *diagf, double *subf, double *b, int ldb, double *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void dptsvx_64(char fact, long n, long nrhs, double *diag, double *sub, double *diagf, double *subf, double *b, long ldb, double *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

dptsvx uses the factorization $A = L^*D^*L^{**T}$ to compute the solution to a real system of linear equations $A^*X = B$, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the matrix A is factored as $A = L^*D^*L^{**T}$, where L is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form

$$A = U^*^T^*D^*U.$$

2. If the leading i-by-i principal minor is not positive definite, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

* FACT (input)

Specifies whether or not the factored form of A has been supplied on entry.

* N (input)

The order of the matrix A. $N \geq 0$.

* NRHS (input)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* DIAG (input)

The n diagonal elements of the tridiagonal matrix A.

* SUB (input)

The (n-1) subdiagonal elements of the tridiagonal matrix A.

* DIAGF (input/output)

If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the diagonal matrix DIAG from the $L^*DIAG^*L^{**T}$ factorization of A. If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the diagonal matrix DIAG from the $L^*DIAG^*L^{**T}$ factorization of A.

* SUBF (input/output)

If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*DIAG^*L^{**T}$ factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L^*DIAG^*L^{**T}$ factorization of A.

* B (input)

The N-by-NRHS right hand side matrix B.

* LDB (input)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

* LDX (input)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* RCOND (output)

The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

* FERR (output)

The forward error bound for each solution vector $X(j)$ (the j -th column of the solution matrix X). If X_{TRUE} is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension(N)

* ***INFO*** (*output*)

NAME

dpstrf - compute the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE DPSTRF( N, DIAG, OFFD, INFO)
INTEGER N, INFO
DOUBLE PRECISION DIAG(*), OFFD(*)

SUBROUTINE DPSTRF_64( N, DIAG, OFFD, INFO)
INTEGER*8 N, INFO
DOUBLE PRECISION DIAG(*), OFFD(*)
```

F95 INTERFACE

```
SUBROUTINE PSTRF( [N], DIAG, OFFD, [INFO])
INTEGER :: N, INFO
REAL(8), DIMENSION(:) :: DIAG, OFFD

SUBROUTINE PSTRF_64( [N], DIAG, OFFD, [INFO])
INTEGER(8) :: N, INFO
REAL(8), DIMENSION(:) :: DIAG, OFFD
```

C INTERFACE

```
#include <sunperf.h>

void dpstrf(int n, double *diag, double *offd, int *info);

void dpstrf_64(long n, double *diag, double *offd, long *info);
```

PURPOSE

dpstrf computes the L^*D^*L' factorization of a real symmetric positive definite tridiagonal matrix A. The factorization may also be regarded as having the form $A = U^*D^*U$.

ARGUMENTS

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** DIAG (input/output)**

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the L^*DIAG^*L' factorization of A.

*** OFFD (input/output)**

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L^*DIAG^*L' factorization of A. OFFD can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U^*DIAG^*U factorization of A.

*** INFO (output)**

NAME

dptrfs - solve a tridiagonal system of the form $A * X = B$ using the $L*D*L'$ factorization of A computed by SPTTRF

SYNOPSIS

```
SUBROUTINE DPTTRS( N, NRHS, DIAG, OFFD, B, LDB, INFO)
INTEGER N, NRHS, LDB, INFO
DOUBLE PRECISION DIAG(*), OFFD(*), B(LDB,*)
```

```
SUBROUTINE DPTTRS_64( N, NRHS, DIAG, OFFD, B, LDB, INFO)
INTEGER*8 N, NRHS, LDB, INFO
DOUBLE PRECISION DIAG(*), OFFD(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE PTTRS( [N], [NRHS], DIAG, OFFD, B, [LDB], [INFO])

REAL(8), DIMENSION(:) :: DIAG, OFFD
REAL(8), DIMENSION(:, :) :: B
```

```
SUBROUTINE PTTRS_64( [N], [NRHS], DIAG, OFFD, B, [LDB], [INFO])
INTEGER(8) :: N, NRHS, LDB, INFO
REAL(8), DIMENSION(:) :: DIAG, OFFD
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dptrfs(int n, int nrhs, double *diag, double *offd, double *b, int ldb, int *info);
```

```
void dptrfs_64(long n, long nrhs, double *diag, double *offd, double *b, long ldb, long *info);
```

PURPOSE

dpttrs solves a tridiagonal system of the form $A * X = B$ using the $L * D * L'$ factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D , L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E , and X and B are N by $NRHS$ matrices.

ARGUMENTS

*** N (input)**

The order of the tridiagonal matrix A . $N \geq 0$.

*** $NRHS$ (input)**

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

*** $DIAG$ (input)**

The n diagonal elements of the diagonal matrix $DIAG$ from the $L * DIAG * L'$ factorization of A .

*** $OFFD$ (input/output)**

The $(n-1)$ subdiagonal elements of the unit bidiagonal factor L from the $L * DIAG * L'$ factorization of A . $OFFD$ can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization $A = U * DIAG * U$.

*** B (input/output)**

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X .

*** LDB (input)**

The leading dimension of the array B . $LDB \geq \max(1, N)$.

*** $INFO$ (output)**

NAME

dptts2 - solve a tridiagonal system of the form $A * X = B$ using the L*D*L' factorization of A computed by SPTTRF

SYNOPSIS

```
SUBROUTINE DPTTS2( N, NRHS, D, E, B, LDB)
  INTEGER N, NRHS, LDB
  DOUBLE PRECISION D(*), E(*), B(LDB,*)
```

```
SUBROUTINE DPTTS2_64( N, NRHS, D, E, B, LDB)
  INTEGER*8 N, NRHS, LDB
  DOUBLE PRECISION D(*), E(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE DPTTS2( N, NRHS, D, E, B, [LDB])
  INTEGER :: N, NRHS, LDB
  REAL(8), DIMENSION(:) :: D, E
  REAL(8), DIMENSION(:, :) :: B
```

```
SUBROUTINE DPTTS2_64( N, NRHS, D, E, B, [LDB])
  INTEGER(8) :: N, NRHS, LDB
  REAL(8), DIMENSION(:) :: D, E
  REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dptts2(int n, int nrhs, double *d, double *e, double *b, int ldb);
```

```
void dptts2_64(long n, long nrhs, double *d, double *e, double *b, long ldb);
```

PURPOSE

dpts2 solves a tridiagonal system of the form $A * X = B$ using the $L * D * L'$ factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D, L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

*** N (input)**

The order of the tridiagonal matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** D (input)**

The n diagonal elements of the diagonal matrix D from the $L * D * L'$ factorization of A.

*** E (input)**

The (n-1) subdiagonal elements of the unit bidiagonal factor L from the $L * D * L'$ factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization $A = U * D * U$.

*** B (input/output)**

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1, N)$.

NAME

dqdots - compute a double precision constant plus an extended precision constant plus the extended precision dot product of two double precision vectors x and y.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DQDOTA( N, DB, QC, DX, INCX, DY, INCY)
INTEGER N, INCX, INCY
REAL * 16 QC
DOUBLE PRECISION DB
DOUBLE PRECISION DX(*), DY(*)
```

```
DOUBLE PRECISION FUNCTION DQDOTA_64( N, DB, QC, DX, INCX, DY, INCY)
INTEGER*8 N, INCX, INCY
REAL * 16 QC
DOUBLE PRECISION DB
DOUBLE PRECISION DX(*), DY(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DQDOTA( [N], DB, QC, DX, [INCX], DY, [INCY])
INTEGER :: N, INCX, INCY
REAL(16) :: QC
REAL(8) :: DB
REAL(8), DIMENSION(:) :: DX, DY
```

```
REAL(8) FUNCTION DQDOTA_64( [N], DB, QC, DX, [INCX], DY, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL(16) :: QC
REAL(8) :: DB
REAL(8), DIMENSION(:) :: DX, DY
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dqdots(int n, double db, long double qc, double *dx, int incx, double *dy, int incy);
```

```
double dqdots_64(long n, double db, long double qc, double *dx, long incx, double *dy, long incy);
```

PURPOSE

dqdot computes a double precision constant plus an extended precision constant plus the extended precision dot product of two double precision vectors x and y .

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. If $N \leq 0$ then the function returns the value $DB+QC$. Unchanged on exit.

* *DB (input)*

On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

* *QC (input/output)*

On entry, the extended precision constant to be added to the dot product. On exit, the extended precision result.

* *DX (input)*

On entry, the incremented array DX must contain the vector x . Unchanged on exit.

* *INCX (input)*

On entry, $INCX$ specifies the increment for the elements of DX . $INCX$ must not be zero. Unchanged on exit.

* *DY (input)*

On entry, the incremented array DY must contain the vector y . Unchanged on exit.

* *INCY (input)*

On entry, $INCY$ specifies the increment for the elements of DY . $INCY$ must not be zero. Unchanged on exit.

NAME

dqdoti - compute a constant plus the extended precision dot product of two double precision vectors x and y.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DQDOTI( N, DB, QC, DX, INCX, DY, INCY)
INTEGER N, INCX, INCY
REAL * 16 QC
DOUBLE PRECISION DB
DOUBLE PRECISION DX(*), DY(*)
```

```
DOUBLE PRECISION FUNCTION DQDOTI_64( N, DB, QC, DX, INCX, DY, INCY)
INTEGER*8 N, INCX, INCY
REAL * 16 QC
DOUBLE PRECISION DB
DOUBLE PRECISION DX(*), DY(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DQDOTI( [N], DB, QC, DX, [INCX], DY, [INCY])
INTEGER :: N, INCX, INCY
REAL(16) :: QC
REAL(8) :: DB
REAL(8), DIMENSION(:) :: DX, DY
```

```
REAL(8) FUNCTION DQDOTI_64( [N], DB, QC, DX, [INCX], DY, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL(16) :: QC
REAL(8) :: DB
REAL(8), DIMENSION(:) :: DX, DY
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dqdoti(int n, double db, long double qc, double *dx, int incx, double *dy, int incy);
```

```
double dqdoti_64(long n, double db, long double qc, double *dx, long incx, double *dy, long incy);
```

PURPOSE

dqdoti computes a constant plus the double precision dot product of x and y where x and y are double precision n-vectors.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. If $N \leq 0$ then the function returns the value DB. Unchanged on exit.

* *DB (input)*

On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

* *QC (output)*

On exit, the extended precision result.

* *DX (input)*

On entry, the incremented array DX must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of DX. INCX must not be zero. Unchanged on exit.

* *DY (input)*

On entry, the incremented array DY must contain the vector y. Unchanged on exit.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of DY. INCY must not be zero. Unchanged on exit.

NAME

dqrdc - (obsolete) compute the QR factorization of a general matrix A. It is typical to follow a call to SQRDC with a call to SQRSL to solve $Ax = b$ or to SPODI to compute the determinant of A.

SYNOPSIS

```
SUBROUTINE DQRDC( A, LDA, N, P, QRAUX, IPIVOT, WORK, JOB)
INTEGER LDA, N, P, JOB
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*), QRAUX(*), WORK(*)
```

```
SUBROUTINE DQRDC_64( A, LDA, N, P, QRAUX, IPIVOT, WORK, JOB)
INTEGER*8 LDA, N, P, JOB
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*), QRAUX(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dqrdc(double *a, int lda, int n, int p, double *qraux, int *ipivot, int job);
```

```
void dqrdc_64(double *a, long lda, long n, long p, double *qraux, long *ipivot, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the matrix A. On exit, the upper triangle of A contains the matrix R and the strict lower triangle of A contains information that will allow construction of the matrix Q. If pivoting was requested, A contains the factorization of the original matrix A permuted by the requested pivots.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows in the matrix A. $N \geq 0$.

*** P (input)**

Number of columns in the matrix A. $P \geq 0$.

*** QRAUX (output)**

On exit, contains information required to construct the orthogonal matrix Q.

*** IPIVOT (input)**

If JOB selected no pivoting, then IPIVOT is not referenced. If JOB selected pivoting, then on entry to the subroutines, IPIVOT contains integers representing array indices that control the selection of pivot elements from the diagonal of A according to the system below:

```
IPIVOT(k) > 0   A(k,k) is an initial element.  
IPIVOT(k) = 0   A(k,k) is a free element.  
IPIVOT(k) < 0   A(k,k) is a final element.
```

Before the decomposition is computed, symmetric row and column interchanges are used to move initial elements to the beginning of A and final elements to the end of A. During the computation, symmetric row and column interchanges are used to move the largest remaining free diagonal element into the pivot position. On exit, IPIVOT(k) contains the index of the diagonal element of A that was moved into the kth position.

