                entries.  Values added for padding in Ellpack are
                not included in the Jagged-Diagonal format.

  INDX()        array of length NNZ consisting of the column indices
                of the corresponding entries in VAL.
  PNTR()        array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
                points to the location in VAL of the first element
                in the row-permuted Ellpack represenation of A.

  MAXNZ         max number of nonzeros elements per row.

  IPERM()       integer array of length M such that I = IPERM(I'),
                where row I in the original Ellpack representation
                corresponds to row I' in the permuted representation.
                If IPERM(1) = 0, it is assumed by convention that
                IPERM(I) = I. IPERM is used to determine the order
                in which rows of C are updated.

  B()           rectangular array with first dimension LDB.

  LDB           leading dimension of B

  BETA          Scalar parameter

  C()           rectangular array with first dimension LDC.

  LDC           leading dimension of C

  WORK()        scratch array of length LWORK. WORK is not
                referenced in the current version.

  LWORK         length of WORK array. LWORK is not referenced
                in the current version.

NAME

djadrp - right permutation of a jagged diagonal matrix

SYNOPSIS

```
 SUBROUTINE DJADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                     IPERM,WORK,LWORK)
 INTEGER    TRANSP, M, K, MAXNZ, LWORK
 INTEGER    INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
 DOUBLE PRECISION VAL(*)

 SUBROUTINE DJADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                     IPERM,WORK,LWORK)
 INTEGER*8  TRANSP, M, K, MAXNZ, LWORK
 INTEGER*8  INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
 DOUBLE PRECISION VAL(*)
```

F95 INTERFACE

```
 SUBROUTINE JADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
 INTEGER TRANSP, M, K,  MAXNZ
 INTEGER, DIMENSION(:) :: INDX, PNTR, IPERM
 DOUBLE PRECISION, DIMENSION(:) :: VAL

 SUBROUTINE JADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
 INTEGER*8 TRANSP, M, K,  MAXNZ
 INTEGER*8, DIMENSION(:) :: INDX, PNTR, IPERM
 DOUBLE PRECISION, DIMENSION(:) :: VAL
```

DESCRIPTION

```
A <- A P
A <- A P'
                                   ( ' indicates matrix transpose)
```

where permutation P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symetrically permuted jagged diagonal matrix P A P', one can explicitly permute the columns P A by calling

```
   SJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP — Indicates how to operate with the permutation matrix
  0 : operate with matrix
  1 : operate with transpose matrix

M — Number of rows in matrix A

K — Number of columns in matrix A

VAL() — array of length PNTR(MAXNZ+1)-PNTR(1) consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format.

INDX() — array of length PNTR(MAXNZ+1)-PNTR(1) consisting of the column indices of the corresponding entries in VAL.

PNTR() — array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack represenation of A.

MAXNZ — max number of nonzeros elements per row.

IPERM() — integer array of length K such that I = IPERM(I').

```
               Array IPERM represents a permutation P, such that
               IPERM(I) is equal to the position of the only nonzero
               element in row I of permutation matrix P.
               For example, if
                              | 0 0 1 |
                          P  =| 1 0 0 |
                              | 0 1 0 |
               then IPERM = (3, 1, 2).

 WORK()        scratch array of length LWORK.  LWORK should be at
               least K.

 LWORK         length of WORK array

               If LWORK = -1, then a workspace query is assumed;
               the routine only calculates the optimal size of the
               WORK array, returns this value as the first entry of
               the WORK array, and no error message related to LWORK
               is issued by XERBLA.
```

*            LDB, LDC, LWORK
 INTEGER    INDX(NNZ), PNTR(MAXNZ+1), IPERM(M)
 DOUBLE PRECISION ALPHA, BETA
 DOUBLE PRECISION DV(M), VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)

 SUBROUTINE DJADSM_64( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*            VAL, INDX, PNTR, MAXNZ, IPERM,
*            B, LDB, BETA, C, LDC, WORK, LWORK )
 INTEGER*8  TRANSA, M, N, UNITD, DESCRA(5), MAXNZ,
*            LDB, LDC, LWORK
 INTEGER*8  INDX(NNZ), PNTR(MAXNZ+1), IPERM(M)
 DOUBLE PRECISION ALPHA, BETA
 DOUBLE PRECISION DV(M), VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)

where NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 is the number of non-zero elements
```

F95 INTERFACE

```
 SUBROUTINE JADSM(TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL, INDX,
*    PNTR, MAXNZ, IPERM, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER    TRANSA, M, MAXNZ
 INTEGER, DIMENSION(:) ::  DESCRA, INDX, PNTR, IPERM
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) ::  VAL, DV
 DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

```
 SUBROUTINE JADSM_64(TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL, INDX,
*    PNTR, MAXNZ, IPERM, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, M, MAXNZ
 INTEGER*8, DIMENSION(:) ::  DESCRA, INDX, PNTR, IPERM
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) ::  VAL, DV
 DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in jagged-diagonal format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          array of length NNZ consisting of entries of A.
               VAL can be viewed as a column major ordering of a
               row permutation of the Ellpack representation of A,
               where the Ellpack representation is permuted so that
               the rows are non-increasing in the number of nonzero
               entries.  Values added for padding in Ellpack are
               not included in the Jagged-Diagonal format.

INDX()         array of length NNZ consisting of the column indices
               of the corresponding entries in VAL.

PNTR()         array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
               points to the location in VAL of the first element
               in the row-permuted Ellpack represenation of A.

MAXNZ          max number of nonzeros elements per row.

IPERM()        integer array of length M such that I = IPERM(I'),
               where row I in the original Ellpack representation
               corresponds to row I' in the permuted representation.
               If IPERM(1)=0,   it's assumed by convention that
               IPERM(I)=I. IPERM is used to determine the order
               in which rows of C are updated.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter
```

```
C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.
               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK          length of WORK array.  LWORK should be at least 2*M.

               For good performance, LWORK should generally be larger.
               For optimum performance on multiple processors, LWORK
               >=2*M*N_CPUS where N_CPUS is the maximum number of
               processors available to the program.

               If LWORK=0, the routine is to allocate workspace needed.

               If LWORK = -1, then a workspace query is assumed; the
               routine only calculates the optimum size of the WORK
               array, returns this value as the first entry of the WORK
               array, and no error message related to LWORK is issued
               by XERBLA.
```

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the JAD representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the JAD representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

NAME

```
dlagtf - factorize the matrix (T-lambda*I), where T is an  n
by  n  tridiagonal  matrix  and  lambda  is  a scalar, as T-
lambda*I = PLU
```

SYNOPSIS

```
SUBROUTINE DLAGTF(N, A, LAMBDA, B, C, TOL, D, IN, INFO)

INTEGER N, INFO
INTEGER IN(*)
DOUBLE PRECISION LAMBDA, TOL
DOUBLE PRECISION A(*), B(*), C(*), D(*)

SUBROUTINE DLAGTF_64(N, A, LAMBDA, B, C, TOL, D, IN, INFO)

INTEGER*8 N, INFO
INTEGER*8 IN(*)
DOUBLE PRECISION LAMBDA, TOL
DOUBLE PRECISION A(*), B(*), C(*), D(*)
```

F95 INTERFACE

```
SUBROUTINE LAGTF([N], A, LAMBDA, B, C, TOL, D, IN, [INFO])

INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IN
REAL(8) :: LAMBDA, TOL
REAL(8), DIMENSION(:) :: A, B, C, D

SUBROUTINE LAGTF_64([N], A, LAMBDA, B, C, TOL, D, IN, [INFO])

INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IN
```

```
REAL(8) :: LAMBDA, TOL
REAL(8), DIMENSION(:) :: A, B, C, D
```

C INTERFACE

```
#include <sunperf.h>

void dlagtf(int n, double *a, double lambda, double *b, dou-
          ble  *c,  double  tol,  double  *d,  int  *in, int
          *info);

void dlagtf_64(long n, double *a, double lambda, double  *b,
          double  *c,  double tol, double *d, long *in, long
          *info);
```

PURPOSE

dlagtf factorizes the matrix (T - lambda*I), where T is an n by n tridiagonal matrix and lambda is a scalar, as where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column.

The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling.

The parameter LAMBDA is included in the routine so that SLAGTF may be used, in conjunction with SLAGTS, to obtain eigenvectors of T by inverse iteration.

ARGUMENTS

N (input) The order of the matrix T.

A (input/output)
On entry, A must contain the diagonal elements of T.

On exit, A is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T.

LAMBDA (input)
On entry, the scalar lambda.

B (input/output)
On entry, B must contain the (n-1) super-diagonal

elements of T.

On exit, B is overwritten by the (n-1) super-diagonal elements of the matrix U of the factorization of T.

C (input/output)

On entry, C must contain the (n-1) sub-diagonal elements of T.

On exit, C is overwritten by the (n-1) sub-diagonal elements of the matrix L of the factorization of T.

TOL (input/output)

On entry, a relative tolerance used to indicate whether or not the matrix (T - lambda*I) is nearly singular. TOL should normally be chose as approximately the largest relative error in the elements of T. For example, if the elements of T are correct to about 4 significant figures, then TOL should be set to about 5*10**(-4). If TOL is supplied as less than eps, where eps is the relative machine precision, then the value eps is used in place of TOL.

D (output)

On exit, D is overwritten by the (n-2) second super-diagonal elements of the matrix U of the factorization of T.

IN (output)

On exit, IN contains details of the permutation matrix P. If an interchange occurred at the kth step of the elimination, then IN(k) = 1, otherwise IN(k) = 0. The element IN(n) returns the smallest positive integer j such that

abs(u(j,j)).le. norm((T - lambda*I)(j))*TOL,

where norm(A(j)) denotes the sum of the absolute values of the jth row of the matrix A. If no such j exists then IN(n) is returned as zero. If IN(n) is returned as positive, then a diagonal element of U is small, indicating that (T - lambda*I) is singular or nearly singular,

INFO (output)

= 0 : successful exit

Contents

NAME

```
dlamrg - will create a permutation list which will merge the
elements of A (which is composed of two independently sorted
sets) into a single set which is sorted in ascending order
```

SYNOPSIS

```
SUBROUTINE DLAMRG(N1, N2, A, TRD1, TRD2, INDEX)

INTEGER N1, N2, TRD1, TRD2
INTEGER INDEX(*)
DOUBLE PRECISION A(*)

SUBROUTINE DLAMRG_64(N1, N2, A, TRD1, TRD2, INDEX)

INTEGER*8 N1, N2, TRD1, TRD2
INTEGER*8 INDEX(*)
DOUBLE PRECISION A(*)
```

F95 INTERFACE

```
SUBROUTINE LAMRG(N1, N2, A, TRD1, TRD2, INDEX)

INTEGER :: N1, N2, TRD1, TRD2
INTEGER, DIMENSION(:) :: INDEX
REAL(8), DIMENSION(:) :: A

SUBROUTINE LAMRG_64(N1, N2, A, TRD1, TRD2, INDEX)

INTEGER(8) :: N1, N2, TRD1, TRD2
INTEGER(8), DIMENSION(:) :: INDEX
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dlamrg(int n1, int n2, double *a, int trd1,  int  trd2,
          int *index);

void dlamrg_64(long n1, long n2, double *a, long trd1,  long
          trd2, long *index);
```

PURPOSE

dlamrg will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

ARGUMENTS

N1 (input)
Length of the first sequence to be merged.

N2 (input)
Length of the second sequence to be merged.

A (input) On entry, the first N1 elements of A contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final N2 elements.

TRD1 (input)
Describes the stride to be taken through the array A for the first N1 elements.
= -1 subset is sorted in descending order.
= 1 subset is sorted in ascending order.

TRD2 (input)
Describes the stride to be taken through the array A for the first N1 elements.
= -1 subset is sorted in descending order.
= 1 subset is sorted in ascending order.

INDEX (output)
On exit this array will contain a permutation such that if B(I) = A(INDEX(I)) for I=1,N1+N2, then B will be sorted in ascending order.

NAME

dlarz - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right

SYNOPSIS

```
SUBROUTINE DLARZ(SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)

CHARACTER * 1 SIDE
INTEGER M, N, L, INCV, LDC
DOUBLE PRECISION TAU
DOUBLE PRECISION V(*), C(LDC,*), WORK(*)

SUBROUTINE DLARZ_64(SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)

CHARACTER * 1 SIDE
INTEGER*8 M, N, L, INCV, LDC
DOUBLE PRECISION TAU
DOUBLE PRECISION V(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE LARZ(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])

CHARACTER(LEN=1) :: SIDE
INTEGER :: M, N, L, INCV, LDC
REAL(8) :: TAU
REAL(8), DIMENSION(:) :: V, WORK
REAL(8), DIMENSION(:,:) :: C

SUBROUTINE LARZ_64(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])

CHARACTER(LEN=1) :: SIDE
```

```
INTEGER(8) :: M, N, L, INCV, LDC
REAL(8) :: TAU
REAL(8), DIMENSION(:) :: V, WORK
REAL(8), DIMENSION(:,:) :: C
```

C INTERFACE

```
#include <sunperf.h>

void dlarz(char side, int m, int n, int l,  double  *v,  int
          incv, double tau, double *c, int ldc);

void dlarz_64(char side, long m, long n, long l, double  *v,
          long incv, double tau, double *c, long ldc);
```

PURPOSE

dlarz applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right. H is represented in the form

```
      H = I - tau * v * v'
```

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

H is a product of k elementary reflectors as returned by STZRZF.

ARGUMENTS

```
SIDE (input)
          = 'L': form  H * C
          = 'R': form  C * H

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

L (input) The number of entries of the vector  V  containing
          the  meaningful  part  of the Householder vectors.
          If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >=  L
          >= 0.

V (input) The  vector  v  in  the  representation  of  H  as
          returned by STZRZF. V is not used if TAU = 0.
```

```
INCV (input)
          The increment between elements of v. INCV <> 0.

TAU (input)
          The value tau in the representation of H.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten  by the matrix H * C if SIDE = 'L', or
          C * H if SIDE = 'R'.
LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          (N) if SIDE = 'L' or (M) if SIDE = 'R'

          ldc, long ldwork);
```

PURPOSE

dlarzb applies a real block reflector H or its transpose H**T to a real distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

SIDE (input)
= 'L': apply H or H' from the Left
= 'R': apply H or H' from the Right

TRANS (input)
= 'N': apply H (No transpose)
= 'C': apply H' (Transpose)

DIRECT (input)
Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet)
= 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV (input)
Indicates how the vectors which define the elementary reflectors are stored:
= 'C': Columnwise (not sup-

ported yet)
= 'R': Rowwise

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

K (input) The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L (input) The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V (input) If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV (input)
The leading dimension of the array V. If STOREV = 'C', LDV >= L; if STOREV = 'R', LDV >= K.

T (input) The triangular K-by-K matrix T in the representation of the block reflector.

LDT (input)
The leading dimension of the array T. LDT >= K.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by H*C or H'*C or C*H or C*H'.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
dimension(MAX(M,N),K)

LDWORK (input)
The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1,N); if SIDE = 'R', LDWORK >= max(1,M).

NAME

dlarzt - form the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors

SYNOPSIS

```
SUBROUTINE DLARZT(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)

CHARACTER * 1 DIRECT, STOREV
INTEGER N, K, LDV, LDT
DOUBLE PRECISION V(LDV,*), TAU(*), T(LDT,*)

SUBROUTINE DLARZT_64(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)

CHARACTER * 1 DIRECT, STOREV
INTEGER*8 N, K, LDV, LDT
DOUBLE PRECISION V(LDV,*), TAU(*), T(LDT,*)
```

F95 INTERFACE

```
SUBROUTINE LARZT(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])

CHARACTER(LEN=1) :: DIRECT, STOREV
INTEGER :: N, K, LDV, LDT
REAL(8), DIMENSION(:) :: TAU
REAL(8), DIMENSION(:,:) :: V, T

SUBROUTINE LARZT_64(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])

CHARACTER(LEN=1) :: DIRECT, STOREV
INTEGER(8) :: N, K, LDV, LDT
REAL(8), DIMENSION(:) :: TAU
```

```
REAL(8), DIMENSION(:,:) :: V, T
```

C INTERFACE

```
#include <sunperf.h>

void dlarzt(char direct, char storev, int n, int  k,  double
          *v, int ldv, double *tau, double *t, int ldt);

void dlarzt_64(char direct, char storev,  long  n,  long  k,
          double  *v, long ldv, double *tau, double *t, long
          ldt);
```

PURPOSE

dlarzt forms the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

```
H  =  I - V * T * V'
```

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

```
H  =  I - V' * T * V
```

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

DIRECT (input)
Specifies the order in which the elementary reflectors are multiplied to form the block reflector:
= 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet)
= 'B': H = H(k) . . . H(2) H(1) (Backward)

```
STOREV (input)
          Specifies how the vectors which define the elemen-
          tary  reflectors  are  stored  (see  also  Further
          Details):
          = 'R': rowwise

N (input) The order of the block reflector H. N >= 0.

K (input) The order of the triangular factor T (= the number
          of elementary reflectors). K >= 1.

V (input) (LDV,K) if STOREV = 'C' (LDV,N) if  STOREV  =  'R'
          The matrix V. See further details.

LDV (input)
          The leading dimension of the array V.  If STOREV =
          'C', LDV >= max(1,N); if STOREV = 'R', LDV >= K.

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i).

T (input) The k by  k  triangular  factor  T  of  the  block
          reflector.   If  DIRECT = 'F', T is upper triangu-
          lar; if DIRECT = 'B', T is lower  triangular.  The
          rest of the array is not used.

LDT (input)
          The leading dimension of the array T. LDT >= K.
```

FURTHER DETAILS

```
Based on contributions by
  A. Petitet, Computer Science Dept., Univ. of Tenn.,  Knox-
ville, USA

The shape of the matrix V and the  storage  of  the  vectors
which  define  the H(i) is best illustrated by the following
example with n = 5 and k = 3. The elements equal  to  1  are
not  stored;  the  corresponding array elements are modified
but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV =  'C':          DIRECT  =  'F'  and
STOREV = 'R':

                                                ______V_____
       (    v1    v2    v3    )                            /
( v1 v2 v3 )                        ( v1 v1 v1 v1 v1 . . . . 1
)
   V = ( v1 v2 v3 )                        ( v2 v2 v2 v2 v2  .
```

```
. . 1   )
       ( v1 v2 v3 )                      ( v3 v3 v3 v3 v3  .
. 1     )
       ( v1 v2 v3 )
          .  .  .
          1  .  .
             1  .
                1

DIRECT = 'B' and STOREV =  'C':          DIRECT  =  'B'  and
STOREV = 'R':

                                                      ______V_____
          1                                                /
.  1                           ( 1 . . . . v1 v1 v1 v1 v1 )
          .  .  1                        ( . 1 . . .  v2  v2
v2 v2 v2 )
          .  .  .                        ( . . 1 . .  v3  v3
v3 v3 v3 )
          .  .  .
       ( v1 v2 v3 )
   V = ( v1 v2 v3 )
       ( v1 v2 v3 )

C INTERFACE

```
#include <sunperf.h>
```

```
void dlasrt(char id, int n, double *d, int *info);

void dlasrt_64(char id, long n, double *d, long *info);
```

PURPOSE

```
dlasrt the numbers in D in increasing order (if ID = 'I') or
in decreasing order (if ID = 'D' ).

Use Quick Sort, reverting to Insertion sort on arrays of
size <= 20. Dimension of STACK limits N to about 2**32.
```

ARGUMENTS

```
ID (input)
          = 'I': sort D in increasing order;
          = 'D': sort D in decreasing order.

N (input) The length of the array D.

D (input/output)
          On entry, the array to be sorted.  On exit, D  has
          been  sorted into increasing order (D(1) <= ... <=
          D(N) ) or into decreasing order (D(1)  >=  ...  >=
          D(N) ), depending on ID.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

REAL(8), DIMENSION(:,:) :: C1, C2
```

C INTERFACE

```
#include <sunperf.h>

void dlatzm(char side, int m, int n, double  *v,  int  incv,
          double tau, double *c1, double *c2, int ldc);

void dlatzm_64(char side, long m, long n,  double  *v,  long
          incv,  double  tau,  double  *c1, double *c2, long
          ldc);
```

PURPOSE

dlatzm routine is deprecated and has been replaced by routine SORMRZ.

SLATZM applies a Householder matrix generated by STZRQF to a matrix.

```
Let P = I - tau*u*u',   u = ( 1 ),
                            ( v )
where v is an (m-1) vector if SIDE = 'L', or a (n-1)  vector
if SIDE = 'R'.

If SIDE equals 'L', let
       C = [ C1 ] 1
           [ C2 ] m-1
             n
Then C is overwritten by P*C.

If SIDE equals 'R', let
       C = [ C1, C2 ] m
              1  n-1
Then C is overwritten by C*P.
```

ARGUMENTS

```
SIDE (input)
          = 'L': form P * C
          = 'R': form C * P
```

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

V (input) (1 + (M-1)*abs(INCV)) if SIDE = 'L' (1 + (N-1)*abs(INCV)) if SIDE = 'R' The vector v in the representation of P. V is not used if TAU = 0.

INCV (input)
The increment between elements of v. INCV <> 0

TAU (input)
The value tau in the representation of P.

C1 (input/output)
(LDC,N) if SIDE = 'L' (M,1) if SIDE = 'R' On entry, the n-vector C1 if SIDE = 'L', or the m-vector C1 if SIDE = 'R'.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

C2 (input/output)
(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

LDC (input)
The leading dimension of the arrays C1 and C2. LDC >= (1,M).

WORK (workspace)
(N) if SIDE = 'L' (M) if SIDE = 'R'

Contents

NAME

```
dnrm2 - Return the Euclidian norm of a vector.
```

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DNRM2(N, X, INCX)

INTEGER N, INCX
DOUBLE PRECISION X(*)

DOUBLE PRECISION FUNCTION DNRM2_64(N, X, INCX)

INTEGER*8 N, INCX
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION NRM2([N], X, [INCX])

INTEGER :: N, INCX
REAL(8), DIMENSION(:) :: X

REAL(8) FUNCTION NRM2_64([N], X, [INCX])

INTEGER(8) :: N, INCX
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>

double dnrm2(int n, double *x, int incx);

double dnrm2_64(long n, double *x, long incx);
```

PURPOSE

dnrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

void dopgtr_64(char uplo, long n, double *ap,  double  *tau,
          double *q, long ldq, long *info);
```

PURPOSE

dopgtr generates a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by SSPTRD using packed storage:
if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

ARGUMENTS

UPLO (input)
= 'U': Upper triangular packed storage used in previous call to SSPTRD; = 'L': Lower triangular packed storage used in previous call to SSPTRD.

N (input) The order of the matrix Q. N >= 0.

AP (input)
The vectors which define the elementary reflectors, as returned by SSPTRD.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

Q (output)
The N-by-N orthogonal matrix Q.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N).

WORK (workspace)
dimension(N-1)

INFO (output)

       [WORK], [INFO])

CHARACTER(LEN=1) :: SIDE, UPLO, TRANS
INTEGER :: M, N, LDC, INFO
REAL(8), DIMENSION(:) :: AP, TAU, WORK
REAL(8), DIMENSION(:,:) :: C

SUBROUTINE OPMTR_64(SIDE, UPLO, [TRANS], [M], [N], AP, TAU, C, [LDC],
       [WORK], [INFO])

CHARACTER(LEN=1) :: SIDE, UPLO, TRANS
```

```
INTEGER(8) :: M, N, LDC, INFO
REAL(8), DIMENSION(:) :: AP, TAU, WORK
REAL(8), DIMENSION(:,:) :: C
```

C INTERFACE

```
#include <sunperf.h>

void dopmtr(char side, char uplo, char trans, int m, int  n,
          double  *ap,  double *tau, double *c, int ldc, int
          *info);

void dopmtr_64(char side, char uplo,  char  trans,  long  m,
          long  n,  double *ap, double *tau, double *c, long
          ldc, long *info);
```

PURPOSE

dopmtr overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by SSPTRD using packed storage:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

ARGUMENTS

SIDE (input)
          = 'L': apply Q or Q**T from the Left;
          = 'R': apply Q or Q**T from the Right.

UPLO (input)
          = 'U': Upper triangular packed storage used in previous call to SSPTRD; = 'L': Lower triangular packed storage used in previous call to SSPTRD.

TRANS (input)
          = 'N': No transpose, apply Q;
          = 'T': Transpose, apply Q**T.

          TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

AP (input)
(M*(M+1)/2) if SIDE = 'L' (N*(N+1)/2) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSPTRD. AP is modified by the routine but restored on exit.

TAU (input)
or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dorg2l(int m, int n, int k, double *a, int lda,  double
```

```
          *tau, int *info);

void dorg2l_64(long m, long n, long k, double *a, long  lda,
          double *tau, long *info);
```

PURPOSE

dorg2l L generates an m by n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

```
      Q  =  H(k) . . . H(2) H(1)
```

as returned by SGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)
On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQLF in the last k columns of its array argument A. On exit, the m by n matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

WORK (workspace)
dimension(N)

INFO (output)

INTEGER*8 M, N, K, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGBR(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: VECT
INTEGER :: M, N, K, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE ORGBR_64(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: VECT
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

```
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dorgbr(char vect, int m, int n, int k, double  *a,  int
          lda, double *tau, int *info);

void dorgbr_64(char vect, long m, long n, long k, double *a,
          long lda, double *tau, long *info);
```

PURPOSE

dorgbr generates one of the real orthogonal matrices Q or P**T determined by SGEBRD when reducing a real matrix A to bidiagonal form: A = Q * B * P**T. Q and P**T are defined as products of elementary reflectors H(i) or G(i) respectively.

If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q is of order M:
if m >= k, Q = H(1) H(2) . . . H(k) and SORGBR returns the first n columns of Q, where m >= n >= k;
if m < k, Q = H(1) H(2) . . . H(m-1) and SORGBR returns Q as an M-by-M matrix.

If VECT = 'P', A is assumed to have been a K-by-N matrix, and P**T is of order N:
if k < n, P**T = G(k) . . . G(2) G(1) and SORGBR returns the first m rows of P**T, where n >= m >= k;
if k >= n, P**T = G(n-1) . . . G(2) G(1) and SORGBR returns P**T as an N-by-N matrix.

ARGUMENTS

VECT (input)
Specifies whether the matrix Q or the matrix P**T is required, as defined in the transformation applied by SGEBRD:
= 'Q': generate Q;
= 'P': generate P**T.

M (input) The number of rows of the matrix Q or P**T to be returned. M >= 0.

N (input) The number of columns of the matrix Q or P**T to

```
          be  returned.   N  >= 0.  If VECT = 'Q', M >= N >=
          min(M,K); if VECT = 'P', N >= M >= min(N,K).

K (input) If VECT = 'Q', the number of columns in the origi-
          nal  M-by-K  matrix  reduced by SGEBRD.  If VECT =
          'P', the number of rows  in  the  original  K-by-N
          matrix reduced by SGEBRD.  K >= 0.

A (input/output)
          On entry, the vectors which define the  elementary
          reflectors,  as  returned by SGEBRD.  On exit, the
          M-by-N matrix Q or P**T.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).

TAU (input)
          (min(M,K)) if VECT = 'Q' (min(N,K)) if VECT =  'P'
          TAU(i)  must contain the scalar factor of the ele-
          mentary reflector H(i) or G(i), which determines Q
          or  P**T, as returned by SGEBRD in its array argu-
          ment TAUQ or TAUP.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  dimension  of  the  array  WORK.   LWORK   >=
          max(1,min(M,N)).  For optimum performance LWORK >=
          min(M,N)*NB, where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

NAME

```
dorghr - generate  a  real  orthogonal  matrix  Q  which  is
defined  as  the product of IHI-ILO elementary reflectors of
order N, as returned by SGEHRD
```

SYNOPSIS

```
SUBROUTINE DORGHR(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER N, ILO, IHI, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)

SUBROUTINE DORGHR_64(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGHR([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK], [INFO])

INTEGER :: N, ILO, IHI, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE ORGHR_64([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorghr(int n, int ilo, int ihi,  double  *a,  int  lda,
          double *tau, int *info);

void dorghr_64(long n, long ilo, long ihi, double  *a,  long
          lda, double *tau, long *info);
```

PURPOSE

dorghr generates a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

ARGUMENTS

N (input) The order of the matrix Q. N >= 0.

ILO (input)
ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description of ILO.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by SGEHRD. On exit, the N-by-N orthogonal matrix Q.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= IHI-ILO. For optimum performance LWORK >= (IHI-ILO)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE DORGR2(M, N, K, A, LDA, TAU, WORK, INFO)

INTEGER M, N, K, LDA, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)

SUBROUTINE DORGR2_64(M, N, K, A, LDA, TAU, WORK, INFO)

INTEGER*8 M, N, K, LDA, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGR2([M], [N], [K], A, [LDA], TAU, [WORK], [INFO])

INTEGER :: M, N, K, LDA, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE ORGR2_64([M], [N], [K], A, [LDA], TAU, [WORK], [INFO])

INTEGER(8) :: M, N, K, LDA, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dorgr2(int m, int n, int k, double *a, int lda,  double
```

```
          *tau, int *info);

void dorgr2_64(long m, long n, long k, double *a, long  lda,
          double *tau, long *info);
```

PURPOSE

dorgr2 generates an m by n real matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

```
      Q  =  H(1) H(2) . . . H(k)
```

as returned by SGERQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)
On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGERQF in the last k rows of its array argument A. On exit, the m by n matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

WORK (workspace)
dimension(M)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument has an illegal value

SUBROUTINE ORGRQ_64(M, [N], [K], A, [LDA], TAU, [WORK], [LDWORK],
       [INFO])

INTEGER(8) :: M, N, K, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dorgrq(int m, int n, int k, double *a, int lda,  double
          *tau, int *info);

void dorgrq_64(long m, long n, long k, double *a, long  lda,
          double *tau, long *info);
```

PURPOSE

dorgrq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

```
      Q  =  H(1) H(2) . . . H(k)
```

as returned by SGERQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)
On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB,

```
            where NB is the optimal blocksize.

            If LDWORK = -1, then a workspace query is assumed;
            the  routine  only  calculates the optimal size of
            the WORK array, returns this value  as  the  first
            entry  of  the  WORK  array,  and no error message
            related to LDWORK is issued by XERBLA.