* **WORK** (*workspace*)

Scratch array with a dimension of N. WORK is not referenced if JOB = 0.

* **JOB** (*input*)

Determines how the factorization is done:

- o 0 with no pivoting

not 0 with pivoting

NAME

dqrs1 - (obsolete) solve the linear system $Ax = b$ for a general matrix A , which has been QR- factored by SQRDC, and vectors b and x .

SYNOPSIS

```
SUBROUTINE DQRSL( A, LDA, N, K, QRAUX, Y, QY, QTY, B, RESID, AB,
*      JOB, INFO)
INTEGER LDA, N, K, JOB, INFO
DOUBLE PRECISION A(LDA,*), QRAUX(*), Y(*), QY(*), QTY(*), B(*), RESID(*), AB(*)

SUBROUTINE DQRSL_64( A, LDA, N, K, QRAUX, Y, QY, QTY, B, RESID, AB,
*      JOB, INFO)
INTEGER*8 LDA, N, K, JOB, INFO
DOUBLE PRECISION A(LDA,*), QRAUX(*), Y(*), QY(*), QTY(*), B(*), RESID(*), AB(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dqrs1(double *a, int lda, int n, int k, double *qraux, double *y, double *qy, double *qty, double *b, double *resid,
double *ab, int job, int *info);
```

```
void dqrs1_64(double *a, long lda, long n, long k, double *qraux, double *y, double *qy, double *qty, double *b, double
*resid, double *ab, long job, long *info);
```

ARGUMENTS

*** A (input)**

Part of the QR factorization of matrix A as computed by SQRDC.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Number of rows in the matrix AK where AK is described below. $N \geq 0$.

*** K (input)**

Number of columns in the matrix AK where AK is described below. $K \geq 0$.

*** QRAUX (input)**

Auxiliary output from SQRDC.

*** Y (input)**

Vector to be manipulated by SQRSL.

* **QY (output)**

On exit, QY contains $Q * Y$ if its computation has been requested in JOB; QY is not referenced if its computation is not requested.

* **QTY (output)**

On exit, QTY contains $QT * Y$ if its computation has been requested in JOB; QTY is not referenced if its computation is not requested.

* **B (input/output)**

On entry, the right-hand side vector b. On exit, the solution vector x. B is not referenced if its computation is not requested.

* **RESID (output)**

On exit, RESID contains the least squares residual $y - AK * b$ if its computation has been requested. RESID also is the orthogonal projection of y onto the orthogonal complement of the column space of AK. RESID is not referenced if its computation is not requested.

* **AB (output)**

On exit, AB contains the least squares approximation $AK * b$ if its computation has been requested. AB is the orthogonal projection of y onto the column space of x. AB is not referenced if its computation is not requested.

* **JOB (input)**

Integer in the form abcde; determines which operation or operations the subroutine will perform:

```
a <> 0  compute QY
b, c, d, or e <> 0      compute QTY
c <> 0  compute B
d <> 0  compute RESID
e <> 0  compute AB
```

* **INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO < 0 Returns a value k if the computation of B has been requested and R is singular; the value of k is then the index of the first zero element of R. The matrix AK is constructed from the factored orthogonal matrix Q and upper triangular matrix R from SQRDC.

NAME

drot - Apply a Given's rotation constructed by SROTG.

SYNOPSIS

```
SUBROUTINE DROT( N, X, INCX, Y, INCY, C, S )
INTEGER N, INCX, INCY
DOUBLE PRECISION C, S
DOUBLE PRECISION X(*), Y(*)
```

```
SUBROUTINE DROT_64( N, X, INCX, Y, INCY, C, S )
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION C, S
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE ROT( [N], X, [INCX], Y, [INCY], C, S )
INTEGER :: N, INCX, INCY
REAL(8) :: C, S
REAL(8), DIMENSION(:) :: X, Y
```

```
SUBROUTINE ROT_64( [N], X, [INCX], Y, [INCY], C, S )
INTEGER(8) :: N, INCX, INCY
REAL(8) :: C, S
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void drot(int n, double *x, int incx, double *y, int incy, double c, double s);
```

```
void drot_64(long n, double *x, long incx, double *y, long incy, double c, double s);
```

PURPOSE

drot Apply a Given's rotation constructed by SROTG.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

*** *X (input)***

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** *Y (input/output)***

$(1 + (m - 1) * \text{abs}(\text{INCY}))$. On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

*** *INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

*** *C (input)***

On entry, the C rotation value constructed by SROTG. Unchanged on exit.

*** *S (input)***

On entry, the S rotation value constructed by SROTG. Unchanged on exit.

NAME

drotg - Construct a Given's plane rotation

SYNOPSIS

```
SUBROUTINE DROTG( A, B, C, S )
DOUBLE PRECISION A, B, C, S

SUBROUTINE DROTG_64( A, B, C, S )
DOUBLE PRECISION A, B, C, S
```

F95 INTERFACE

```
SUBROUTINE ROTG( A, B, C, S )
REAL(8) :: A, B, C, S

SUBROUTINE ROTG_64( A, B, C, S )
REAL(8) :: A, B, C, S
```

C INTERFACE

```
#include <sunperf.h>

void drotg(double *a, double *b, double *c, double *s);

void drotg_64(double *a, double *b, double *c, double *s);
```

PURPOSE

drotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

* ***A*** (*input/output*)

On entry, *A* contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

* ***B*** (*input/output*)

On entry, *B* contains the entry to be annihilated in the second vector. On exit, contains either *S* or $1/C$ depending on which of the input values of *A* and *B* is larger.

* ***C*** (*output*)

On exit, *C* and *S* are the elements of the rotation matrix that will be applied to annihilate *B*.

* ***S*** (*output*)

See the description of *C*.

NAME

droti, sroti - Apply a Givens rotation to x and y

SYNOPSIS

```
SUBROUTINE DROTI( NZ, X, INDX, Y, C, S)
INTEGER NZ
INTEGER INDX(*)
DOUBLE PRECISION C, S
DOUBLE PRECISION X(*), Y(*)

SUBROUTINE DROTI_64( NZ, X, INDX, Y, C, S)
INTEGER*8 NZ
INTEGER*8 INDX(*)
DOUBLE PRECISION C, S
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE ROTI( [NZ], X, INDX, Y, C, S)
INTEGER :: NZ
INTEGER, DIMENSION(:) :: INDX
REAL(8) :: C, S
REAL(8), DIMENSION(:) :: X, Y

SUBROUTINE ROTI_64( [NZ], X, INDX, Y, C, S)
INTEGER(8) :: NZ
INTEGER(8), DIMENSION(:) :: INDX
REAL(8) :: C, S
REAL(8), DIMENSION(:) :: X, Y
```

PURPOSE

droti xROTI - Applies a Givens rotation to a sparse vector x stored in compressed form and another vector y in full storage form

```
do 10, i = 1, n
  temp = -s * x(i) + c * y(indx(i))
  x(i) = c * x(i) + s * y(indx(i))
  y(indx(i)) = temp
10 continue
```

ARGUMENTS

* *NZ (input)*

- INTEGER

Number of elements in the compressed form. Unchanged on exit.

* *X (input)*

Vector containing the values of the compressed form.

* *INDX (input)*

- INTEGER

Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

* *Y (input/output)*

Vector on input which contains the vector Y in full storage form. On exit, only the elements corresponding to the indices in INDX have been modified.

* *C (input)*

Scalar defining the Givens rotation

* *S (input)*

Scalar defining the Givens rotation

NAME

drotm - Apply a Gentleman's modified Given's rotation constructed by SROTMG.

SYNOPSIS

```
SUBROUTINE DROTM( N, X, INCX, Y, INCY, PARAM)
INTEGER N, INCX, INCY
DOUBLE PRECISION X(*), Y(*), PARAM(*)
```

```
SUBROUTINE DROTM_64( N, X, INCX, Y, INCY, PARAM)
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION X(*), Y(*), PARAM(*)
```

F95 INTERFACE

```
SUBROUTINE ROTM( [N], X, [INCX], Y, [INCY], PARAM)
INTEGER :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y, PARAM
```

```
SUBROUTINE ROTM_64( [N], X, [INCX], Y, [INCY], PARAM)
INTEGER(8) :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y, PARAM
```

C INTERFACE

```
#include <sunperf.h>
```

```
void drotm(int n, double *x, int incx, double *y, int incy, double *param);
```

```
void drotm_64(long n, double *x, long incx, double *y, long incy, double *param);
```

PURPOSE

drotm Apply a Given's rotation constructed by SROTMG.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *X (input)*

($1 + (n - 1) * \text{abs}(\text{INCX})$). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

* *PARAM (input)*

On entry, the rotation values constructed by SROTMG. Unchanged on exit.

NAME

drotmg - Construct a Gentleman's modified Given's plane rotation

SYNOPSIS

```
SUBROUTINE DROTMG( D1, D2, B1, B2, PARAM)
DOUBLE PRECISION D1, D2, B1, B2
DOUBLE PRECISION PARAM(*)
```

```
SUBROUTINE DROTMG_64( D1, D2, B1, B2, PARAM)
DOUBLE PRECISION D1, D2, B1, B2
DOUBLE PRECISION PARAM(*)
```

F95 INTERFACE

```
SUBROUTINE ROTMG( D1, D2, B1, B2, PARAM)
REAL(8) :: D1, D2, B1, B2
REAL(8), DIMENSION(:) :: PARAM
```

```
SUBROUTINE ROTMG_64( D1, D2, B1, B2, PARAM)
REAL(8) :: D1, D2, B1, B2
REAL(8), DIMENSION(:) :: PARAM
```

C INTERFACE

```
#include <sunperf.h>
```

```
void drotmg(double d1, double d2, double b1, double b2, double *param);
```

```
void drotmg_64(double d1, double d2, double b1, double b2, double *param);
```

PURPOSE

drotmg Construct Gentleman's modified a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

* ***D1*** (*input/output*)

On entry, the first diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

* ***D2*** (*input/output*)

On entry, the second diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

* ***B1*** (*input/output*)

On entry, the first element of the vector to which the H matrix is applied. On exit, changed to reflect the effect of the transformation.

* ***B2*** (*input/output*)

On entry, the second element of the vector to which the H matrix is applied. On exit, changed to reflect the effect of the transformation.

* ***PARAM*** (*input/output*)

On entry, PARAM(1) describes the form of the H matrix. On exit, PARAM(2..5) contain the H matrix.

NAME

dsbev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

SYNOPSIS

```
SUBROUTINE DSBEV( JOBZ, UPLO, N, NDIAG, A, LDA, W, Z, LDZ, WORK,  
*             INFO)  
CHARACTER * 1 JOBZ, UPLO  
INTEGER N, NDIAG, LDA, LDZ, INFO  
DOUBLE PRECISION A(LDA,*), W(*), Z(LDZ,*), WORK(*)  
  
SUBROUTINE DSBEV_64( JOBZ, UPLO, N, NDIAG, A, LDA, W, Z, LDZ, WORK,  
*             INFO)  
CHARACTER * 1 JOBZ, UPLO  
INTEGER*8 N, NDIAG, LDA, LDZ, INFO  
DOUBLE PRECISION A(LDA,*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SBEV( JOBZ, UPLO, [N], NDIAG, A, [LDA], W, Z, [LDZ],  
*             [WORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, NDIAG, LDA, LDZ, INFO  
REAL(8), DIMENSION(:) :: W, WORK  
REAL(8), DIMENSION(:, :) :: A, Z  
  
SUBROUTINE SBEV_64( JOBZ, UPLO, [N], NDIAG, A, [LDA], W, Z, [LDZ],  
*             [WORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, NDIAG, LDA, LDZ, INFO  
REAL(8), DIMENSION(:) :: W, WORK  
REAL(8), DIMENSION(:, :) :: A, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsbev(char jobz, char uplo, int n, int ndiag, double *a, int lda, double *w, double *z, int ldz, int *info);
```

```
void dsbev_64(char jobz, char uplo, long n, long ndiag, double *a, long lda, double *w, double *z, long ldz, long *info);
```

PURPOSE

dsbev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $NDIAG \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $NDIAG+1$ rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows NDIAG and NDIAG+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG + 1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

$\text{dimension}(\text{MAX}(1,3*N-2))$

* **INFO** (*output*)

NAME

dsbevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

SYNOPSIS

```
SUBROUTINE DSBEVD( JOBZ, UPLO, N, KD, AB, LDAB, W, Z, LDZ, WORK,

```

F95 INTERFACE

```
SUBROUTINE SBEVD( JOBZ, UPLO, [N], KD, AB, [LDAB], W, Z, [LDZ],  
*               [WORK], [LWORK], [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER :: N, KD, LDAB, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: W, WORK  
REAL(8), DIMENSION(:, :) :: AB, Z  
  
SUBROUTINE SBEVD_64( JOBZ, UPLO, [N], KD, AB, [LDAB], W, Z, [LDZ],  
*                   [WORK], [LWORK], [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, KD, LDAB, LDZ, LWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: W, WORK  
REAL(8), DIMENSION(:, :) :: AB, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsbevd(char jobz, char uplo, int n, int kd, double *ab, int ldab, double *w, double *z, int ldz, int *info);
```

```
void dsbevd_64(char jobz, char uplo, long n, long kd, double *ab, long ldab, double *w, double *z, long ldz, long *info);
```

PURPOSE

dsbevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$.

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and $KD+1$ of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KD + 1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*output*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i -th column of Z holding the eigenvector associated with $W(i)$. If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 2$, LWORK must be at least $2*N$. If JOBZ = 'V' and $N > 2$, LWORK must be at least $(1 + 5*N + 2*N**2)$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK

array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array LIWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 2$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO** (*output*)

NAME

dsbevz - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

SYNOPSIS

```
SUBROUTINE DSBEVX( JOBZ, RANGE, UPLO, N, NDIAG, A, LDA, Q, LDQ, VL,

REAL(8), DIMENSION(:,:) :: A, Q, Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsbev(x(char jobz, char range, char uplo, int n, int ndiag, double *a, int lda, double *q, int ldq, double vl, double vu, int il, int iu, double abtol, int *nfound, double *w, double *z, int ldz, int *ifail, int *info);
```

```
void dsbev_64(char jobz, char range, char uplo, long n, long ndiag, double *a, long lda, double *q, long ldq, double vl, double vu, long il, long iu, double abtol, long *nfound, double *w, double *z, long ldz, long *ifail, long *info);
```

PURPOSE

dsbev computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NDIAG** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG ≥ 0 .

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', $A(kd+1+i-j, j) = A(i, j)$ for $\max(1, j-kd) \leq i \leq j$; if UPLO = 'L', $A(1+i-j, j) = A(i, j)$ for $j \leq i \leq \min(n, j+kd)$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows NDIAG and NDIAG+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

* **LDA** (*input*)

The leading dimension of the array A. $LDA \geq NDIAG + 1$.

* **Q** (*output*)

If JOBZ = 'V', the N-by-N orthogonal matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q. If JOBZ = 'V', then $LDQ \geq \max(1, N)$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

See the description of IL.

*** ABTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABTOL + EPS * \max(|a|,|b|),$$

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2*SLAMCH('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

*** NFOUND (output)**

The total number of eigenvalues found. $0 \leq NFOUND \leq N$. If RANGE = 'A', $NFOUND = N$, and if RANGE = 'I', $NFOUND = IU - IL + 1$.

*** W (output)**

The first NFOUND elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if $INFO = 0$, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, NFOUND)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

*** WORK (workspace)**

dimension(7*N)

*** IWORK2 (workspace)**

*** IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first NFOUND elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

dsbgst - reduce a real symmetric-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$,

SYNOPSIS

```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsbgst(char vect, char uplo, int n, int ka, int kb, double *ab, int ldab, double *bb, int ldbb, double *x, int ldx, int *info);
```

```
void dsbgst_64(char vect, char uplo, long n, long ka, long kb, double *ab, long ldab, double *bb, long ldbb, double *x, long ldx, long *info);
```

PURPOSE

dsbgst reduces a real symmetric-definite banded generalized eigenproblem $A*x = \lambda*B*x$ to standard form $C*y = \lambda*y$, such that C has the same bandwidth as A .

B must have been previously factorized as $S**T*S$ by SPBSTF, using a split Cholesky factorization. A is overwritten by $C = X**T*A*X$, where $X = S**(-1)*Q$ and Q is an orthogonal matrix chosen to preserve the bandwidth of A .

ARGUMENTS

* **VECT** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B . $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KA \geq KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the transformed matrix $X**T*A*X$, stored in the same format as A .

* **LDAB** (*input*)

The leading dimension of the array AB . $LDAB \geq KA+1$.

* **BB** (*input*)

The banded factor S from the split Cholesky factorization of B , as returned by SPBSTF, stored in the first $KB+1$ rows of the array.

* **LDBB** (*input*)

The leading dimension of the array BB . $LDBB \geq KB+1$.

* **X** (*output*)

If $VECT = 'V'$, the n -by- n matrix X . If $VECT = 'N'$, the array X is not referenced.

* **LDX** (*input*)

The leading dimension of the array X . $LDX \geq \max(1,N)$ if $VECT = 'V'$; $LDX \geq 1$ otherwise.

* **WORK** (*workspace*)

dimension($2*N$)

* **INFO** (*output*)

```

PURPOSE

dsbgv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(kb+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

* **LDBB** (*input*)

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i -th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so that $Z^*T^*B^*Z = I$. If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq N$.

* **WORK** (*workspace*)
dimension(3*N)

* **INFO** (*output*)

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsbgvd(char jobz, char uplo, int n, int ka, int kb, double *ab, int ldab, double *bb, int ldbb, double *w, double *z, int ldz, int *info);
```

```
void dsbgvd_64(char jobz, char uplo, long n, long ka, long kb, double *ab, long ldab, double *bb, long ldbb, double *w, double *z, long ldz, long *info);
```

PURPOSE

dsbgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(ka+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

* **LDBB** (*input*)

The leading dimension of the array BB. $LDBB \geq KB+1$.

* **W** (*output*)

If $INFO = 0$, the eigenvalues in ascending order.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so $Z^*T^*B^*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $N \leq 1$, $LWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LWORK \geq 3*N$. If $JOBZ = 'V'$ and $N > 1$, $LWORK \geq 1 + 5*N + 2*N**2$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if $LIWORK > 0$, $IWORK(1)$ returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array IWORK. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK \geq 1$. If $JOBZ = 'V'$ and $N > 1$, $LIWORK \geq 3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO** (*output*)

```

PURPOSE

dsbgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form $A*x=(\lambda)*B*x$. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrices A and B. $N \geq 0$.

* **KA** (*input*)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KA \geq 0$.

* **KB** (*input*)

The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. $KB \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first $ka+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if UPLO = 'U', $AB(ka+1+i-j,j) = A(i,j)$ for $\max(1,j-ka) \leq i \leq j$; if UPLO = 'L', $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+ka)$.

On exit, the contents of AB are destroyed.

* **LDAB** (*input*)

The leading dimension of the array AB. $LDAB \geq KA+1$.

* **BB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first $kb+1$ rows of the array. The j -th column of B is stored in the j -th column of the array BB as follows: if UPLO = 'U', $BB(ka+1+i-j,j) = B(i,j)$ for $\max(1,j-kb) \leq i \leq j$; if UPLO = 'L', $BB(1+i-j,j) = B(i,j)$ for $j \leq i \leq \min(n,j+kb)$.

On exit, the factor S from the split Cholesky factorization $B = S^*T^*S$, as returned by SPBSTF.

*** *LDBB (input)***

The leading dimension of the array BB. $LDBB \geq KB+1$.

*** *Q (output)***

If $JOBZ = 'V'$, the n-by-n matrix used in the reduction of $A*x = (\lambda)*B*x$ to standard form, i.e. $C*x = (\lambda)*x$, and consequently C to tridiagonal form. If $JOBZ = 'N'$, the array Q is not referenced.

*** *LDQ (input)***

The leading dimension of the array Q. If $JOBZ = 'N'$, $LDQ \geq 1$. If $JOBZ = 'V'$, $LDQ \geq \max(1,N)$.

*** *VL (input)***

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if $RANGE = 'A'$ or $'I'$.

*** *VU (input)***

See the description of VL.

*** *IL (input)***

If $RANGE='I'$, the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if $RANGE = 'A'$ or $'V'$.

*** *IU (input)***

See the description of IL.

*** *ABSTOL (input)***

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|),$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO>0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

*** *M (output)***

The total number of eigenvalues found. $0 \leq M \leq N$. If $RANGE = 'A'$, $M = N$, and if $RANGE = 'I'$, $M = IU-IL+1$.

*** *W (output)***

If $INFO = 0$, the eigenvalues in ascending order.

*** *Z (input)***

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized so $Z^{*T}*B*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

*** *LDZ (input)***

The leading dimension of the array Z. $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1,N)$.

*** *WORK (workspace)***

dimension(7*N)

*** *IWORK (workspace)***

dimension(5*N)

*** *IFAIL (input)***

If $JOBZ = 'V'$, then if $INFO = 0$, the first M elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvalues that failed to converge. If $JOBZ = 'N'$, then IFAIL is not referenced.

*** *INFO (output)***

```

```
void dsbmv(char uplo, int n, int ndiag, double alpha, double *a, int lda, double *x, int incx, double beta, double *y, int incy);
```

```
void dsbmv_64(char uplo, long n, long ndiag, double alpha, double *a, long lda, double *x, long incx, double beta, double *y, long incy);
```

PURPOSE

dsbmv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric band matrix, with k super-diagonals.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u' The upper triangular part of A is being supplied.

UPLO = 'L' or 'l' The lower triangular part of A is being supplied.

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *NDIAG* (input)

On entry, NDIAG specifies the number of super-diagonals of the matrix A. $NDIAG \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A* (input)

Before entry with UPLO = 'U' or 'u', the leading $(k + 1)$ by n part of the array A must contain the upper triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row $(k + 1)$ of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = NDIAG + 1 - J
      O 10, I = MAX( 1, J - NDIAG ), J
          A( M + I, J ) = matrix( I, J )
```

```
10 CONTINUE
```

```
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading $(k + 1)$ by n part of the array A must contain the lower triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
      DO 20, J = 1, N
        = 1 - J
    O 10, I = J, MIN( N, J + NDIAG )
        A( M + I, J ) = matrix( I, J )
```

10 CONTINUE

20 CONTINUE

Unchanged on exit.

*** LDA (input)**

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. $LDA \geq (k + 1)$. Unchanged on exit.

*** X (input)**

$(1 + (n - 1) * \text{abs}(INCX))$. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

*** INCX (input)**

On entry, INCX specifies the increment for the elements of X. $INCX \neq 0$. Unchanged on exit.

*** BETA (input)**

On entry, BETA specifies the scalar beta. Unchanged on exit.

*** Y (input/output)**

$(1 + (n - 1) * \text{abs}(INCY))$. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

*** INCY (input)**

On entry, INCY specifies the increment for the elements of Y. $INCY \neq 0$. Unchanged on exit.

NAME

dsbtrd - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```
SUBROUTINE DSBTRD( VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ, WORK,  
* INFO)  
CHARACTER * 1 VECT, UPLO  
INTEGER N, KD, LDAB, LDQ, INFO  
DOUBLE PRECISION AB(LDAB,*), D(*), E(*), Q(LDQ,*), WORK(*)  
  
SUBROUTINE DSBTRD_64( VECT, UPLO, N, KD, AB, LDAB, D, E, Q, LDQ,  
* WORK, INFO)  
CHARACTER * 1 VECT, UPLO  
INTEGER*8 N, KD, LDAB, LDQ, INFO  
DOUBLE PRECISION AB(LDAB,*), D(*), E(*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SBTRD( VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],  
* [WORK], [INFO])  
CHARACTER(LEN=1) :: VECT, UPLO  
INTEGER :: N, KD, LDAB, LDQ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: AB, Q  
  
SUBROUTINE SBTRD_64( VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],  
* [WORK], [INFO])  
CHARACTER(LEN=1) :: VECT, UPLO  
INTEGER(8) :: N, KD, LDAB, LDQ, INFO  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: AB, Q
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsbtrd(char vect, char uplo, int n, int kd, double *ab, int ldab, double *d, double *e, double *q, int ldq, int *info);
```

```
void dsbtrd_64(char vect, char uplo, long n, long kd, double *ab, long ldab, double *d, double *e, double *q, long ldq, long *info);
```

PURPOSE

dsbtrd reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation:
 $Q^* T^* A^* Q = T$.