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument has an ille-
            gal value
```

NAME

```
dorgtr - generate  a  real  orthogonal  matrix  Q  which  is
defined as the product of n-1 elementary reflectors of order
N, as returned by SSYTRD
```

SYNOPSIS

```
SUBROUTINE DORGTR(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)

CHARACTER * 1 UPLO
INTEGER N, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)

SUBROUTINE DORGTR_64(UPLO, N, A, LDA, TAU, WORK, LWORK, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGTR(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE ORGTR_64(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dorgtr(char uplo, int n, double  *a,  int  lda,  double
          *tau, int *info);

void dorgtr_64(char uplo, long n, double *a, long lda,  dou-
          ble *tau, long *info);
```

PURPOSE

dorgtr generates a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD:
if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A contains elementary reflectors from SSYTRD; = 'L': Lower triangle of A contains elementary reflectors from SSYTRD.

N (input) The order of the matrix Q. N >= 0.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by SSYTRD. On exit, the N-by-N orthogonal matrix Q.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSYTRD.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >=

max(1,N-1). For optimum performance LWORK >= (N-1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

CHARACTER * 1 VECT, SIDE, TRANS
INTEGER*8 M, N, K, LDA, LDC, LWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORMBR(VECT, SIDE, [TRANS], [M], [N], K, A, [LDA], TAU, C,
       [LDC], [WORK], [LWORK], [INFO])

CHARACTER(LEN=1) :: VECT, SIDE, TRANS
INTEGER :: M, N, K, LDA, LDC, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A, C

SUBROUTINE ORMBR_64(VECT, SIDE, [TRANS], [M], [N], K, A, [LDA], TAU,
       C, [LDC], [WORK], [LWORK], [INFO])

CHARACTER(LEN=1) :: VECT, SIDE, TRANS
```

```
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A, C
```

C INTERFACE

```
#include <sunperf.h>

void dormbr(char vect, char side, char trans, int m, int  n,
          int k, double *a, int lda, double *tau, double *c,
          int ldc, int *info);

void dormbr_64(char vect, char side,  char  trans,  long  m,
          long  n, long k, double *a, long lda, double *tau,
          double *c, long ldc, long *info);
```

PURPOSE

```
dormbr VECT = 'Q', SORMBR overwrites the general real M-by-N
matrix C with
                SIDE = 'L'      SIDE  =  'R'  TRANS  =  'N':
Q  *  C           C * Q TRANS = 'T':      Q**T * C       C *
Q**T

If VECT = 'P', SORMBR overwrites  the  general  real  M-by-N
matrix C with
                SIDE = 'L'     SIDE = 'R'
TRANS = 'N':      P * C          C * P
TRANS = 'T':      P**T * C       C * P**T
```

Here Q and P**T are the orthogonal matrices determined by SGEBRD when reducing a real matrix A to bidiagonal form: A = Q * B * P**T. Q and P**T are defined as products of elementary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the order of the orthogonal matrix Q or P**T that is applied.

```
If VECT = 'Q', A is assumed to have been an NQ-by-K  matrix:
if nq >= k, Q = H(1) H(2) . . . H(k);
if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a  K-by-NQ  matrix:
if k < nq, P = G(1) G(2) . . . G(k);
if k >= nq, P = G(1) G(2) . . . G(nq-1).
```

ARGUMENTS

```
VECT (input)
          = 'Q': apply Q or Q**T;
          = 'P': apply P or P**T.

SIDE (input)
          = 'L': apply Q, Q**T, P or P**T from the Left;
          = 'R': apply Q, Q**T, P or P**T from the Right.

TRANS (input)
          = 'N':  No transpose, apply Q  or P;
          = 'T':  Transpose, apply Q**T or P**T.

          TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.
N (input) The number of columns of the matrix C. N >= 0.

K (input) If VECT = 'Q', the number of columns in the origi-
          nal  matrix reduced by SGEBRD.  If VECT = 'P', the
          number of rows in the original matrix  reduced  by
          SGEBRD.  K >= 0.

A (input) (LDA,min(nq,K)) if VECT = 'Q'  (LDA,nq)         if
          VECT = 'P' The vectors which define the elementary
          reflectors H(i) and G(i), whose products determine
          the matrices Q and P, as returned by SGEBRD.

LDA (input)
          The leading dimension of the array A.  If  VECT  =
          'Q',  LDA  >=  max(1,nq);  if  VECT  = 'P', LDA >=
          max(1,min(nq,K)).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary  reflector H(i) or G(i) which determines Q
          or P, as returned by SGEBRD in the array  argument
          TAUQ or TAUP.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten  by  Q*C or Q**T*C or C*Q**T or C*Q or
          P*C or P**T*C or C*P or C*P**T.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
```

LWORK.

LWORK (input)

The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void dormhr(char side, char trans, int m, int  n,  int  ilo,
          int  ihi,  double *a, int lda, double *tau, double
          *c, int ldc, int *info);

void dormhr_64(char side, char trans, long m, long  n,  long
          ilo,  long  ihi, double *a, long lda, double *tau,
          double *c, long ldc, long *info);
```

PURPOSE

dormhr overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by SGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

ILO (input)
ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix   except   in   the   submatrix

```
          Q(ilo+1:ihi,ilo+1:ihi).   If SIDE = 'L', then 1 <=
          ILO <= IHI <= M, if M > 0, and ILO = 1 and  IHI  =
          0,  if  M = 0; if SIDE = 'R', then 1 <= ILO <= IHI
          <= N, if N > 0, and ILO = 1 and IHI = 0, if N = 0.

IHI (input)
          See the description of ILO.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE  =  'R'  The
          vectors which define the elementary reflectors, as
          returned by SGEHRD.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M)  if SIDE = 'L'; LDA >= max(1,N) if SIDE =
          'R'.

TAU (input)
          (M-1) if SIDE = 'L' (N-1) if  SIDE  =  'R'  TAU(i)
          must  contain  the scalar factor of the elementary
          reflector H(i), as returned by SGEHRD.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

          The leading dimension  of  the  array  A.  LDA  >=
          max(1,K).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by SGELQF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

```
dormql overwrites the general  real  M-by-N  matrix  C  with
TRANS = 'T':      Q**T * C       C * Q**T

where Q is a real orthogonal matrix defined as  the  product
of k elementary reflectors

      Q = H(k) . . . H(2) H(1)

as returned by SGEQLF. Q is of order M if SIDE = 'L' and  of
order N if SIDE = 'R'.
```

ARGUMENTS

```
SIDE (input)
          = 'L': apply Q or Q**T from the Left;
          = 'R': apply Q or Q**T from the Right.

TRANS (input)
          = 'N':  No transpose, apply Q;
          = 'T':  Transpose, apply Q**T.

          TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose  product
          defines the matrix Q.  If SIDE = 'L', M >= K >= 0;
          if SIDE = 'R', N >= K >= 0.
```

```
A (input) The i-th column  must  contain  the  vector  which
          defines  the  elementary  reflector  H(i), for i =
          1,2,...,k, as returned by SGEQLF  in  the  last  k
          columns of its array argument A.  A is modified by
          the routine but restored on exit.

LDA (input)
          The leading dimension of the array A.  If  SIDE  =
          'L',  LDA  >=  max(1,M);  if  SIDE  =  'R', LDA >=
          max(1,N).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by SGEQLF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

PURPOSE

dormqr overwrites the general real M-by-N matrix C with
TRANS = 'T': Q**T * C C * Q**T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

Q = H(1) H(2) . . . H(k)

as returned by SGEQRF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

```
A (input) The i-th column  must  contain  the  vector  which
          defines  the  elementary  reflector  H(i), for i =
          1,2,...,k, as returned by SGEQRF in  the  first  k
          columns of its array argument A.  A is modified by
          the routine but restored on exit.

LDA (input)
          The leading dimension of the array A.  If  SIDE  =
          'L',  LDA  >=  max(1,M);  if  SIDE  =  'R', LDA >=
          max(1,N).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by SGEQRF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

PURPOSE

dormrq overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

      Q = H(1) H(2) . . . H(k)

as returned by SGERQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

```
A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE =  'R'  The
          i-th row must contain the vector which defines the
          elementary reflector H(i), for i =  1,2,...,k,  as
          returned by SGERQF in the last k rows of its array
          argument A.  A is  modified  by  the  routine  but
          restored on exit.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,K).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by SGERQF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

          k,  long l, double *a, long lda, double *tau, dou-
          ble *c, long ldc, long *info);
```

PURPOSE

dormrz overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

      Q = H(1) H(2) . . . H(k)

as returned by STZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

```
L (input) The number of columns of the matrix  A  containing
          the meaningful part of the Householder reflectors.
          If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >=  L
          >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE =  'R'  The
          i-th row must contain the vector which defines the
          elementary reflector H(i), for i =  1,2,...,k,  as
          returned by STZRZF in the last k rows of its array
          argument A.  A is  modified  by  the  routine  but
          restored on exit.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,K).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by STZRZF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

          double  *a,  int  lda, double *tau, double *c, int
          ldc, int *info);

void dormtr_64(char side, char uplo,  char  trans,  long  m,
          long  n,  double *a, long lda, double *tau, double
          *c, long ldc, long *info);
```

PURPOSE

```
dormtr overwrites the general  real  M-by-N  matrix  C  with
TRANS = 'T':      Q**T * C       C * Q**T

where Q is a real orthogonal matrix of order nq, with nq = m
if  SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the
product  of  nq-1  elementary  reflectors,  as  returned  by
SSYTRD:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).
```

ARGUMENTS

```
SIDE (input)
          = 'L': apply Q or Q**T from the Left;
          = 'R': apply Q or Q**T from the Right.

UPLO (input)
          = 'U': Upper triangle  of  A  contains  elementary
          reflectors from SSYTRD; = 'L': Lower triangle of A
          contains elementary reflectors from SSYTRD.

TRANS (input)
          = 'N':  No transpose, apply Q;
          = 'T':  Transpose, apply Q**T.

          TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.
```

```
N (input) The number of columns of the matrix C. N >= 0.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE  =  'R'  The
          vectors which define the elementary reflectors, as
          returned by SSYTRD.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M)  if SIDE = 'L'; LDA >= max(1,N) if SIDE =
          'R'.

TAU (input)
          (M-1) if SIDE = 'L' (N-1) if  SIDE  =  'R'  TAU(i)
          must  contain  the scalar factor of the elementary
          reflector H(i), as returned by SSYTRD.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

void dpbcon_64(char uplo, long n, long kd, double  *a,  long
          lda, double anorm, double *rcond, long *info);
```

PURPOSE

dpbcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangular factor stored in A;
          = 'L':  Lower triangular factor stored in A.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

A (input) The triangular factor U or  L  from  the  Cholesky
```

factorization A = U**T*U or A = L*L**T of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO ='U', A(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', A(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

ANORM (input)
The 1-norm (or infinity-norm) of the symmetric band matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(3*N)

```
       [INFO])

    CHARACTER(LEN=1) :: UPLO
    INTEGER(8) :: N, KD, LDA, INFO
    REAL(8) :: SCOND, AMAX
    REAL(8), DIMENSION(:) :: SCALE
    REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
    #include <sunperf.h>

    void dpbequ(char uplo, int n, int kd, double  *a,  int  lda,
              double  *scale,  double  *scond, double *amax, int
              *info);
    void dpbequ_64(char uplo, long n, long kd, double  *a,  long
              lda,  double  *scale, double *scond, double *amax,
              long *info);
```

PURPOSE

dpbequ computes row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
= 'U': Upper triangular of A is stored;
= 'L': Lower triangular of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input) The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          long ldb, double *x, long ldx, double *ferr,  dou-
          ble *berr, long *info);
```

PURPOSE

dpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the band matrix A as computed by SPBTRF, in the same storage format as A (see A).

LDAF (input)
The leading dimension of the array AF. LDAF >= KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative

```
            change in any element of A or B that makes X(j) an
            exact solution).

WORK (workspace)
            dimension(3*N)
WORK2 (workspace)
            dimension(N)

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value

NAME

dpbstf - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

SYNOPSIS

```
SUBROUTINE DPBSTF(UPLO, N, KD, AB, LDAB, INFO)

CHARACTER * 1 UPLO
INTEGER N, KD, LDAB, INFO
DOUBLE PRECISION AB(LDAB,*)

SUBROUTINE DPBSTF_64(UPLO, N, KD, AB, LDAB, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, KD, LDAB, INFO
DOUBLE PRECISION AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE PBSTF(UPLO, [N], KD, AB, [LDAB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, KD, LDAB, INFO
REAL(8), DIMENSION(:,:) :: AB

SUBROUTINE PBSTF_64(UPLO, [N], KD, AB, [LDAB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDAB, INFO
REAL(8), DIMENSION(:,:) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void dpbstf(char uplo, int n, int kd, double *ab, int  ldab,
          int *info);

void dpbstf_64(char uplo, long n, long kd, double *ab,  long
          ldab, long *info);
```

PURPOSE

dpbstf computes a split Cholesky factorization of a real symmetric positive definite band matrix A.

This routine is designed to be used in conjunction with SSBGST.
The factorization has the form A = S**T*S   where S is a band matrix of the same bandwidth as A and the following structure:

```
  S = ( U    )
      ( M  L )
```

where U is upper triangular of order m = (n+kd)/2, and L is lower triangular of order n-m.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j)   = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the factor S from the split Cholesky factorization A = S**T*S. See Further Details.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 7, KD = 2:

```
S = ( s11  s12  s13                     )
    (      s22  s23  s24                )
    (           s33  s34                )
    (                s44                )
    (           s53  s54  s55           )
    (                s64  s65  s66      )
    (                     s75  s76  s77 )
```

If UPLO = 'U', the array AB holds:

```
on entry:                          on exit:

 *    *   a13  a24  a35  a46  a57   *    *   s13   s24   s53
s64  s75
 *   a12  a23  a34  a45  a56  a67   *   s12  s23   s34   s54
s65   s76  a11   a22  a33  a44  a55  a66  a77  s11  s22  s33
s44  s55  s66  s77
```

If UPLO = 'L', the array AB holds:

```
on entry:                          on exit:

a11  a22  a33  a44  a55  a66  a77  s11  s22  s33   s44   s55
s66   s77  a21   a32  a43  a54  a65  a76   *   s12  s23  s34
s54  s65  s76   * a31  a42  a53  a64   a64    *     *    s13
s24  s53  s64  s75   *    *
```

Array elements marked * are not used by the routine.

          ble  *a,  long  lda,  double  *b,  long  ldb, long
          *info);
```

PURPOSE

```
dpbsv computes the solution to a real system of linear equa-
tions
   A * X = B, where A is an N-by-N symmetric positive defin-
ite band matrix and X and B are N-by-NRHS matrices.
The Cholesky decomposition is used to factor A as
   A = U**T * U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower
triangular  band matrix, with the same number of superdiago-
nals or subdiagonals as A.  The factored form of A  is  then
used to solve the system of equations A * X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NDIAG (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  NDIAG >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band matrix A, stored in the first NDIAG+1
          rows of the array.  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
```

```
UPLO  =  'U',  A(NDIAG+1+i-j,j)   =   A(i,j)   for
max(1,j-NDIAG)<=i<=j;  if  UPLO  = 'L', A(1+i-j,j)
= A(i,j) for j<=i<=min(N,j+NDIAG).  See below  for
further details.

On exit, if INFO = 0, the triangular factor U or L
from  the Cholesky factorization A = U**T*U or A =
L*L**T of the band matrix A, in the  same  storage
format as A.
```

```
LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          NDIAG+1.
B (input/output)
          On entry, the N-by-NRHS right hand side matrix  B.
          On  exit,  if  INFO  =  0,  the N-by-NRHS solution
          matrix X.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, the leading minor of order i of
          A  is  not positive definite, so the factorization
          could not be completed, and the solution  has  not
          been computed.
```

FURTHER DETAILS

```
The band storage scheme  is  illustrated  by  the  following
example, when N = 6, NDIAG = 2, and UPLO = 'U':

On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66

Similarly, if UPLO = 'L' the format of A is as follows:

On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
```

```
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

#include <sunperf.h>

void dpbsvx(char fact, char uplo,  int  n,  int  ndiag,  int
          nrhs,  double  *a,  int lda, double *af, int ldaf,
          char equed, double *s, double *b, int ldb,  double
          *x,  int  ldx, double *rcond, double *ferr, double
          *berr, int *info);

void dpbsvx_64(char fact, char uplo,  long  n,  long  ndiag,
          long  nrhs,  double *a, long lda, double *af, long
          ldaf, char equed, double *s, double *b, long  ldb,
          double  *x, long ldx, double *rcond, double *ferr,
          double *berr, long *info);
```

PURPOSE

dpbsvx uses the Cholesky factorization A = U**T*U or A = L*L**T to compute the solution to a real system of linear equations
   A * X = B, where A is an N-by-N symmetric positive defin- ite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to

```
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is  used
to
   factor the matrix A (after equilibration if FACT  =  'E')
as
      A = U**T * U,  if UPLO = 'U', or
      A = L * L**T,  if UPLO = 'L',
   where U is an upper triangular band matrix, and  L  is  a
lower
   triangular band matrix.
3. If the leading i-by-i principal  minor  is  not  positive
definite,
   then the routine returns with INFO =  i.  Otherwise,  the
factored
   form of A is used to estimate the condition number of the
matrix
   A.  If the reciprocal of the  condition  number  is  less
than machine
   precision, INFO = N+1 is returned as a warning,  but  the
routine
   still goes on to solve for X and compute error bounds as
   described below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.

6. If equilibration was used, the matrix X is  premultiplied
by
   diag(S) so that it solves the original system before
   equilibration.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored form of  the
          matrix A is supplied on entry, and if not, whether
          the matrix A should be equilibrated before  it  is
          factored.   = 'F':  On entry, AF contains the fac-
          tored form of A.  If EQUED = 'Y', the matrix A has
          been equilibrated with scaling factors given by S.
          A and AF will not be modified.  = 'N':  The matrix
          A will be copied to AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.
NDIAG (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  NDIAG >= 0.

NRHS (input)
          The number of right-hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band matrix A, stored in the first NDIAG+1
          rows of the array, except if FACT = 'F' and  EQUED
          = 'Y', then A must contain the equilibrated matrix
          diag(S)*A*diag(S).  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
          UPLO  =  'U',  A(NDIAG+1+i-j,j)   =   A(i,j)   for
          max(1,j-NDIAG)<=i<=j;  if  UPLO  = 'L', A(1+i-j,j)
          = A(i,j) for j<=i<=min(N,j+NDIAG).  See below  for
          further details.

          On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
          overwritten by diag(S)*A*diag(S).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          NDIAG+1.

AF (input/output)
          If FACT = 'F', then AF is an input argument and on
          entry  contains  the triangular factor U or L from
          the Cholesky factorization  A  =  U**T*U  or  A  =
```

L*L**T of the band matrix A, in the same storage format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >= NDIAG+1.

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)

The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would

suggest.

FURTHER DETAILS

```
The band storage scheme  is  illustrated  by  the  following
example, when N = 6, NDIAG = 2, and UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:
   a11  a12  a13
        a22  a23  a24
             a33  a34  a35
                  a44  a45  a46
                       a55  a56
   (aij=conjg(aji))         a66

Band storage of the upper triangle of A:

    *    *   a13  a24  a35  a46
    *   a12  a23  a34  a45  a56
   a11  a22  a33  a44  a55  a66

Similarly, if UPLO = 'L' the format of A is as follows:

   a11  a22  a33  a44  a55  a66
   a21  a32  a43  a54  a65   *
   a31  a42  a53  a64   *    *

Array elements marked * are not used by the routine.

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDAB, INFO
REAL(8), DIMENSION(:,:) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void dpbtf2(char uplo, int n, int kd, double *ab, int  ldab,
          int *info);

void dpbtf2_64(char uplo, long n, long kd, double *ab,  long
          ldab, long *info);
```

PURPOSE

dpbtf2 computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form
```
   A = U' * U ,  if UPLO = 'U', or
   A = L  * L',  if UPLO = 'L',
```
where U is an upper triangular matrix, U' is the transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j)   = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L

from the Cholesky factorization A = U'*U or A = L*L' of the band matrix A, in the same storage format as A.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65

          lda, long *info);
```

PURPOSE

dpbtrf computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

```
   A = U**T * U,  if UPLO = 'U', or
   A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)
- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the band matrix A, in the same storage format as A.

LDA (input)

The leading dimension of the array A. LDA >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

Array elements marked * are not used by the routine.

SUBROUTINE PBTRS_64(UPLO, [N], KD, [NRHS], A, [LDA], B, [LDB],
       [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dpbtrs(char uplo, int n, int kd, int nrhs,  double  *a,
          int lda, double *b, int ldb, int *info);

void dpbtrs_64(char uplo, long n, long kd, long nrhs, double
          *a, long lda, double *b, long ldb, long *info);
```

PURPOSE

dpbtrs solves a system of linear equations A*X = B with a symmetric positive definite band matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPBTRF.

ARGUMENTS

UPLO (input)
- = 'U': Upper triangular factor stored in A;
- = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO ='U', A(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', A(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

B (input/output)
On entry, the right hand side matrix B. On exit,

the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

void dpocon_64(char uplo, long n, double *a, long lda,  dou-
          ble anorm, double *rcond, long *info);
```

PURPOSE

dpocon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPOTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ANORM (input)
The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE POEQU([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])

INTEGER :: N, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE POEQU_64([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])

INTEGER(8) :: N, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dpoequ(int n, double *a, int lda, double *scale, double
          *scond, double *amax, int *info);

void dpoequ_64(long n, double *a, long lda,  double  *scale,
          double *scond, double *amax, long *info);
```

PURPOSE

dpoequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

A (input) The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          *x, int  ldx,  double  *ferr,  double  *berr,  int
          *info);

void dporfs_64(char uplo, long n, long nrhs, double *a, long
          lda,  double  *af, long ldaf, double *b, long ldb,
          double *x, long ldx, double *ferr,  double  *berr,
          long *info);
```

PURPOSE

dporfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The symmetric matrix A.  If UPLO = 'U', the  lead-
          ing N-by-N upper triangular part of A contains the
          upper triangular part of the  matrix  A,  and  the
          strictly  lower triangular part of A is not refer-
          enced.  If UPLO = 'L', the  leading  N-by-N  lower
```

triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPOTRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPOTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

```
WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO =  -i,  the  i-th  argument  had  an
          illegal value

```

C INTERFACE

```
#include <sunperf.h>
```

```
void dposv(char uplo, int n, int nrhs, double *a,  int  lda,
          double *b, int ldb, int *info);

void dposv_64(char uplo, long n, long nrhs, double *a,  long
          lda, double *b, long ldb, long *info);
```

PURPOSE

```
dposv computes the solution to a real system of linear equa-
tions
   A * X = B, where A is an N-by-N symmetric positive defin-
ite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as
   A = U**T* U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower  tri-
angular  matrix.   The  factored  form  of A is then used to
solve the system of equations A * X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A,
          and the strictly lower triangular part of A is not
          referenced.  If UPLO =  'L',  the  leading  N-by-N
          lower triangular part of A contains the lower tri-
          angular part of the matrix  A,  and  the  strictly
          upper triangular part of A is not referenced.

          On exit, if INFO = 0, the factor U or L  from  the
          Cholesky factorization A = U**T*U or A = L*L**T.
```

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

void dposvx(char fact, char uplo, int n,  int  nrhs,  double
          *a,  int  lda,  double  *af, int ldaf, char equed,
          double *s, double *b, int ldb, double *x, int ldx,
          double  *rcond,  double  *ferr,  double *berr, int
          *info);

void dposvx_64(char fact, char uplo, long n, long nrhs, dou-
          ble  *a,  long  lda,  double  *af, long ldaf, char
          equed, double *s, double *b, long ldb, double  *x,
          long  ldx,  double  *rcond,  double  *ferr, double
          *berr, long *info);
```

PURPOSE

```
dposvx uses the Cholesky factorization A =  U**T*U  or  A  =
L*L**T  to  compute  the solution to a real system of linear
equations
   A * X = B, where A is an N-by-N symmetric positive defin-
ite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
```

the
   scaling of the matrix A, but if equilibration is used, A
is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used
to
   factor the matrix A (after equilibration if FACT = 'E')
as
      A = U**T* U, if UPLO = 'U', or
      A = L * L**T, if UPLO = 'L',
   where U is an upper triangular matrix and L is a lower
triangular
   matrix.

3. If the leading i-by-i principal minor is not positive
definite,
   then the routine returns with INFO = i. Otherwise, the
factored
   form of A is used to estimate the condition number of the
matrix
   A. If the reciprocal of the condition number is less
than machine
   precision, INFO = N+1 is returned as a warning, but the
routine
   still goes on to solve for X and compute error bounds as
   described below.

4. The system of equations is solved for X using the fac-
tored form
   of A.

5. Iterative refinement is applied to improve the computed
solution
   matrix and calculate error bounds and backward error
estimates
   for it.

6. If equilibration was used, the matrix X is premultiplied
by
   diag(S) so that it solves the original system before
   equilibration.

ARGUMENTS

FACT (input)
          Specifies whether or not the factored form of the
          matrix A is supplied on entry, and if not, whether

```
          the matrix A should be equilibrated before  it  is
          factored.   = 'F':  On entry, AF contains the fac-
          tored form of A.  If EQUED = 'Y', the matrix A has
          been equilibrated with scaling factors given by S.
          A and AF will not be modified.  = 'N':  The matrix
          A will be copied to AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
A (input/output)
          On entry, the symmetric matrix A, except if FACT =
          'F'  and  EQUED  =  'Y',  then  A must contain the
          equilibrated matrix diag(S)*A*diag(S).  If UPLO  =
          'U', the leading N-by-N upper triangular part of A
          contains the upper triangular part of  the  matrix
          A,  and the strictly lower triangular part of A is
          not referenced.  If UPLO = 'L', the leading N-by-N
          lower triangular part of A contains the lower tri-
          angular part of the matrix  A,  and  the  strictly
          upper  triangular  part of A is not referenced.  A
          is not modified if FACT = 'F' or 'N', or if FACT =
          'E' and EQUED = 'N' on exit.

          On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
          overwritten by diag(S)*A*diag(S).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

AF (input/output)
          If FACT = 'F', then AF is an input argument and on
          entry  contains  the triangular factor U or L from
          the Cholesky factorization  A  =  U**T*U  or  A  =
          L*L**T, in the same storage format as A.  If EQUED
          .ne. 'N', then AF is  the  factored  form  of  the
          equilibrated matrix diag(S)*A*diag(S).

          If FACT = 'N', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
```

the Cholesky factorization A = U**T*U or A = L*L**T of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is

<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

SUBROUTINE POTF2(UPLO, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE POTF2_64(UPLO, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpotf2(char uplo,  int  n,  double  *a,  int  lda,  int
          *info);

void dpotf2_64(char uplo, long n, double *a, long lda,  long
          *info);
```

PURPOSE

dpotf2 computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

```
   A = U' * U ,  if UPLO = 'U', or
   A = L  * L',  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U'*U or A = L*L'.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE POTRF_64(UPLO, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dpotrf(char uplo,  int  n,  double  *a,  int  lda,  int
          *info);

void dpotrf_64(char uplo, long n, double *a, long lda,  long
          *info);
```

PURPOSE

dpotrf computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form

```
   A = U**T * U,  if UPLO = 'U', or
   A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

void dpotri_64(char uplo, long n, double *a, long lda,  long
          *info);
```

PURPOSE

dpotri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPOTRF. On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

NAME

dppcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF

SYNOPSIS

```
SUBROUTINE DPPCON(UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)

CHARACTER * 1 UPLO
INTEGER N, INFO
INTEGER WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(*), WORK(*)

SUBROUTINE DPPCON_64(UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, INFO
INTEGER*8 WORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PPCON(UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: A, WORK
```

```
SUBROUTINE PPCON_64(UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>

void dppcon(char uplo, int n, double *a, double anorm,  dou-
          ble *rcond, int *info);
void dppcon_64(char uplo, long n, double *a,  double  anorm,
          double *rcond, long *info);
```

PURPOSE

dppcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

ANORM (input)
The 1-norm (or infinity-norm) of the symmetric matrix A.

```
RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix  A, computed as RCOND = 1/(ANORM * AINVNM),
          where AINVNM is  an  estimate  of  the  1-norm  of
          inv(A) computed in this routine.

WORK (workspace)
          dimension(3*N)

WORK2 (workspace)
          dimension(N)
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

Contents

NAME

dppequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE DPPEQU(UPLO, N, A, SCALE, SCOND, AMAX, INFO)

CHARACTER * 1 UPLO
INTEGER N, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION A(*), SCALE(*)

SUBROUTINE DPPEQU_64(UPLO, N, A, SCALE, SCOND, AMAX, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION A(*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PPEQU(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: A, SCALE

SUBROUTINE PPEQU_64(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])

CHARACTER(LEN=1) :: UPLO
```

```
INTEGER(8) :: N, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: A, SCALE
```

C INTERFACE

```
#include <sunperf.h>

void dppequ(char uplo, int n, double *a, double *scale, dou-
          ble *scond, double *amax, int *info);

void dppequ_64(char uplo, long n, double *a, double  *scale,
          double *scond, double *amax, long *info);
```

PURPOSE

dppequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i)=1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j)=S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input) The upper  or  lower  triangle  of  the  symmetric
          matrix  A,  packed  columnwise  in a linear array.
          The j-th column of A is stored in the array  A  as
          follows:  if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j)
          for 1<=i<=j; if UPLO = 'L', A(i +  (j-1)*(2n-j)/2)
          = A(i,j) for j<=i<=n.

SCALE (output)
          If INFO = 0, SCALE contains the scale factors  for
          A.

SCOND (output)
          If INFO = 0, SCALE contains the ratio of the smal-
          lest  SCALE(i)  to the largest SCALE(i).  If SCOND
```

>= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          ble *ferr, double *berr, int *info);

void dpprfs_64(char uplo, long n, long nrhs, double *a, dou-
          ble *af, double *b, long ldb, double *x, long ldx,
          double *ferr, double *berr, long *info);
```

PURPOSE

dpprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The upper  or  lower  triangle  of  the  symmetric
          matrix  A,  packed  columnwise  in a linear array.
          The j-th column of A is stored in the array  A  as
          follows:  if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j)
          for 1<=i<=j; if UPLO = 'L', A(i +  (j-1)*(2n-j)/2)
          = A(i,j) for j<=i<=n.
```

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see A).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

REAL(8), DIMENSION(:,:) :: B
```

C INTERFACE

```
#include <sunperf.h>

void dppsv(char uplo, int n, int nrhs, double *a, double *b,
          int ldb, int *info);

void dppsv_64(char uplo, long n, long nrhs, double *a,  dou-
          ble *b, long ldb, long *info);
```

PURPOSE

```
dppsv computes the solution to a real system of linear equa-
tions
   A * X = B, where A is an N-by-N symmetric positive defin-
ite matrix stored in packed format and X and B are N-by-NRHS
matrices.

The Cholesky decomposition is used to factor A as
   A = U**T* U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower  tri-
angular  matrix.   The  factored  form  of A is then used to
solve the system of equations A * X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  A  as  follows:   if  UPLO = 'U', A(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i +
          (j-1)*(2n-j)/2)  =  A(i,j) for j<=i<=n.  See below
          for further details.
```

```
            On exit, if INFO = 0, the factor U or L  from  the
            Cholesky  factorization  A = U**T*U or A = L*L**T,
            in the same storage format as A.

  B (input/output)
            On entry, the N-by-NRHS right hand side matrix  B.
            On  exit,  if  INFO  =  0,  the N-by-NRHS solution
            matrix X.

  LDB (input)
            The leading dimension of  the  array  B.   LDB  >=
            max(1,N).

  INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  if INFO = i, the leading minor of order i of
            A  is  not positive definite, so the factorization
            could not be completed, and the solution  has  not
            been computed.
```

FURTHER DETAILS

```
  The packed storage scheme is illustrated  by  the  following
  example when N = 4, UPLO = 'U':

  Two-dimensional storage of the symmetric matrix A:

     a11 a12 a13 a14
         a22 a23 a24
             a33 a34     (aij = conjg(aji))
                 a44

  Packed storage of the upper triangle of A:

  A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

C INTERFACE

```
#include <sunperf.h>

void dppsvx(char fact, char uplo, int n,  int  nrhs,  double
          *a,  double *af, char equed, double *s, double *b,
          int ldb, double *x, int ldx, double *rcond, double
          *ferr, double *berr, int *info);

void dppsvx_64(char fact, char uplo, long n, long nrhs, dou-
          ble  *a, double *af, char equed, double *s, double
          *b, long ldb, double *x, long ldx, double  *rcond,
          double *ferr, double *berr, long *info);
```

PURPOSE

```
dppsvx uses the Cholesky factorization A =  U**T*U  or  A  =
L*L**T  to  compute  the solution to a real system of linear
equations
   A * X = B, where A is an N-by-N symmetric positive defin-
ite matrix stored in packed format and X and B are N-by-NRHS
matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
```

is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
factor the matrix A (after equilibration if FACT = 'E') as
A = U**T* U, if UPLO = 'U', or
A = L * L**T, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.