ARGUMENTS

* **VECT** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **KD** (*input*)

The number of superdiagonals of the matrix A if $UPLO = 'U'$, or the number of subdiagonals if $UPLO = 'L'$. $KD \geq 0$.

* **AB** (*input/output*)

On entry, the upper or lower triangle of the symmetric band matrix A , stored in the first $KD+1$ rows of the array. The j -th column of A is stored in the j -th column of the array AB as follows: if $UPLO = 'U'$, $AB(kd+1+i-j,j) = A(i,j)$ for $\max(1,j-kd) \leq i \leq j$; if $UPLO = 'L'$, $AB(1+i-j,j) = A(i,j)$ for $j \leq i \leq \min(n,j+kd)$. On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T ; if $KD > 0$, the elements on the first superdiagonal (if $UPLO = 'U'$) or the first subdiagonal (if $UPLO = 'L'$) are overwritten by the off-diagonal elements of T ; the rest of AB is overwritten by values generated during the reduction.

* **LDAB** (*input*)

The leading dimension of the array AB . $LDAB \geq KD+1$.

* **D** (*output*)

The diagonal elements of the tridiagonal matrix T .

* **E** (*output*)

The off-diagonal elements of the tridiagonal matrix T : $E(i) = T(i,i+1)$ if $UPLO = 'U'$; $E(i) = T(i+1,i)$ if $UPLO = 'L'$.

* **Q** (*input/output*)

On entry, if $VECT = 'U'$, then Q must contain an N -by- N matrix X ; if $VECT = 'N'$ or $'V'$, then Q need not be set.

On exit: if $VECT = 'V'$, Q contains the N -by- N orthogonal matrix Q ; if $VECT = 'U'$, Q contains the product X^*Q ; if $VECT = 'N'$, the array Q is not referenced.

* **LDQ** (*input*)

The leading dimension of the array Q . $LDQ \geq 1$, and $LDQ \geq N$ if $VECT = 'V'$ or $'U'$.

* **WORK** (*workspace*)

dimension(N)

* **INFO** (*output*)

NAME

dscal - Compute $y := \alpha * y$

SYNOPSIS

```
SUBROUTINE DSCAL( N, ALPHA, Y, INCY)
INTEGER N, INCY
DOUBLE PRECISION ALPHA
DOUBLE PRECISION Y(*)
```

```
SUBROUTINE DSCAL_64( N, ALPHA, Y, INCY)
INTEGER*8 N, INCY
DOUBLE PRECISION ALPHA
DOUBLE PRECISION Y(*)
```

F95 INTERFACE

```
SUBROUTINE SCAL( [N], ALPHA, Y, [INCY])
INTEGER :: N, INCY
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: Y
```

```
SUBROUTINE SCAL_64( [N], ALPHA, Y, [INCY])
INTEGER(8) :: N, INCY
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dscal(int n, double alpha, double *y, int incy);
```

```
void dscal_64(long n, double alpha, double *y, long incy);
```

PURPOSE

dscal Compute $y := \text{alpha} * y$ where alpha is a scalar and y is an n-vector.

ARGUMENTS

* *N (input)*

On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *Y (input/output)*

($1 + (m - 1) * \text{abs}(\text{INCY})$). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

dsdot - compute the double precision dot product of two single precision vectors x and y.

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DSDOT( N, X, INCX, Y, INCY)
INTEGER N, INCX, INCY
REAL X(*), Y(*)
```

```
DOUBLE PRECISION FUNCTION DSDOT_64( N, X, INCX, Y, INCY)
INTEGER*8 N, INCX, INCY
REAL X(*), Y(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DSDOT( [N], X, [INCX], Y, [INCY])
INTEGER :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

```
REAL(8) FUNCTION DSDOT_64( [N], X, [INCX], Y, [INCY])
INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dsdot(int n, float *x, int incx, float *y, int incy);
```

```
double dsdot_64(long n, float *x, long incx, float *y, long incy);
```

PURPOSE

dsdot compute the double precision dot product of x and y where x and y are single precision n-vectors.

ARGUMENTS

*** *N (input)***

On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

*** *X (input)***

(1 + (n - 1) * abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

*** *INCX (input)***

On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

*** *Y (input)***

(1 + (m - 1) * abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

*** *INCY (input)***

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

dsecnd - return the user time for a process in seconds

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DSECND( )
```

```
DOUBLE PRECISION FUNCTION DSECND_64( )
```

F95 INTERFACE

```
REAL(8) FUNCTION DSECND( )
```

```
REAL(8) FUNCTION DSECND_64( )
```

C INTERFACE

```
#include <sunperf.h>
```

```
double dsecnd();
```

```
double dsecnd_64();
```

PURPOSE

dsecnd returns the user time for a process in seconds. This version gets the time from the system function ETIME.

ARGUMENTS

NAME

dsico - (obsolete) compute the UDU factorization and condition number of a symmetric matrix A. If the condition number is not needed then SSIFA is slightly faster. It is typical to follow a call to SSICO with a call to SSISL to solve $Ax = b$ or to SSIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE DSICO( A, LDA, N, IPIVOT, RCOND, WORK)
  INTEGER LDA, N
  INTEGER IPIVOT(*)
  DOUBLE PRECISION RCOND
  DOUBLE PRECISION A(LDA,*), WORK(*)
```

```
SUBROUTINE DSICO_64( A, LDA, N, IPIVOT, RCOND, WORK)
  INTEGER*8 LDA, N
  INTEGER*8 IPIVOT(*)
  DOUBLE PRECISION RCOND
  DOUBLE PRECISION A(LDA,*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsico(double *a, int lda, int n, int *ipivot, double *rcond);
```

```
void dsico_64(double *a, long lda, long n, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

* **LDA** (*input*)

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq \text{RCOND} \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $\text{RCOND} + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

dsidi - (obsolete) compute the determinant, inertia, and inverse of a symmetric matrix A, which has been UDU-factored by SSICO or SSIFA.

SYNOPSIS

```
SUBROUTINE DSIDI( A, LDA, N, IPIVOT, DET, INERT, WORK, JOB)
INTEGER LDA, N, JOB
INTEGER IPIVOT(*), INERT(*)
DOUBLE PRECISION A(LDA,*), DET(*), WORK(*)
```

```
SUBROUTINE DSIDI_64( A, LDA, N, IPIVOT, DET, INERT, WORK, JOB)
INTEGER*8 LDA, N, JOB
INTEGER*8 IPIVOT(*), INERT(*)
DOUBLE PRECISION A(LDA,*), DET(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsidi(double *a, int lda, int n, int *ipivot, double *det, int *inert, int job);
```

```
void dsidi_64(double *a, long lda, long n, long *ipivot, double *det, long *inert, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by SSICO or SSIFA. On exit, if the c digit of JOB <> 0, then the upper triangle of A contains the upper triangle of the inverse of the original matrix A if the inverse was requested, otherwise unchanged. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. LDA >= max(1,N).

*** N (input)**

Order of the original matrix A. N >= 0.

*** IPIVOT (input)**

Pivot vector as computed by SSICO or SSIFA.

*** DET (output)**

On exit, if the b digit of JOB <> 0, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) =$

0.0. If the b digit of JOB = 0, DET is not referenced.

* **INERT** (*output*)

On exit, if the a digit of JOB \neq 0, then INERT contains an integer triplet where:

INERT(1) = number of positive eigenvalues

INERT(2) = number of negative eigenvalues

INERT(3) = number of zero eigenvalues

If the a digit of JOB = 0 then INERT is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form abc; determines operation the subroutine will perform:

```
a  $\neq$  0  Compute the inertia.  
b  $\neq$  0  Compute the determinant.  
c  $\neq$  0  Compute the inverse.
```

Note that the inverse should not be computed if SSICO has set RCOND = 0 or if SSIFA has set INFO \geq 0.

NAME

dsifa - (obsolete) compute the UDU factorization of a symmetric matrix A. It is typical to follow a call to SSIFA with a call to SSISL to solve $Ax = b$ or to SSIDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE DSIFA( A, LDA, N, IPIVOT, INFO)
INTEGER LDA, N, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(LDA,*)

SUBROUTINE DSIFA_64( A, LDA, N, IPIVOT, INFO)
INTEGER*8 LDA, N, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION A(LDA,*)
```

C INTERFACE

```
#include <sunperf.h>

void dsifa(double *a, int lda, int n, int *ipivot, int *info);

void dsifa_64(double *a, long lda, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A. The strict lower triangle of A is not referenced.

*** LDA (input)**

Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.

*** N (input)**

Order of the matrix A. $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the kth pivot block is singular to indicate that SSISL or SSIDI will divide by zero if called.

NAME

dsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE DSINQB( N, X, WSAVE)
INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)
```

```
SUBROUTINE DSINQB_64( N, X, WSAVE)
INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQB( [N], X, WSAVE)
INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

```
SUBROUTINE SINQB_64( [N], X, WSAVE)
INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsinqb(int n, double *x, double *wsave);
```

```
void dsinqb_64(long n, double *x, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine synthesis of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$ for scalar subroutines, initialized by SINQI.

NAME

dsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by $4 * N$.

SYNOPSIS

```
SUBROUTINE DSINQF( N, X, WSAVE)
  INTEGER N
  DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DSINQF_64( N, X, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQF( [N], X, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE SINQF_64( [N], X, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinqf(int n, double *x, double *wsave);

void dsinqf_64(long n, double *x, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes.
N \geq 0.

* *X (input/output)*

On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine transform of the input.

* *WSAVE (input)*

On entry, an array with dimension of at least $(3 * N + 15)$ for scalar subroutines, initialized by SINQI.

NAME

dsinqi - initialize the array xWSAVE, which is used in both SINQF and SINQB.

SYNOPSIS

```
SUBROUTINE DSINQI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE DSINQI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE SINQI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinqi(int n, double *wsave);

void dsinqi_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

* *WSAVE (input)*

On entry, an array of dimension $(3 * N + 15)$ or greater. `SINQI` needs to be called only once to initialize `WSAVE` before calling `SINQF` and/or `SINQB` if N and `WSAVE` remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

dsint - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by $2 * (N+1)$.

SYNOPSIS

```
SUBROUTINE DSINT( N, X, WSAVE)
INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DSINT_64( N, X, WSAVE)
INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT( [N], X, WSAVE)
INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE SINT_64( [N], X, WSAVE)
INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsint(int n, double *x, double *wsave);

void dsint_64(long n, double *x, double *wsave);
```

ARGUMENTS

*** N (input)**

Length of the sequence to be transformed. These subroutines are most efficient when $N+1$ is a product of small primes. $N \geq 0$.

*** X (input/output)**

On entry, an array of length N containing the sequence to be transformed. On exit, the sine transform of the input.

*** $WSAVE$ (input/output)**

On entry, an array with dimension of at least $\text{int}(2.5 * N + 15)$ initialized by SINT1.

NAME

dsinti - initialize the array WSAVE, which is used in subroutine SINT.

SYNOPSIS

```
SUBROUTINE DSINTI( N, WSAVE)
  INTEGER N
  DOUBLE PRECISION WSAVE(*)

SUBROUTINE DSINTI_64( N, WSAVE)
  INTEGER*8 N
  DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINTI( N, WSAVE)
  INTEGER :: N
  REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE SINTI_64( N, WSAVE)
  INTEGER(8) :: N
  REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinti(int n, double *wsave);

void dsinti_64(long n, double *wsave);
```

ARGUMENTS

* *N (input)*

Length of the sequence to be transformed. $N \geq 0$.

* *WSAVE (input/output)*

On entry, an array of dimension $(2N + N/2 + 15)$ or greater. SINTI is called once to initialize WSAVE before calling SINT and need not be called again between calls to SINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

dsisl - (obsolete) solve the linear system $Ax = b$ for a symmetric matrix A , which has been UDU-factored by SSICO or SSIFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE DSISL( A, LDA, N, IPIVOT, B)
  INTEGER LDA, N
  INTEGER IPIVOT(*)
  DOUBLE PRECISION A(LDA,*), B(*)

SUBROUTINE DSISL_64( A, LDA, N, IPIVOT, B)
  INTEGER*8 LDA, N
  INTEGER*8 IPIVOT(*)
  DOUBLE PRECISION A(LDA,*), B(*)
```

C INTERFACE

```
#include <sunperf.h>

void dsisl(double *a, int lda, int n, int *ipivot, double *b);

void dsisl_64(double *a, long lda, long n, long *ipivot, double *b);
```

ARGUMENTS

- * **A** (*input*)
UDU factorization of the matrix A , as computed by SSICO or SSIFA.
- * **LDA** (*input*)
Leading dimension of the array A as specified in a dimension or type statement. $LDA \geq \max(1, N)$.
- * **N** (*input*)
Order of the matrix A . $N \geq 0$.
- * **IPIVOT** (*input*)
Pivot vector as computed by SSICO or SSIFA.
- * **B** (*input/output*)
On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

dspco - (obsolete) compute the UDU factorization and condition number of a symmetric matrix A in packed storage. If the condition number is not needed then SSPFA is slightly faster. It is typical to follow a call to SSPCO with a call to SSPSL to solve $Ax = b$ or to SSPDI to compute the determinant, inverse, and inertia of A.

SYNOPSIS

```
SUBROUTINE DSPCO( A, N, IPIVOT, RCOND, WORK)
  INTEGER N
  INTEGER IPIVOT(*)
  DOUBLE PRECISION RCOND
  DOUBLE PRECISION A(*), WORK(*)

SUBROUTINE DSPCO_64( A, N, IPIVOT, RCOND, WORK)
  INTEGER*8 N
  INTEGER*8 IPIVOT(*)
  DOUBLE PRECISION RCOND
  DOUBLE PRECISION A(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>

void dspco(double *a, int n, int *ipivot, double *rcond);

void dspco_64(double *a, long n, long *ipivot, double *rcond);
```

ARGUMENTS

* **A** (*input/output*)

On entry, the upper triangle of the matrix A. On exit, a UDU factorization of the matrix A.

* **N** (*input*)

Order of the matrix A. $N \geq 0$.

* **IPIVOT** (*output*)

On exit, a vector of pivot indices.

* **RCOND** (*output*)

On exit, an estimate of the reciprocal condition number of A. $0.0 \leq RCOND \leq 1.0$. As the value of RCOND gets smaller, operations with A such as solving $Ax = b$ may become less stable. If RCOND satisfies $RCOND + 1.0 = 1.0$ then A may be singular to working precision.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

NAME

dspcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ computed by SSPTRF

SYNOPSIS

```
SUBROUTINE DSPCON( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK, IWORK2,  
*      INFO)  
CHARACTER * 1 UPLO  
INTEGER N, INFO  
INTEGER IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION A(*), WORK(*)  
  
SUBROUTINE DSPCON_64( UPLO, N, A, IPIVOT, ANORM, RCOND, WORK,  
*      IWORK2, INFO)  
CHARACTER * 1 UPLO  
INTEGER*8 N, INFO  
INTEGER*8 IPIVOT(*), IWORK2(*)  
DOUBLE PRECISION ANORM, RCOND  
DOUBLE PRECISION A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPCON( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],  
*      [IWORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER :: N, INFO  
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: A, WORK  
  
SUBROUTINE SPCON_64( UPLO, [N], A, IPIVOT, ANORM, RCOND, [WORK],  
*      [IWORK2], [INFO])  
CHARACTER(LEN=1) :: UPLO  
INTEGER(8) :: N, INFO  
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2  
REAL(8) :: ANORM, RCOND  
REAL(8), DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspcon(char uplo, int n, double *a, int *ipivot, double anorm, double *rcond, int *info);
```

```
void dspcon_64(char uplo, long n, double *a, long *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

dspcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF.

An estimate is obtained for $\text{norm}(\text{inv}(A))$, and the reciprocal of the condition number is computed as $\text{RCOND} = 1 / (\text{ANORM} * \text{norm}(\text{inv}(A)))$.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSPTRF.

* **ANORM** (*input*)

The 1-norm of the original matrix A.

* **RCOND** (*output*)

The reciprocal of the condition number of the matrix A, computed as $\text{RCOND} = 1/(\text{ANORM} * \text{AINVNM})$, where AINVNM is an estimate of the 1-norm of $\text{inv}(A)$ computed in this routine.

* **WORK** (*workspace*)

dimension(2*N)

* **IWORK2** (*workspace*)

* **INFO** (*output*)

NAME

dspdi - (obsolete) compute the determinant, inertia, and inverse of a symmetric matrix A in packed storage, which has been UDU-factored by SSPCO or SSPFA.

SYNOPSIS

```
SUBROUTINE DSPDI( A, N, IPIVOT, DET, INERT, WORK, JOB)
INTEGER N, JOB
INTEGER IPIVOT(*), INERT(*)
DOUBLE PRECISION A(*), DET(*), WORK(*)
```

```
SUBROUTINE DSPDI_64( A, N, IPIVOT, DET, INERT, WORK, JOB)
INTEGER*8 N, JOB
INTEGER*8 IPIVOT(*), INERT(*)
DOUBLE PRECISION A(*), DET(*), WORK(*)
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspdi(double *a, int n, int *ipivot, double *det, int *inert, int job);
```

```
void dspdi_64(double *a, long n, long *ipivot, double *det, long *inert, long job);
```

ARGUMENTS

*** A (input/output)**

On entry, the UDU factorization of the matrix A, as computed by SSPCO or SSPFA. On exit, if the c digit of JOB $\neq 0$, then A contains the upper triangle of the inverse of the original matrix A; otherwise unchanged.

*** N (input)**

Order of the original matrix A. $N \neq 0$.

*** IPIVOT (input)**

Pivot vector as computed by SSPCO or SSPFA.

*** DET (output)**

On exit, if the b digit of JOB $\neq 0$, then DET contains the determinant of the matrix A. The determinant is stored as $b * (10^{**} \text{expon})$ where b is stored in DET(1) and expon is stored in DET(2). $1.0 \leq |\text{DET}(1)| \leq 10.0$ or $\text{DET}(1) = 0.0$. If the b digit of JOB = 0, DET is not referenced.

*** INERT (output)**

On exit, if the a digit of JOB $\neq 0$ then INERT contains an integer triplet where:

INERT(1) = number of positive eigenvalues

INERT(2) = number of negative eigenvalues

INERT(3) = number of zero eigenvalues

If the a digit of JOB = 0 then INERT is not referenced.

* **WORK** (*workspace*)

Scratch array with a dimension of N.

* **JOB** (*input*)

Integer in the form abc; determines operation the subroutine will perform:

a <> 0 Compute the inertia.
b <> 0 Compute the determinant.
c <> 0 Compute the inverse.

Note that the inverse should not be computed if SSPCO has set RCOND = 0 or if SSPFA has set INFO <> 0.

NAME

dspev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

SYNOPSIS

```
SUBROUTINE DSPEV( JOBZ, UPLO, N, A, W, Z, LDZ, WORK, INFO)

REAL(8), DIMENSION(:) :: A, W, WORK
REAL(8), DIMENSION(:, :) :: Z
```

```
SUBROUTINE SPEV_64( JOBZ, UPLO, [N], A, W, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: A, W, WORK
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspev(char jobz, char uplo, int n, double *a, double *w, double *z, int ldz, int *info);
```

```
void dspev_64(char jobz, char uplo, long n, double *a, double *w, double *z, long ldz, long *info);
```

PURPOSE

dspev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A , packed columnwise in a linear array. The j -th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If $UPLO = 'U'$, the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A , and if $UPLO = 'L'$, the diagonal and first subdiagonal of T overwrite the corresponding elements of A .

* **W** (*output*)

If $INFO = 0$, the eigenvalues in ascending order.

* **Z** (*input*)

If $JOBZ = 'V'$, then if $INFO = 0$, Z contains the orthonormal eigenvectors of the matrix A , with the i -th column of Z holding the eigenvector associated with $W(i)$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension($3*N$)

* **INFO** (*output*)

NAME

SUBROUTINE SPEVD_64( JOBZ, UPLO, [N], AP, W, Z, [LDZ], [WORK],  
*      [LWORK], [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: JOBZ, UPLO  
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: AP, W, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspevd(char jobz, char uplo, int n, double *ap, double *w, double *z, int ldz, int *info);
```

```
void dspevd_64(char jobz, char uplo, long n, double *ap, double *w, double *z, long ldz, long *info);
```

PURPOSE

dspevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

* **JOBZ** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **AP** (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **W** (*output*)

If INFO = 0, the eigenvalues in ascending order.

* **Z** (*input*)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $N \leq 1$, LWORK must be at least 1. If JOBZ = 'N' and $N > 1$, LWORK must be at least $2*N$. If JOBZ = 'V' and $N > 1$, LWORK must be at least $1 + 6*N + N**2$.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK** (*workspace*)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK** (*input*)

The dimension of the array IWORK. If JOBZ = 'N' or $N \leq 1$, LIWORK must be at least 1. If JOBZ = 'V' and $N > 1$, LIWORK must be at least $3 + 5*N$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* *INFO* (output)

NAME

dspevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

SYNOPSIS

```
SUBROUTINE DSPEVX( JOBZ, RANGE, UPLO, N, A, VL, VU, IL, IU, ABTOL,

INTEGER(8), DIMENSION(:) :: IWORK2, IFAIL
REAL(8) :: VL, VU, ABTOL
REAL(8), DIMENSION(:) :: A, W, WORK
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspevx(char jobz, char range, char uplo, int n, double *a, double vl, double vu, int il, int iu, double abtol, int *nfound, double *w, double *z, int ldz, int *ifail, int *info);
```

```
void dspevx_64(char jobz, char range, char uplo, long n, double *a, double vl, double vu, long il, long iu, double abtol, long *nfound, double *w, double *z, long ldz, long *ifail, long *info);
```

PURPOSE

dspevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **A** (*input/output*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABTOL** (*input*)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$ABTOL + EPS * \max(|a|,|b|)$,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then $\text{EPS} * |T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold $2 * \text{SLAMCH}('S')$, not zero. If this routine returns with $\text{INFO} > 0$, indicating that some eigenvectors did not converge, try setting ABTOL to $2 * \text{SLAMCH}('S')$.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

* **NFOUND (output)**

The total number of eigenvalues found. $0 \leq \text{NFOUND} \leq N$. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

* **W (output)**

If INFO = 0, the selected eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, \text{NFOUND})$ columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. $\text{LDZ} \geq 1$, and if JOBZ = 'V', $\text{LDZ} \geq \max(1, N)$.

* **WORK (workspace)**

dimension(8*N)

* **IWORK2 (workspace)**

* **IFAIL (output)**

If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

* **INFO (output)**

NAME

dspfa - (obsolete) compute the UDU factorization of a symmetric matrix A in packed storage. It is typical to follow a call to SSPFA with a call to SSPSL to solve $Ax = b$ or to SSPDI to compute the determinant, inverse, and inertia of A .

SYNOPSIS

```
SUBROUTINE DSPFA( A, N, IPIVOT, INFO)
  INTEGER N, INFO
  INTEGER IPIVOT(*)
  DOUBLE PRECISION A(*)

SUBROUTINE DSPFA_64( A, N, IPIVOT, INFO)
  INTEGER*8 N, INFO
  INTEGER*8 IPIVOT(*)
  DOUBLE PRECISION A(*)
```

C INTERFACE

```
#include <sunperf.h>

void dspfa(double *a, int n, int *ipivot, int *info);

void dspfa_64(double *a, long n, long *ipivot, long *info);
```

ARGUMENTS

*** A (input/output)**

On entry, the upper triangle of the matrix A . On exit, a UDU factorization of the matrix A .

*** N (input)**

Order of the matrix A . $N \geq 0$.

*** IPIVOT (output)**

On exit, a vector of pivot indices.

*** INFO (output)**

On exit:

INFO = 0 Subroutine completed normally.

INFO > 0 Returns a value k if the k th pivot block is singular to indicate that SSPSL or SSPDI will divide by zero if called.

NAME

dspgst - reduce a real symmetric-definite generalized eigenproblem to standard form, using packed storage

SYNOPSIS

```
SUBROUTINE DSPGST( ITYPE, UPLO, N, AP, BP, INFO)
CHARACTER * 1 UPLO
INTEGER ITYPE, N, INFO
DOUBLE PRECISION AP(*), BP(*)
```

```
SUBROUTINE DSPGST_64( ITYPE, UPLO, N, AP, BP, INFO)
CHARACTER * 1 UPLO
INTEGER*8 ITYPE, N, INFO
DOUBLE PRECISION AP(*), BP(*)
```

F95 INTERFACE

```
SUBROUTINE SPGST( ITYPE, UPLO, N, AP, BP, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: ITYPE, N, INFO
REAL(8), DIMENSION(:) :: AP, BP
```

```
SUBROUTINE SPGST_64( ITYPE, UPLO, N, AP, BP, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: ITYPE, N, INFO
REAL(8), DIMENSION(:) :: AP, BP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspgst(int itype, char uplo, int n, double *ap, double *bp, int *info);
```

```
void dspgst_64(long itype, char uplo, long n, double *ap, double *bp, long *info);
```

PURPOSE

dspgst reduces a real symmetric-definite generalized eigenproblem to standard form, using packed storage.