3. If the leading i-by-i principal minor is not positive definite,
then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.

4. The system of equations is solved for X using the factored form
of A.

5. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

6. If equilibration was used, the matrix X is premultiplied by
diag(S) so that it solves the original system before
equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the fac-

```
          tored form of A.  If EQUED = 'Y', the matrix A has
          been equilibrated with scaling factors given by S.
          A and AF will not be modified.  = 'N':  The matrix
          A will be copied to AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  matrix  A,  packed  columnwise in a linear
          array, except if FACT = 'F' and EQUED = 'Y',  then
          A    must    contain    the    equilibrated    matrix
          diag(S)*A*diag(S).  The j-th column of A is stored
          in  the  array A as follows:  if UPLO = 'U', A(i +
          (j-1)*j/2) = A(i,j) for 1<=i<=j; if  UPLO  =  'L',
          A(i  +  (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.  See
          below for further details.  A is not  modified  if
          FACT  =  'F'  or 'N', or if FACT = 'E' and EQUED =
          'N' on exit.

          On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
          overwritten by diag(S)*A*diag(S).

AF (input/output)
          (N*(N+1)/2) If FACT = 'F', then  AF  is  an  input
          argument and on entry contains the triangular fac-
          tor U or L from the  Cholesky  factorization  A  =
          U'*U or A = L*L', in the same storage format as A.
          If EQUED .ne. 'N', then AF is the factored form of
          the equilibrated matrix A.

          If FACT = 'N', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
          the Cholesky factorization A = U'*U or A = L*L' of
          the original matrix A.

          If FACT = 'E', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
          the Cholesky factorization A = U'*U or A = L*L' of
          the  equilibrated matrix A (see the description of
```

A for the form of the equilibrated matrix).

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (output)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest ele-

ment in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
a11 a12 a13 a14
    a22 a23 a24
        a33 a34     (aij = conjg(aji))
            a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

```
#include <sunperf.h>

void dpptrf(char uplo, int n, double *a, int *info);

void dpptrf_64(char uplo, long n, double *a, long *info);
```

PURPOSE

dpptrf computes the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format.

The factorization has the form

```
   A = U**T * U,  if UPLO = 'U', or
   A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, in the same storage format as A.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

          double *rcond, int *info);

void dptcon_64(long n, double *diag,  double  *offd,  double
          anorm, double *rcond, long *info);
```

PURPOSE

dptcon computes the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization A = L*D*L**T or A = U**T*D*U computed by SPTTRF.
Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as
RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

DIAG (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by SPTTRF.

OFFD (input)
The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by SPTTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The method used is described in Nicholas J. Higham, "Efficient Algorithms for Computing the Condition Number of a Tridiagonal Matrix", SIAM J. Sci. Stat. Comput., Vol. 7, No. 1, January 1986.

```

C INTERFACE

```
#include <sunperf.h>

void dpteqr(char compz, int n, double *d, double *e,  double
          *z, int ldz, int *info);

void dpteqr_64(char compz, long n,  double  *d,  double  *e,
          double *z, long ldz, long *info);
```

PURPOSE

dpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band symmetric positive definite matrix can also be found if SSYTRD, SSPTRD, or SSBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvectors of original symmetric matrix also. Array Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', the orthogonal matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original symmetric matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK (workspace)
dimension(4*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

          ble *berr, long *info);
```

PURPOSE

dptrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input)
The n diagonal elements of the tridiagonal matrix A.

OFFD (input)
The (n-1) subdiagonal elements of the tridiagonal matrix A.

DIAGF (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization computed by SPTTRF.

OFFDF (input)
The (n-1) subdiagonal elements of the unit bidiag-

```
          onal  factor  L from the factorization computed by
          SPTTRF.

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).
X (input/output)
          On entry, the solution matrix X,  as  computed  by
          SPTTRS.  On exit, the improved solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The forward error bound for each  solution  vector
          X(j)  (the  j-th column of the solution matrix X).
          If XTRUE is the  true  solution  corresponding  to
          X(j),  FERR(j) is an estimated upper bound for the
          magnitude of the largest element in (X(j) - XTRUE)
          divided by the magnitude of the largest element in
          X(j).

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(2*N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

          ble *b, int ldb, int *info);

void dptsv_64(long n, long nrhs, double *diag, double  *sub,
          double *b, long ldb, long *info);
```

PURPOSE

dptsv computes the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as A = L*D*L**T, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the factorization A = L*DIAG*L**T.

SUB (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**T factorization of A. (SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U**T*DIAG*U factorization of A.)

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >=

max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

```
#include <sunperf.h>

void dptsvx(char fact, int n, int nrhs, double *diag, double
          *sub,  double *diagf, double *subf, double *b, int
          ldb, double *x, int  ldx,  double  *rcond,  double
          *ferr, double *berr, int *info);

void dptsvx_64(char fact, long n, long nrhs,  double  *diag,
          double  *sub,  double *diagf, double *subf, double
          *b, long ldb, double *x, long ldx, double  *rcond,
          double *ferr, double *berr, long *info);
```

PURPOSE

```
dptsvx uses the factorization A = L*D*L**T  to  compute  the
solution to a real system of linear equations A*X = B, where
A is  an  N-by-N  symmetric  positive  definite  tridiagonal
matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'N', the matrix A is factored as A =  L*D*L**T,
where L
   is a unit lower bidiagonal matrix and D is diagonal.  The
   factorization can also be regarded as having the form
   A = U**T*D*U.

2. If the leading i-by-i principal  minor  is  not  positive
definite,
   then the routine returns with INFO =  i.  Otherwise,  the
factored
   form of A is used to estimate the condition number of the
```

matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form
of A.

4. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, DIAGF and SUBF contain the factored form of A. DIAG, SUB, DIAGF, and SUBF will not be modified. = 'N': The matrix A will be copied to DIAGF and SUBF and factored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

DIAG (input)
The n diagonal elements of the tridiagonal matrix A.

SUB (input)
The (n-1) subdiagonal elements of the tridiagonal matrix A.

DIAGF (input/output)
If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the diagonal matrix DIAG from the L*DIAG*L**T factorization of A. If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal

elements of the diagonal matrix DIAG from the L*DIAG*L**T factorization of A.

SUBF (input/output)
If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**T factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**T factorization of A.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 of INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is

<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

DOUBLE PRECISION FUNCTION DQDOTA_64(N, DB, QC, DX, INCX, DY, INCY)

INTEGER*8 N, INCX, INCY
REAL * 16 QC
DOUBLE PRECISION DB
DOUBLE PRECISION DX(*), DY(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DQDOTA(N, DB, QC, DX, INCX, DY, INCY)

INTEGER :: N, INCX, INCY
REAL(16) :: QC
REAL(8) :: DB
REAL(8), DIMENSION(:) :: DX, DY

REAL(8) FUNCTION DQDOTA_64(N, DB, QC, DX, INCX, DY, INCY)

INTEGER(8) :: N, INCX, INCY
REAL(16) :: QC
```

```
REAL(8) :: DB
REAL(8), DIMENSION(:) :: DX, DY
```

C INTERFACE

```
#include <sunperf.h>

double dqdota(int n, double db, long double *qc, double *dx,
          int incx, double *dy, int incy);

double dqdota_64(long n, double db, long double *qc,  double
          *dx, long incx, double *dy, long incy);
```

PURPOSE

dqdota compute a double precision constant plus an extended precision constant plus the extended precision dot product of two double precision vectors x and y.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. If N <= 0 then the function returns the value DB+QC. Unchanged on exit.

DB (input)
On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

QC (input/output)
On entry, the extended precision constant to be added to the dot product. On exit, the extended precision result.

DX (input)
On entry, the incremented array DX must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of DX. INCX must not be zero. Unchanged on exit.

DY (input)
On entry, the incremented array DY must contain the vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of DY. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
dqdoti - compute a constant plus the extended precision  dot
product of two double precision vectors x and y.
```

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DQDOTI(N, DB, QC, DX, INCX, DY, INCY)

INTEGER N, INCX, INCY
REAL * 16 QC
DOUBLE PRECISION DB
DOUBLE PRECISION DX(*), DY(*)

DOUBLE PRECISION FUNCTION DQDOTI_64(N, DB, QC, DX, INCX, DY, INCY)

INTEGER*8 N, INCX, INCY
REAL * 16 QC
DOUBLE PRECISION DB
DOUBLE PRECISION DX(*), DY(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DQDOTI(N, DB, QC, DX, INCX, DY, INCY)

INTEGER :: N, INCX, INCY
REAL(16) :: QC
REAL(8) :: DB
REAL(8), DIMENSION(:) :: DX, DY

REAL(8) FUNCTION DQDOTI_64(N, DB, QC, DX, INCX, DY, INCY)

INTEGER(8) :: N, INCX, INCY
REAL(16) :: QC
REAL(8) :: DB
```

```
REAL(8), DIMENSION(:) :: DX, DY
```

C INTERFACE

```
#include <sunperf.h>

double dqdoti(int n, double db, long double *qc, double *dx,
          int incx, double *dy, int incy);

double dqdoti_64(long n, double db, long double *qc,  double
          *dx, long incx, double *dy, long incy);
```

PURPOSE

dqdoti computes a constant plus the double precision dot product of x and y where x and y are double precision n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. If N <= 0 then the function returns the value DB. Unchanged on exit.

DB (input)
On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

QC (output)
On exit, the extended precision result.

DX (input)
On entry, the incremented array DX must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of DX. INCX must not be zero. Unchanged on exit.

DY (input)
On entry, the incremented array DY must contain the vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the

elements of DY. INCY must not be zero. Unchanged
on exit.

NAME

```
drot - Apply a Given's rotation constructed by SROTG.
```

SYNOPSIS

```
SUBROUTINE DROT(N, X, INCX, Y, INCY, C, S)

INTEGER N, INCX, INCY
DOUBLE PRECISION C, S
DOUBLE PRECISION X(*), Y(*)

SUBROUTINE DROT_64(N, X, INCX, Y, INCY, C, S)

INTEGER*8 N, INCX, INCY
DOUBLE PRECISION C, S
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)

INTEGER :: N, INCX, INCY
REAL(8) :: C, S
REAL(8), DIMENSION(:) :: X, Y

SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)

INTEGER(8) :: N, INCX, INCY
REAL(8) :: C, S
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void drot(int n, double *x, int incx, double *y,  int  incy,
          double c, double s);

void drot_64(long n, double *x, long incx, double  *y,  long
          incy, double c, double s);
```

PURPOSE

drot Apply a Given's rotation constructed by SROTG.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input/output)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

C (input) On entry, the C rotation value constructed by SROTG. Unchanged on exit.

S (input) On entry, the S rotation value constructed by SROTG. Unchanged on exit.

NAME

```
drotg - Construct a Given's plane rotation
```

SYNOPSIS

```
SUBROUTINE DROTG(A, B, C, S)

DOUBLE PRECISION A, B, C, S

SUBROUTINE DROTG_64(A, B, C, S)

DOUBLE PRECISION A, B, C, S
```

F95 INTERFACE

```
SUBROUTINE ROTG(A, B, C, S)

REAL(8) :: A, B, C, S

SUBROUTINE ROTG_64(A, B, C, S)

REAL(8) :: A, B, C, S
```

C INTERFACE

```
#include <sunperf.h>

void drotg(double *a, double *b, double *c, double *s);

void drotg_64(double *a, double *b, double *c, double *s);
```

PURPOSE

drotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

A (input/output)
: On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

B (input/output)
: On entry, B contains the entry to be annihilated in the second vector. On exit, contains either S or 1/C depending on which of the input values of A and B is larger.

C (output)
: On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

S (output)
: See the description of C.

NAME

```
droti -  Apply an indexed Givens rotation.
```

SYNOPSIS

```
 SUBROUTINE DROTI(NZ, X, INDX, Y, C, S)

 INTEGER NZ
 INTEGER INDX(*)
 DOUBLE PRECISION C, S
 DOUBLE PRECISION X(*), Y(*)

 SUBROUTINE DROTI_64(NZ, X, INDX, Y, C, S)

 INTEGER*8 NZ
 INTEGER*8 INDX(*)
 DOUBLE PRECISION C, S
 DOUBLE PRECISION X(*), Y(*)

F95 INTERFACE
 SUBROUTINE ROTI([NZ], X, INDX, Y, C, S)

 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX
 REAL(8) :: C, S
 REAL(8), DIMENSION(:) :: X, Y

 SUBROUTINE ROTI_64([NZ], X, INDX, Y, C, S)

 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
 REAL(8) :: C, S
 REAL(8), DIMENSION(:) :: X, Y
```

PURPOSE

```
DROTI - Applies a Givens rotation to a sparse vector x
stored in compressed form and another vector y in full
storage form

 do i = 1, n
   temp = -s * x(i) + c * y(indx(i))
   x(i) = c * x(i) + s * y(indx(i))
   y(indx(i)) = temp
 enddo
```

ARGUMENTS

```
NZ (input) - INTEGER
        Number of elements in the compressed form.
        Unchanged on exit.
X (input)
        Vector containing the values of the compressed form.

INDX (input) - INTEGER
        Vector containing the indices of the compressed
        form.  It is assumed that the elements in INDX are
        distinct and greater than zero.  Unchanged on exit.

Y (input/output)
        Vector on input which contains the vector Y in full
        storage form.  On exit, only the elements
        corresponding to the indices in INDX have been
        modified.

C (input)
        Scalar defining the Givens rotation

S (input)
        Scalar defining the Givens rotation
```

INTEGER :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y, PARAM

SUBROUTINE ROTM_64([N], X, [INCX], Y, [INCY], PARAM)

INTEGER(8) :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y, PARAM
```

C INTERFACE

```
#include <sunperf.h>

void drotm(int n, double *x, int incx, double *y, int  incy,
          double *param);
```

```
void drotm_64(long n, double *x, long incx, double *y,  long
          incy, double *param);
```

PURPOSE

drotm Apply a Given's rotation constructed by SROTMG.

ARGUMENTS

```
N (input)
          On entry, N specifies the number  of  elements  in
          the  vector.   N must be at least one for the sub-
          routine to have any visible effect.  Unchanged  on
          exit.
X (input/output)
          ( 1 + ( n - 1 )*abs( INCX  )  ).   On  entry,  the
          incremented  array X must contain the vector x. On
          exit, X is overwritten by the updated vector x.

INCX (input)
          On entry, INCX specifies  the  increment  for  the
          elements  of  X. INCX must not be zero.  Unchanged
          on exit.

Y (input/output)
          ( 1 + ( n - 1 )*abs( INCY  )  ).   On  entry,  the
          incremented  array Y must contain the vector y. On
          exit, Y is overwritten by the updated vector y.

INCY (input)
          On entry, INCY specifies  the  increment  for  the
          elements  of  Y. INCY must not be zero.  Unchanged
          on exit.

PARAM (input)
          On  entry,  the  rotation  values  constructed  by
          SROTMG.  Unchanged on exit.
```

SUBROUTINE ROTMG_64(D1, D2, B1, B2, PARAM)

REAL(8) :: D1, D2, B1, B2
REAL(8), DIMENSION(:) :: PARAM
```

C INTERFACE

```
#include <sunperf.h>

void drotmg(double d1, double d2, double b1, double b2, dou-
          ble *param);
```

```
void drotmg_64(double d1, double d2, double b1,  double  b2,
          double *param);
```

PURPOSE

drotmg Construct Gentleman's modified a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

D1 (input/output)
On entry, the first diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

D2 (input/output)
On entry, the second diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

B1 (input/output)
On entry, the first element of the vector to which the H matrix is applied. On exit, changed to reflect the effect of the transformation.

B2 (input)
On entry, the second element of the vector to which the H matrix is applied. Unchanged on exit.

PARAM (output)
On exit, PARAM(1) describes the form of the rotation matrix H, and PARAM(2..5) contain the H matrix.

If PARAM(1) = -2 then H = I and no elements of PARAM are modified.

If PARAM(1) = -1 then PARAM(2) = h11, PARAM(3) = h21, PARAM(4) = h12, and PARAM(5) = h22.

If PARAM(1) = 0 then h11 = h22 = 1, PARAM(3) = h21, and PARAM(4) = h12.

If PARAM(1) = 1 then h12 = 1, h21 = -1, PARAM(2) = h11, and PARAM(5) = h22.

          *info);

void dsbev_64(char jobz, char uplo, long n, long kd,  double
          *a, long lda, double *w, double *z, long ldz, long
          *info);
```

PURPOSE

dsbev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band  matrix  A,  stored in the first KD+1
          rows of the array.  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
          UPLO = 'U', A(kd+1+i-j,j) =  A(i,j)  for  max(1,j-
          kd)<=i<=j;  if  UPLO = 'L', A(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+kd).

          On exit, A is overwritten by values generated dur-
          ing  the reduction to tridiagonal form.  If UPLO =
```

'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

LDA (input)
The leading dimension of the array A. LDA >= KD + 1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(MAX(1,3*N-2))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

   INTEGER(8), DIMENSION(:) :: IWORK
   REAL(8), DIMENSION(:) :: W, WORK
   REAL(8), DIMENSION(:,:) :: AB, Z
```

C INTERFACE

```
   #include <sunperf.h>

   void dsbevd(char jobz, char uplo, int n, int kd, double *ab,
             int  ldab,  double  *w,  double  *z,  int ldz, int
             *info);
   void dsbevd_64(char jobz, char uplo, long n, long kd, double
             *ab,  long  ldab,  double *w, double *z, long ldz,
             long *info);
```

PURPOSE

dsbevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO

= 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD + 1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (output)
If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 2, LWORK must be at least 2*N. If JOBZ = 'V' and N > 2, LWORK must be at least (1 + 5*N + 2*N**2).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

```
            the WORK array, returns this value  as  the  first
            entry  of  the  WORK  array,  and no error message
            related to LWORK is issued by XERBLA.

  IWORK (workspace/output)
            On exit, if INFO = 0, IWORK(1) returns the optimal
            LIWORK.
  LIWORK (input)
            The dimension of the array LIWORK.  If JOBZ  = 'N'
            or  N <= 1, LIWORK must be at least 1.  If JOBZ  =
            'V' and N > 2, LIWORK must be at least 3 + 5*N.

            If LIWORK = -1, then a workspace query is assumed;
            the  routine  only  calculates the optimal size of
            the IWORK array, returns this value as  the  first
            entry  of  the  IWORK  array, and no error message
            related to LIWORK is issued by XERBLA.

  INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  if INFO = i, the algorithm  failed  to  con-
            verge;  i off-diagonal elements of an intermediate
            tridiagonal form did not converge to zero.

```
#include <sunperf.h>

void dsbevx(char jobz, char range, char uplo, int n, int kd,
          double *a, int lda, double *q, int ldq, double vl,
          double vu, int  il,  int  iu,  double  abtol,  int
          *nfound,  double  *w,  double  *z,  int  ldz,  int
          *ifail, int *info);

void dsbevx_64(char jobz, char range,  char  uplo,  long  n,
          long kd, double *a, long lda, double *q, long ldq,
          double vl, double vu, long  il,  long  iu,  double
          abtol,  long  *nfound,  double *w, double *z, long
          ldz, long *ifail, long *info);
```

PURPOSE

dsbevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found;
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be  found; = 'I': the IL-th through
          IU-th eigenvalues will be found.
```

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band  matrix  A,  stored in the first KD+1
          rows of the array.  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
          UPLO = 'U', A(kd+1+i-j,j) =  A(i,j)  for  max(1,j-
          kd)<=i<=j;  if  UPLO = 'L', A(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+kd).

          On exit, A is overwritten by values generated dur-
          ing  the reduction to tridiagonal form.  If UPLO =
          'U', the first superdiagonal and the  diagonal  of
          the  tridiagonal  matrix T are returned in rows KD
          and KD+1 of A, and if UPLO = 'L', the diagonal and
          first  subdiagonal  of T are returned in the first
          two rows of A.

LDA (input)
          The leading dimension of the array A.  LDA >= KD +
          1.

Q (output)
          If JOBZ = 'V', the N-by-N orthogonal  matrix  used
          in  the  reduction to tridiagonal form.  If JOBZ =
          'N', the array Q is not referenced.

LDQ (input)
          The leading dimension of the array Q.  If  JOBZ  =
          'V', then LDQ >= max(1,N).

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

VU (input)
          See the description of VL.

IL (input)
```

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tri- diagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvec- tor fails to converge, then that column of Z con- tains the latest approximation to the eigenvector, and the index of the eigenvector is returned in

```
            IFAIL.  If JOBZ = 'N', then Z is  not  referenced.
            Note:   the   user   must  ensure  that  at  least
            max(1,NFOUND) columns are supplied in the array Z;
            if  RANGE  = 'V', the exact value of NFOUND is not
            known in advance and an upper bound must be used.
LDZ (input)
            The leading dimension of the array Z.  LDZ  >=  1,
            and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
            dimension(7*N)

IWORK2 (workspace)

IFAIL (output)
            If JOBZ = 'V', then if INFO = 0, the first  NFOUND
            elements  of  IFAIL  are  zero.  If INFO > 0, then
            IFAIL contains the  indices  of  the  eigenvectors
            that  failed  to  converge.   If  JOBZ = 'N', then
            IFAIL is not referenced.

INFO (output)
            = 0:  successful exit.
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value.
            > 0:  if INFO = i, then i eigenvectors  failed  to
            converge.   Their  indices  are  stored  in  array
            IFAIL.

C INTERFACE

```
#include <sunperf.h>

void dsbgst(char vect, char uplo, int n,  int  ka,  int  kb,
          double *ab, int ldab, double *bb, int ldbb, double
          *x, int ldx, int *info);

void dsbgst_64(char vect, char uplo, long n, long  ka,  long
          kb,  double *ab, long ldab, double *bb, long ldbb,
          double *x, long ldx, long *info);
```

PURPOSE

dsbgst reduces a real symmetric-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y, such that C has the same bandwidth as A.

B must have been previously factorized as S**T*S by SPBSTF, using a split Cholesky factorization. A is overwritten by C = X**T*A*X, where X = S**(-1)*Q and Q is an orthogonal matrix chosen to preserve the bandwidth of A.

ARGUMENTS

VECT (input)
- = 'N': do not form the transformation matrix X;
- = 'V': form X.

UPLO (input)
- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO

= 'L'. KA >= KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the sym- metric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j- ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the transformed matrix X**T*A*X, stored in the same format as A.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input)
The banded factor S from the split Cholesky fac- torization of B, as returned by SPBSTF, stored in the first KB+1 rows of the array.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

X (output)
If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N) if VECT = 'V'; LDX >= 1 otherwise.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value.

             double *w, double *z, long ldz, long *info);
```

PURPOSE

dsbgv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S**T*S, as returned by SPBSTF.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z**T*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is:
<= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then SPBSTF
returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

#include <sunperf.h>
void dsbgvd(char jobz, char uplo, int n,  int  ka,  int  kb,
          double *ab, int ldab, double *bb, int ldbb, double
          *w, double *z, int ldz, int *info);

void dsbgvd_64(char jobz, char uplo, long n, long  ka,  long
          kb,  double *ab, long ldab, double *bb, long ldbb,
          double *w, double *z, long ldz, long *info);
```

PURPOSE

dsbgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)

= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if
UPLO = 'U', or the number of subdiagonals if UPLO
= 'L'. KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the sym-
metric band matrix A, stored in the first ka+1
rows of the array. The j-th column of A is stored
in the j-th column of the array AB as follows: if
UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-
ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j)   = A(i,j)
for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB.   LDAB >=
KA+1.

BB (input/output)
On entry, the upper or lower triangle of the sym-
metric band matrix B, stored in the first kb+1
rows of the array. The j-th column of B is stored
in the j-th column of the array BB as follows: if
UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-
kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j)   = B(i,j)
for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky fac-
torization B = S**T*S, as returned by SPBSTF.

LDBB (input)
The leading dimension of the array BB.   LDBB >=
KB+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the
matrix Z of eigenvectors, with the i-th column of

```
           Z holding the eigenvector  associated  with  W(i).
           The  eigenvectors  are normalized so Z**T*B*Z = I.
           If JOBZ = 'N', then Z is not referenced.

 LDZ (input)
           The leading dimension of the array Z.  LDZ  >=  1,
           and if JOBZ = 'V', LDZ >= max(1,N).

 WORK (workspace)
           On exit, if INFO = 0, WORK(1) returns the  optimal
           LWORK.

 LWORK (input)
           The dimension of the  array  WORK.   If  N  <=  1,
           LWORK  >=  1.   If  JOBZ = 'N' and N > 1, LWORK >=
           3*N.  If JOBZ = 'V' and N > 1, LWORK >= 1 + 5*N  +
           2*N**2.

           If LWORK = -1, then a workspace query is  assumed;
           the  routine  only  calculates the optimal size of
           the WORK array, returns this value  as  the  first
           entry  of  the  WORK  array,  and no error message
           related to LWORK is issued by XERBLA.

 IWORK (workspace/output)
           On exit, if  LIWORK  >  0,  IWORK(1)  returns  the
           optimal LIWORK.

 LIWORK (input)
           The dimension of the array IWORK.  If JOBZ  =  'N'
           or N <= 1, LIWORK >= 1.  If JOBZ  = 'V' and N > 1,
           LIWORK >= 3 + 5*N.

           If LIWORK = -1, then a workspace query is assumed;
           the  routine  only  calculates the optimal size of
           the IWORK array, returns this value as  the  first
           entry  of  the  IWORK  array, and no error message
           related to LIWORK is issued by XERBLA.

 INFO (output)
           = 0:  successful exit
           < 0:  if INFO = -i, the i-th argument had an ille-
           gal value
           > 0:  if INFO = i, and i is:
           <= N:  the algorithm failed to converge:   i  off-
           diagonal  elements  of an intermediate tridiagonal
           form did not converge to zero; > N:   if INFO =  N
           + i, for 1 <= i <= N, then SPBSTF
           returned INFO = i: B  is  not  positive  definite.
           The  factorization of B could not be completed and
```

no eigenvalues or eigenvectors were computed.

          long *info);
```

PURPOSE

dsbgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S**T*S, as returned by SPBSTF.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

Q (output)
If JOBZ = 'V', the n-by-n matrix used in the reduction of A*x = (lambda)*B*x to standard form, i.e. C*x = (lambda)*x, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so Z**T*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(7*N)

IWORK (workspace/output)
dimension(5*N)

IFAIL (input)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvalues that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0 : successful exit
< 0 : if INFO = -i, the i-th argument had an illegal value
<= N: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in IFAIL. > N : SPBSTF returned an error code; i.e., if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

NAME

```
dsbmv - perform the matrix-vector operation   y := alpha*A*x
+ beta*y
```

SYNOPSIS

```
SUBROUTINE DSBMV(UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y,
      INCY)

CHARACTER * 1 UPLO
INTEGER N, K, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)

SUBROUTINE DSBMV_64(UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y,
      INCY)

CHARACTER * 1 UPLO
INTEGER*8 N, K, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SBMV(UPLO, [N], K, ALPHA, A, [LDA], X, [INCX], BETA,
       Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, K, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE SBMV_64(UPLO, [N], K, ALPHA, A, [LDA], X, [INCX],
```

```
          BETA, Y, [INCY])

   CHARACTER(LEN=1) :: UPLO
   INTEGER(8) :: N, K, LDA, INCX, INCY
   REAL(8) :: ALPHA, BETA
   REAL(8), DIMENSION(:) :: X, Y
   REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsbmv(char uplo, int n, int k, double alpha, double *a,
          int  lda, double *x, int incx, double beta, double
          *y, int incy);
void dsbmv_64(char uplo, long n, long k, double alpha,  dou-
          ble  *a,  long  lda,  double *x, long incx, double
          beta, double *y, long incy);
```

PURPOSE

dsbmv performs the matrix-vector operation y := alpha*A*x + beta*y, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric band matrix, with k super-diagonals.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is being supplied.

UPLO = 'L' or 'l'   The lower triangular part of A is being supplied.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry, K specifies the number of super-diagonals of the matrix A. K >= 0. Unchanged on

exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (

k + 1). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

SUBROUTINE SBTRD(VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],
       [WORK], [INFO])

CHARACTER(LEN=1) :: VECT, UPLO
INTEGER :: N, KD, LDAB, LDQ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:,:) :: AB, Q

SUBROUTINE SBTRD_64(VECT, UPLO, [N], KD, AB, [LDAB], D, E, Q, [LDQ],
       [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: VECT, UPLO
INTEGER(8) :: N, KD, LDAB, LDQ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:,:) :: AB, Q
```

C INTERFACE

```
#include <sunperf.h>

void dsbtrd(char vect, char uplo, int n, int kd, double *ab,
          int  ldab,  double  *d,  double *e, double *q, int
          ldq, int *info);

void dsbtrd_64(char vect, char uplo, long n, long kd, double
          *ab,  long  ldab, double *d, double *e, double *q,
          long ldq, long *info);
```

PURPOSE

dsbtrd reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: Q**T * A * Q = T.

ARGUMENTS

VECT (input)
= 'N': do not form Q;
= 'V': form Q;
= 'U': update a matrix X, by forming X*Q.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-

kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if KD > 0, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

D (output)
The diagonal elements of the tridiagonal matrix T.

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = T(i,i+1) if UPLO = 'U'; E(i) = T(i+1,i) if UPLO = 'L'.

Q (input/output)
On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N orthogonal matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
void dscal(int n, double alpha, double *y, int incy);

void dscal_64(long n, double alpha, double *y, long incy);
```

PURPOSE

```
dscal Compute y := alpha * y where alpha is a scalar  and  y
is an n-vector.
```

ARGUMENTS

```
N (input)
          On entry, N specifies the number  of  elements  in
          the  vector.   N  must  be  at  least  one for the
          subroutine to have any visible effect.   Unchanged
          on exit.

ALPHA (input)
          On  entry,  ALPHA  specifies  the  scalar   alpha.
          Unchanged on exit.

Y (input/output)
          ( 1 + ( n - 1 )*abs( INCY  )  ).   On  entry,  the
          incremented  array Y must contain the vector y. On
          exit, Y is overwritten by the updated vector y.

INCY (input)
          On entry, INCY specifies  the  increment  for  the
          elements  of  Y. INCY must not be zero.  Unchanged
          on exit.

NAME

```
dsctr - Scatters elements from x into y.
```

SYNOPSIS

```
 SUBROUTINE DSCTR(NZ, X, INDX, Y)

 DOUBLE PRECISION X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE DSCTR_64(NZ, X, INDX, Y)

 DOUBLE PRECISION X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE SCTR([NZ], X, INDX, Y)

 REAL(8), DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE SCTR_64([NZ], X, INDX, Y)

 REAL(8), DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
DSCTR - Scatters the components of a sparse vector x stored
in compressed form into specified components of a vector y
```

in full storage form.

```
 do i = 1, n
   y(indx(i)) = x(i)
 enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form.
Unchanged on exit.

X (input)
Vector containing the values to be scattered from compressed form into full storage form. Unchanged on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (output)
Vector whose elements specified by indx have been set to the corresponding entries of x. Only the elements corresponding to the indices in indx have been modified.

Contents

NAME

```
dsdot - compute the double precision dot product of two sin-
gle precision vectors x and y.
```

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DSDOT(N, X, INCX, Y, INCY)

INTEGER N, INCX, INCY
REAL X(*), Y(*)

DOUBLE PRECISION FUNCTION DSDOT_64(N, X, INCX, Y, INCY)

INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>

double dsdot(int n, float *x, int incx, float *y, int incy);

double dsdot_64(long n, float *x, long incx, float *y,  long
```

```
          incy);
```

PURPOSE

```
dsdot compute the double precision dot product of  x  and  y
where x and y are single precision n-vectors.
```

ARGUMENTS

```
N (input)
          On entry, N specifies the number  of  elements  in
          the  vector.   If N is not positive then the func-
          tion returns the value 0.0.  Unchanged on exit.
X (input)
          ( 1 + ( n - 1 )*abs( INCX  )  ).   On  entry,  the
          incremented  array  X  must  contain the vector x.
          Unchanged on exit.

INCX (input)
          On entry, INCX specifies  the  increment  for  the
          elements  of  X. INCX must not be zero.  Unchanged
          on exit.

Y (input)
          ( 1 + ( n - 1 )*abs( INCY  )  ).   On  entry,  the
          incremented  array  Y  must  contain the vector y.
          Unchanged on exit.

INCY (input)
          On entry, INCY specifies  the  increment  for  the
          elements  of  Y. INCY must not be zero.  Unchanged
          on exit.

Contents

NAME

```
dsinqb - synthesize a Fourier sequence from its  representa-
tion  in  terms of a sine series with odd wave numbers.  The
SINQ operations are unnormalized inverses of themselves,  so
a  call  to  SINQF followed by a call to SINQB will multiply
the input sequence by 4 * N.
```

SYNOPSIS

```
SUBROUTINE DSINQB(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DSINQB_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQB([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE SINQB_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinqb(int n, double *x, double *wsave);
```

```
void dsinqb_64(long n, double *x, double *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence   to   be   transformed.   On  exit,  the
          quarter-wave sine synthesis of the input.
WSAVE (input)
          On entry, an array with dimension of at least (3 *
          N  +  15)  for  scalar subroutines, initialized by
          SINQI.
```

Contents

NAME

```
dsinqf - compute the Fourier coefficients in a  sine  series
representation  with only odd wave numbers.  The SINQ opera-
tions are unnormalized inverses of themselves, so a call  to
SINQF  followed  by  a call to SINQB will multiply the input
sequence by 4 * N.
```

SYNOPSIS

```
SUBROUTINE DSINQF(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DSINQF_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQF([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE SINQF_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinqf(int n, double *x, double *wsave);
```

```
void dsinqf_64(long n, double *x, double *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence   to   be   transformed.   On  exit,  the
          quarter-wave sine transform of the input.
WSAVE (input)
          On entry, an array with dimension of at least   (3
          *  N  + 15) for scalar subroutines, initialized by
          SINQI.
```

Contents

NAME

```
dsinqi - initialize the array xWSAVE, which is used in  both
SINQF and SINQB.
```

SYNOPSIS

```
SUBROUTINE DSINQI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE DSINQI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE SINQI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinqi(int n, double *wsave);

void dsinqi_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array of dimension (3 * N + 15) or greater. SINQI needs to be called only once to initialize WSAVE before calling SINQF and/or SINQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

```
dsint - compute the discrete Fourier sine  transform  of  an
odd sequence.  The SINT transforms are unnormalized inverses
of themselves, so a call of SINT followed by another call of
SINT will multiply the input sequence by 2 * (N+1).
```

SYNOPSIS

```
SUBROUTINE DSINT(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DSINT_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE SINT_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsint(int n, double *x, double *wsave);
```

```
void dsint_64(long n, double *x, double *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines  are most efficient when N+1 is a pro-
          duct of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence  to  be  transformed.   On exit, the sine
          transform of the input.
WSAVE (input/output)
          On entry, an array  with  dimension  of  at  least
          int(2.5 * N + 15) initialized by SINTI.
```

Contents

NAME

```
dsinti - initialize the array WSAVE, which is used  in  sub-
routine SINT.
```

SYNOPSIS

```
SUBROUTINE DSINTI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE DSINTI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINTI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE SINTI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dsinti(int n, double *wsave);

void dsinti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input/output)
On entry, an array of dimension (2N + N/2 + 15) or greater. SINTI is called once to initialize WSAVE before calling SINT and need not be called again between calls to SINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

     *    PNTR,  B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
      INTEGER*8    TRANSA, M, K
      INTEGER*8, DIMENSION(:) ::  DESCRA,  PNTR
      DOUBLE PRECISION    ALPHA, BETA
      DOUBLE PRECISION, DIMENSION(:) ::  VAL
      DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
         C <- alpha op(A) B + beta C
where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in skyline format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general (NOT SUPPORTED)
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
```

```
                 DESCRA(2) upper/lower triangular indicator
                   1 : lower
                   2 : upper
                 DESCRA(3) main diagonal type
                   0 : non-unit
                   1 : unit
                 DESCRA(4) Array base  (NOT IMPLEMENTED)
                   0 : C/C++ compatible
                   1 : Fortran compatible
                 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                   0 : unknown
                   1 : no repeated indices

   VAL()         array contain the nonzeros of A in skyline profile form.
                 Row-oriented if DESCRA(2) = 1 (lower triangular),
                 column oriented if DESCRA(2) = 2 (upper triangular).
   PNTR()        integer array of length M+1 (lower triangular) or
                 K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
                 points to the location in VAL of the first element of
                 the skyline profile in row (column) I.

   B()           rectangular array with first dimension LDB.

   LDB           leading dimension of B

   BETA          Scalar parameter

   C()           rectangular array with first dimension LDC.

   LDC           leading dimension of C

   WORK()        scratch array of length LWORK. WORK is not
                 referenced in the current version.

   LWORK         length of WORK array. LWORK is not referenced
                 in the current version.

lower triangular matrix represented in skyline format and
op( A )  is one  of

 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' )).
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row or column scaling (see section
                    NOTES for further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter
```

```
DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))

              Note: For the routine, DESCRA(1)=3 is only supported.
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
                0 : non-unit
                1 : unit
              DESCRA(4) Array base  (NOT IMPLEMENTED)
                0 : C/C++ compatible
                1 : Fortran compatible
              DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                0 : unknown
                1 : no repeated indices

VAL()         array contain the nonzeros of A in skyline profile form.
              Row-oriented if DESCRA(2) = 1 (lower triangular),
              column oriented if DESCRA(2) = 2 (upper triangular).

PNTR()        integer array of length M+1 (lower triangular) or
              K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
              points to the location in VAL of the first element of
              the skyline profile in row (column) I.

B()           rectangular array with first dimension LDB.

LDB           leading dimension of B

BETA          Scalar parameter

C()           rectangular array with first dimension LDC.

LDC           leading dimension of C

WORK()        scratch array of length LWORK.
              On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK         length of WORK array.  LWORK should be at least M.

              For good performance, LWORK should generally be larger.
```

For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

NIST FORTRAN Sparse Blas User's Guide available at:

http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. Also not supported:
   a. lower triangular matrix A of size m by n where m > n
   b. upper triangular matrix A of size m by n where m < n

2. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

3. If UNITD =4, the routine scales the rows of A if *DESCRA*(2)=1 and the columns of A if *DESCRA*(2)=2 such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in this particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows (columns) have been scaled. UNITD=2 if *DESCRA*(2)=1 and UNITD=3 if *DESCRA*(2)=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row (column) number which 2-norm is exactly zero.

4. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements

might or might not be referenced in the SKY representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the SKY representation.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

Contents

NAME

dspcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by DSPTRF

SYNOPSIS

```
SUBROUTINE DSPCON(UPLO, N, AP, IPIVOT, ANORM, RCOND, WORK, IWORK2,
      INFO)

CHARACTER * 1 UPLO
INTEGER N, INFO
INTEGER IPIVOT(*), IWORK2(*)

      INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*), IWORK2(*)
DOUBLE PRECISION ANORM, RCOND
DOUBLE PRECISION AP(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPCON(UPLO, N, AP, IPIVOT, ANORM, RCOND, [WORK], [IWORK2],
       [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2
```

```
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: AP, WORK

SUBROUTINE SPCON_64(UPLO, N, AP, IPIVOT, ANORM, RCOND, [WORK],
       [IWORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: AP, WORK
```

C INTERFACE

```
#include <sunperf.h>
void dspcon(char uplo, int n, double *ap, int *ipivot,  dou-
          ble anorm, double *rcond, int *info);

void dspcon_64(char uplo, long n, double *ap, long  *ipivot,
          double anorm, double *rcond, long *info);
```

PURPOSE

dspcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by DSPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

AP (input)
Double precision array, dimension (N*(N+1)/2) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by DSPTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
Double precision array, dimension(2*N)

IWORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

DOUBLE PRECISION AP(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPEV(JOBZ, UPLO, N, AP, W, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: AP, W, WORK
REAL(8), DIMENSION(:,:) :: Z

SUBROUTINE SPEV_64(JOBZ, UPLO, N, AP, W, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: AP, W, WORK
REAL(8), DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dspev(char jobz, char uplo, int n, double  *ap,  double
          *w, double *z, int ldz, int *info);

void dspev_64(char jobz, char uplo, long n, double *ap, dou-
          ble *w, double *z, long ldz, long *info);
```

PURPOSE

dspev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)
Double precision array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)

Double precision array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

Double precision array, dimension(3*N)

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

REAL(8), DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dspevd(char jobz, char uplo, int n, double *ap,  double
          *w, double *z, int ldz, int *info);
void dspevd_64(char jobz, char uplo,  long  n,  double  *ap,
          double *w, double *z, long ldz, long *info);
```

PURPOSE

dspevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
  = 'N': Compute eigenvalues only;
  = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
  = 'U': Upper triangle of A is stored;
  = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
  Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear

array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)

Double precision array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (input) Double precision array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

Real array, dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least 2*N. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6*N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)

Integer array, dimension (LIWORK) On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ =

'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

REAL(8), DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>
void dspevx(char jobz, char range, char uplo, int n,  double
          *ap,  double vl, double vu, int il, int iu, double
          abtol, int *nfound, double *w, double *z, int ldz,
          int *ifail, int *info);

void dspevx_64(char jobz, char range,  char  uplo,  long  n,
          double  *ap,  double  vl, double vu, long il, long
          iu, double abtol, long *nfound, double *w,  double
          *z, long ldz, long *ifail, long *info);
```

PURPOSE

dspevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
- = 'A': all eigenvalues will be found;
- = 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS *   max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
Double precision array, dimension (N) If INFO = 0, the selected eigenvalues in ascending order.

Z (output)
Double precision array, dimension (LDZ, max(1,M)) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
Double precision array, dimension(8*N)

IWORK2 (workspace)
Integer array, dimension(5*N)

IFAIL (output)
Integer array, dimension(N) If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the

indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

NAME

dspgst - reduce a real symmetric-definite generalized eigen-
problem to standard form, using packed storage

SYNOPSIS

```
SUBROUTINE DSPGST(ITYPE, UPLO, N, AP, BP, INFO)

CHARACTER * 1 UPLO
INTEGER ITYPE, N, INFO
DOUBLE PRECISION AP(*), BP(*)

SUBROUTINE DSPGST_64(ITYPE, UPLO, N, AP, BP, INFO)

CHARACTER * 1 UPLO
INTEGER*8 ITYPE, N, INFO
DOUBLE PRECISION AP(*), BP(*)
```

F95 INTERFACE

```
SUBROUTINE SPGST(ITYPE, UPLO, N, AP, BP, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: ITYPE, N, INFO
REAL(8), DIMENSION(:) :: AP, BP

SUBROUTINE SPGST_64(ITYPE, UPLO, N, AP, BP, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: ITYPE, N, INFO
REAL(8), DIMENSION(:) :: AP, BP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dspgst(int itype, char uplo, int n, double *ap,  double
          *bp, int *info);

void dspgst_64(long itype, char uplo, long  n,  double  *ap,
          double *bp, long *info);
```

PURPOSE

dspgst reduces a real symmetric-definite generalized eigen-problem to standard form, using packed storage.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T)
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U**T or L**T*A*L.

B must have been previously factorized as U**T*U or L*L**T by SPPTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T);
= 2 or 3: compute U*A*U**T or L**T*A*L.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as U**T*U; = 'L': Lower triangle of A is stored and B is factored as L*L**T.

N (input) The order of the matrices A and B. N >= 0.

AP (input/output)
Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP (input)
Double precision array, dimension (N*(N+1)/2) The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by SPPTRF.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

Contents

NAME

       [INFO])
```

```
CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: ITYPE, N, LDZ, INFO
REAL(8), DIMENSION(:) :: AP, BP, W, WORK
REAL(8), DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dspgv(int itype, char jobz, char uplo,  int  n,  double
          *ap,  double  *bp,  double *w, double *z, int ldz,
          int *info);

void dspgv_64(long itype, char jobz, char uplo, long n, dou-
          ble  *ap,  double  *bp, double *w, double *z, long
          ldz, long *info);
```

PURPOSE

dspgv computes all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

ARGUMENTS

ITYPE (input)
Specifies the problem type to be solved:
= 1: A*x = (lambda)*B*x
= 2: A*B*x = (lambda)*x
= 3: B*A*x = (lambda)*x

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

AP (input/output)
Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the

array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of A are destroyed.

BP (input/output)

Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T, in the same storage format as B.

W (output)

Double precision array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)

Double precision array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

Double precision array, dimension(3*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: SPPTRF or SSPEV returned an error code:

<= N: if INFO = i, SSPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero. > N: if INFO = n + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

PURPOSE

dspgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:

```
= 1:  A*x = (lambda)*B*x
= 2:  A*B*x = (lambda)*x
= 3:  B*A*x = (lambda)*x
```

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

AP (input/output)
          Double precision array, dimension  (N*(N+1)/2)  On
          entry,  the  upper  or  lower triangle of the sym-
          metric matrix A, packed  columnwise  in  a  linear
          array.   The  j-th  column  of  A is stored in the
          array AP as follows:  if UPLO = 'U',  AP(i  +  (j-
          1)*j/2)  = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i
          + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

          On exit, the contents of AP are destroyed.

BP (input/output)
          Double precision array, dimension  (N*(N+1)/2)  On
          entry,  the  upper  or  lower triangle of the sym-
          metric matrix B, packed  columnwise  in  a  linear
          array.   The  j-th  column  of  B is stored in the
          array BP as follows:  if UPLO = 'U',  BP(i  +  (j-
          1)*j/2)  = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i
          + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

          On exit, the triangular factor U  or  L  from  the
          Cholesky  factorization  B = U**T*U or B = L*L**T,
          in the same storage format as B.

W (output)
          Double precision array, dimension (N) If INFO = 0,
          the eigenvalues in ascending order.

Z (output)
          Double precision array, dimension (LDZ, N) If JOBZ
          =  'V',  then if INFO = 0, Z contains the matrix Z
          of eigenvectors.  The eigenvectors are  normalized
          as  follows:   if ITYPE = 1 or 2, Z**T*B*Z = I; if
          ITYPE = 3, Z**T*inv(B)*Z = I.  If JOBZ = 'N', then
          Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).
```

```
WORK (workspace/output)
          Double precision array, dimension (LWORK) On exit,
          if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
          The dimension of the  array  WORK.   If  N  <=  1,
          LWORK  >=  1.   If  JOBZ = 'N' and N > 1, LWORK >=
          2*N.  If JOBZ = 'V' and N > 1, LWORK >= 1 + 6*N  +
          2*N**2.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace/output)
          Integer array, dimension (LIWORK) On exit, if INFO
          = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
          The dimension of the array IWORK.  If JOBZ  =  'N'
          or N <= 1, LIWORK >= 1.  If JOBZ  = 'V' and N > 1,
          LIWORK >= 3 + 5*N.

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  SPPTRF or SSPEVD returned an error code:
          <= N:  if INFO = i, SSPEVD failed to  converge;  i
          off-diagonal elements of an intermediate tridiago-
          nal form did not converge to zero; > N:   if  INFO
          =  N  + i, for 1 <= i <= N, then the leading minor
          of order i of B is  not  positive  definite.   The
          factorization  of  B could not be completed and no
          eigenvalues or eigenvectors were computed.

          ble  *w,  double  *z,  long ldz, long *ifail, long
          *info);
```

PURPOSE

dspgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed storage, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

ITYPE (input)
Specifies the problem type to be solved:
= 1: A*x = (lambda)*B*x
= 2: A*B*x = (lambda)*x
= 3: B*A*x = (lambda)*x

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A and B are stored;
= 'L': Lower triangle of A and B are stored.

N (input) The order of the matrix pencil (A,B). N >= 0.

AP (input/output)
Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP (input/output)
Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T, in the same storage format as B.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be

returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
Double precision array, dimension (N) On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (output)
Double precision array, dimension (LDZ, max(1,M)) If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
Double precision array, dimension(8*N)

IWORK (workspace)
Integer array, dimension(5*N)

IFAIL (output)
Integer array, dimension (N) If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPPTRF or SSPEVX returned an error code:
<= N: if INFO = i, SSPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

DOUBLE PRECISION A(*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SPMV(UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: A, X, Y

SUBROUTINE SPMV_64(UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX, INCY
REAL(8) :: ALPHA, BETA
```

```
REAL(8), DIMENSION(:) :: A, X, Y
```

C INTERFACE

```
#include <sunperf.h>

void dspmv(char uplo, int n, double alpha, double *a, double
          *x, int incx, double beta, double *y, int incy);

void dspmv_64(char uplo, long n, double  alpha,  double  *a,
          double *x, long incx, double beta, double *y, long
          incy);
```

PURPOSE

dspmv performs the matrix-vector operation y := alpha*A*x + beta*y, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l'   The lower triangular part of A is supplied in A.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that A(1)

contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Unchanged on exit.

X (input)

(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>
void dsprfs(char uplo, int n, int nrhs, double  *ap,  double
          *af,  int  *ipivot, double *b, int ldb, double *x,
          int ldx, double *ferr, double *berr, int *info);

void dsprfs_64(char uplo, long n,  long  nrhs,  double  *ap,
          double  *af,  long  *ipivot,  double *b, long ldb,
          double *x, long ldx, double *ferr,  double  *berr,
          long *info);
```

PURPOSE

dsprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP (input)
Double precsion array, dimension (N*(N+1)/2) The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows:

if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AF (input)
Double precsion array, dimension (N*(N+1)/2) The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

B (input) Double precision array, dimension (LDB,NRHS) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
Double precision array, dimension (LDX,NRHS) On entry, the solution matrix X, as computed by SSPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
Double precision array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Double precision array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an

exact solution).

WORK (workspace)
Double precision array, dimension(3*N)

WORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

C INTERFACE

```
#include <sunperf.h>

void dspsv(char uplo,  int  n,  int  nrhs,  double  *a,  int
          *ipivot, double *b, int ldb, int *info);

void dspsv_64(char uplo, long n, long nrhs, double *a,  long
          *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dspsv computes the solution to a real system of linear equations
   A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
   A = U * D * U**T, if UPLO = 'U', or
   A = L * D * L**T, if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
          = 'U': Upper triangle of A is stored;
          = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
          The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
          Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear

array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (output)
Integer array, dimension (N) Details of the interchanges and the block structure of D, as determined by SSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
Double precision array, dimension (LDB, NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

#include <sunperf.h>

void dspsvx(char fact, char uplo, int n,  int  nrhs,  double
          *a,  double  *af, int *ipivot, double *b, int ldb,
          double *x, int ldx, double *rcond,  double  *ferr,
          double *berr, int *info);

void dspsvx_64(char fact, char uplo, long n, long nrhs, dou-
          ble  *a, double *af, long *ipivot, double *b, long
          ldb, double *x, long ldx,  double  *rcond,  double
          *ferr, double *berr, long *info);
```

PURPOSE

DSPSVX uses the diagonal pivoting factorization A = U*D*U**T or A = L*D*L**T to compute the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the routine
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A. If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form
of A.
4. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. AP, AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP (input)
Double precision array, dimension (N*(N+1)/2) The upper or lower triangle of the symmetric matrix A,

packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AF (input/output)
Double precision array, dimension (N*(N+1)/2) If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)
Integer array, dimension (N) If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSPTRF.

B (input) Double precision array, dimension (LDB, NRHS) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
Double precision array, dimension (LDX, NRHS) If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
Double precision array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Double precision array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
Double precision array, dimension(3*N)

WORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could

not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44
```

Packed storage of the upper triangle of A:

AP = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

void dsptrd(char uplo, int n, double *ap, double *d,  double
          *e, double *tau, int *info);

void dsptrd_64(char uplo, long n,  double  *ap,  double  *d,
          double *e, double *tau, long *info);
```

PURPOSE

dsptrd reduces a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation: Q**T * A * Q = T.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input)
 Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

D (output)
 Double precision array, dimension (N) The diagonal elements of the tridiagonal matrix T: D(i) =

```
          A(i,i).

E (output)
          Double precision array, dimension (N-1)  The  off-
          diagonal  elements  of  the  tridiagonal matrix T:
          E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i)  if
          UPLO = 'L'.

TAU (output)
          Double precision array, dimension (N-1) The scalar
          factors  of the elementary reflectors (see Further
          Details).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
If UPLO = 'U', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(n-1) . . . H(2) H(1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in AP,
overwriting A(1:i-1,i+1), and tau is stored in TAU(i).

If UPLO = 'L', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is stored on exit in AP,
overwriting A(i+2:n,i), and tau is stored in TAU(i).

#include <sunperf.h>

void dsptrf(char uplo, int n, double *ap, int  *ipivot,  int
          *info);

void dsptrf_64(char uplo, long n, double *ap, long  *ipivot,
          long *info);
```

PURPOSE

dsptrf computes the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

A = U*D*U**T or A = L*D*L**T

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Double precision array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then A = U*D*U', where
U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where
L = P(1)*L(1)* ... *P(k)*L(k)* ...,

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

#include <sunperf.h>

void dsptri(char uplo, int n, double *a,  int  *ipivot,  int
          *info);

void dsptri_64(char uplo, long n, double *a,  long  *ipivot,
          long *info);
```

PURPOSE

dsptri computes the inverse of a real symmetric indefinite matrix A in packed storage using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Double precision array, dimension (N*(N+1)/2) On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by DSPTRF.

```
WORK (workspace)
          Double precision array, dimension(N)

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          > 0: if INFO = i, D(i,i) = 0; the matrix is singu-
          lar and its inverse could not be computed.

```

PURPOSE

dsptrs solves a system of linear equations A*X = B with a real symmetric matrix A stored in packed format using the factorization A = U*D*U**T or A = L*D*L**T computed by DSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP (input)
Double precision array, dimension (N*(N+1)/2) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by DSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by DSPTRF.

B (input/output)

Double precision array, dimension (LDB,NRHS) On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void dstebz(char range, char order, int n, double vl, double
          vu,  int  il,  int  iu,  double abstol, double *d,
          double *e, int *m, int  *nsplit,  double  *w,  int
          *iblock, int *isplit, int *info);

void dstebz_64(char range, char order, long  n,  double  vl,
          double vu, long il, long iu, double abstol, double
          *d, double *e, long *m, long *nsplit,  double  *w,
          long *iblock, long *isplit, long *info);
```

PURPOSE

dstebz computes the eigenvalues of a symmetric tridiagonal matrix T. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

ARGUMENTS

RANGE (input)
= 'A': ("All") all eigenvalues will be found.
= 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found. = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

```
ORDER (input)
          =  'B':  ("By  Block")  the  eigenvalues  will  be
          grouped  by  split-off  block (see IBLOCK, ISPLIT)
          and ordered from smallest to  largest  within  the
          block.   =  'E': ("Entire matrix") the eigenvalues
          for the entire matrix will be ordered  from  smal-
          lest to largest.

N (input) The order of the tridiagonal matrix T.  N >= 0.

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to  be searched for eigenvalues.  Eigen-
          values less than or equal to VL, or  greater  than
          VU,   will   not  be  returned.   VL  <  VU.   Not
          referenced if RANGE = 'A' or 'I'.

VU (input)
          See the description of VL.

IL (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.

IU (input)
          See the description of IL.

ABSTOL (input)
          The absolute tolerance for  the  eigenvalues.   An
          eigenvalue   (or  cluster)  is  considered  to  be
          located if it has been determined  to  lie  in  an
          interval whose width is ABSTOL or less.  If ABSTOL
          is less than or equal to zero, then  ULP*|T|  will
          be used, where |T| means the 1-norm of T.

          Eigenvalues will be computed most accurately  when
          ABSTOL  is  set  to  twice the underflow threshold
          2*SLAMCH('S'), not zero.

D (input) The n diagonal elements of the tridiagonal  matrix
          T.

E (input) The (n-1) off-diagonal elements of the tridiagonal
          matrix T.

M (output)
```

The actual number of eigenvalues found. 0 <= M <= N. (See also the description of INFO=2,3.)

NSPLIT (output)
The number of diagonal blocks in the matrix T. 1 <= NSPLIT <= N.

W (output)
On exit, the first M elements of W will contain the eigenvalues. (SSTEBZ may use the remaining N-M elements as workspace.)

IBLOCK (output)
At each row/column j where E(j) is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if INFO = 0, IBLOCK(i) specifies to which block (from 1 to the number of blocks) the eigenvalue W(i) belongs. (SSTEBZ may use the remaining N-M elements as workspace.)

ISPLIT (output)
The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N. (Only the first NSPLIT elements will actually be used, but since the user cannot know a priori what value NSPLIT will have, N words must be reserved for ISPLIT.)

WORK (workspace)
dimension(4*N)

IWORK (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: some or all of the eigenvalues failed to converge or
were not computed:
=1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. This is generally caused

by unexpectedly inaccurate arithmetic. =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found.
Effect: M < IU+1-IL
Cause: non-monotonic arithmetic, causing the Sturm sequence to be non-monotonic. Cure: recalculate, using RANGE='A', and pick
out eigenvalues IL:IU. = 4: RANGE='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed.

```

F95 INTERFACE

```
SUBROUTINE STEDC(COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],
       [LIWORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
INTEGER :: N, LDZ, LWORK, LIWORK, INFO
INTEGER, DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:,:) :: Z
```

```
SUBROUTINE STEDC_64(COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],
       [LIWORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dstedc(char compz, int n, double *d, double *e,  double
          *z, int ldz, int *info);
void dstedc_64(char compz, long n,  double  *d,  double  *e,
          double *z, long ldz, long *info);
```

PURPOSE

dstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'I': Compute eigenvectors of tridiagonal matrix also.
= 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

N (input) The dimension of the symmetric tridiagonal matrix.

```
          N >= 0.

D (input/output)
          On entry, the diagonal elements of the tridiagonal
          matrix.   On exit, if INFO = 0, the eigenvalues in
          ascending order.

E (input/output)
          On entry, the subdiagonal elements of the tridiag-
          onal matrix.  On exit, E has been destroyed.

Z (input) On entry, if COMPZ =  'V',  then  Z  contains  the
          orthogonal  matrix used in the reduction to tridi-
          agonal form.  On exit, if INFO = 0, then if  COMPZ
          =  'V', Z contains the orthonormal eigenvectors of
          the original symmetric matrix, and if COMPZ = 'I',
          Z  contains  the  orthonormal  eigenvectors of the
          symmetric tridiagonal matrix.  If   COMPZ  =  'N',
          then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1.
          If eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
          dimension (LWORK) On exit, if INFO  =  0,  WORK(1)
          returns the optimal LWORK.

LWORK (input)
          The dimension of the array WORK.  If COMPZ  =  'N'
          or N <= 1 then LWORK must be at least 1.  If COMPZ
          = 'V' and N > 1 then LWORK must be at least ( 1  +
          3*N  +  2*N*lg N + 3*N**2 ), where lg( N ) = smal-
          lest integer k such that 2**k >= N.   If  COMPZ  =
          'I'  and  N  > 1 then LWORK must be at least ( 1 +
          4*N + N**2 ).

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LIWORK.

LIWORK (input)
          The dimension of the array IWORK.  If COMPZ =  'N'
          or  N  <=  1  then  LIWORK must be at least 1.  If
```

COMPZ = 'V' and N > 1 then LIWORK must be at least (6 + 6*N + 5*N*lg N). If COMPZ = 'I' and N > 1 then LIWORK must be at least (3 + 5*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

```

PURPOSE

```
dstegr b) Compute the  eigenvalues,  lambda_j,  of  L_i  D_i
L_i^T to high
       relative accuracy by the dqds algorithm,
   (c) If there is a cluster of close eigenvalues,  "choose"
sigma_i
       close to the cluster, and go to step (a),
   (d) Given the approximate eigenvalue lambda_j of L_i  D_i
L_i^T,
       compute the corresponding eigenvector by forming a
       rank-revealing twisted factorization.
The desired accuracy of the output can be specified  by  the
input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for  the  sym-
metric   tridiagonal   eigenvalue/eigenvector  problem",  by
Inderjit Dhillon, Computer Science Division Technical Report
No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently SSTEGR is only set up to find ALL  the  n
eigenvalues and eigenvectors of T in O(n^2) time
Note 2 : Currently the routine  SSTEIN  is  called  when  an
appropriate  sigma_i  cannot  be  chosen  in step (c) above.
```

SSTEIN invokes modified Gram-Schmidt when eigenvalues are close.
Note 3 : SSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E; E(N) need not be set. On exit, E is overwritten.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues/eigenvectors. IF JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than N*EPS*|T|, then N*EPS*|T| will be used in its place, where EPS is the machine precision and |T| is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of EPS*|T| irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,18*N)
If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= max(1,10*N)

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = 1, internal error in SLARRE, if INFO = 2, internal error in SLARRV.

DOUBLE PRECISION D(*), E(*), W(*), Z(LDZ,*), WORK(*)

SUBROUTINE DSTEIN_64(N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,
      IWORK, IFAIL, INFO)

INTEGER*8 N, M, LDZ, INFO
INTEGER*8 IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
DOUBLE PRECISION D(*), E(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEIN(N, D, E, M, W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],
       [IWORK], IFAIL, [INFO])

INTEGER :: N, M, LDZ, INFO
INTEGER, DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL(8), DIMENSION(:) :: D, E, W, WORK
REAL(8), DIMENSION(:,:) :: Z

SUBROUTINE STEIN_64(N, D, E, M, W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],
       [IWORK], IFAIL, [INFO])
```

```
INTEGER(8) :: N, M, LDZ, INFO
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL(8), DIMENSION(:) :: D, E, W, WORK
REAL(8), DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dstein(int n, double *d, double *e, int m,  double  *w,
          int  *iblock, int *isplit, double *z, int ldz, int
          *ifail, int *info);

void dstein_64(long n, double *d, double *e, long m,  double
          *w,  long  *iblock,  long *isplit, double *z, long
          ldz, long *ifail, long *info);
```

PURPOSE

dstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

ARGUMENTS

N (input) The order of the matrix. N >= 0.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix T, in elements 1 to N-1. E(N) need not be set.

M (input) The number of eigenvectors to be found. 0 <= M <= N.

W (input) The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBZ with ORDER = 'B' is expected here.)

IBLOCK (input)

The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBZ is expected here.)

ISPLIT (input)

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBZ is expected here.)

Z (output)

The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations.

LDZ (input)

The leading dimension of the array Z. LDZ >= max(1,N).