If $ITYPE = 1$, the problem is $A*x = \lambda*B*x$,

and A is overwritten by $\text{inv}(U^{**T})*A*\text{inv}(U)$ or $\text{inv}(L)*A*\text{inv}(L^{**T})$

If $ITYPE = 2$ or 3 , the problem is $A*B*x = \lambda*x$ or

$B*A*x = \lambda*x$, and A is overwritten by $U*A*U^{**T}$ or $L^{**T}*A*L$.

B must have been previously factorized as $U^{**T}*U$ or $L*L^{**T}$ by SPPTRF.

ARGUMENTS

* *ITYPE* (input)

* *UPLO* (input)

* *N* (input)

The order of the matrices A and B. $N \geq 0$.

* *AP* (input/output)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if $UPLO = 'U'$, $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $AP(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, if $INFO = 0$, the transformed matrix, stored in the same format as A.

* *BP* (input)

The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by SPPTRF.

* *INFO* (output)

NAME

dspgv - compute all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\text{lambda})*B*x$, $A*Bx=(\text{lambda})*x$, or $B*A*x=(\text{lambda})*x$

SYNOPSIS

```
SUBROUTINE DSPGV( ITYPE, JOBZ, UPLO, N, A, B, W, Z, LDZ, WORK, INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER ITYPE, N, LDZ, INFO
DOUBLE PRECISION A(*), B(*), W(*), Z(LDZ,*), WORK(*)

SUBROUTINE DSPGV_64( ITYPE, JOBZ, UPLO, N, A, B, W, Z, LDZ, WORK,
* INFO)
CHARACTER * 1 JOBZ, UPLO
INTEGER*8 ITYPE, N, LDZ, INFO
DOUBLE PRECISION A(*), B(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPGV( ITYPE, JOBZ, UPLO, [N], A, B, W, Z, [LDZ], [WORK],
* [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: ITYPE, N, LDZ, INFO
REAL(8), DIMENSION(:) :: A, B, W, WORK
REAL(8), DIMENSION(:,) :: Z

SUBROUTINE SPGV_64( ITYPE, JOBZ, UPLO, [N], A, B, W, Z, [LDZ], [WORK],
* [INFO])
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: ITYPE, N, LDZ, INFO
REAL(8), DIMENSION(:) :: A, B, W, WORK
REAL(8), DIMENSION(:,) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspgv(int itype, char jobz, char uplo, int n, double *a, double *b, double *w, double *z, int ldz, int *info);
```

```
void dspgv_64(long itype, char jobz, char uplo, long n, double *a, double *b, double *w, double *z, long ldz, long *info);
```

PURPOSE

dspgv computes all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** A (input/output)**

$(N*(N+1)/2)$ On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of A are destroyed.

*** B (input/output)**

On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array B as follows: if UPLO = 'U', $B(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $B(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**T*U$ or $B = L*L**T$, in the same storage format as B.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, $Z**T*B*Z = I$; if ITYPE = 3, $Z**T*inv(B)*Z = I$. If JOBZ = 'N', then Z is not referenced.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

*** WORK (workspace)**

dimension(3*N)

*** INFO (output)**

NAME

dspgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\text{lambda})*B*x$, $A*Bx=(\text{lambda})*x$, or $B*A*x=(\text{lambda})*x$

SYNOPSIS

```

REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspgvd(int itype, char jobz, char uplo, int n, double *ap, double *bp, double *w, double *z, int ldz, int *info);
```

```
void dspgvd_64(long itype, char jobz, char uplo, long n, double *ap, double *bp, double *w, double *z, long ldz, long *info);
```

PURPOSE

dspgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)B*x$, $A*Bx=(\lambda)x$, or $B*A*x=(\lambda)x$. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrices A and B. $N \geq 0$.

*** AP (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

*** BP (input/output)**

On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U^*T*U$ or $B = L*L^*T$, in the same storage format as B.

*** W (output)**

If INFO = 0, the eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as

follows: if $ITYPE = 1$ or 2 , $Z^{**T}B^*Z = I$; if $ITYPE = 3$, $Z^{**T}inv(B)^*Z = I$. If $JOBZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z . $LDZ \geq 1$, and if $JOBZ = 'V'$, $LDZ \geq \max(1,N)$.

* **WORK** (*workspace*)

On exit, if $INFO = 0$, $WORK(1)$ returns the optimal $LWORK$.

* **LWORK** (*input*)

The dimension of the array $WORK$. If $N \leq 1$, $LWORK \geq 1$. If $JOBZ = 'N'$ and $N > 1$, $LWORK \geq 2*N$. If $JOBZ = 'V'$ and $N > 1$, $LWORK \geq 1 + 6*N + 2*N^{**2}$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $WORK$ array, returns this value as the first entry of the $WORK$ array, and no error message related to $LWORK$ is issued by $XERBLA$.

* **IWORK** (*workspace*)

On exit, if $INFO = 0$, $IWORK(1)$ returns the optimal $LIWORK$.

* **LIWORK** (*input*)

The dimension of the array $IWORK$. If $JOBZ = 'N'$ or $N \leq 1$, $LIWORK \geq 1$. If $JOBZ = 'V'$ and $N > 1$, $LIWORK \geq 3 + 5*N$.

If $LIWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the $IWORK$ array, returns this value as the first entry of the $IWORK$ array, and no error message related to $LIWORK$ is issued by $XERBLA$.

* **INFO** (*output*)

void dspgvx(int itype, char jobz, char range, char uplo, int n, double *ap, double *bp, double vl, double vu, int il, int iu, double abstol, int *m, double *w, double *z, int ldz, int *ifail, int *info);
```

```
void dspgvx_64(long itype, char jobz, char range, char uplo, long n, double *ap, double *bp, double vl, double vu, long il, long iu, double abstol, long *m, double *w, double *z, long ldz, long *ifail, long *info);
```

PURPOSE

dspgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form $A*x=(\lambda)*B*x$, $A*Bx=(\lambda)*x$, or $B*A*x=(\lambda)*x$. Here A and B are assumed to be symmetric, stored in packed storage, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

*** ITYPE (input)**

Specifies the problem type to be solved:

*** JOBZ (input)**

*** RANGE (input)**

*** UPLO (input)**

*** N (input)**

The order of the matrix pencil (A,B). $N \geq 0$.

*** AP (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the contents of AP are destroyed.

*** BP (input/output)**

On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', $BP(i + (j-1)*j/2) = B(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $BP(i + (j-1)*(2*n-j)/2) = B(i,j)$ for $j \leq i \leq n$.

On exit, the triangular factor U or L from the Cholesky factorization $B = U**T*U$ or $B = L*L**T$, in the same storage format as B.

*** VL (input)**

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

*** VU (input)**

See the description of VL.

*** IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

*** IU (input)**

See the description of IL.

*** ABSTOL (input)**

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a,b]$ of width less than or equal to

$$ABSTOL + EPS * \max(|a|,|b|) ,$$

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then $EPS*|T|$ will be used in its place, where $|T|$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold $2*SLAMCH('S')$, not zero. If this routine returns with $INFO > 0$, indicating that some eigenvectors did not converge, try setting ABSTOL to $2*SLAMCH('S')$.

*** M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

*** W (output)**

On normal exit, the first M elements contain the selected eigenvalues in ascending order.

*** Z (input)**

If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if $INFO = 0$, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with $W(i)$. The eigenvectors are normalized as follows: if $ITYPE = 1$ or 2 , $Z**T*B*Z = I$; if $ITYPE = 3$, $Z**T*inv(B)*Z = I$.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least $\max(1,M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

*** LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1,N)$.

*** WORK (workspace)**

dimension(8*N)

*** IWORK (workspace)**

dimension(5*N)

*** IFAIL (output)**

If JOBZ = 'V', then if $INFO = 0$, the first M elements of IFAIL are zero. If $INFO > 0$, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

*** INFO (output)**

NAME

dspmv - perform the matrix-vector operation $y := \alpha * A * x + \beta * y$

SYNOPSIS

```
SUBROUTINE DSPMV( UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
INTEGER N, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(*), X(*), Y(*)
```

```
SUBROUTINE DSPMV_64( UPLO, N, ALPHA, A, X, INCX, BETA, Y, INCY)
CHARACTER * 1 UPLO
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SPMV( UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: A, X, Y
```

```
SUBROUTINE SPMV_64( UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: A, X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspmv(char uplo, int n, double alpha, double *a, double *x, int incx, double beta, double *y, int incy);
```

```
void dspmv_64(char uplo, long n, double alpha, double *a, double *x, long incx, double beta, double *y, long incy);
```

PURPOSE

dspmv performs the matrix-vector operation $y := \alpha * A * x + \beta * y$, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

* *UPLO (input)*

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A.

Unchanged on exit.

* *N (input)*

On entry, N specifies the order of the matrix A. $N \geq 0$. Unchanged on exit.

* *ALPHA (input)*

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

* *A (input)*

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Unchanged on exit.

* *X (input)*

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

* *INCX (input)*

On entry, INCX specifies the increment for the elements of X. $\text{INCX} \neq 0$. Unchanged on exit.

* *BETA (input)*

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

* *Y (input/output)*

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

* *INCY (input)*

On entry, INCY specifies the increment for the elements of Y. $\text{INCY} \neq 0$. Unchanged on exit.

NAME

dspr - perform the symmetric rank 1 operation $A := \alpha * x * x' + A$

SYNOPSIS

```
SUBROUTINE DSPR( UPLO, N, ALPHA, X, INCX, A)
CHARACTER * 1 UPLO
INTEGER N, INCX
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), A(*)

SUBROUTINE DSPR_64( UPLO, N, ALPHA, X, INCX, A)
CHARACTER * 1 UPLO
INTEGER*8 N, INCX
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), A(*)
```

F95 INTERFACE

```
SUBROUTINE SPR( UPLO, N, ALPHA, X, [INCX], A)
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INCX
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, A

SUBROUTINE SPR_64( UPLO, N, ALPHA, X, [INCX], A)
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspr(char uplo, int n, double alpha, double *x, int incx, double *a);
```

```
void dspr_64(char uplo, long n, double alpha, double *x, long incx, double *a);
```

PURPOSE

dspr performs the symmetric rank 1 operation $A := \alpha * x * x' + A$, where α is a real scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *A* (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix.

NAME

dspr2 - perform the symmetric rank 2 operation $A := \alpha*x*y' + \alpha*y*x' + A$

SYNOPSIS