WORK (workspace)

dimension(5*N)

IWORK (workspace)

dimension(N)

IFAIL (output)

On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

REAL(8), DIMENSION(:,:) :: Z

SUBROUTINE STEQR_64(COMPZ, N, D, E, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dsteqr(char compz, int n, double *d, double *e,  double
          *z, int ldz, int *info);

void dsteqr_64(char compz, long n,  double  *d,  double  *e,
          double *z, long ldz, long *info);
```

PURPOSE

dsteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors of the original symmetric matrix. On entry, Z must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original symmetric matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
dimension(max(1,2*N-2)) If COMPZ = 'N', then WORK is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: the algorithm has failed to find all the eigenvalues in a total of 30*N iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is orthogonally similar to the original matrix.

REAL(8), DIMENSION(:,:) :: Z

SUBROUTINE STEVD_64(JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],
```

```
      [LIWORK], [INFO])

CHARACTER(LEN=1) :: JOBZ
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: D, E, WORK
REAL(8), DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void dstevd(char jobz, int n, double *d, double  *e,  double
          *z, int ldz, int *info);
void dstevd_64(char jobz, long n, double *d, double *e, dou-
          ble *z, long ldz, long *info);
```

PURPOSE

dstevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
  = 'N': Compute eigenvalues only;
  = 'V': Compute eigenvalues and eigenvectors.

N (input) The order of the matrix. N >= 0.

D (input/output)
  On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
  On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of E; E(N) need not be set, but is used by the

```
          routine.   On  exit,  the  contents  of E are des-
          troyed.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          orthonormal eigenvectors of the matrix A, with the
          i-th column of Z holding the  eigenvector  associ-
          ated  with  D(i).   If  JOBZ  = 'N', then Z is not
          referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).
WORK (workspace)
          dimension (LWORK) On exit, if INFO  =  0,  WORK(1)
          returns the optimal LWORK.

LWORK (input)
          The dimension of the array WORK.  If JOBZ   =  'N'
          or  N <= 1 then LWORK must be at least 1.  If JOBZ
          = 'V' and N > 1 then LWORK must be at least ( 1  +
          4*N + N**2 ).

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LIWORK.

LIWORK (input)
          The dimension of the array IWORK.  If JOBZ  =  'N'
          or N <= 1 then LIWORK must be at least 1.  If JOBZ
          = 'V' and N > 1  then  LIWORK  must  be  at  least
          3+5*N.

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, the algorithm  failed  to  con-
          verge;  i  off-diagonal elements of E did not con-
```

verge to zero.

          ldz, long *isuppz, long *info);
```

PURPOSE

dstevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSTEVR calls SSTEGR to compute the eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

```
   (a) Compute T - sigma_i = L_i D_i L_i^T,  such  that  L_i
D_i L_i^T
        is a relatively robust representation,
   (b) Compute the eigenvalues, lambda_j, of L_i  D_i  L_i^T
to high
       relative accuracy by the dqds algorithm,
   (c) If there is a cluster of close eigenvalues,  "choose"
```

```
sigma_i
       close to the cluster, and go to step (a),
   (d) Given the approximate eigenvalue lambda_j of L_i  D_i
L_i^T,
       compute the corresponding eigenvector by forming a
       rank-revealing twisted factorization.
The desired accuracy of the output can be specified  by  the
input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for  the  sym-
metric   tridiagonal   eigenvalue/eigenvector  problem",  by
Inderjit Dhillon, Computer Science Division Technical Report
No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : SSTEVR calls  SSTEGR  when  the  full  spectrum  is
requested on machines which conform to the ieee-754 floating
point standard.  SSTEVR calls SSTEBZ and SSTEIN on  non-ieee
machines and
when partial spectrum requests are made.

Normal execution of SSTEGR may create  NaNs  and  infinities
and  hence  may  abort  due to a floating point exception in
environments which do not handle NaNs and infinities in  the
ieee standard default manner.
```

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

N (input) The order of the matrix.  N >= 0.

D (input/output)
          On entry, the n diagonal elements of the tridiago-
          nal  matrix  A.  On exit, D may be multiplied by a
          constant factor chosen to avoid over/underflow  in
          computing the eigenvalues.

E (input/output)
          On entry, the (n-1) subdiagonal  elements  of  the
          tridiagonal  matrix  A  in elements 1 to N-1 of E;
```

E(N) need not be set. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 20*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= 10*N.

```
            If LIWORK = -1, then a workspace query is assumed;
            the  routine  only  calculates the optimal size of
            the IWORK array, returns this value as  the  first
            entry  of  the  IWORK  array, and no error message
            related to LIWORK is issued by XERBLA.
INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  Internal error
```

C INTERFACE

```
#include <sunperf.h>
void dstevx(char jobz, char range, int n, double *diag, dou-
          ble  *offd,  double vl, double vu, int il, int iu,
          double abtol, int *nfound, double *w,  double  *z,
          int ldz, int *ifail, int *info);

void dstevx_64(char jobz, char range, long n, double  *diag,
          double  *offd, double vl, double vu, long il, long
          iu, double abtol, long *nfound, double *w,  double
          *z, long ldz, long *ifail, long *info);
```

PURPOSE

dstevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. N >= 0.

DIAG (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, DIAG may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

OFFD (input/output)

On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of OFFD; OFFD(N) need not be set. On exit, OFFD may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal

Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge (INFO > 0), then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(5*N)

IWORK2 (workspace)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

          *subl, double *b, int ldb, int *ipiv, int *info);

void dstsv_64(long n, long nrhs, double *l, double *d,  dou-
          ble  *subl,  double *b, long ldb, long *ipiv, long
          *info);
```

PURPOSE

dstsv computes the solution to a system of linear equations
A * X = B where A is a symmetric tridiagonal matrix.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides in B.

L (input/output)
REAL array, dimension (N)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
REAL array, dimension (N)
On exit, part of the factorization of A.

B (input/output)
The columns of B contain the right hand sides.

LDB (input)
The leading dimension of B as specified in a type or DIMENSION statement.

IPIV (output)

INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

void dsttrf_64(long n, double *l, double *d,  double  *subl,
          long *ipiv, long *info);
```

PURPOSE

dsttrf computes the factorization of a complex Hermitian tridiagonal matrix A.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. N >= 0.

L (input/output)
REAL array, dimension (N)
On entry, the n-1 subdiagonal elements of the tri- diagonal matrix A. On exit, part of the factori- zation of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiago- nal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the L*D*L**H factoriza- tion of A.

SUBL (output)
REAL array, dimension (N)
On exit, part of the factorization of A.

IPIV (output)
INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value
> 0: if INFO = i, D(k,k) is exactly zero.   The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system

of equations.

          *subl, double *b, int ldb, int *ipiv, int *info);

void dsttrs_64(long n, long nrhs, double *l, double *d, dou-
          ble  *subl,  double *b, long ldb, long *ipiv, long
          *info);
```

PURPOSE

dsttrs computes the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. N >= 0.

NRHS (input)
INTEGER
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

L (input) REAL array, dimension (N-1)
On entry, the subdiagonal elements of LL and DD.

D (input) REAL array, dimension (N)
On entry, the diagonal elements of DD.

SUBL (input)
REAL array, dimension (N-2)
On entry, the second subdiagonal elements of LL.

B (input/output)
REAL array, dimension
(LDB, NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
INTEGER
The leading dimension of the array B. LDB >= max(1, N)

```
IPIV (output)
          INTEGER array, dimension (N)
          Details of the interchanges and block  pivot.   If
          IPIV(K)  > 0, 1 by 1 pivot, and if IPIV(K) = K + 1
          an interchange done;  If  IPIV(K)  <  0,  2  by  2
          pivot, no interchange required.

INFO (output)
          INTEGER
          = 0:  successful exit
          < 0:  if INFO = -k, the k-th argument had an ille-
          gal value
```

REAL(8), DIMENSION(:) :: X, Y

SUBROUTINE SWAP_64([N], X, [INCX], Y, [INCY])

INTEGER(8) :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>

void dswap(int n, double *x, int incx, double *y, int incy);

void dswap_64(long n, double *x, long incx, double *y,  long
          incy);
```

PURPOSE

dswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, the y vector.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

void dsycon_64(char uplo, long n, double *a, long lda,  long
          *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

dsycon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDA (input)
The leading dimension of the array A. LDA >=

max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by SSYTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

IWORK2 (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE SYEV_64(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK],
       [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: W, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsyev(char jobz, char uplo, int n, double *a, int  lda,
          double *w, int *info);

void dsyev_64(char jobz, char uplo, long n, double *a,  long
          lda, double *w, long *info);
```

PURPOSE

dsyev computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the  matrix  A.   On  exit, if JOBZ = 'V', then if
          INFO = 0, A contains the orthonormal  eigenvectors
          of  the matrix A.  If JOBZ = 'N', then on exit the
          lower triangle (if UPLO='L') or the upper triangle
          (if  UPLO='U')  of  A,  including the diagonal, is
          destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

W (output)
          If INFO = 0, the eigenvalues in ascending order.
```

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,3*N-1). For optimal efficiency, LDWORK >= (NB+2)*N, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

C INTERFACE

```
#include <sunperf.h>

void dsyevd(char jobz, char uplo, int n, double *a, int lda,
          double *w, int *info);
void dsyevd_64(char jobz, char uplo, long n, double *a, long
          lda, double *w, long *info);
```

PURPOSE

dsyevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Because of large use of BLAS of level 3, SSYEVD needs N**2 more workspace than SSYEVX.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
```

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least 2*N+1. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6*N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

PURPOSE

dsyevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSYEVR calls SSTEGR to compute the eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,
   (a) Compute T - sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T
        is a relatively robust representation,
   (b) Compute the eigenvalues, lambda_j, of L_i D_i L_i^T to high

relative accuracy by the dqds algorithm,
(c) If there is a cluster of close eigenvalues, "choose" sigma_i
close to the cluster, and go to step (a),
(d) Given the approximate eigenvalue lambda_j of L_i D_i L_i^T,
compute the corresponding eigenvector by forming a
rank-revealing twisted factorization.
The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.
Note 1 : SSYEVR calls SSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSYEVR calls SSTEBZ and SSTEIN on non-ieee machines and
when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A.

```
            If UPLO = 'L', the leading N-by-N lower triangular
            part of A contains the lower  triangular  part  of
            the  matrix  A.   On  exit, the lower triangle (if
            UPLO='L') or the upper triangle (if  UPLO='U')  of
            A, including the diagonal, is destroyed.

LDA (input)
            The leading dimension of  the  array  A.   LDA  >=
            max(1,N).

VL (input)
            If RANGE='V', the lower and upper  bounds  of  the
            interval  to be searched for eigenvalues. VL < VU.
            Not referenced if RANGE = 'A' or 'I'.

VU (input)
            See the description of VL.

IL (input)
            If RANGE='I', the indices (in ascending order)  of
            the   smallest   and  largest  eigenvalues  to  be
            returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
            and  IU  =  0 if N = 0.  Not referenced if RANGE =
            'A' or 'V'.

IU (input)
            See the description of IL.

ABSTOL (input)
            The absolute error tolerance for the  eigenvalues.
            An approximate eigenvalue is accepted as converged
            when it is determined to lie in an interval  [a,b]
            of width less than or equal to

            ABSTOL + EPS *   max( |a|,|b| ) ,

            where EPS is the machine precision.  If ABSTOL  is
            less than or equal to zero, then  EPS*|T|  will be
            used in its place, where |T| is the 1-norm of  the
            tridiagonal  matrix obtained by reducing A to tri-
            diagonal form.

            See "Computing Small Singular Values of Bidiagonal
            Matrices  with Guaranteed High Relative Accuracy,"
            by Demmel and Kahan, LAPACK Working Note #3.

            If high relative accuracy is important, set ABSTOL
            to  SLAMCH(  'Safe  minimum'  ).   Doing  so  will
            guarantee that eigenvalues are  computed  to  high
            relative   accuracy   when   possible   in  future
```

releases. The current code does not make any guarantees about high relative accuracy, but furu- tre releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diago- nally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigen- values in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,26*N). For optimal efficiency, LWORK >= (NB+6)*N, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value
> 0: Internal error

          *w, double *z, long ldz, long *ifail, long *info);
```

PURPOSE

dsyevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
```

```
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the  matrix  A.   On  exit, the lower triangle (if
          UPLO='L') or the upper triangle (if  UPLO='U')  of
          A, including the diagonal, is destroyed.
LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

VU (input)
          See the description of VL.

IL (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.

IU (input)
          See the description of IL.

ABTOL (input)
          The absolute error tolerance for the  eigenvalues.
          An approximate eigenvalue is accepted as converged
          when it is determined to lie in an interval  [a,b]
          of width less than or equal to

          ABTOL + EPS *   max( |a|,|b| ) ,

          where EPS is the machine precision.  If  ABTOL  is
          less than or equal to zero, then  EPS*|T|  will be
          used in its place, where |T| is the 1-norm of  the
          tridiagonal  matrix obtained by reducing A to tri-
          diagonal form.

          Eigenvalues will be computed most accurately  when
```

ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,8*N). For optimal efficiency, LDWORK >= (NB+3)*N, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

IWORK2 (workspace)
IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

SUBROUTINE SYGS2(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: ITYPE, N, LDA, LDB, INFO
REAL(8), DIMENSION(:,:) :: A, B

SUBROUTINE SYGS2_64(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: ITYPE, N, LDA, LDB, INFO
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dsygs2(int itype, char uplo, int n, double *a, int lda,
          double *b, int ldb, int *info);

void dsygs2_64(long itype, char uplo,  long  n,  double  *a,
          long lda, double *b, long ldb, long *info);
```

PURPOSE

dsygs2 reduces a real symmetric-definite generalized eigen-problem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U')*A*inv(U) or inv(L)*A*inv(L')
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U` or L'*A*L.

B must have been previously factorized as U'*U or L*L' by SPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U')*A*inv(U) or inv(L)*A*inv(L');
= 2 or 3: compute U*A*U' or L'*A*L.

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored, and how B has been factorized. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

void dsygst_64(long itype, char uplo,  long  n,  double  *a,
          long lda, double *b, long ldb, long *info);
```

PURPOSE

dsygst reduces a real symmetric-definite generalized eigen-
problem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and   A   is   overwritten   by   inv(U**T)*A*inv(U)   or
inv(L)*A*inv(L**T)
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U**T or
L**T*A*L.

B must have been previously factorized as U**T*U or L*L**T
by SPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T);
= 2 or 3: compute U*A*U**T or L**T*A*L.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as U**T*U; = 'L': Lower triangle of A is stored and B is factored as L*L**T.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix,

stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          ble  *a, long lda, double *b, long ldb, double *w,
          long *info);
```

PURPOSE

dsygv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also
positive definite.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
```

tains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the symmetric positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,3*N-1). For optimal efficiency, LDWORK >= (NB+2)*N, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPOTRF or SSYEV returned an error code:
<= N: if INFO = i, SSYEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

          *info);

void dsygvd_64(long itype, char jobz,  char  uplo,  long  n,
          double  *a,  long lda, double *b, long ldb, double
          *w, long *info);
```

PURPOSE

dsygvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:
= 1: A*x = (lambda)*B*x
= 2: A*B*x = (lambda)*x
= 3: B*A*x = (lambda)*x

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the matrix A.

          On exit, if JOBZ = 'V', then if INFO = 0,  A  con-
          tains the matrix Z of eigenvectors.  The eigenvec-
          tors are normalized as follows:  if ITYPE =  1  or
          2,  Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I.
          If JOBZ = 'N', then on exit the upper triangle (if
          UPLO='U')  or  the lower triangle (if UPLO='L') of
          A, including the diagonal, is destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input/output)
          On entry, the symmetric matrix B.  If UPLO =  'U',
          the leading N-by-N upper triangular part of B con-
          tains the upper triangular part of the  matrix  B.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of B contains the lower  triangular  part  of
          the matrix B.

          On exit, if INFO <= N, the part  of  B  containing
          the matrix is overwritten by the triangular factor
          U or L from the Cholesky factorization B =  U**T*U
          or B = L*L**T.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

W (output)
          If INFO = 0, the eigenvalues in ascending order.
```

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 2*N+1. If JOBZ = 'V' and N > 1, LWORK >= 1 + 6*N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If N <= 1, LIWORK >= 1. If JOBZ = 'N' and N > 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPOTRF or SSYEVD returned an error code:
<= N: if INFO = i, SSYEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

PURPOSE

dsygvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangle of A and B are stored;
          = 'L':  Lower triangle of A and B are stored.

N (input) The order of the matrix pencil (A,B).  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the matrix A.

          On exit, the lower triangle (if UPLO='L')  or  the
          upper  triangle  (if UPLO='U') of A, including the
          diagonal, is destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input/output)
          On entry, the symmetric matrix B.  If UPLO =  'U',
          the leading N-by-N upper triangular part of B con-
          tains the upper triangular part of the  matrix  B.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of B contains the lower  triangular  part  of
          the matrix B.

          On exit, if INFO <= N, the part  of  B  containing
          the matrix is overwritten by the triangular factor
          U or L from the Cholesky factorization B =  U**T*U
          or B = L*L**T.
```

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tri- diagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
On normal exit, the first M elements contain the selected eigenvalues in ascending order.

```
Z (input) If JOBZ = 'N', then Z is not referenced.  If  JOBZ
          =  'V', then if INFO = 0, the first M columns of Z
          contain the orthonormal eigenvectors of the matrix
          A  corresponding to the selected eigenvalues, with
          the i-th column of Z holding the eigenvector asso-
          ciated with W(i).  The eigenvectors are normalized
          as follows:  if ITYPE = 1 or 2, Z**T*B*Z =  I;  if
          ITYPE = 3, Z**T*inv(B)*Z = I.
          If an eigenvector fails  to  converge,  then  that
          column  of  Z contains the latest approximation to
          the eigenvector, and the index of the  eigenvector
          is  returned in IFAIL.  Note: the user must ensure
          that at least max(1,M) columns are supplied in the
          array  Z;  if RANGE = 'V', the exact value of M is
          not known in advance and an upper  bound  must  be
          used.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  length  of  the   array   WORK.    LWORK   >=
          max(1,8*N).   For  optimal  efficiency,  LWORK  >=
          (NB+3)*N, where NB is  the  blocksize  for  SSYTRD
          returned by ILAENV.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace)
          dimension(5*N)

IFAIL (output)
          If JOBZ = 'V', then if INFO = 0, the first M  ele-
          ments  of IFAIL are zero.  If INFO > 0, then IFAIL
          contains the  indices  of  the  eigenvectors  that
          failed  to converge.  If JOBZ = 'N', then IFAIL is
          not referenced.

INFO (output)
          = 0:  successful exit
```

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPOTRF or SSYEVX returned an error code:
<= N: if INFO = i, SSYEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

NAME

dsymm - perform one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C

SYNOPSIS

```
SUBROUTINE DSYMM(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
      LDC)

CHARACTER * 1 SIDE, UPLO
INTEGER M, N, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE DSYMM_64(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
      LDC)

CHARACTER * 1 SIDE, UPLO
INTEGER*8 M, N, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYMM(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])

CHARACTER(LEN=1) :: SIDE, UPLO
INTEGER :: M, N, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,:) :: A, B, C

SUBROUTINE SYMM_64(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO
INTEGER(8) :: M, N, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>

void dsymm(char side, char uplo, int m, int n, double alpha,
          double  *a,  int  lda,  double *b, int ldb, double
          beta, double *c, int ldc);

void dsymm_64(char side, char uplo, long m, long  n,  double
          alpha,  double  *a, long lda, double *b, long ldb,
          double beta, double *c, long ldc);
```

PURPOSE

dsymm performs one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

M (input)
On entry, M specifies the number of rows of the matrix C. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix C. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
DOUBLE PRECISION array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When

SIDE = 'L' or 'l' then LDA >= max(1, m), otherwise LDA >= max(1, n). Unchanged on exit.

B (input)
DOUBLE PRECISION array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB >= max(1, m). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)
DOUBLE PRECISION array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC >= max(1, m). Unchanged on exit.

SUBROUTINE DSYMV_64(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)

CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SYMV(UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE SYMV_64(UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO
```

```
INTEGER(8) :: N, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsymv(char uplo, int n, double alpha,  double  *a,  int
          lda,  double *x, int incx, double beta, double *y,
          int incy);

void dsymv_64(char uplo, long n, double  alpha,  double  *a,
          long  lda, double *x, long incx, double beta, dou-
          ble *y, long incy);
```

PURPOSE

dsymv performs the matrix-vector operation y := alpha*A*x + beta*y, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading

n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

X (input)

(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>

void dsyr(char uplo, int n, double  alpha,  double  *x,  int
          incx, double *a, int lda);

void dsyr_64(char uplo, long n,  double  alpha,  double  *x,
          long incx, double *a, long lda);
```

PURPOSE

dsyr performs the symmetric rank 1 operation A := alpha*x*x' + A, where alpha is a real scalar, x is an n element vector and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYR2K(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])

CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER :: N, K, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,:) :: A, B, C

SUBROUTINE SYR2K_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], B,
```

```
          [LDB], BETA, C, [LDC])

   CHARACTER(LEN=1) :: UPLO, TRANSA
   INTEGER(8) :: N, K, LDA, LDB, LDC
   REAL(8) :: ALPHA, BETA
   REAL(8), DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>

void dsyr2k(char uplo, char transa, int  n,  int  k,  double
          alpha,  double  *a,  int  lda, double *b, int ldb,
          double beta, double *c, int ldc);
void dsyr2k_64(char uplo, char transa, long n, long k,  dou-
          ble  alpha,  double  *a, long lda, double *b, long
          ldb, double beta, double *c, long ldc);
```

PURPOSE

dsyr2k performs one of the symmetric rank 2k operations C := alpha*A*B' + alpha*B*A' + beta*C or C := alpha*A'*B + alpha*B'*A + beta*C where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   C := alpha*A*B' + alpha*B*A' + beta*C.

TRANSA = 'T' or 't'   C := alpha*A'*B + alpha*B'*A + beta*C.

TRANSA = 'C' or 'c'   C := alpha*A'*B + alpha*B'*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)
On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
DOUBLE PRECISION array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

B (input)
DOUBLE PRECISION array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

DOUBLE PRECISION array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

          *b, long ldb, double *x, long ldx,  double  *ferr,
          double *berr, long *info);
```

PURPOSE

dsyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not refer-

enced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSYTRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by SSYTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SSYTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

```
            The componentwise relative backward error of  each
            solution  vector X(j) (i.e., the smallest relative
            change in any element of A or B that makes X(j) an
            exact solution).

WORK (workspace)
            dimension(3*N)

WORK2 (workspace)
            dimension(N)

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
```

DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), C(LDC,*)

SUBROUTINE DSYRK_64(UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)

CHARACTER * 1 UPLO, TRANSA
INTEGER*8 N, K, LDA, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYRK(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA, C,
       [LDC])

CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER :: N, K, LDA, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,:) :: A, C

SUBROUTINE SYRK_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
       C, [LDC])

CHARACTER(LEN=1) :: UPLO, TRANSA
```

```
INTEGER(8) :: N, K, LDA, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,:) :: A, C
```

C INTERFACE

```
#include <sunperf.h>

void dsyrk(char uplo, char transa,  int  n,  int  k,  double
          alpha, double *a, int lda, double beta, double *c,
          int ldc);

void dsyrk_64(char uplo, char transa, long n, long k, double
          alpha,  double  *a,  long lda, double beta, double
          *c, long ldc);
```

PURPOSE

dsyrk performs one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   C := alpha*A*A' + beta*C.

TRANSA = 'T' or 't'   C := alpha*A'*A + beta*C.

TRANSA = 'C' or 'c'   C := alpha*A'*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

DOUBLE PRECISION array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

DOUBLE PRECISION array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated

matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

    INTEGER(8), DIMENSION(:) :: IPIV
    REAL(8), DIMENSION(:) :: WORK
    REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
    #include <sunperf.h>

    void dsysv(char uplo, int n, int nrhs, double *a,  int  lda,
              int *ipiv, double *b, int ldb, int *info);
    void dsysv_64(char uplo, long n, long nrhs, double *a,  long
              lda, long *ipiv, double *b, long ldb, long *info);
```

PURPOSE

```
    dsysv computes the solution to a real system of linear equa-
    tions
       A * X = B, where A is an N-by-N symmetric  matrix  and  X
    and B are N-by-NRHS matrices.

    The diagonal pivoting method is used to factor A as
       A = U * D * U**T,  if UPLO = 'U', or
       A = L * D * L**T,  if UPLO = 'L',
    where U (or L) is a product of permutation  and  unit  upper
    (lower)  triangular  matrices,  and D is symmetric and block
    diagonal with 1-by-1 and 2-by-2 diagonal blocks.   The  fac-
    tored  form  of  A is then used to solve the system of equa-
    tions A * X = B.
```

ARGUMENTS

```
    UPLO (input)
              = 'U':  Upper triangle of A is stored;
              = 'L':  Lower triangle of A is stored.

    N (input) The number of linear equations, i.e., the order of
              the matrix A.  N >= 0.

    NRHS (input)
              The number of right hand sides, i.e.,  the  number
              of columns of the matrix B.  NRHS >= 0.

    A (input/output)
              On entry, the symmetric matrix A.  If UPLO =  'U',
```

the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSYTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)
Details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of WORK. LWORK >= 1, and for best performance LWORK >= N*NB, where NB is the optimal blocksize for SSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

void dsysvx(char fact, char uplo, int n,  int  nrhs,  double
          *a,  int  lda,  double *af, int ldaf, int *ipivot,
          double *b, int ldb, double  *x,  int  ldx,  double
          *rcond, double *ferr, double *berr, int *info);

void dsysvx_64(char fact, char uplo, long n, long nrhs, dou-
          ble  *a,  long  lda,  double  *af, long ldaf, long
          *ipivot, double *b, long ldb, double *x, long ldx,
          double  *rcond,  double  *ferr, double *berr, long
          *info);
```

PURPOSE

```
dsysvx uses the diagonal pivoting factorization  to  compute
the solution to a real system of linear equations A * X = B,
where A is an N-by-N symmetric matrix and X and B are  N-by-
NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method  is  used  to
factor A.
   The form of the factorization is
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper
(lower)
   triangular matrices, and D is symmetric and block  diago-
```

nal with
1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not refer-

enced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSYTRF.
If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSYTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >= 3*N, and for best performance LDWORK >= N*NB, where NB is the optimal blocksize for SSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```
SUBROUTINE SYTD2(UPLO, N, A, [LDA], D, E, TAU, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
REAL(8), DIMENSION(:) :: D, E, TAU
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE SYTD2_64(UPLO, N, A, [LDA], D, E, TAU, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL(8), DIMENSION(:) :: D, E, TAU
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsytd2(char uplo, int n, double *a, int lda, double *d,
          double *e, double *tau, int *info);

void dsytd2_64(char uplo, long n, double *a, long lda,  dou-
          ble *d, double *e, double *tau, long *info);
```

PURPOSE

dsytd2 reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: Q' * A * Q = T.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input) On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

```
LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

D (output)
          The diagonal elements of the tridiagonal matrix T:
          D(i) = A(i,i).

E (output)
          The  off-diagonal  elements  of  the   tridiagonal
          matrix  T:   E(i) = A(i,i+1) if UPLO = 'U', E(i) =
          A(i+1,i) if UPLO = 'L'.

TAU (output)
          The scalar factors of  the  elementary  reflectors
          (see Further Details).
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
```

FURTHER DETAILS

```
If UPLO = 'U', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(n-1) . . . H(2) H(1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in
A(1:i-1,i+1), and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is  stored  on  exit  in
A(i+2:n,i), and tau in TAU(i).

The contents of A on exit are illustrated by  the  following
```

```
examples with n = 5:

if UPLO = 'U':                       if UPLO = 'L':

  (  d   e   v2  v3  v4  )                (  d
)
  (     d   e   v3  v4  )               (  e   d
)
  (         d   e   v4  )              (  v1  e   d
)
  (            d   e  )             (  v1  v2  e   d
)
  (                d  )            (  v1  v2  v3  e   d
)

where d and e denote diagonal and off-diagonal  elements  of
T, and vi denotes an element of the vector defining H(i).

INTEGER(8) :: N, LDA, INFO
```

```
INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dsytf2(char uplo, int n, double *a, int lda, int *ipiv,
          int *info);

void dsytf2_64(char uplo, long n, double *a, long lda,  long
          *ipiv, long *info);
```

PURPOSE

dsytf2 computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

A = U*D*U' or A = L*D*L'

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)
Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then A = U*D*U', where
U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-

1,k).   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

          double *e, double *tau, int *info);

void dsytrd_64(char uplo, long n, double *a, long lda,  dou-
          ble *d, double *e, double *tau, long *info);
```

PURPOSE

dsytrd reduces a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation: Q**T * A * Q = T.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

D (output)
The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

```
Q = H(n-1) . . . H(2) H(1).
```

Each H(i) has the form

```
H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in

```
A(1:i-1,i+1), and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is  stored  on  exit  in
A(i+2:n,i), and tau in TAU(i).
The contents of A on exit are illustrated by  the  following
examples with n = 5:

if UPLO = 'U':                       if UPLO = 'L':

  (    d     e     v2    v3    v4   )                (     d
)
  (       d    e    v3    v4   )                (    e     d
)
  (           d    e    v4  )              (   v1   e     d
)
  (              d   e  )              (   v1   v2   e    d
)
  (                  d  )              (  v1  v2  v3  e    d
)

where d and e denote diagonal and off-diagonal  elements  of
T, and vi denotes an element of the vector defining H(i).
```

void dsytrf(char uplo,  int  n,  double  *a,  int  lda,  int
          *ipivot, int *info);

void dsytrf_64(char uplo, long n, double *a, long lda,  long
          *ipivot, long *info);
```

PURPOSE

dsytrf computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >=1. For best performance LDWORK >= N*NB, where NB is the block size returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If UPLO = 'U', then A = U*D*U', where

```
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
```
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where
```
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
```
i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

          *ipivot, int *info);

void dsytri_64(char uplo, long n, double *a, long lda,  long
          *ipivot, long *info);
```

PURPOSE

dsytri computes the inverse of a real symmetric indefinite matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by SSYTRF.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          lda,  long  *ipivot,  double  *b,  long  ldb, long
          *info);
```

PURPOSE

dsytrs solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by SSYTRF.

B (input/output)
On entry, the right hand side matrix B. On exit,

the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TBCON(NORM, UPLO, DIAG, N, KD, A, [LDA], RCOND, [WORK],
       [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER :: N, KD, LDA, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8) :: RCOND
```

```
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE TBCON_64(NORM, UPLO, DIAG, N, KD, A, [LDA], RCOND,
       [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, KD, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
void dtbcon(char norm, char uplo, char diag, int n, int  kd,
          double *a, int lda, double *rcond, int *info);

void dtbcon_64(char norm, char uplo, char diag, long n, long
          kd,  double  *a,  long  lda,  double  *rcond, long
          *info);
```

PURPOSE

```
dtbcon estimates the reciprocal of the condition number of a
triangular  band  matrix  A,  in  either  the  1-norm or the
infinity-norm.

The norm of A is computed and an estimate  is  obtained  for
norm(inv(A)), then the reciprocal of the condition number is
computed as
   RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
```

```
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals  or  subdiagonals  of
          the triangular band matrix A.  KD >= 0.

A (input) The upper  or  lower  triangular  band  matrix  A,
          stored  in  the  first kd+1 rows of the array. The
          j-th column of A is stored in the j-th  column  of
          the  array A as follows:  if UPLO = 'U', A(kd+1+i-
          j,j) = A(i,j) for  max(1,j-kd)<=i<=j;  if  UPLO  =
          'L', A(1+i-j,j)    = A(i,j) for j<=i<=min(n,j+kd).
          If DIAG = 'U', the diagonal elements of A are  not
          referenced and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          KD+1.

RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix   A,  computed  as  RCOND  =  1/(norm(A)  *
          norm(inv(A))).

WORK (workspace)
          dimension(3*N)

WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

REAL(8), DIMENSION(:,:) :: A

SUBROUTINE TBMV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, K, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtbmv(char uplo, char transa, char diag, int n, int  k,
          double *a, int lda, double *y, int incy);

void dtbmv_64(char uplo, char transa,  char  diag,  long  n,
          long  k,  double  *a,  long  lda,  double *y, long
          incy);
```

PURPOSE

dtbmv performs one of the matrix-vector operations x := A*x, or x := A'*x, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := A'*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower

triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tran- formed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>
void dtbrfs(char uplo, char transa, char diag,  int  n,  int
          kd,  int  nrhs, double *a, int lda, double *b, int
          ldb, double *x,  int  ldx,  double  *ferr,  double
          *berr, int *info);

void dtbrfs_64(char uplo, char transa, char  diag,  long  n,
          long  kd,  long  nrhs, double *a, long lda, double
          *b, long ldb, double *x, long ldx,  double  *ferr,
          double *berr, long *info);
```

PURPOSE

dtbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by STBTRS or some other means before entering this routine. STBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)
= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER :: N, K, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE TBSV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, K, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtbsv(char uplo, char transa, char diag, int n, int  k,
          double *a, int lda, double *y, int incy);

void dtbsv_64(char uplo, char transa,  char  diag,  long  n,
          long  k,  double  *a,  long  lda,  double *y, long
          incy);
```

PURPOSE

dtbsv solves one of the systems of equations A*x = b, or A'*x = b, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' A*x = b.

TRANSA = 'T' or 't' A'*x = b.

TRANSA = 'C' or 'c' A'*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the

leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

          *b, long ldb, long *info);
```

PURPOSE

dtbtrs solves a triangular system of the form

where A is a triangular band matrix of order N, and B is an N-by NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form the system of equations:
          = 'N':  A * X = B  (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals  or  subdiagonals  of
          the triangular band matrix A.  KD >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.
```

A (input) The upper or lower triangular band matrix A, stored in the first kd+1 rows of A. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

```
#include <sunperf.h>
void dtgevc(char side, char howmny, int *select, int n, dou-
          ble  *a,  int lda, double *b, int ldb, double *vl,
          int ldvl, double *vr, int ldvr, int  mm,  int  *m,
          int *info);

void dtgevc_64(char side, char howmny, long *select, long n,
          double  *a,  long lda, double *b, long ldb, double
          *vl, long ldvl, double *vr, long  ldvr,  long  mm,
          long *m, long *info);
```

PURPOSE

dtgevc computes some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

(A - wB) * x = 0 and y**H * (A - wB) = 0

where y**H denotes the conjugate tranpose of y.

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products Z*X and/or Q*Y, where Z and Q are input orthogonal matrices. If (A,B) was obtained from the generalized real-Schur factorization of an original pair of matrices
   (A0,B0) = (Q*A*Z**H,Q*B*Z**H),

then Z*X and Q*Y are the matrices of right or left eigenvectors of A.

A must be block upper triangular, with 1-by-1 and 2-by-2 diagonal blocks. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one
eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

SIDE (input)
= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)
= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input)
If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to the real eigenvalue w(j), SELECT(j) must be set to .TRUE. To select the complex eigenvector corresponding to a complex conjugate pair w(j) and w(j+1), either SELECT(j) or SELECT(j+1) must be set to .TRUE..

N (input) The order of the matrices A and B. N >= 0.

A (input) The upper quasi-triangular matrix A.

LDA (input)
The leading dimension of array A. LDA >= max(1, N).

B (input) The upper triangular matrix B. If A has a 2-by-2 diagonal block, then the corresponding 2-by-2 block of B must be diagonal with positive elements.

LDB (input)
The leading dimension of array B. LDB >= max(1,N).

VL (input/output)
On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of left Schur vectors returned by SHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

LDVL (input)
The leading dimension of array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Z of right Schur vectors returned by SHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)
dimension(6*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the 2-by-2 block (INFO:INFO+1) does not have a complex eigenvalue.

FURTHER DETAILS

```
Allocation of workspace:
---------- -- ---------

   WORK( j ) = 1-norm of j-th column of A, above the  diago-
nal
   WORK( N+j ) = 1-norm of j-th column of B, above the diag-
onal
   WORK( 2*N+1:3*N ) = real part of eigenvector
   WORK( 3*N+1:4*N ) = imaginary part of eigenvector
   WORK( 4*N+1:5*N ) = real part of back-transformed  eigen-
vector
   WORK( 5*N+1:6*N ) = imaginary  part  of  back-transformed
eigenvector

Rowwise vs. columnwise solution methods:
------- --  ---------- -------- -------

Finding a  generalized  eigenvector  consists  basically  of
solving the singular triangular system

 (A - w B) x = 0     (for right) or:   (A - w B)**H  y  =  0
(for left)

Consider finding the  i-th  right  eigenvector  (assume  all
eigenvalues are real). The equation to be solved is:
0 = sum  C(j,k) v(k)  = sum  C(j,k) v(k)     for j =  i,.  .
.,1
```

```
    k=j                 k=j

where  C = (A - w B)  (The components v(i+1:n) are 0.)

The "rowwise" method is:

(1)  v(i) := 1
for j = i-1,. . .,1:
                        i
    (2) compute  s = - sum C(j,k) v(k)   and
                      k=j+1
    (3) v(j) := s / C(j,j)
```

Step 2 is sometimes called the "dot product" step, since it is an inner product between the j-th row and the portion of the eigenvector that has been computed so far.

The "columnwise" method consists basically in doing the sums for all the rows in parallel. As each v(j) is computed, the contribution of v(j) times the j-th column of C is added to the partial sums. Since FORTRAN arrays are stored column-wise, this has the advantage that at each step, the elements of C that are accessed are adjacent to one another, whereas with the rowwise method, the elements accessed at a step are spaced LDA (and LDB) words apart.

When finding left eigenvectors, the matrix in question is the transpose of the one in storage, so the rowwise method then actually accesses columns of A and B at each step, and so is the preferred method.

LOGICAL(8) :: WANTQ, WANTZ
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A, B, Q, Z
```

C INTERFACE

```
#include <sunperf.h>

void dtgexc(int wantq, int wantz, int n, double *a, int lda,
          double *b, int ldb, double *q, int ldq, double *z,
          int ldz, int *ifst, int *ilst, int *info);
void dtgexc_64(long wantq, long wantz, long  n,  double  *a,
          long  lda,  double  *b,  long ldb, double *q, long
          ldq, double *z, long ldz, long *ifst, long  *ilst,
          long *info);
```

PURPOSE

dtgexc reorders the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation

so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
       Q(in) * A(in) * Z(in)' = Q(out) * A(out) * Z(out)'
       Q(in) * B(in) * Z(in)' = Q(out) * B(out) * Z(out)'
```

ARGUMENTS

WANTQ (input)

WANTZ (input)

N (input) The order of the matrices A and B. N >= 0.

A (input/output)

On entry, the matrix A in generalized real Schur canonical form. On exit, the updated matrix A, again in generalized real Schur canonical form.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the matrix B in generalized real Schur canonical form (A,B). On exit, the updated matrix B, again in generalized real Schur canonical form (A,B).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

Q (input/output)
On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

Z (input/output)
On entry, if WANTZ = .TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

IFST (input/output)
Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST, ILST <= N.

ILST (input/output)
See the description of IFST.

```
WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK. LWORK  >=  4*N  +
          16.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          =0:  successful exit.
          <0:  if INFO = -i, the i-th argument had an  ille-
          gal value.
          =1:  The transformed matrix pair (A, B)  would  be
          too  far  from generalized Schur form; the problem
          is ill- conditioned. (A, B)  may  have  been  par-
          tially reordered, and ILST points to the first row
          of the current position of the block being moved.

          *info);
```

PURPOSE

dtgsen reorders the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence trans- formation Q' * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B. The leading columns of Q and Z form orthonormal bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

DTGSEN also computes the generalized eigenvalues

w(j) = (ALPHAR(j) + i*ALPHAI(j))/BETA(j)

of the reordered matrix pair (A, B).

Optionally, DTGSEN computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

IJOB (input)
Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):
=0: Only reorder w.r.t. SELECT. No extras.
=1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate
(DIF(1:2)).
=3: Estimate of Difu and Difl. 1-norm-based estimate
(DIF(1:2)). About 5 times as expensive as IJOB = 2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ (input)

WANTZ (input)

SELECT (input)
SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue w(j), SELECT(j) must be set to w(j) and w(j+1), corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to either both included in the cluster or both excluded.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the upper quasi-triangular matrix A, with (A, B) in generalized real Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the upper triangular matrix B, with (A, B) in generalized real Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A,B) were further reduced to triangular form using complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

ALPHAI (output)
See the description of ALPHAR.

BETA (output)
See the description of ALPHAR.

Q (input/output)

On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ (input)

The leading dimension of the array Q. LDQ >= 1; and if WANTQ = .TRUE., LDQ >= N.

Z (input/output)

On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

M (output)

The dimension of the specified pair of left and right eigen- spaces (deflating subspaces). 0 <= M <= N.

PL (output)

If IJOB = 1, 4 or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. 0 < PL, PR <= 1. If M = 0 or M = N, PL = PR = 1. If IJOB = 0, 2 or 3, PL and PR are not referenced.

PR (output)

See the description of PL.

DIF (output)

If IJOB >= 2, DIF(1:2) store the estimates of Difu and Difl.
If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on
Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK (workspace)
If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 4*N+16. If IJOB = 1, 2 or 4, LWORK >= MAX(4*N+16, 2*M*(N-M)). If IJOB = 3 or 5, LWORK >= MAX(4*N+16, 4*M*(N-M)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+6. If IJOB = 3 or 5, LIWORK >= MAX(2*M*(N-M), N+6).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
=0: Successful exit.
<0: If INFO = -i, the i-th argument had an illegal value.
=1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

FURTHER DETAILS

DTGSEN first collects the selected eigenvalues by computing orthogonal U and W that move them to the top left corner of (A, B). In other words, the selected eigenvalues are the eigenvalues of (A11, B11) in:

```
              U'*(A, B)*W = (A11 A12) (B11 B12) n1
                            ( 0  A22),( 0  B22) n2
                              n1  n2    n1  n2
```

where N = n1+n2 and U' means the transpose of U. The first n1 columns of U and W span the specified pair of left and right eigenspaces (deflating subspaces) of (A, B).

If (A, B) has been obtained from the generalized real Schur decomposition of a matrix pair (C, D) = Q*(A, B)*Z', then the reordered generalized real Schur form of (C, D) is given by

```
         (C, D) = (Q*U)*(U'*(A, B)*W)*(Z*W)',
```

and the first n1 columns of Q*U and Z*W span the corresponding deflating subspaces of (C, D) (Q and Z store Q*U and Z*W, resp.).

Note that if the selected eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

The reciprocal condition numbers of the left and right eigenspaces spanned by the first n1 columns of U and W (or Q*U and Z*W) may be returned in DIF(1:2), corresponding to Difu and Difl, resp.

The Difu and Difl are defined as:
ifu[(A11, B11), (A22, B22)] = sigma-min(Zu)
and

where sigma-min(Zu) is the smallest singular value of the (2*n1*n2)-by-(2*n1*n2) matrix

```
u = [ kron(In2, A11)  -kron(A22', In1) ]
          [ kron(In2, B11)  -kron(B22', In1) ].
```

Here, Inx is the identity matrix of size nx and A22' is the transpose of A22. kron(X, Y) is the Kronecker product between the matrices X and Y.

When DIF(2) is small, small changes in (A, B) can cause large changes in the deflating subspace. An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is PS * norm((A, B)) / DIF(2),

where EPS is the machine precision.

```
The reciprocal norm of the projectors on the left and  right
eigenspaces associated with (A11, B11) may be returned in PL
and PR.  They are computed as follows. First  we  compute  L
and R so that P*(A, B)*Q is block diagonal, where
 = ( I -L ) n1           Q = ( I R ) n1
        ( 0  I ) n2    and        ( 0 I ) n2
          n1 n2                    n1 n2

and (L, R) is the  solution  to  the  generalized  Sylvester
equation 11*R - L*A22 = -A12

Then  PL   =   (F-norm(L)**2+1)**(-1/2)   and   PR   =   (F-
norm(R)**2+1)**(-1/2).  An approximate (asymptotic) bound on
the average absolute error of the selected eigenvalues is
PS * norm((A, B)) / PL.

There are also global error bounds which valid for perturba-
tions up to a certain restriction:  A lower bound (x) on the
smallest F-norm(E,F) for which an eigenvalue of  (A11,  B11)
may move and coalesce with an eigenvalue of (A22, B22) under
perturbation (E,F), (i.e. (A + E, B + F), is

 x                                                         =
min(Difu,Difl)/((1/(PL*PL)+1/(PR*PR))**(1/2)+2*max(1/PL,1/PR)).

An approximate bound on x can be computed from DIF(1:2),  PL
and PR.

If y = ( F-norm(E,F) / x) <= 1, the angles between the  per-
turbed  (L',  R')  and  unperturbed  (L,  R)  left and right
deflating subspaces associated with the selected cluster  in
the (1,1)-blocks can be bounded as

 max-angle(L, L') <= arctan( y * PL / (1 - y *  (1  -  PL  *
PL)**(1/2))
 max-angle(R, R') <= arctan( y * PR / (1 - y *  (1  -  PR  *
PR)**(1/2))

See LAPACK User's Guide section 4.11 or the following refer-
ences for more information.

Note  that  if  the  default  method   for   computing   the
Frobenius-norm-  based  estimate  DIF  is  not  wanted  (see
SLATDF), then the parameter IDIFJB  (see  below)  should  be
changed  from  3  to  4  (routine  SLATDF  (IJOB = 2 will be
used)). See STGSYL for more details.

```

PURPOSE

dtgsja computes the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine SGGSVP from a general M-by-N matrix A and P-by-N matrix B:

```
             N-K-L  K    L
   A =    K ( 0    A12  A13 ) if M-K-L >= 0;
          L ( 0     0   A23 )
      M-K-L ( 0     0    0  )
```

```
           N-K-L  K    L
   A =  K ( 0    A12  A13 ) if M-K-L < 0;
      M-K ( 0     0   A23 )

           N-K-L  K    L
   B =  L ( 0     0   B13 )
      P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

```
            U'*A*Q = D1*( 0 R ),    V'*B*Q = D2*( 0 R ),
```

where U, V and Q are orthogonal matrices, Z' denotes the transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are ``diagonal'' matrices, which are of the following structures:

If M-K-L >= 0,

```
                    K  L
       D1 =     K ( I  0 )
                L ( 0  C )
            M-K-L ( 0  0 )

                  K  L
       D2 = L   ( 0  S )
            P-L ( 0  0 )

              N-K-L  K    L
  ( 0 R ) = K (  0   R11  R12 ) K
            L (  0    0   R22 ) L
```

where

```
  C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
  S = diag( BETA(K+1),  ... , BETA(K+L) ),
  C**2 + S**2 = I.

  R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
              K M-K K+L-M
    D1 =   K ( I  0    0   )
         M-K ( 0  C    0   )
```

```
                 K M-K K+L-M
    D2 =   M-K ( 0  S    0   )
         K+L-M ( 0  0    I   )
           P-L ( 0  0    0   )

               N-K-L  K   M-K  K+L-M

          M-K ( 0     0   R22  R23  )
        K+L-M ( 0     0    0   R33  )
```

where
C = diag(ALPHA(K+1), ... , ALPHA(M)),
S = diag(BETA(K+1), ... , BETA(M)),
C**2 + S**2 = I.

R = (R11 R12 R13) is stored in A(1:M, N-K-L+1:N) and R33 is stored
    (0 R22 R23)
in B(M-K+1:L,N+M-K-L+1:N) on exit.

The computation of the orthogonal transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices U1, V1, or Q1.
STGSJA essentially uses a variant of Kogbetliantz algorithm to reduce min(L,M-K)-by-L triangular (or trapezoidal) matrix A23 and L-by-L matrix B13 to the form:
   U1'*A13*Q1 = C1*R1; V1'*B13*Q1 = S1*R1,
where U1, V1 and Q1 are orthogonal matrix, and Z' is the transpose of Z. C1 and S1 are diagonal matrices satisfying
   C1**2 + S1**2 = I,
and R1 is an L-by-L nonsingular upper triangular matrix.

ARGUMENTS

JOBU (input)
= 'U': U must contain an orthogonal matrix U1 on entry, and the product U1*U is returned; = 'I': U is initialized to the unit matrix, and the orthogonal matrix U is returned; = 'N': U is not computed.

JOBV (input)
= 'V': V must contain an orthogonal matrix V1 on entry, and the product V1*V is returned; = 'I': V is initialized to the unit matrix, and the orthogonal matrix V is returned; = 'N': V is not computed.

JOBQ (input)
= 'Q': Q must contain an orthogonal matrix Q1 on entry, and the product Q1*Q is returned; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

K (input) K and L specify the subblocks in the input matrices A and B:
A23 = A(K+1:MIN(K+L,M),N-L+1:N) and B13 = B(1:L,N-L+1:N) of A and B, whose GSVD is going to be computed by STGSJA. See Further details.

L (input) See the description of K.

A (input/output)
On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L,M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

TOLA (input)
TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say TOLA = max(M,N)*norm(A)*MACHEPS, TOLB = max(P,N)*norm(B)*MACHEPS.

TOLB (input)
See the description of TOLA.

```
ALPHA (output)
          On exit, ALPHA and BETA  contain  the  generalized
          singular value pairs of A and B; ALPHA(1:K) = 1,
          BETA(1:K)  = 0, and if M-K-L >= 0,  ALPHA(K+1:K+L)
          = diag(C),
          BETA(K+1:K+L)   =  diag(S),  or  if  M-K-L  <   0,
          ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0
          BETA(K+1:M) = S, BETA(M+1:K+L) = 1.   Furthermore,
          if K+L < N, ALPHA(K+L+1:N) = 0 and
          BETA(K+L+1:N)  = 0.
BETA (output)
          See the description of ALPHA.

U (input) On entry, if JOBU = 'U', U must contain  a  matrix
          U1  (usually  the  orthogonal  matrix  returned by
          SGGSVP).  On exit, if JOBU = 'I', U  contains  the
          orthogonal matrix U; if JOBU = 'U', U contains the
          product U1*U.  If JOBU = 'N', U is not referenced.

LDU (input)
          The leading dimension  of  the  array  U.  LDU  >=
          max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) On entry, if JOBV = 'V', V must contain  a  matrix
          V1  (usually  the  orthogonal  matrix  returned by
          SGGSVP).  On exit, if JOBV = 'I', V  contains  the
          orthogonal matrix V; if JOBV = 'V', V contains the
          product V1*V.  If JOBV = 'N', V is not referenced.

LDV (input)
          The leading dimension  of  the  array  V.  LDV  >=
          max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) On entry, if JOBQ = 'Q', Q must contain  a  matrix
          Q1  (usually  the  orthogonal  matrix  returned by
          SGGSVP).  On exit, if JOBQ = 'I', Q  contains  the
          orthogonal matrix Q; if JOBQ = 'Q', Q contains the
          product Q1*Q.  If JOBQ = 'N', Q is not referenced.

LDQ (input)
          The leading dimension  of  the  array  Q.  LDQ  >=
          max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)
          dimension(2*N)

NCYCLE (output)
          The number of cycles required for convergence.
```

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1: the procedure does not converge after MAXIT cycles.

          double *dif, long mm, long *m, long *info);
```

PURPOSE

dtgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q*A*Z', Q*B*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z.

(A, B) must be in generalized real Schur form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):
= 'E': for eigenvalues only (S);
= 'V': for eigenvectors only (DIF);
= 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNT (input)
= 'A': compute condition numbers for all eigenpairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

N (input) The order of the square matrix pair (A, B). N >= 0.

A (input) The upper quasi-triangular matrix A in the pair (A,B).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The upper triangular matrix B in the pair (A,B).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

VL (input)
If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by STGEVC. If JOB = 'V', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. LDVL >= 1. If JOB = 'E' or 'B', LDVL >= N.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns ov VR, as returned by STGEVC. If JOB = 'V', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= 1. If JOB = 'E' or 'B', LDVR >= N.

S (output)
If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), DIF(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

DIF (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of DIF are set to the same value. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', DIF is not referenced.

MM (input)
The number of elements in the arrays S and DIF. MM >= M.

M (output)
The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected real eigenvalue one element is used, and for each selected complex conjugate pair of eigenvalues, two elements are used. If HOWMNT = 'A', M is set to N.

WORK (workspace)
If JOB = 'E', WORK is not referenced. Otherwise,

```
          on  exit, if INFO = 0, WORK(1) returns the optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK. LWORK >=  N.   If
          JOB = 'V' or 'B' LWORK >= 2*N*(N+2)+16.
          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace)
          dimension(N+6) If JOB = 'E', IWORK is  not  refer-
          enced.

INFO (output)
          =0: Successful exit
          <0: If INFO = -i, the i-th argument had an illegal
          value
```

FURTHER DETAILS

```
The reciprocal of the  condition  number  of  a  generalized
eigenvalue w = (a, b) is defined as
(w) = (|u'Av|**2 + |u'Bv|**2)**(1/2) / (norm(u)*norm(v))

where u and v are the left and right eigenvectors of (A,  B)
corresponding  to  w;  |z| denotes the absolute value of the
complex number, and norm(u) denotes the 2-norm of the vector
u.
The pair (a, b) corresponds to an  eigenvalue  w  =  a/b  (=
u'Av/u'Bv)  of the matrix pair (A, B). If both a and b equal
zero, then (A B) is singular and S(I) = -1 is returned.

An approximate error bound on the chordal  distance  between
the   i-th   computed   generalized  eigenvalue  w  and  the
corresponding exact eigenvalue lambda is
hord(w, lambda) <= EPS * norm(A, B) / S(I)

where EPS is the machine precision.

The reciprocal of  the  condition  number  DIF(i)  of  right
eigenvector  u  and  left eigenvector v corresponding to the
generalized eigenvalue w is defined as follows:

a) If the i-th eigenvalue w = (a,b) is real

   Suppose U and V are orthogonal transformations such that
```

```
              U'*(A, B)*V  = (S, T) = ( a   *  ) ( b   *   )
1
                                        ( 0  S22 ),( 0  T22  )
n-1
                                          1  n-1     1 n-1

   Then the reciprocal condition number DIF(i) is
              Difl((a, b), (S22, T22)) = sigma-min( Zl ),

   where sigma-min(Zl) denotes the smallest  singular  value
of the
   2(n-1)-by-2(n-1) matrix

       Zl = [ kron(a, In-1)  -kron(1, S22) ]
            [ kron(b, In-1)  -kron(1, T22) ] .

   Here In-1 is the identity matrix of size n-1. kron(X,  Y)
is the
   Kronecker product between the matrices X and Y.

   Note that if the default method for computing  DIF(i)  is
wanted
   (see SLATDF),  then  the  parameter  DIFDRI  (see  below)
should be
   changed from 3 to 4 (routine  SLATDF(IJOB  =  2  will  be
used)).
   See STGSYL for more details.

b) If the i-th and (i+1)-th eigenvalues are  complex  conju-
gate pair,

   Suppose U and V are orthogonal transformations such that

              U'*(A, B)*V = (S, T) = ( S11  *   ) (  T11   *
)  2
                                       (  0      S22   ),(   0
T22) n-2
                                         2    n-2     2    n-2

   and (S11,  T11)  corresponds  to  the  complex  conjugate
eigenvalue
   pair (w, conjg(w)). There exist unitary matrices  U1  and
V1 such
   that

       U1'*S11*V1 = ( s11 s12 )   and U1'*T11*V1 = ( t11 t12
)
                    (  0  s22 )                    (  0  t22
)
```

```
   where the generalized eigenvalues w = s11/t11 and
   conjg(w) = s22/t22.

   Then the reciprocal condition number DIF(i) is bounded by

       min( d1, max( 1, |real(s11)/real(s22)| )*d2 )

   where, d1 = Difl((s11, t11), (s22, t22)) = sigma-min(Z1),
where
   Z1 is the complex 2-by-2 matrix

            Z1 =  [ s11  -s22 ]
                  [ t11  -t22 ],

   This is done by computing (using real arithmetic) the
   roots of the characteristical polynomial det(Z1' *  Z1  -
lambda I),
   where Z1' denotes  the  conjugate  transpose  of  Z1  and
det(X) denotes
   the determinant of X.

   and d2 is an upper bound on Difl((S11, T11), (S22, T22)),
i.e. an
   upper bound on sigma-min(Z2), where Z2 is  (2n-2)-by-(2n-
2)

            Z2 = [ kron(S11', In-2)  -kron(I2, S22) ]
                 [ kron(T11', In-2)  -kron(I2, T22) ]

   Note that if the default  method  for  computing  DIF  is
wanted (see
   SLATDF), then the parameter DIFDRI (see below) should  be
changed
   from 3 to 4 (routine SLATDF(IJOB = 2 will be used)).  See
STGSYL
   for more details.

For each eigenvalue/vector specified by SELECT, DIF stores a
Frobenius norm-based estimate of Difl.

An approximate error bound for the i-th computed eigenvector
VL(i) or VR(i) is given by

           EPS * norm(A, B) / DIF(i).

See ref. [2-3] for more details and further references.

          long *info);
```

PURPOSE

dtgsyl solves the generalized Sylvester equation:

```
            A * R - L * B = scale * C                 (1)
            D * R - L * E = scale * F
```

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with real entries. (A, D) and (B, E) must be in generalized (real) Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve Zx = scale b, where Z is defined as

```
           Z = [ kron(In, A)  -kron(B', Im) ]         (2)
               [ kron(In, D)  -kron(E', Im) ].
```

Here Ik is the identity matrix of size k and X' is the transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'T', STGSYL solves the transposed system Z'*y = scale*b, which is equivalent to solve for R and L in

```
            A' * R  + D' * L   = scale *  C           (3)
            R  * B' + L  * E'  = scale * (-F)
```

This case (TRANS = 'T') is used to compute an one-norm-based estimate of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D) and (B,E), using SLACON.

If IJOB >= 1, STGSYL computes a Frobenius norm-based estimate of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z. See [1-2] for more information.

This is a level 3 BLAS algorithm.

ARGUMENTS

TRANS (input)
: = 'N', solve the generalized Sylvester equation (1). = 'T', solve the 'transposed' system (3).

IJOB (input)
: Specifies what kind of functionality to be performed. =0: solve (1) only.
=1: The functionality of 0 and 3.
=2: The functionality of 0 and 4.
=3: Only an estimate of Dif[(A,D), (B,E)] is computed. (look ahead strategy IJOB = 1 is used).
=4: Only an estimate of Dif[(A,D), (B,E)] is computed. (SGECON on sub-systems is used). Not referenced if TRANS = 'T'.

M (input)
: The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

```
N (input) The order of the matrices B and E, and the  column
          dimension of the matrices C, F, R and L.

A (input) The upper quasi triangular matrix A.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1, M).

B (input) The upper quasi triangular matrix B.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1, N).
C (input/output)
          On entry, C contains the  right-hand-side  of  the
          first  matrix equation in (1) or (3).  On exit, if
          IJOB = 0, 1 or 2, C has been  overwritten  by  the
          solution  R.  If  IJOB = 3 or 4 and TRANS = 'N', C
          holds R, the solution achieved during the computa-
          tion of the Dif-estimate.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1, M).

D (input) The upper triangular matrix D.

LDD (input)
          The leading dimension  of  the  array  D.  LDD  >=
          max(1, M).

E (input) The upper triangular matrix E.

LDE (input)
          The leading dimension  of  the  array  E.  LDE  >=
          max(1, N).

F (input/output)
          On entry, F contains the  right-hand-side  of  the
          second matrix equation in (1) or (3).  On exit, if
          IJOB = 0, 1 or 2, F has been  overwritten  by  the
          solution  L.  If  IJOB = 3 or 4 and TRANS = 'N', F
          holds L, the solution achieved during the computa-
          tion of the Dif-estimate.

LDF (input)
          The leading dimension  of  the  array  F.  LDF  >=
          max(1, M).
```

SCALE (output)
On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of Dif[(A,D), (B,E)] = sigma_min(Z), where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

DIF (output)
On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of Dif[(A,D), (B,E)] = sigma_min(Z), where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

WORK (workspace)
If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK > = 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(M+N+2)

INFO (output)
=0: successful exit
<0: If INFO = -i, the i-th argument had an illegal value.
>0: (A, D) and (B, E) have common or close eigen- values.

void dtpcon(char norm, char uplo, char diag, int  n,  double
          *a, double *rcond, int *info);
void dtpcon_64(char norm, char uplo, char diag, long n, dou-
          ble *a, double *rcond, long *info);
```

PURPOSE

dtpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.
```

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          *a, double *y, int incy);

void dtpmv_64(char uplo, char transa,  char  diag,  long  n,
          double *a, double *y, long incy);
```

PURPOSE

dtpmv performs one of the matrix-vector operations x := A*x, or x := A'*x, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

```
UPLO (input)
          On entry, UPLO specifies whether the matrix is  an
          upper or lower triangular matrix as follows:

          UPLO = 'U' or  'u'    A  is  an  upper  triangular
          matrix.

          UPLO = 'L'  or  'l'    A  is  a  lower  triangular
          matrix.

          Unchanged on exit.

TRANSA (input)
          On entry, TRANSA specifies  the  operation  to  be
          performed as follows:

          TRANSA = 'N' or 'n'   x := A*x.

          TRANSA = 'T' or 't'   x := A'*x.

          TRANSA = 'C' or 'c'   x := A'*x.

          Unchanged on exit.