```
SUBROUTINE DSPR2( UPLO, N, ALPHA, X, INCX, Y, INCY, A)

```

```
void dspr2_64(char uplo, long n, double alpha, double *x, long incx, double *y, long incy, double *a);
```

PURPOSE

dspr2 performs the symmetric rank 2 operation $A := \alpha x y' + \alpha y x' + A$, where α is a scalar, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

* *UPLO* (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A .

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A .

Unchanged on exit.

* *N* (input)

On entry, N specifies the order of the matrix A . $N \geq 0$. Unchanged on exit.

* *ALPHA* (input)

On entry, ALPHA specifies the scalar α . Unchanged on exit.

* *X* (input)

$(1 + (n - 1) * \text{abs}(\text{INCX}))$. Before entry, the incremented array X must contain the n element vector x . Unchanged on exit.

* *INCX* (input)

On entry, INCX specifies the increment for the elements of X . $\text{INCX} \neq 0$. Unchanged on exit.

* *Y* (input)

$(1 + (n - 1) * \text{abs}(\text{INCY}))$. Before entry, the incremented array Y must contain the n element vector y . Unchanged on exit.

* *INCY* (input)

On entry, INCY specifies the increment for the elements of Y . $\text{INCY} \neq 0$. Unchanged on exit.

* *A* (input/output)

$((n * (n + 1)) / 2)$. Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(1, 2)$ and $a(2, 2)$ respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that $A(1)$ contains $a(1, 1)$, $A(2)$ and $A(3)$ contain $a(2, 1)$ and $a(3, 1)$ respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix.

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, WORK2
REAL(8), DIMENSION(:) :: A, AF, FERR, BERR, WORK
REAL(8), DIMENSION(:, :) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsprfs(char uplo, int n, int nrhs, double *a, double *af, int *ipivot, double *b, int ldb, double *x, int ldx, double *ferr, double *berr, int *info);
```

```
void dsprfs_64(char uplo, long n, long nrhs, double *a, double *af, long *ipivot, double *b, long ldb, double *x, long ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dsprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

* **UPLO** (*input*)

* **N** (*input*)

The order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. $NRHS \geq 0$.

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

* **AF** (*input*)

The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSPTRF.

* **B** (*input*)

The right hand side matrix B.

* **LDB** (*input*)

The leading dimension of the array B. $LDB \geq \max(1,N)$.

* **X** (*input/output*)

On entry, the solution matrix X, as computed by SSPTRS. On exit, the improved solution matrix X.

* **LDX** (*input*)

The leading dimension of the array X. $LDX \geq \max(1,N)$.

* **FERR** (*output*)

The estimated forward error bound for each solution vector $X(j)$ (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to $X(j)$, $FERR(j)$ is an estimated upper bound for the magnitude of the

largest element in $(X(j) - X_{TRUE})$ divided by the magnitude of the largest element in $X(j)$. The estimate is as reliable as the estimate for $RCOND$, and is almost always a slight overestimate of the true error.

* ***BERR*** (*output*)

The componentwise relative backward error of each solution vector $X(j)$ (i.e., the smallest relative change in any element of A or B that makes $X(j)$ an exact solution).

* ***WORK*** (*workspace*)

dimension(3*N)

* ***WORK2*** (*workspace*)

* ***INFO*** (*output*)

NAME

dpspl - (obsolete) solve the linear system $Ax = b$ for a symmetric matrix A in packed storage, which has been UDU-factored by SSPCO or SSPFA, and vectors b and x .

SYNOPSIS

```
SUBROUTINE DSPSL( A, N, IPIVOT, B)
  INTEGER N
  INTEGER IPIVOT(*)
  DOUBLE PRECISION A(*), B(*)

SUBROUTINE DSPSL_64( A, N, IPIVOT, B)
  INTEGER*8 N
  INTEGER*8 IPIVOT(*)
  DOUBLE PRECISION A(*), B(*)
```

C INTERFACE

```
#include <sunperf.h>

void dpspl(double *a, int n, int *ipivot, double *b);

void dpspl_64(double *a, long n, long *ipivot, double *b);
```

ARGUMENTS

- * **A** (*input*)
UDU factorization of the matrix A , as computed by SSPCO or SSPFA.
- * **N** (*input*)
Order of the matrix A . $N \geq 0$.
- * **IPIVOT** (*input*)
Pivot vector as computed by SSPCO or SSPFA.
- * **B** (*input/output*)
On entry, the right-hand side vector b . On exit, the solution vector x .

NAME

dspsv - compute the solution to a real system of linear equations $A * X = B$,

SYNOPSIS

```
SUBROUTINE DSPSV( UPLO, N, NRHS, A, IPIVOT, B, LDB, INFO)
CHARACTER * 1 UPLO
INTEGER N, NRHS, LDB, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(*), B(LDB,*)
```

```
SUBROUTINE DSPSV_64( UPLO, N, NRHS, A, IPIVOT, B, LDB, INFO)

REAL(8), DIMENSION(:, :) :: B
```

```
SUBROUTINE SPSV_64( UPLO, N, NRHS, A, IPIVOT, B, [LDB], [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: A
REAL(8), DIMENSION(:, :) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspsv(char uplo, int n, int nrhs, double *a, int *ipivot, double *b, int ldb, int *info);
```

```
void dspsv_64(char uplo, long n, long nrhs, double *a, long *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dpsv computes the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as

$$\begin{aligned} A &= U * D * U^{**T}, & \text{if } UPLO = 'U', & \text{ or} \\ A &= L * D * L^{**T}, & \text{if } UPLO = 'L', \end{aligned}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations $A * X = B$.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

*** NRHS (input)**

The number of right hand sides, i.e., the number of columns of the matrix B. $NRHS \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U * D * U^{**T}$ or $A = L * D * L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (output)**

Details of the interchanges and the block structure of D, as determined by SSPTRF. If $IPIVOT(k) > 0$, then rows and columns k and $IPIVOT(k)$ were interchanged, and $D(k,k)$ is a 1-by-1 diagonal block. If $UPLO = 'U'$ and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and $-IPIVOT(k)$ were interchanged and $D(k-1:k,k-1:k)$ is a 2-by-2 diagonal block. If $UPLO = 'L'$ and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and $-IPIVOT(k)$ were interchanged and $D(k:k+1,k:k+1)$ is a 2-by-2 diagonal block.

*** B (input/output)**

On entry, the N-by-NRHS right hand side matrix B. On exit, if $INFO = 0$, the N-by-NRHS solution matrix X.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** INFO (output)**

NAME

dspsvx - use the diagonal pivoting factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

SYNOPSIS

REAL(8), DIMENSION(:, :) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspsvx(char fact, char uplo, int n, int nrhs, double *a, double *af, int *ipivot, double *b, int ldb, double *x, int ldx, double *rcond, double *ferr, double *berr, int *info);
```

```
void dspsvx_64(char fact, char uplo, long n, long nrhs, double *a, double *af, long *ipivot, double *b, long ldb, double *x, long ldx, double *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

dspsvx uses the diagonal pivoting factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ to compute the solution to a real system of linear equations $A * X = B$, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A as $A = U * D * U^{**T}$, if UPLO = 'U', or

```
    A = L * D * L^{**T},  if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.
```

2. If some $D(i,i)=0$, so that D is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
 3. The system of equations is solved for X using the factored form of A.
 4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
-

ARGUMENTS

* **FACT** (*input*)

Specifies whether or not the factored form of A has been supplied on entry.

* **UPLO** (*input*)

* **N** (*input*)

The number of linear equations, i.e., the order of the matrix A. $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS ≥ 0 .

* **A** (*input*)

The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. See below for further details.

*** AF (input/output)**

$(N*(N+1)/2)$ If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization $A = U*D*U^{**T}$ or $A = L*D*L^{**T}$ as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

*** IPIVOT (input)**

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSPTRF. If $IPIVOT(k) > 0$, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and $IPIVOT(k) = IPIVOT(k-1) < 0$, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and $IPIVOT(k) = IPIVOT(k+1) < 0$, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSPTRF.

*** B (input)**

The N-by-NRHS right hand side matrix B.

*** LDB (input)**

The leading dimension of the array B. $LDB \geq \max(1,N)$.

*** X (output)**

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

*** LDX (input)**

The leading dimension of the array X. $LDX \geq \max(1,N)$.

*** RCOND (output)**

The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

*** FERR (output)**

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in $(X(j) - XTRUE)$ divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

*** BERR (output)**

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

*** WORK (workspace)**

dimension(3*N)

*** WORK2 (workspace)**

*** INFO (output)**

NAME

dsptrd - reduce a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation

SYNOPSIS

```

SUBROUTINE SPTRD( UPLO, N, AP, D, E, TAU, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL(8), DIMENSION(:) :: AP, D, E, TAU

SUBROUTINE SPTRD_64( UPLO, N, AP, D, E, TAU, [INFO])
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
REAL(8), DIMENSION(:) :: AP, D, E, TAU
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsptrd(char uplo, int n, double *ap, double *d, double *e, double *tau, int *info);
```

```
void dsptrd_64(char uplo, long n, double *ap, double *d, double *e, double *tau, long *info);
```

PURPOSE

dsprtd reduces a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation: $Q^*T * A * Q = T$.

ARGUMENTS

* *UPLO* (*input*)

* *N* (*input*)

The order of the matrix A. $N \geq 0$.

* *AP* (*input*)

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', $AP(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $AP(i + (j-1)*(2*n-j)/2) = A(i,j)$ for $j \leq i \leq n$. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO

* *D* (*output*)

The diagonal elements of the tridiagonal matrix T: $D(i) = A(i,i)$.

* *E* (*output*)

The off-diagonal elements of the tridiagonal matrix T: $E(i) = A(i,i+1)$ if UPLO = 'U', $E(i) = A(i+1,i)$ if UPLO = 'L'.

* *TAU* (*output*)

The scalar factors of the elementary reflectors (see Further Details).

* *INFO* (*output*)

NAME

dsptf - compute the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

SYNOPSIS

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsptf(char uplo, int n, double *a, int *ipivot, int *info);
```

```
void dsptf_64(char uplo, long n, double *a, long *ipivot, long *info);
```

PURPOSE

dsptf computes the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

$$A = U^*D^*U^{**T} \quad \text{or} \quad A = L^*D^*L^{**T}$$

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

*** UPLO (input)**

*** N (input)**

The order of the matrix A. $N \geq 0$.

*** A (input/output)**

On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', $A(i + (j-1)*j/2) = A(i,j)$ for $1 \leq i \leq j$; if UPLO = 'L', $A(i + (j-1)*(2n-j)/2) = A(i,j)$ for $j \leq i \leq n$.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

*** IPIVOT (output)**

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

*** INFO (output)**

NAME

dsptri - compute the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF

SYNOPSIS

```
SUBROUTINE DSPTRI( UPLO, N, A, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO
INTEGER N, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION A(*), WORK(*)

SUBROUTINE DSPTRI_64( UPLO, N, A, IPIVOT, WORK, INFO)
CHARACTER * 1 UPLO

void dsptri(char uplo, int n, double *a, int *ipivot, int *info);

void dsptri_64(char uplo, long n, double *a, long *ipivot, long *info);
```

PURPOSE

dsptri computes the inverse of a real symmetric indefinite matrix A in packed storage using the factorization $A = U*D*U**T$ or $A = L*D*L**T$ computed by SSPTRF.

ARGUMENTS

*** UPLO (input)**

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

*** N (input)**

The order of the matrix A . $N \geq 0$.

*** A (input/output)**

On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

On exit, if $INFO = 0$, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j -th column of $inv(A)$ is stored in the array A as follows: if $UPLO = 'U'$, $A(i + (j-1)*j/2) = inv(A)(i,j)$ for $1 \leq i \leq j$; if $UPLO = 'L'$, $A(i + (j-1)*(2n-j)/2) = inv(A)(i,j)$ for $j \leq i \leq n$.

*** IPIVOT (input)**

Details of the interchanges and the block structure of D as determined by SSPTRF.

*** WORK (workspace)**

dimension(N)

*** INFO (output)**

PURPOSE

dsptsr solves a system of linear equations $A \cdot X = B$ with a real symmetric matrix A stored in packed format using the factorization $A = U \cdot D \cdot U^{**T}$ or $A = L \cdot D \cdot L^{**T}$ computed by SSPTRF.

ARGUMENTS

* **UPLO** (*input*)

Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.

* **N** (*input*)

The order of the matrix A . $N \geq 0$.

* **NRHS** (*input*)

The number of right hand sides, i.e., the number of columns of the matrix B . $NRHS \geq 0$.

* **A** (*input*)

The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

* **IPIVOT** (*input*)

Details of the interchanges and the block structure of D as determined by SSPTRF.

* **B** (*input/output*)

On entry, the right hand side matrix B . On exit, the solution matrix X .

* **LDB** (*input*)

The leading dimension of the array B . $LDB \geq \max(1, N)$.

* **INFO** (*output*)

NAME

dstebz - compute the eigenvalues of a symmetric tridiagonal matrix T

SYNOPSIS