          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
          On entry, DIAG specifies whether or not A is  unit
          triangular as follows:

          DIAG = 'U' or 'u'   A is assumed to be  unit  tri-
```

angular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tranformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>
void dtprfs(char uplo, char transa, char diag,  int  n,  int
          nrhs,  double  *a,  double *b, int ldb, double *x,
          int ldx, double *ferr, double *berr, int *info);

void dtprfs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs, double *a, double *b, long ldb, double
          *x, long ldx, double  *ferr,  double  *berr,  long
          *info);
```

PURPOSE

dtprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by STPTRS or some other means before entering this routine. STPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B  (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.
```

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

```
dtpsv - solve one of the systems of equations A*x  =  b,  or
A'*x = b
```

SYNOPSIS

```
SUBROUTINE DTPSV(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, INCY
DOUBLE PRECISION A(*), Y(*)

SUBROUTINE DTPSV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, INCY
DOUBLE PRECISION A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPSV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, INCY
REAL(8), DIMENSION(:) :: A, Y

SUBROUTINE TPSV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, INCY
REAL(8), DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtpsv(char uplo, char transa, char diag, int n,  double
          *a, double *y, int incy);

void dtpsv_64(char uplo, char transa,  char  diag,  long  n,
          double *a, double *y, long incy);
```

PURPOSE

dtpsv solves one of the systems of equations A*x = b, or A'*x = b, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   A'*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

Contents

NAME

```
dtptri - compute the inverse of a real upper or  lower  tri-
angular matrix A stored in packed format
```

SYNOPSIS

```
SUBROUTINE DTPTRI(UPLO, DIAG, N, A, INFO)

CHARACTER * 1 UPLO, DIAG
INTEGER N, INFO
DOUBLE PRECISION A(*)

SUBROUTINE DTPTRI_64(UPLO, DIAG, N, A, INFO)

CHARACTER * 1 UPLO, DIAG
INTEGER*8 N, INFO
DOUBLE PRECISION A(*)
```

F95 INTERFACE

```
SUBROUTINE TPTRI(UPLO, DIAG, N, A, [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER :: N, INFO

SUBROUTINE TPTRI_64(UPLO, DIAG, N, A, [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER(8) :: N, INFO
REAL(8), DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtptri(char uplo, char diag,  int  n,  double  *a,  int
          *info);

void dtptri_64(char uplo, char diag, long n, double *a, long
          *info);
```

PURPOSE

dtptri computes the inverse of a real upper or lower triangular matrix A stored in packed format.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the upper or lower triangular matrix  A,
          stored  columnwise  in  a  linear array.  The j-th
          column of A is stored in the array A  as  follows:
          if  UPLO  =  'U',  A(i  +  (j-1)*j/2) = A(i,j) for
          1<=i<=j; if UPLO = 'L', A(i + (j-1)*((2*n-j)/2)  =
          A(i,j)   for   j<=i<=n.   See  below  for  further
          details.  On exit, the (triangular) inverse of the
          original  matrix,  in the same packed storage for-
          mat.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, A(i,i) is  exactly  zero.   The
          triangular  matrix is singular and its inverse can
          not be computed.
```

FURTHER DETAILS

A triangular matrix A can be transferred to packed storage using one of the following program segments:

UPLO = 'U':

```
      JC = 1
      DO 2 J = 1, N
         DO 1 I = 1, J
            A(JC+I-1) = A(I,J)
    1    CONTINUE
         JC = JC + J
    2 CONTINUE
```

UPLO = 'L':

```
      JC = 1
      DO 2 J = 1, N
         DO 1 I = J, N
            A(JC+I-J) = A(I,J)
    1    CONTINUE
         JC = JC + N - J + 1
    2 CONTINUE
```

          nrhs, double *a, double *b, int ldb, int *info);

void dtptrs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs,  double  *a, double *b, long ldb, long
          *info);
```

PURPOSE

dtptrs solves a triangular system of the form

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

UPLO (input)
= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose = Transpose)

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

dtrans - transpose and scale source matrix
```

SYNOPSIS

```
SUBROUTINE DTRANS(PLACE, SCALE, SOURCE, M, N, DEST)

CHARACTER * 1 PLACE
INTEGER M, N
DOUBLE PRECISION SCALE
DOUBLE PRECISION SOURCE(*), DEST(*)

SUBROUTINE DTRANS_64(PLACE, SCALE, SOURCE, M, N, DEST)

CHARACTER * 1 PLACE
INTEGER*8 M, N
DOUBLE PRECISION SCALE
DOUBLE PRECISION SOURCE(*), DEST(*)
```

F95 INTERFACE

```
SUBROUTINE TRANS([PLACE], SCALE, SOURCE, M, N, [DEST])

CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N
REAL(8) :: SCALE
REAL(8), DIMENSION(:) :: SOURCE, DEST

SUBROUTINE TRANS_64([PLACE], SCALE, SOURCE, M, N, [DEST])

CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N
REAL(8) :: SCALE
REAL(8), DIMENSION(:) :: SOURCE, DEST
```

C INTERFACE

```
#include <sunperf.h>

void dtrans(char place, double scale, double *source, int m,
          int n, double *dest);

void dtrans_64(char place,  double  scale,  double  *source,
          long m, long n, double *dest);
```

PURPOSE

dtrans scales and transposes the source matrix. The N2 x N1 result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE'

PLACE = 'O' or 'o': DEST = SCALE * SOURCE'

ARGUMENTS

PLACE (input)
: Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place. 'I' is default.

SCALE (input)
: Scale factor on the SOURCE matrix.

SOURCE (input/output)
: (M, N) on input. Array of (N, M) on output if in-place transpose.

M (input)
: Number of rows in the SOURCE matrix on input.

N (input)
: Number of columns in the SOURCE matrix on input.

DEST (output)
: Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

NAME

dtrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE DTRCON(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,
      INFO)

CHARACTER * 1 NORM, UPLO, DIAG
INTEGER N, LDA, INFO
INTEGER WORK2(*)
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)

SUBROUTINE DTRCON_64(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,
      INFO)

CHARACTER * 1 NORM, UPLO, DIAG
INTEGER*8 N, LDA, INFO
INTEGER*8 WORK2(*)
DOUBLE PRECISION RCOND
DOUBLE PRECISION A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON(NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK], [WORK2],
       [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8) :: RCOND
```

```
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE TRCON_64(NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],
       [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
void dtrcon(char norm, char uplo, char diag, int  n,  double
          *a, int lda, double *rcond, int *info);

void dtrcon_64(char norm, char uplo, char diag, long n, dou-
          ble *a, long lda, double *rcond, long *info);
```

PURPOSE

dtrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.
```

N (input) The order of the matrix A. N >= 0.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          ble *t, int ldt, double *vl, int ldvl, double *vr,
          int ldvr, int mm, int *m, int *info);
void dtrevc_64(char side, char howmny, long *select, long n,
          double *t, long ldt, double *vl, long ldvl, double
          *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

dtrevc computes some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

T*x = w*x,   y'*T = w*y'

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input orthogonal
matrix. If T was obtained from the real-Schur factorization of an original matrix A = Q*T*Q', then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigenvectors; only one eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

```
SIDE (input)
          = 'R':  compute right eigenvectors only;
          = 'L':  compute left eigenvectors only;
          = 'B':  compute both right and left eigenvectors.

HOWMNY (input)
          = 'A':  compute all right  and/or  left  eigenvec-
          tors;
          = 'B':  compute all right  and/or  left  eigenvec-
          tors,  and  backtransform  them  using  the  input
          matrices supplied in VR and/or VL; = 'S':  compute
          selected right and/or left eigenvectors, specified
          by the logical array SELECT.
SELECT (input/output)
          If HOWMNY = 'S', SELECT specifies the eigenvectors
          to be computed.  If HOWMNY = 'A' or 'B', SELECT is
          not referenced.  To select  the  real  eigenvector
          corresponding to a real eigenvalue w(j), SELECT(j)
          must be set to  .TRUE..   To  select  the  complex
          eigenvector  corresponding  to a complex conjugate
          pair  w(j)  and  w(j+1),   either   SELECT(j)   or
          SELECT(j+1)  must  be  set to .TRUE.; then on exit
          SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

N (input) The order of the matrix T. N >= 0.

T (input/output)
          The  upper  quasi-triangular  matrix  T  in  Schur
          canonical form.

LDT (input)
          The leading dimension  of  the  array  T.  LDT  >=
          max(1,N).

VL (input/output)
          On entry, if SIDE = 'L' or 'B' and HOWMNY  =  'B',
          VL  must  contain  an N-by-N matrix Q (usually the
          orthogonal matrix Q of Schur vectors  returned  by
          SHSEQR).   On  exit, if SIDE = 'L' or 'B', VL con-
          tains:  if HOWMNY = 'A',  the  matrix  Y  of  left
          eigenvectors  of  T;  VL  has the same quasi-lower
          triangular form as T'. If T(i,i) is a real  eigen-
          value,  then  the  i-th column VL(i) of VL  is its
          corresponding eigenvector. If T(i:i+1,i:i+1) is  a
          2-by-2   block   whose  eigenvalues  are  complex-
          conjugate  eigenvalues  of  T,  then  VL(i)+sqrt(-
```

1)*VL(i+1) is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR has the same quasi-upper triangular form as T. If T(i,i) is a real eigenvalue, then the i-th column VR(i) of VR is its corresponding eigenvector. If T(i:i+1,i:i+1) is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then VR(i)+sqrt(-1)*VR(i+1) is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR

actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The algorithm used in this program is basically backward (forward) substitution, with scaling to make the the code robust against possible overflow.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|.

NAME

```
dtrexc - reorder the real  Schur  factorization  of  a  real
matrix  A  =  Q*T*Q**T, so that the diagonal block of T with
row index IFST is moved to row ILST
```

SYNOPSIS

```
SUBROUTINE DTREXC(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK, INFO)

CHARACTER * 1 COMPQ
INTEGER N, LDT, LDQ, IFST, ILST, INFO
DOUBLE PRECISION T(LDT,*), Q(LDQ,*), WORK(*)

SUBROUTINE DTREXC_64(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK,
      INFO)

CHARACTER * 1 COMPQ
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
DOUBLE PRECISION T(LDT,*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TREXC(COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],
       [INFO])

CHARACTER(LEN=1) :: COMPQ
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: T, Q

SUBROUTINE TREXC_64(COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],
       [INFO])

CHARACTER(LEN=1) :: COMPQ
```

```
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: T, Q
```

C INTERFACE

```
#include <sunperf.h>

void dtrexc(char compq, int n, double *t,  int  ldt,  double
          *q, int ldq, int *ifst, int *ilst, int *info);

void dtrexc_64(char compq, long n, double *t, long ldt, dou-
          ble  *q,  long  ldq,  long *ifst, long *ilst, long
          *info);
```

PURPOSE

dtrexc reorders the real Schur factorization of a real matrix A = Q*T*Q**T, so that the diagonal block of T with row index IFST is moved to row ILST.

The real Schur form T is reordered by an orthogonal similarity transformation Z**T*T*Z, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

COMPQ (input)
= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q.

N (input) The order of the matrix T. N >= 0.

T (input/output)
On entry, the upper quasi-triangular matrix T, in Schur Schur canonical form. On exit, the reordered upper quasi-triangular matrix, again in Schur canonical form.

LDT (input)
The leading dimension of the array T. LDT >= max(1,N).

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N).

IFST (input/output)
Specify the reordering of the diagonal blocks of T. The block with row index IFST is moved to row ILST, by a sequence of transpositions between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST <= N; 1 <= ILST <= N.

ILST (input/output)
See the description of IFST.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1: two adjacent blocks were too close to swap (the problem is very ill-conditioned); T may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

NAME

dtrmm - perform one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A)

SYNOPSIS

```
SUBROUTINE DTRMM(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
      LDB)

CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER M, N, LDA, LDB
DOUBLE PRECISION ALPHA
DOUBLE PRECISION A(LDA,*), B(LDB,*)

SUBROUTINE DTRMM_64(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
      LDB)

CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER*8 M, N, LDA, LDB
DOUBLE PRECISION ALPHA
DOUBLE PRECISION A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRMM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],
       B, [LDB])

CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL(8) :: ALPHA
REAL(8), DIMENSION(:,:) :: A, B

SUBROUTINE TRMM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
       [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
REAL(8) :: ALPHA
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dtrmm(char side, char uplo, char transa, char diag, int
          m, int n, double alpha, double *a, int lda, double
          *b, int ldb);

void dtrmm_64(char side, char uplo, char transa, char  diag,
          long m, long n, double alpha, double *a, long lda,
          double *b, long ldb);
```

PURPOSE

dtrmm performs one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A) where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

op(A) = A   or   op(A) = A'.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether op(A) multiplies B from the left or right as follows:

SIDE = 'L' or 'l'   B := alpha*op(A)*B.

SIDE = 'R' or 'r'   B := alpha*B*op(A).

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = A'.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)
On entry, M specifies the number of rows of B. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of B. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)
DOUBLE PRECISION array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not refer-

enced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1, m), when SIDE = 'R' or 'r' then LDA >= max(1, n). Unchanged on exit.

B (input/output)
DOUBLE PRECISION array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB >= max(1, m). Unchanged on exit.

DOUBLE PRECISION A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TRMV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE TRMV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtrmv(char uplo, char transa, char diag, int n,  double
          *a, int lda, double *y, int incy);

void dtrmv_64(char uplo, char transa,  char  diag,  long  n,
          double *a, long lda, double *y, long incy);
```

PURPOSE

dtrmv performs one of the matrix-vector operations x := A*x, or x := A'*x, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := A'*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tranformed vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

INTEGER :: N, NRHS, LDA, LDB, LDX, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL(8), DIMENSION(:) :: FERR, BERR, WORK
```

```
REAL(8), DIMENSION(:,:) :: A, B, X

SUBROUTINE TRRFS_64(UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B, [LDB],
       X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDA, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL(8), DIMENSION(:) :: FERR, BERR, WORK
REAL(8), DIMENSION(:,:) :: A, B, X
```

C INTERFACE

```
#include <sunperf.h>
void dtrrfs(char uplo, char transa, char diag,  int  n,  int
          nrhs, double *a, int lda, double *b, int ldb, dou-
          ble *x, int ldx, double *ferr, double  *berr,  int
          *info);

void dtrrfs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs,  double  *a, long lda, double *b, long
          ldb, double *x, long  ldx,  double  *ferr,  double
          *berr, long *info);
```

PURPOSE

dtrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by STRTRS or some other means before entering this routine. STRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)
- = 'U': A is upper triangular;
- = 'L': A is lower triangular.

TRANSA (input)
Specifies the form of the system of equations:
- = 'N': A * X = B (No transpose)
- = 'T': A**T * X = B (Transpose)
- = 'C': A**H * X = B (Conjugate transpose = Transpose)

```
          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
A (input) The triangular matrix A.  If UPLO = 'U', the lead-
          ing  N-by-N  upper  triangular part of the array A
          contains the  upper  triangular  matrix,  and  the
          strictly  lower triangular part of A is not refer-
          enced.  If UPLO = 'L', the  leading  N-by-N  lower
          triangular  part of the array A contains the lower
          triangular matrix, and the strictly upper triangu-
          lar  part  of A is not referenced.  If DIAG = 'U',
          the diagonal elements of A are also not referenced
          and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
```

```
            The componentwise relative backward error of  each
            solution  vector X(j) (i.e., the smallest relative
            change in any element of A or B that makes X(j) an
            exact solution).
WORK (workspace)
            dimension(3*N)

WORK2 (workspace)
            dimension(N)

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
```

C INTERFACE

```
#include <sunperf.h>

void dtrsen(char job, char compq, int *select, int n, double
          *t,  int ldt, double *q, int ldq, double *wr, dou-
          ble *wi, int  *m,  double  *s,  double  *sep,  int
          *info);

void dtrsen_64(char job, char compq, long *select,  long  n,
          double  *t,  long ldt, double *q, long ldq, double
          *wr, double *wi, long *m, double *s, double  *sep,
          long *info);
```

PURPOSE

dtrsen reorders the real Schur factorization of a real matrix A = Q*T*Q**T, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elemnts equal and its off-diagonal elements of opposite sign.

ARGUMENTS

```
JOB (input)
          Specifies whether condition numbers  are  required
          for  the cluster of eigenvalues (S) or the invari-
          ant subspace (SEP):
          = 'N': none;
          = 'E': for eigenvalues only (S);
          = 'V': for invariant subspace only (SEP);
          = 'B': for both eigenvalues and invariant subspace
          (S and SEP).

COMPQ (input)
          = 'V': update the matrix Q of Schur vectors;
          = 'N': do not update Q.

SELECT (input)
          SELECT specifies the eigenvalues in  the  selected
          cluster.   To   select  a  real  eigenvalue  w(j),
          SELECT(j)  must  be  set  to  w(j)   and   w(j+1),
          corresponding  to  a 2-by-2 diagonal block, either
          SELECT(j) or SELECT(j+1) or both must  be  set  to
          either  both  included  in  the  cluster  or  both
          excluded.

N (input) The order of the matrix T. N >= 0.

T (input/output)
          On entry, the upper quasi-triangular matrix T,  in
          Schur  canonical  form.  On exit, T is overwritten
          by the reordered matrix T, again in Schur  canoni-
          cal  form,  with  the  selected eigenvalues in the
          leading diagonal blocks.

LDT (input)
          The leading dimension  of  the  array  T.  LDT  >=
          max(1,N).

Q (input) On entry, if COMPQ = 'V', the matrix  Q  of  Schur
          vectors.   On  exit,  if  COMPQ  = 'V', Q has been
          postmultiplied by  the  orthogonal  transformation
          matrix  which reorders T; the leading M columns of
          Q form an  orthonormal  basis  for  the  specified
          invariant  subspace.   If  COMPQ  =  'N', Q is not
          referenced.

LDQ (input)
```

The leading dimension of the array Q. LDQ >= 1; and if COMPQ = 'V', LDQ >= N.

WR (output)
The real and imaginary parts, respectively, of the reordered eigenvalues of T. The eigenvalues are stored in the same order as on the diagonal of T, with WR(i) = T(i,i) and, if T(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) > 0 and WI(i+1) = -WI(i). Note that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

WI (output)
See the description of WR.

M (output)
The dimension of the specified invariant subspace. 0 < = M <= N.

S (output)
If JOB = 'E' or 'B', S is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. S cannot underestimate the true reciprocal condition number by more than a factor of sqrt(N). If M = 0 or N, S = 1. If JOB = 'N' or 'V', S is not referenced.

SEP (output)
If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If JOB = 'N', LWORK >= max(1,N); if JOB = 'E', LWORK >= M*(N-M); if JOB = 'V' or 'B', LWORK >= 2*M*(N-M).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
If JOB = 'N' or 'E', IWORK is not referenced.

LIWORK (input)
The dimension of the array IWORK. If JOB = 'N' or 'E', LIWORK >= 1; if JOB = 'V' or 'B', LIWORK >= M*(N-M).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1: reordering of T failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); T may have been partially reordered, and WR and WI contain the eigenvalues in the same order as in T; S and SEP (if requested) are set to zero.

FURTHER DETAILS

STRSEN first collects the selected eigenvalues by computing an orthogonal transformation Z to move them to the top left corner of T. In other words, the selected eigenvalues are the eigenvalues of T11 in:

```
Z'*T*Z = ( T11 T12 ) n1
         (  0  T22 ) n2
            n1  n2
```

where N = n1+n2 and Z' means the transpose of Z. The first n1 columns of Z span the specified invariant subspace of T.

If T has been obtained from the real Schur factorization of a matrix A = Q*T*Q', then the reordered real Schur factorization of A is given by A = (Q*Z)*(Z'*T*Z)*(Q*Z)', and the first n1 columns of Q*Z span the corresponding invariant subspace of A.

The reciprocal condition number of the average of the eigenvalues of T11 may be returned in S. S lies between 0 (very badly conditioned) and 1 (very well conditioned). It is computed as follows. First we compute R so that

```
                     P = ( I  R ) n1
                         ( 0  0 ) n2
                           n1 n2
```

is the projector on the invariant subspace associated with T11. R is the solution of the Sylvester equation:

```
                    T11*R - R*T22 = T12.
```

Let F-norm(M) denote the Frobenius-norm of M and 2-norm(M) denote the two-norm of M. Then S is computed as the lower bound

```
                  (1 + F-norm(R)**2)**(-1/2)
```

on the reciprocal of 2-norm(P), the true reciprocal condition number. S cannot underestimate 1 / 2-norm(P) by more than a factor of sqrt(N).

An approximate error bound for the computed average of the eigenvalues of T11 is

```
                     EPS * norm(T) / S
```

where EPS is the machine precision.

The reciprocal condition number of the right invariant subspace spanned by the first n1 columns of Z (or of Q*Z) is returned in SEP. SEP is defined as the separation of T11 and T22:

```
                 sep( T11, T22 ) = sigma-min( C )
```

where sigma-min(C) is the smallest singular value of the n1*n2-by-n1*n2 matrix

```
   C  = kprod( I(n2), T11 ) - kprod( transpose(T22), I(n1) )
```

I(m) is an m by m identity matrix, and kprod denotes the Kronecker product. We estimate sigma-min(C) by the reciprocal of an estimate of the 1-norm of inverse(C). The true reciprocal 1-norm of inverse(C) cannot differ from sigma-min(C) by more than a factor of sqrt(n1*n2).

When SEP is small, small changes in T can cause large changes in the invariant subspace. An approximate bound on the maximum angular error in the computed right invariant subspace is

```
                  EPS * norm(T) / SEP
```

INTEGER(8) :: M, N, LDA, LDB
REAL(8) :: ALPHA
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dtrsm(char side, char uplo, char transa, char diag, int
          m, int n, double alpha, double *a, int lda, double
          *b, int ldb);

void dtrsm_64(char side, char uplo, char transa, char  diag,
          long m, long n, double alpha, double *a, long lda,
          double *b, long ldb);
```

PURPOSE

dtrsm solves one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

op(A) = A   or   op(A) = A'.

The matrix X is overwritten on B.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l'   op(A)*X = alpha*B.

SIDE = 'R' or 'r'   X*op(A) = alpha*B.

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n'   op(A) = A.

TRANSA = 'T' or 't'   op(A) = A'.

TRANSA = 'C' or 'c'   op(A) = A'.

Unchanged on exit.
TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N >= 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

DOUBLE PRECISION array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.
Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the

strictly lower triangular part of A is not referenced.
Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.
Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1, m), when SIDE = 'R' or 'r' then LDA >= max(1, n). Unchanged on exit.

B (input/output)
DOUBLE PRECISION array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB >= max(1, m). Unchanged on exit.

          *vr, long ldvr, double *s, double *sep,  long  mm,
          long *m, long ldwork, long *info);
```

PURPOSE

dtrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix Q*T*Q**T with Q orthogonal).

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):

= 'E': for eigenvalues only (S);
= 'V': for eigenvectors only (SEP);
= 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY (input)
= 'A': compute condition numbers for all eigenpairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N (input) The order of the matrix T. N >= 0.

T (input) The upper quasi-triangular matrix T, in Schur canonical form.

LDT (input)
The leading dimension of the array T. LDT >= max(1,N).

VL (input)
If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q*T*Q**T with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by SHSEIN or STREVC. If JOB = 'V', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= 1; and if JOB = 'E' or 'B', LDVL >= N.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q*T*Q**T with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by

SHSEIN or STREVC. If JOB = 'V', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= 1; and if JOB = 'E' or 'B', LDVR >= N.

S (output)
If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of SEP are set to the same value. If the eigenvalues cannot be reordered to compute SEP(j), SEP(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', SEP is not referenced.

MM (input)
The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M (output)
The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK (workspace)
dimension(LDWORK,N+1) If JOB = 'E', WORK is not referenced.

LDWORK (input)
The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

WORK1 (workspace)
dimension(N) If JOB = 'E', WORK1 is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of an eigenvalue lambda is defined as

```
        S(lambda) = |v'*u| / (norm(u)*norm(v))
```

where u and v are the right and left eigenvectors of T corresponding to lambda; v' denotes the conjugate-transpose of v, and norm(u) denotes the Euclidean norm. These reciprocal condition numbers always lie between zero (very badly conditioned) and one (very well conditioned). If n = 1, S(lambda) is defined to be 1.

An approximate error bound for a computed eigenvalue W(i) is given by

```
                    EPS * norm(T) / S(i)
```

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u corresponding to lambda is defined as follows. Suppose

```
            T = ( lambda  c  )
                (   0    T22 )
```

Then the reciprocal condition number is

```
        SEP( lambda, T22 ) = sigma-min( T22 - lambda*I )
```

where sigma-min denotes the smallest singular value. We approximate the smallest singular value by the reciprocal of an estimate of the one-norm of the inverse of T22 - lambda*I. If n = 1, SEP(1) is defined to be abs(T(1,1)).

An approximate error bound for a computed right eigenvector VR(i) is given by

```
                    EPS * norm(T) / SEP(i)
```

SUBROUTINE TRSV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, LDA, INCY
REAL(8), DIMENSION(:) :: Y
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dtrsv(char uplo, char transa, char diag, int n,  double
          *a, int lda, double *y, int incy);

void dtrsv_64(char uplo, char transa,  char  diag,  long  n,
          double *a, long lda, double *y, long incy);
```

PURPOSE

dtrsv solves one of the systems of equations A*x = b, or A'*x = b, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' A*x = b.

TRANSA = 'T' or 't' A'*x = b.

TRANSA = 'C' or 'c' A'*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

       [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB
INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL(8) :: SCALE
REAL(8), DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>

void dtrsyl(char trana, char tranb, int isgn, int m, int  n,
          double *a, int lda, double *b, int ldb, double *c,
          int ldc, double *scale, int *info);

void dtrsyl_64(char trana, char tranb, long  isgn,  long  m,
          long  n, double *a, long lda, double *b, long ldb,
          double *c, long ldc, double *scale, long *info);
```

PURPOSE

dtrsyl solves the real Sylvester matrix equation:

```
op(A)*X + X*op(B) = scale*C or
op(A)*X - X*op(B) = scale*C,
```

where op(A) = A or A**T, and A and B are both upper quasi-triangular. A is M-by-M and B is N-by-N; the right hand side C and the solution X are M-by-N; and scale is an output scale factor, set <= 1 to avoid overflow in X.

A and B must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

TRANA (input)
Specifies the option op(A):
= 'N': op(A) = A   (No transpose)
= 'T': op(A) = A**T (Transpose)
= 'C': op(A) = A**H (Conjugate transpose = Transpose)

TRANB (input)
Specifies the option op(B):
= 'N': op(B) = B   (No transpose)
= 'T': op(B) = B**T (Transpose)

```
          = 'C': op(B) = B**H (Conjugate transpose  =  Tran-
          spose)

ISGN (input)
          Specifies the sign in the equation:
          = +1: solve op(A)*X + X*op(B) = scale*C
          = -1: solve op(A)*X - X*op(B) = scale*C

M (input) The order of the matrix A, and the number of  rows
          in the matrices X and C. M >= 0.

N (input) The order of the  matrix  B,  and  the  number  of
          columns in the matrices X and C. N >= 0.

A (input) The upper  quasi-triangular  matrix  A,  in  Schur
          canonical form.
LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).

B (input) The upper  quasi-triangular  matrix  B,  in  Schur
          canonical form.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

C (input/output)
          On entry, the M-by-N right hand side matrix C.  On
          exit, C is overwritten by the solution matrix X.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M)

SCALE (output)
          The scale factor, scale, set <= 1 to  avoid  over-
          flow in X.

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          = 1: A and B have  common  or  very  close  eigen-
          values;  perturbed  values  were used to solve the
          equation (but the matrices A and B are unchanged).

          lda, long *info);
```

PURPOSE

dtrtri computes the inverse of a real upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value
> 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dtrtrs(char uplo, char transa, char diag,  int  n,  int
          nrhs,  double *a, int lda, double *b, int ldb, int
          *info);

void dtrtrs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs,  double  *a, long lda, double *b, long
          ldb, long *info);
```

PURPOSE

dtrtrs solves a triangular system of the form
where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B  (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input) The triangular matrix A.  If UPLO = 'U', the lead-
          ing  N-by-N  upper  triangular part of the array A
          contains the  upper  triangular  matrix,  and  the
```

strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

dtzrqf - routine is deprecated and has been replaced by routine STZRZF

SYNOPSIS

```
SUBROUTINE DTZRQF(M, N, A, LDA, TAU, INFO)

INTEGER M, N, LDA, INFO
DOUBLE PRECISION A(LDA,*), TAU(*)

SUBROUTINE DTZRQF_64(M, N, A, LDA, TAU, INFO)

INTEGER*8 M, N, LDA, INFO
DOUBLE PRECISION A(LDA,*), TAU(*)
```

F95 INTERFACE

```
SUBROUTINE TZRQF(M, N, A, [LDA], TAU, [INFO])

INTEGER :: M, N, LDA, INFO
REAL(8), DIMENSION(:) :: TAU
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE TZRQF_64(M, N, A, [LDA], TAU, [INFO])

INTEGER(8) :: M, N, LDA, INFO
REAL(8), DIMENSION(:) :: TAU
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtzrqf(int m, int n, double *a, int lda,  double  *tau,
          int *info);

void dtzrqf_64(long m, long n, double *a, long  lda,  double
          *tau, long *info);
```

PURPOSE

dtzrqf routine is deprecated and has been replaced by routine STZRZF.

STZRQF reduces the M-by-N (M<=N) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

```
   A = ( R  0 ) * Z,
```

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= M.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

The factorization is obtained by Householder's method. The kth transformation matrix, Z(k), which is used to introduce zeros into the (m - k + 1)th row of A, is given in the form

```
   Z( k ) = ( I     0   ),
            ( 0  T( k ) )
```

where

```
   T( k ) = I - tau*u( k )*u( k )',   u( k ) = (   1    ),
                                               (   0    )
                                               ( z( k ) )
```

tau is a scalar and z(k) is an (n - m) element vector. tau and z(k) are chosen to annihilate the elements of the kth row of X.

The scalar tau is returned in the kth element of TAU and the vector u(k) in the kth row of A, such that the elements of z(k) are in a(k, m + 1), ..., a(k, n). The elements of R are returned in the upper triangular part of A.

Z is given by

```
   Z =  Z( 1 ) * Z( 2 ) * ... * Z( m ).
```

Contents

NAME

REAL(8), DIMENSION(:,:) :: A

SUBROUTINE TZRZF_64([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])

INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dtzrzf(int m, int n, double *a, int lda,  double  *tau,
          int *info);

void dtzrzf_64(long m, long n, double *a, long  lda,  double
          *tau, long *info);
```

PURPOSE

dtzrzf reduces the M-by-N (M<=N) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

```
   A = ( R  0 ) * Z,
```

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

Based on contributions by
A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The factorization is obtained by Householder's method. The kth transformation matrix, Z(k), which is used to introduce zeros into the (m - k + 1)th row of A, is given in the form

```
   Z( k ) = ( I     0   ),
            ( 0  T( k ) )
```

where

```
   T( k ) = I - tau*u( k )*u( k )',   u( k ) = (   1    ),
                                               (   0    )
                                               ( z( k ) )
```

tau is a scalar and z(k) is an (n - m) element vector. tau and z(k) are chosen to annihilate the elements of the kth row of X.

The scalar tau is returned in the kth element of TAU and the vector u(k) in the kth row of A, such that the elements of z(k) are in a(k, m + 1), ..., a(k, n). The elements of R are returned in the upper triangular part of A.

Z is given by

```
   Z =  Z( 1 ) * Z( 2 ) * ... * Z( m ).
```

 INTEGER*8, DIMENSION(:) ::  RPNTR, CPNTR, BPNTRB, BPNTRE
 REAL*8    ALPHA, BETA
 REAL*8, DIMENSION(:) :: VAL
 REAL*8, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
         C <- alpha op(A) B + beta C
where ALPHA and BETA are scalar, C and B are  matrices,
A is a matrix represented in variable block sparse row  format
and op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if the matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
```

```
                  DESCRA(2) upper/lower triangular indicator
                    1 : lower
                    2 : upper
                  DESCRA(3) main diagonal type
                    0 : non-unit
                    1 : unit
                  DESCRA(4) Array base  (NOT IMPLEMENTED)
                    0 : C/C++ compatible
                    1 : Fortran compatible
                  DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                    0 : unknown
                    1 : no repeated indices

VAL()             scalar array of length NNZ consisting of the block entries
                  of A where each block entry is a dense rectangular matrix
                  stored column by column.
                  NNZ is the total number of point entries in all nonzero
                  block  entries of a matrix A.
INDX()            integer array of length BNNZ+1 where BNNZ is the number of
                  block entries of a matrix A such that the I-th element of
                  INDX[] points to the location in VAL of the (1,1) element
                  of the I-th block entry.

BINDX()           integer array of length BNNZ consisting of the block
                  column indices of the block entries of A where BNNZ is
                  the number block entries of a matrix A.

RPNTR()           integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1
                  is the row index of the first point row in the I-th block
                  row.
                  RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of
                  rows in matrix A.
                  Thus, the number of point rows in the I-th block row is
                  RPNTR(I+1)-RPNTR(I).

CPNTR()           integer array of length KB+1 such that CPNTR(J)-CPNTR(1)+1
                  is the column index of the first point column in the J-th
                  block column. CPNTR(KB+1) is set to K+CPNTR(1) where K is
                  the number of columns in matrix A.
                  Thus, the number of point columns in the J-th block column
                  is CPNTR(J+1)-CPNTR(J).

BPNTRB()          integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1
                  points to location in BINDX of the first block entry of
                  the I-th block row of A.

BPNTRE()          integer array of length MB such that BPNTRE(I)-BPNTRB(1)
                  points to location in BINDX of the last block entry of
                  the I-th block row of A.
```

B()   rectangular array with first dimension LDB.