```

```

PURPOSE

dstebz computes the eigenvalues of a symmetric tridiagonal matrix T. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its

largest element is no greater than $\text{overflow}^{1/2}$ *

$\text{underflow}^{1/4}$ in absolute value, and for greatest

accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

ARGUMENTS

* **RANGE** (*input*)

* **ORDER** (*input*)

* **N** (*input*)

The order of the tridiagonal matrix T. $N \geq 0$.

* **VL** (*input*)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. $VL < VU$. Not referenced if RANGE = 'A' or 'I'.

* **VU** (*input*)

See the description of VL.

* **IL** (*input*)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU** (*input*)

See the description of IL.

* **ABSTOL** (*input*)

The absolute tolerance for the eigenvalues. An eigenvalue (or cluster) is considered to be located if it has been determined to lie in an interval whose width is ABSTOL or less. If ABSTOL is less than or equal to zero, then

$ULP*|T|$ will be used, where $|T|$ means the 1-norm of T .

Eigenvalues will be computed most accurately when $ABSTOL$ is set to twice the underflow threshold $2*SLAMCH('S')$, not zero.

* ***D (input)***

The n diagonal elements of the tridiagonal matrix T .

* ***E (input)***

The $(n-1)$ off-diagonal elements of the tridiagonal matrix T .

* ***M (output)***

The actual number of eigenvalues found. $0 \leq M \leq N$. (See also the description of $INFO=2,3$.)

* ***NSPLIT (output)***

The number of diagonal blocks in the matrix T . $1 \leq NSPLIT \leq N$.

* ***W (output)***

On exit, the first M elements of W will contain the eigenvalues. (SSTEBZ may use the remaining $N-M$ elements as workspace.)

* ***IBLOCK (output)***

At each row/column j where $E(j)$ is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if $INFO = 0$, $IBLOCK(i)$ specifies to which block (from 1 to the number of blocks) the eigenvalue $W(i)$ belongs. (SSTEBZ may use the remaining $N-M$ elements as workspace.)

* ***ISPLIT (output)***

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to $ISPLIT(1)$, the second of rows/columns $ISPLIT(1)+1$ through $ISPLIT(2)$, etc., and the $NSPLIT$ -th consists of rows/columns $ISPLIT(NSPLIT-1)+1$ through $ISPLIT(NSPLIT)=N$. (Only the first $NSPLIT$ elements will actually be used, but since the user cannot know a priori what value $NSPLIT$ will have, N words must be reserved for $ISPLIT$.)

* ***WORK (workspace)***

dimension($4*N$)

* ***IWORK (workspace)***

dimension($3*N$)

* ***INFO (output)***

NAME

dstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

SYNOPSIS

```
SUBROUTINE DSTEDC( COMPZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,  
*      LIWORK, INFO)

DOUBLE PRECISION D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEDC( COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],  
*      [LIWORK], [INFO])  
CHARACTER(LEN=1) :: COMPZ  
INTEGER :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER, DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z  
  
SUBROUTINE STEDC_64( COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK],  
*      [IWORK], [LIWORK], [INFO])  
CHARACTER(LEN=1) :: COMPZ  
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO  
INTEGER(8), DIMENSION(:) :: IWORK  
REAL(8), DIMENSION(:) :: D, E, WORK  
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dstedc(char compz, int n, double *d, double *e, double *z, int ldz, int *info);
```

```
void dstedc_64(char compz, long n, double *d, double *e, double *z, long ldz, long *info);
```

PURPOSE

dstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The dimension of the symmetric tridiagonal matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if $COMPZ = 'V'$, then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if $INFO = 0$, then if $COMPZ = 'V'$, Z contains the orthonormal eigenvectors of the original symmetric matrix, and if $COMPZ = 'I'$, Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $COMPZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$. If eigenvectors are desired, then $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

dimension (LWORK) On exit, if $INFO = 0$, $WORK(1)$ returns the optimal LWORK.

* **LWORK** (*input*)

The dimension of the array WORK. If $COMPZ = 'N'$ or $N \leq 1$ then LWORK must be at least 1. If $COMPZ = 'V'$ and $N > 1$ then LWORK must be at least $(1 + 3*N + 2*N*\lg N + 3*N**2)$, where $\lg(N) =$ smallest integer k such that $2**k \geq N$. If $COMPZ = 'I'$ and $N > 1$ then LWORK must be at least $(1 + 4*N + N**2)$.

If $LWORK = -1$, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

*** *IWORK* (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

*** *LIWORK* (input)**

The dimension of the array IWORK. If COMPZ = 'N' or $N \leq 1$ then LIWORK must be at least 1. If COMPZ = 'V' and $N > 1$ then LIWORK must be at least $(6 + 6*N + 5*N*\lg N)$. If COMPZ = 'I' and $N > 1$ then LIWORK must be at least $(3 + 5*N)$.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

*** *INFO* (output)**

NAME

dstegr - (a) Compute $T\text{-}\sigma_i = L_i D_i L_i^T$, such that $L_i D_i L_i^T$ is a relatively robust representation

SYNOPSIS

```
SUBROUTINE DSTEGR( JOBZ, RANGE, N, D, E, VL, VU, IL, IU, ABSTOL, M,

#include <sunperf.h>
```

```
void dstegr(char jobz, char range, int n, double *d, double *e, double vl, double vu, int il, int iu, double abstol, int *m, double *w, double *z, int ldz, int *isuppz, int *info);
```

```
void dstegr_64(char jobz, char range, long n, double *d, double *e, double vl, double vu, long il, long iu, double abstol, long *m, double *w, double *z, long ldz, long *isuppz, long *info);
```

PURPOSE

dstegr b) Compute the eigenvalues, λ_j , of $L_i D_i L_i^T$ to high relative accuracy by the dqds algorithm,

- (c) If there is a cluster of close eigenvalues, "choose" σ_i close to the cluster, and go to step (a),
- (d) Given the approximate eigenvalue λ_j of $L_i D_i L_i^T$, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new $O(n^2)$ algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently SSTEGR is only set up to find ALL the n eigenvalues and eigenvectors of T in $O(n^2)$ time

Note 2 : Currently the routine SSTEIN is called when an appropriate σ_i cannot be chosen in step (c) above. SSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : SSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

* **JOBZ** (*input*)

* **RANGE** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix T . On exit, D is overwritten.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 1 to $N-1$ of E ; $E(N)$ need not be set. On exit, E is overwritten.

* **VL** (*input*)

If $RANGE='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $VL < VU$. Not referenced

if RANGE = 'A' or 'I'.

* **VU (input)**

See the description of VL.

* **IL (input)**

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. $1 \leq IL \leq IU \leq N$, if $N > 0$; $IL = 1$ and $IU = 0$ if $N = 0$. Not referenced if RANGE = 'A' or 'V'.

* **IU (input)**

See the description of IL.

* **ABSTOL (input)**

The absolute error tolerance for the eigenvalues/eigenvectors. If JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than $N \cdot \text{EPS} \cdot |T|$, then $N \cdot \text{EPS} \cdot |T|$ will be used in its place, where EPS is the machine precision and $|T|$ is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of $\text{EPS} \cdot |T|$ irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

* **M (output)**

The total number of eigenvalues found. $0 \leq M \leq N$. If RANGE = 'A', $M = N$, and if RANGE = 'I', $M = IU - IL + 1$.

* **W (output)**

The first M elements contain the selected eigenvalues in ascending order.

* **Z (input)**

If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least $\max(1, M)$ columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

* **LDZ (input)**

The leading dimension of the array Z. $LDZ \geq 1$, and if JOBZ = 'V', $LDZ \geq \max(1, N)$.

* **ISUPPZ (output)**

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ($2 \cdot i - 1$) through ISUPPZ($2 \cdot i$).

* **WORK (workspace)**

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

* **LWORK (input)**

The dimension of the array WORK. $LWORK \geq \max(1, 18 \cdot N)$

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

* **IWORK (workspace)**

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

* **LIWORK (input)**

The dimension of the array IWORK. $LIWORK \geq \max(1, 10 \cdot N)$

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

* **INFO (output)**

NAME

dstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

SYNOPSIS

```
SUBROUTINE DSTEIN( N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,
*      IWORK, IFAIL, INFO)
INTEGER N, M, LDZ, INFO
INTEGER IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
DOUBLE PRECISION D(*), E(*), W(*), Z(LDZ,*), WORK(*)

SUBROUTINE DSTEIN_64( N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,
*      IWORK, IFAIL, INFO)
INTEGER*8 N, M, LDZ, INFO
INTEGER*8 IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
DOUBLE PRECISION D(*), E(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEIN( N, D, E, M, W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],
*      [IWORK], IFAIL, [INFO])
INTEGER :: N, M, LDZ, INFO
INTEGER, DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL(8), DIMENSION(:) :: D, E, W, WORK
REAL(8), DIMENSION(:,) :: Z

SUBROUTINE STEIN_64( N, D, E, M, W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],
*      [IWORK], IFAIL, [INFO])
INTEGER(8) :: N, M, LDZ, INFO
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL(8), DIMENSION(:) :: D, E, W, WORK
REAL(8), DIMENSION(:,) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dstein(int n, double *d, double *e, int m, double *w, int *iblock, int *isplit, double *z, int ldz, int *ifail, int *info);
```

```
void dstein_64(long n, double *d, double *e, long m, double *w, long *iblock, long *isplit, double *z, long ldz, long *ifail, long *info);
```

PURPOSE

dstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

ARGUMENTS

* ***N (input)***

The order of the matrix. $N \geq 0$.

* ***D (input)***

The n diagonal elements of the tridiagonal matrix T.

* ***E (input)***

The (n-1) subdiagonal elements of the tridiagonal matrix T, in elements 1 to N-1. E(N) need not be set.

* ***M (input)***

The number of eigenvectors to be found. $0 \leq M \leq N$.

* ***W (input)***

The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBSZ with ORDER = 'B' is expected here.)

* ***IBLOCK (input)***

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBSZ is expected here.)

* ***ISPLIT (input)***

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBSZ is expected here.)

* ***Z (output)***

The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations.

* ***LDZ (input)***

The leading dimension of the array Z. $LDZ \geq \max(1,N)$.

* ***WORK (workspace)***

dimension(5*N)

* ***IWORK (workspace)***

dimension(N)

* ***IFAIL (output)***

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

* ***INFO (output)***

NAME

dsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```
SUBROUTINE DSTEQR( COMPZ, N, D, E, Z, LDZ, WORK, INFO)

```

```
void dsteqr(char compz, int n, double *d, double *e, double *z, int ldz, int *info);
```

```
void dsteqr_64(char compz, long n, double *d, double *e, double *z, long ldz, long *info);
```

PURPOSE

dsteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

* **COMPZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **D** (*input/output*)

On entry, the diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **E** (*input/output*)

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* **Z** (*input*)

On entry, if $COMPZ = 'V'$, then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if $INFO = 0$, then if $COMPZ = 'V'$, Z contains the orthonormal eigenvectors of the original symmetric matrix, and if $COMPZ = 'I'$, Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $COMPZ = 'N'$, then Z is not referenced.

* **LDZ** (*input*)

The leading dimension of the array Z. $LDZ \geq 1$, and if eigenvectors are desired, then $LDZ \geq \max(1, N)$.

* **WORK** (*workspace*)

If $COMPZ = 'N'$, then WORK is not referenced.

* **INFO** (*output*)

NAME

dsterf - compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm

SYNOPSIS

```
SUBROUTINE DSTERF( N, D, E, INFO)

void dsterf_64(long n, double *d, double *e, long *info);
```

PURPOSE

dsterf computes all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm.

ARGUMENTS

* *N (input)*

The order of the matrix. $N \geq 0$.

* *D (input/output)*

On entry, the n diagonal elements of the tridiagonal matrix. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* *E (input/output)*

On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

* *INFO (output)*

NAME

dstev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

SYNOPSIS

```
SUBROUTINE DSTEV( JOBZ, N, DIAG, OFFD, Z, LDZ, WORK, INFO)
CHARACTER * 1 JOBZ
INTEGER N, LDZ, INFO
DOUBLE PRECISION DIAG(*), OFFD(*), Z(LDZ,*), WORK(*)
```

```
SUBROUTINE DSTEV_64( JOBZ, N, DIAG, OFFD, Z, LDZ, WORK, INFO)
CHARACTER * 1 JOBZ
INTEGER*8 N, LDZ, INFO
DOUBLE PRECISION DIAG(*), OFFD(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEV( JOBZ, N, DIAG, OFFD, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ
INTEGER :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: DIAG, OFFD, WORK
REAL(8), DIMENSION(:, :) :: Z
```

```
SUBROUTINE STEV_64( JOBZ, N, DIAG, OFFD, Z, [LDZ], [WORK], [INFO])
CHARACTER(LEN=1) :: JOBZ
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: DIAG, OFFD, WORK
REAL(8), DIMENSION(:, :) :: Z
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dstev(char jobz, int n, double *diag, double *offd, double *z, int ldz, int *info);
```

```
void dstev_64(char jobz, long n, double *diag, double *offd, double *z, long ldz, long *info);
```

PURPOSE

dstev computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A.

ARGUMENTS

* **JOBZ** (*input*)

* **N** (*input*)

The order of the matrix. $N \geq 0$.

* **DIAG** (*input/output*)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if $INFO = 0$, the eigenvalues in ascending order.

* **OFFD** (*input/output*)