LDB   leading dimension of B

BETA   Scalar parameter

C()   rectangular array with first dimension LDC.

LDC   leading dimension of C

WORK()   scratch array of length LWORK. WORK is not referenced in the current version.

LWORK   length of WORK array. LWORK is not referenced in the current version.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. For a general matrix (*DESCRA*(1)=0), array CPNTR can be different from RPNTR. For all other matrix types, RPNTR must equal CPNTR and a single array can be passed for both arguments.

2. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
  SUBROUTINE SVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *           VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

NAME

dvbrsm - variable block sparse row format triangular solve

SYNOPSIS

 INTEGER    TRANSA, MB, UNITD
 INTEGER, DIMENSION(:) ::  DESCRA, INDX, BINDX
 INTEGER, DIMENSION(:) ::  RPNTR, CPNTR, BPNTRB, BPNTRE
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) :: VAL, DV
 DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

```
      SUBROUTINE VBRSM_64(TRANSA, MB, [N], UNITD, DV, ALPHA, DESCRA,
     *           VAL, INDX, BINDX, RPNTR, CPNTR, BPNTRB, BPNTRE,
     *           B, [LDB], BETA, C,[LDC], [WORK], [LWORK])
      INTEGER*8    TRANSA, MB, UNITD
      INTEGER*8, DIMENSION(:) ::  DESCRA, INDX, BINDX
      INTEGER*8, DIMENSION(:) ::  RPNTR, CPNTR, BPNTRB, BPNTRE
      DOUBLE PRECISION    ALPHA, BETA
      DOUBLE PRECISION, DIMENSION(:) :: VAL, DV
      DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
       C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
       C <- ALPHA op(A) D B + BETA C
     where ALPHA and BETA are scalar, C and B are m by n dense matrices,
     D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
     lower triangular matrix represented in variable block sparse row
     format and  op( A )  is one  of

      op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
      (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
     TRANSA        Indicates how to operate with the sparse matrix
                     0 : operate with matrix
                     1 : operate with transpose matrix
                     2 : operate with the conjugate transpose of matrix.
                         2 is equivalent to 1 if matrix is real.

     MB            Number of block rows in matrix A

     N             Number of columns in matrix C

     UNITD         Type of scaling:
                     1 : Identity matrix (argument DV[] is ignored)
                     2 : Scale on left (row block scaling)
                     3 : Scale on right (column block scaling)

     DV()          Array containing the block entries of the block
                   diagonal matrix D.  The size of the J-th block is
                   RPNTR(J+1)-RPNTR(J) and each block contains matrix
                   entries stored column-major.  The total length of
                   array DV is given by the formula:

                   sum over J from 1 to MB:
```

```
                 ((RPNTR(J+1)-RPNTR(J))*(RPNTR(J+1)-RPNTR(J)))

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              Note: For the routine, DESCRA(1)=3 is only supported.
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
                0 : non-identity blocks on the main diagonal
                1 : identity diagonal block
                2 : diagonal blocks are dense matrices
              DESCRA(4) Array base  (NOT IMPLEMENTED)
                0 : C/C++ compatible
                1 : Fortran compatible
              DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                0 : unknown
                1 : no repeated indices

VAL()         scalar array of length NNZ consisting of the block entries
              of A where each block entry is a dense rectangular matrix
              stored column by column.
              NNZ is the total number of point entries in all nonzero
              block  entries of a matrix A.

INDX()        integer array of length BNNZ+1 where BNNZ is the number
              block entries of a matrix A such that the I-th element of
              INDX[] points to the location in VAL of the (1,1) element
              of the I-th block entry.

BINDX()       integer array of length BNNZ consisting of the block
              column indices of the block entries of A where BNNZ is
              the number block entries of a matrix A.   Block column
              indices MUST be sorted in increasing order for each block
              row.

RPNTR()       integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1
              is the row index of the first point row in the I-th block
              row.
              RPNTR(MB+1) is set to M+RPNTR(1) where M is the number
              of rows  in square triangular matrix A.
```

Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR() integer array of length MB+1 such that CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(MB+1) is set to M+CPNTR(1). Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

BPNTRB() integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A.

BPNTRE() integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least M = RPNTR(MB+1)-RPNTR(1).

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued

by XERBLA.

NIST FORTRAN Sparse Blas User's Guide available at:

http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the VBR representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

6. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row

format the following calling sequence should be used

```
  SUBROUTINE DVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

NAME

```
dwiener - perform Wiener deconvolution of two signals
```

SYNOPSIS

```
SUBROUTINE DWIENER(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)

INTEGER N_POINTS, ISW, IERR
DOUBLE PRECISION ACOR(*), XCOR(*), FLTR(*), EROP(*)

SUBROUTINE DWIENER_64(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)

INTEGER*8 N_POINTS, ISW, IERR
DOUBLE PRECISION ACOR(*), XCOR(*), FLTR(*), EROP(*)
```

F95 INTERFACE

```
SUBROUTINE WIENER(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)

INTEGER :: N_POINTS, ISW, IERR
REAL(8), DIMENSION(:) :: ACOR, XCOR, FLTR, EROP

SUBROUTINE WIENER_64(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)

INTEGER(8) :: N_POINTS, ISW, IERR
REAL(8), DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

C INTERFACE

```
#include <sunperf.h>

void dwiener(int n_points, double *acor, double *xcor,  dou-
          ble *fltr, double *erop, int *isw, int *ierr);

void dwiener_64(long n_points, double *acor,  double  *xcor,
```

```
double   *fltr,  double  *erop,  long  *isw,  long
*ierr);
```

PURPOSE

dwiener performs Wiener deconvolution of two signals.

ARGUMENTS

N_POINTS (input)
On entry, the number of points in the input correlations. Unchanged on exit.

ACOR (input)
On entry, autocorrelation coefficients. Unchanged on exit.

XCOR (input)
On entry, cross-correlation coefficients. Unchanged on exit.

FLTR (output)
On exit, filter coefficients.

EROP (output)
On exit, the prediction error.

ISW (input)
On entry, if ISW .EQ. 0 then perform spiking deconvolution, otherwise perform general deconvolution. Unchanged on exit.

IERR (output)
On exit, the deconvolution was successful iff IERR .EQ. 0, otherwise there was an error.

Contents

NAME

```
dzasum - Return the sum of the absolute values of  a  vector
x.
```

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DZASUM(N, X, INCX)

DOUBLE COMPLEX X(*)
INTEGER N, INCX

DOUBLE PRECISION FUNCTION DZASUM_64(N, X, INCX)

DOUBLE COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL(8) FUNCTION ASUM([N], X, [INCX])

COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N, INCX

REAL(8) FUNCTION ASUM_64([N], X, [INCX])

COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>

double dzasum(int n, doublecomplex *x, int incx);

double dzasum_64(long n, doublecomplex *x, long incx);
```

PURPOSE

dzasum Return the sum of the absolute values of the elements of x where x is an n-vector. This is the sum of the absolute values of the real and complex elements and not the sum of the squares of the real and complex elements.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Contents

NAME

```
dznrm2 - Return the Euclidian norm of a vector.
```

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DZNRM2(N, X, INCX)

DOUBLE COMPLEX X(*)
INTEGER N, INCX

DOUBLE PRECISION FUNCTION DZNRM2_64(N, X, INCX)

DOUBLE COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL(8) FUNCTION NRM2([N], X, [INCX])

COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N, INCX

REAL(8) FUNCTION NRM2_64([N], X, [INCX])

COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>

double dznrm2(int n, doublecomplex *x, int incx);

double dznrm2_64(long n, doublecomplex *x, long incx);
```

PURPOSE

dznrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

Contents

```

```
void ezfftb(int n, float *r, float azero,  float  *a,  float
          *b, float *wsave);

void ezfftb_64(long n, float  *r,  float  azero,  float  *a,
          float *b, float *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence  to  be  synthesized.   The
          method  is most efficient when N is the product of
          small primes.  N >= 0.

R (output)
          On exit, the Fourier synthesis of the inputs.
AZERO (input)
          On entry, the  constant  Fourier  coefficient  A0.
          Unchanged on exit.

A (input/output)
          On  entry,  arrays  that  contain  the   remaining
          Fourier  coefficients.   On exit, these arrays are
          unchanged.

B (input/output)
          On  entry,  arrays  that  contain  the   remaining
          Fourier  coefficients.   On exit, these arrays are
          unchanged.

WSAVE (input)
          On entry, an array with dimension of at least (3 *
          N + 15), initialized by EZFFTI.
```

Contents

NAME

```
ezfftf - computes the Fourier  coefficients  of  a  periodic
sequence.   EZFFTF  is  a  simplified  but slower version of
RFFTF.
```

SYNOPSIS

```
SUBROUTINE EZFFTF(N, R, AZERO, A, B, WSAVE)

INTEGER N
REAL AZERO
REAL R(*), A(*), B(*), WSAVE(*)

SUBROUTINE EZFFTF_64(N, R, AZERO, A, B, WSAVE)

INTEGER*8 N
REAL AZERO
REAL R(*), A(*), B(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE EZFFTF(N, R, AZERO, A, B, WSAVE)

INTEGER :: N
REAL :: AZERO
REAL, DIMENSION(:) :: R, A, B, WSAVE

SUBROUTINE EZFFTF_64(N, R, AZERO, A, B, WSAVE)

INTEGER(8) :: N
REAL :: AZERO
REAL, DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ezfftf(int n, float *r, float azero,  float  *a,  float
          *b, float *wsave);

void ezfftf_64(long n, float  *r,  float  azero,  float  *a,
          float *b, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is the product of small primes. N >= 0.

R (output)
A real array of length N containing the sequence to be transformed. On exit, R is unchanged.

AZERO (output)
On exit, the sum from i=1 to i=n of r(i)/n.

A (input/output)
On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

B (input/output)
On entry, arrays that contain the remaining Fourier coefficients. On exit, these arrays are unchanged.

WSAVE (input)
On entry, an array with dimension of at least (3 * N + 15), initialized by EZFFTI.

Contents

NAME

```
ezffti - initializes the array WSAVE, which is used in  both
EZFFTF and EZFFTB.
```

SYNOPSIS

```
SUBROUTINE EZFFTI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE EZFFTI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE EZFFTI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE EZFFTI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void ezffti(int n, float *wsave);

void ezffti_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input)
On entry, an array with a dimension of at least (3 * N + 15). The same work array can be used for both EZFFTF and EZFFTB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to EZFFTF or EZFFTB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

fft - Fast Fourier transform subroutines

OVERVIEW

The signal processing software in Sun Performance Library includes a set of routines based on public domain packages FFTPACK and VFFPACK that computes the Fast Fourier Transform. These routines are now being replaced by a new interface (Perflib interface).

MAPPING

Below is a mapping of routines from the FFTPACK interface and the new Perflib interface. See individual man pages for more detail.

FFTPACK interface	Perflib interface
RFFTF (DFFTF)	SFFTC (DFFTZ)
RFFTB (DFFTB)	CFFTS (ZFFTD)
CFFTF (ZFFTF)	CFFTC (ZFFTZ)
EZFFTF (DEZFFTF)	SFFTC (DFFTZ)
EZFFTB (DEZFFTB)	CFFTS (ZFFTD)
CFFTB (ZFFTB)	CFFTC (ZFFTZ)
RFFT2F (DFFT2F)	SFFT2C (DFFT2Z)
RFFT2B (DFFT2B)	CFFT2S (ZFFT2D)
CFFT2F (ZFFT2F)	CFFT2C (ZFFT2Z)
CFFT2B (ZFFT2B)	CFFT2C (ZFFT2Z)
RFFT3F (DFFT3F)	SFFT3C (DFFT3Z)
RFFT3B (DFFT3B)	CFFT3S (ZFFT3D)
CFFT3B (ZFFT3B)	CFFT3C (ZFFT3Z)
CFFT3F (ZFFT3F)	CFFT3C (ZFFT3Z)

```
VCFFTF (VZFFTF)         CFFTCM (ZFFTZM)
VCFFTB (VZFFTB)         CFFTCM (ZFFTZM)
VRFFTF (VDFFTF)         SFFTCM (DFFTZM)
VRFFTB (VDFFTB)         CFFTSM (ZFFTDM)
RFFTI (DFFTI)           SFFTC (DFFTZ), CFFTS (ZFFTD)
CFFTI (ZFFTI)           CFFTC (ZFFTZ)
EZFFTI (DEZFFTI)        SFFTC (DFFTZ), CFFTS (ZFFTD)
RFFT2I (DFFT2I)         SFFTC2 (DFFTZ2), CFFTS2 (ZFFTD2)
RFFT3I (DFFT3I)         SFFTC3 (DFFTZ3), CFFTS3 (ZFFTD3)
CFFT2I (ZFFT2I)         CFFTC2 (ZFFTZ2)
CFFT3I (ZFFT3I)         CFFTC3 (ZFFTZ3)
VCFFTI (VZFFTI)         CFFTCM (ZFFTZM)
VRFFTI (VDFFTI)         SFFTCM (DFFTZM), CFFTSM (ZFFTDM)
```

NOTES

Unlike the FFTPACK interface, the Perflib interface does not provide separate routines for initialization. Computation and initialization can be selected by an argument in the calling sequence of each routine. Similar to the FFTPACK routines, the weight and factor tables need to be initialized once for a particular transform length. Once these tables are initialized, they can be used repeatedly to compute the forward and inverse tranforms for different data sets until, of course, the transform length is changed. The appropriate transform routine is then called to initialize the tables for the new length.

The Perflib interface gives the user the option of computing the FFT in-place (input overwritten by transform results) or out-of-place (input unchanged) in every routine. When an out-of-place transform is requested, the input and output arrays must not overlap in memory. In-place transforms require that there be perfect overlay between the input and output arrays. That is, the arrays must begin at the same memory location. The routines assume (and therefore do not check) that these conditions are satisfied. In some cases, the dimension(s) of the input and output arrays are related to each other. Below is a summary of requirements of the array dimensions. LDX1 and LDX are leading dimensions of the input arrays and LDY1 and LDY are leading dimensions of the output arrays. LDX2 and LDY2 are the second dimensions of the input and output arrays, respectively. N1 and N2 are the first and second actual dimensions of the problem.

```
Routine name      in-place       out-of-place

SFFTCM, DFFTZM    LDX = 2*LDY    LDX >= N1
                  LDY >= N1/2+1  LDY >= N1/2+1
```

CFFTSM, ZFFTDM	LDX >= N1/2+1	LDX >= N1/2+1
	LDY = 2*LDX	LDY >= N1
CFFTCM, ZFFTZM	LDX >= N1	LDX >= N1
	LDY = LDX	LDY >= N1
SFFTC2, DFFTZ2	LDX = 2*LDY	LDX >= N1
	LDY >= N1/2+1	LDY >= N1/2+1
CFFTS2, ZFFTD2	LDX >= N1/2+1	LDX >= N1/2+1
	LDY = 2*LDX	LDY >= 2*LDX; LDY is even
CFFTC2, ZFFTZ2	LDX >= N1	LDX >= N1
	LDY = LDX	LDY >= N1
CFFTS3, ZFFTD3	LDX1 >= N1/2+1	LDX1 >= N1/2+1
	LDX2 >= N2	LDX2 >= N2
	LDY1 = 2*LDX1	LDY1 >= 2*LDX1; LDY1 is even
	LDY2 = LDX2	LDY2 >= N2
CFFTC3, ZFFTZ3	LDX1 >= N1	LDX1 >= N1
	LDX2 >= N2	LDX2 >= N2
	LDY1 = LDX1	LDY1 >= N1
	LDY2 = LDX2	LDY2 >= N2
SFFTC3, DFFTZ3	LDX1 = 2*LDY1	LDX1 >= N1
	LDX2 >= N2	LDX2 >= N2
	LDY1 >= N1/2+1	LDY1 >= N1/2+1
	LDY2 = LDX2	LDY2 >= N2

In routines that compute transforms between complex and real data type such as SFFTC2 or CFFTS3 even though the transform length is N1, only (N1/2+1) complex data points are referenced or computed. These data points make up the positive-frequency half of the spectrum of the Discrete Fourier Transform. The remaining N1-(N1/2+1) data points can be easily derived since they are complex conjugates and therefore are not stored or referenced.

Contents

NAME

```
icamax - return the index of the element with largest  abso-
lute value.
```

SYNOPSIS

```
INTEGER FUNCTION ICAMAX(N, X, INCX)

COMPLEX X(*)
INTEGER N, INCX

INTEGER*8 FUNCTION ICAMAX_64(N, X, INCX)

COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX([N], X, [INCX])

COMPLEX, DIMENSION(:) :: X
INTEGER :: N, INCX

INTEGER(8) FUNCTION IAMAX_64([N], X, [INCX])

COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>

int icamax(int n, complex *x, int incx);
```

```
long icamax_64(long n, complex *x, long incx);
```

PURPOSE

icamax return the index of the element in x with largest absolute value where x is an n-vector and absolute value is defined as the sum of the absolute value of the real part and the absolute value of the imaginary part.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NOTES

If the vector contains all NaNs, the function returns 1. If the vector contains valid complex numbers and one or more NaNs, the routine returns the index of the element containing the largest absolute value.

Contents

NAME

```
idamax - return the index of the element with largest  abso-
lute value.
```

SYNOPSIS

```
INTEGER FUNCTION IDAMAX(N, X, INCX)

INTEGER N, INCX
DOUBLE PRECISION X(*)

INTEGER*8 FUNCTION IDAMAX_64(N, X, INCX)

INTEGER*8 N, INCX
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX([N], X, [INCX])

INTEGER :: N, INCX
REAL(8), DIMENSION(:) :: X

INTEGER(8) FUNCTION IAMAX_64([N], X, [INCX])

INTEGER(8) :: N, INCX
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>

int idamax(int n, double *x, int incx);
```

```
long idamax_64(long n, double *x, long incx);
```

PURPOSE

idamax return the index of the element in x with largest absolute value where x is an n-vector.

ARGUMENTS

N (input)
    On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
    (1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
    On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NOTES

If the vector contains all NaNs, the function returns 1. If the vector contains valid floating point numbers and one or more NaNs, the routine returns the index of the lement containing the largest absolute value.

Contents

NAME

```
ilaenv - The name of the calling subroutine, in either upper
case or lower case.
```

SYNOPSIS

```
INTEGER FUNCTION ILAENV(ISPEC, NAME, OPTS, N1, N2, N3, N4)

CHARACTER * 6 NAME CHARACTER * 4 OPTS
INTEGER ISPEC, N1, N2, N3, N4

INTEGER*8 FUNCTION ILAENV_64(ISPEC, NAME, OPTS, N1, N2, N3, N4)

CHARACTER * 6 NAME CHARACTER * 4 OPTS
INTEGER*8 ISPEC, N1, N2, N3, N4
```

F95 INTERFACE

```
INTEGER FUNCTION ILAENV(ISPEC, NAME, OPTS, N1, N2, N3, N4)

CHARACTER(LEN=6) :: NAME CHARACTER(LEN=4) :: OPTS
INTEGER :: ISPEC, N1, N2, N3, N4

INTEGER(8) FUNCTION ILAENV_64(ISPEC, NAME, OPTS, N1, N2, N3, N4)

CHARACTER(LEN=6) :: NAME CHARACTER(LEN=4) :: OPTS
INTEGER(8) :: ISPEC, N1, N2, N3, N4
```

C INTERFACE

```
#include <sunperf.h>

int ilaenv(int ispec, char *name, char *opts,  int  n1,  int
          n2, int n3, int n4);
```

```
long ilaenv_64(long ispec, char *name, char *opts, long  n1,
          long n2, long n3, long n4);
```

PURPOSE

ilaenv is called from the LAPACK routines to choose problem-dependent parameters for the local environment. See ISPEC for a description of the parameters.

This version provides a set of parameters which should give good, but not optimal, performance on many of the currently available computers. Users are encouraged to modify this subroutine to set the tuning parameters for their particular machine using the option and problem size information in the arguments.
This routine will not function correctly if it is converted to all lower case. Converting it to all upper case is allowed.

ARGUMENTS

ISPEC (input)
Specifies the parameter to be returned as the value of ILAENV. = 1: the optimal blocksize; if this value is 1, an unblocked algorithm will give the best performance. = 2: the minimum block size for which the block routine should be used; if the usable block size is less than this value, an unblocked routine should be used. = 3: the cross-over point (in a block routine, for N less than this value, an unblocked routine should be used) = 4: the number of shifts, used in the nonsymmetric eigenvalue routines = 5: the minimum column dimension for blocking to be used; rectangular blocks must have dimension at least k by m, where k is given by ILAENV(2,...) and m by ILAENV(5,...) = 6: the crossover point for the SVD (when reducing an m by n matrix to bidiagonal form, if max(m,n)/min(m,n) exceeds this value, a QR factorization is used first to reduce the matrix to a triangular form.) = 7: the number of processors = 8: the crossover point for the multishift QR and QZ methods for nonsymmetric eigenvalue problems. = 9: maximum size of the subproblems at the bottom of the computation tree in the divide-and-conquer algorithm (used by xGELSD and xGESDD) =10: ieee NaN arithmetic can be trusted not to trap

=11: infinity arithmetic can be trusted not to trap

NAME (input)

The name of the calling subroutine, in either upper case or lower case.

OPTS (input)

The character options to the subroutine NAME, concatenated into a single character string. For example, UPLO = 'U', TRANS = 'T', and DIAG = 'N' for a triangular routine would be specified as OPTS = 'UTN'.

N1 (input)

INTEGER

N2 (input)

INTEGER

N3 (input)

INTEGER

N4 (input)

INTEGER

N1, N2, N3, N4 are problem dimensions for the subroutine NAME; these may not all be required.

>= 0: the value of the parameter specified by ISPEC

< 0: if ILAENV = -k, the k-th argument had an illegal value.

< 0: if ILAENV = -k, the k-th argument had an illegal value.

FURTHER DETAILS

The following conventions have been used when calling ILAENV from the LAPACK routines:

1) OPTS is a concatenation of all of the character options to
subroutine NAME, in the same order that they appear in the
argument list for NAME, even if they are not used in determining
the value of the parameter specified by ISPEC.

2) The problem dimensions N1, N2, N3, N4 are specified in the order
that they appear in the argument list for NAME. N1 is used
first, N2 second, and so on, and unused problem dimensions are

passed a value of -1.
3) The parameter value returned by ILAENV is checked for validity in
the calling subroutine. For example, ILAENV is used to retrieve
the optimal blocksize for STRTRI as follows:

```
NB = ILAENV( 1, 'STRTRI', UPLO // DIAG, N, -1, -1, -1 )
IF( NB.LE.1 ) NB = MAX( 1, N )
```

Contents

NAME

```
isamax - return the index of the element with largest  abso-
lute value.
```

SYNOPSIS

```
INTEGER FUNCTION ISAMAX(N, X, INCX)

INTEGER N, INCX
REAL X(*)

INTEGER*8 FUNCTION ISAMAX_64(N, X, INCX)

INTEGER*8 N, INCX
REAL X(*)
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX([N], X, [INCX])

INTEGER :: N, INCX
REAL, DIMENSION(:) :: X

INTEGER(8) FUNCTION IAMAX_64([N], X, [INCX])

INTEGER(8) :: N, INCX
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>

int isamax(int n, float *x, int incx);
```

```
long isamax_64(long n, float *x, long incx);
```

PURPOSE

isamax return the index of the element in x with largest absolute value where x is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NOTES

If the vector contains all NaNs, the function returns 1. If the vector contains valid floating point numbers and one or more NaNs, the routine returns the index of the element containing the largest absolute value.

Contents

NAME

```
izamax - return the index of the element with largest  abso-
lute value.
```

SYNOPSIS

```
INTEGER FUNCTION IZAMAX(N, X, INCX)

DOUBLE COMPLEX X(*)
INTEGER N, INCX

INTEGER*8 FUNCTION IZAMAX_64(N, X, INCX)

DOUBLE COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
INTEGER FUNCTION IAMAX([N], X, [INCX])

COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N, INCX

INTEGER(8) FUNCTION IAMAX_64([N], X, [INCX])

COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>

int izamax(int n, doublecomplex *x, int incx);
```

```
long izamax_64(long n, doublecomplex *x, long incx);
```

PURPOSE

izamax return the index of the element in x with largest absolute value where x is an n-vector and absolute value is defined as the sum of the absolute value of the real part and the absolute value of the imaginary part.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the sub- routine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

NOTES

If the vector contains all NaNs, the function returns 1. If the vector contains valid double complex numbers and one or more NaNs, the routine returns the index of the element con- taining the largest absolute value.

Contents

NAME

```
lsame - returns .TRUE. if  CA  is  the  same  letter  as  CB
regardless of case
```

SYNOPSIS

```
LOGICAL FUNCTION LSAME(CA, CB)

CHARACTER * 1 CA, CB

LOGICAL*8 FUNCTION LSAME_64(CA, CB)

CHARACTER * 1 CA, CB
```

F95 INTERFACE

```
LOGICAL FUNCTION LSAME(CA, CB)

CHARACTER(LEN=1) :: CA, CB

LOGICAL(8) FUNCTION LSAME_64(CA, CB)

CHARACTER(LEN=1) :: CA, CB
```

C INTERFACE

```
#include <sunperf.h>

int lsame(char ca, char cb);

long lsame_64(char ca, char cb);
```

PURPOSE

lsame returns .TRUE. if CA is the same letter as CB regardless of case.

ARGUMENTS

CA (input)
On entry, CA is a single character to compare with CB. Unchanged on exit.

CB (input)
On entry, CB is a single character to compare with CA. Unchanged on exit.

Contents

NAME

```
rfft2b - compute a periodic sequence from its Fourier  coef-
ficients.   The  RFFT operations are unnormalized, so a call
of RFFT2F followed by a call of  RFFT2B  will  multiply  the
input sequence by M*N.
```

SYNOPSIS

```
SUBROUTINE RFFT2B(PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)

CHARACTER * 1 PLACE
INTEGER M, N, LDA, LDB, LWORK
REAL A(LDA,*), B(LDB,*), WORK(*)

SUBROUTINE RFFT2B_64(PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)

CHARACTER * 1 PLACE
INTEGER*8 M, N, LDA, LDB, LWORK
REAL A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B(PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)

CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE FFT2B_64(PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)

CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void rfft2b(char place, int m, int n,  float  *a,  int  lda,
          float *b, int ldb, float *work, int lwork);

void rfft2b_64(char place, long m, long n,  float  *a,  long
          lda, float *b, long ldb, float *work, long lwork);
```

ARGUMENTS

PLACE (input)
Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. M >= 0; when M = 0, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. N >= 0; when N = 0, the subroutine returns immediately without changing any data.

A (input/output)
Real array of dimension (LDA,N). On entry, the two-dimensional array A(LDA,N) contains the input data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N).

LDA (input)
Integer specifying the leading dimension of A. If an out-of-place transform is desired LDA >= M. Else if an in-place transform is desired LDA >= 2*(M/2+1).

B (input/output)
Real array of dimension (2*LDB, N). On entry, if an out-of-place transform is requested B contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

LDB (input)

Integer. If an out-of-place transform is desired, 2*LDB is the leading dimension of the array B which contains the data to be transformed and 2*LDB >= 2*(M/2+1). Otherwise it is not referenced.

WORK (input/output)

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by RFFT2I.

LWORK (input)

Integer. LWORK >= (M + 2*N + MAX(M, 2*N) + 30)

Contents

NAME

```
rfft2f - compute the  Fourier  coefficients  of  a  periodic
sequence.   The  RFFT operations are unnormalized, so a call
of RFFT2F followed by a call of  RFFT2B  will  multiply  the
input sequence by M*N.
```

SYNOPSIS

```
SUBROUTINE RFFT2F(PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)

          int  lda,  float  *b,  int  ldb,  float *work, int
          lwork);

void rfft2f_64(char place, char full, long m, long n,  float
          *a,  long  lda,  float  *b, long ldb, float *work,
          long lwork);
```

ARGUMENTS

PLACE (input)
Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

FULL (input)
Indicates whether or not to generate the full result matrix. 'F' or 'f' will cause RFFT2F to generate the full result matrix. Otherwise only a partial matrix that takes advantage of symmetry will be generated.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. M >= 0; when M = 0, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. N >= 0; when N = 0, the subroutine returns immediately without changing any data.

A (input/output)
On entry, a two-dimensional array A(LDA,N) that contains the data to be transformed. Upon exit, A is unchanged if an out-of-place transform is done. If an in-place transform with partial result is requested, A(1:(M/2+1)*2,1:N) will contain the transformed results. If an in-place transform

with full result is requested, A(1:2*M,1:N) will contain complete transformed results.

LDA (input)
Leading dimension of the array containing the data to be transformed. LDA must be even if the transformed sequences are to be stored in A.
If PLACE = ('O' or 'o') LDA >= M
If PLACE = ('I' or 'i') LDA must be even. If
FULL = ('F' or 'f'), LDA >= 2*M
FULL is not ('F' or 'f'), LDA >= (M/2+1)*2

B (input/output)
Upon exit, a two-dimensional array B(2*LDB,N) that contains the transformed results if an out-of-place transform is done. Otherwise, B is not used.
If an out-of-place transform is done and FULL is not 'F' or 'f', B(1:(M/2+1)*2,1:N) will contain the partial transformed results. If FULL = 'F' or 'f', B(1:2*M,1:N) will contain the complete transformed results.

LDB (input)
2*LDB is the leading dimension of the array B. If an in-place transform is desired LDB is ignored.
If PLACE is ('O' or 'o') and
FULL is ('F' or 'f'), LDB >= M
FULL is not ('F' or 'f'), LDB >= M/2+1
Note that even though LDB is used in the argument list, 2*LDB is the actual leading dimension of B.

WORK (input/output)
One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by RFFT2I.

LWORK (input)
Integer. LWORK >= (M + 2*N + MAX(M, 2*N) + 30)

Contents

NAME

```
rfft2i - initialize the array WSAVE, which is used  in  both
the forward and backward transforms.
```

SYNOPSIS

```
SUBROUTINE RFFT2I(M, N, WORK)

INTEGER M, N
REAL WORK(*)

SUBROUTINE RFFT2I_64(M, N, WORK)

INTEGER*8 M, N
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2I(M, N, WORK)

INTEGER :: M, N
REAL, DIMENSION(:) :: WORK

SUBROUTINE FFT2I_64(M, N, WORK)

INTEGER(8) :: M, N
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void rfft2i(int m, int n, float *work);

void rfft2i_64(long m, long n, float *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

WORK (input/output)
On entry, an array of dimension (M + 2*N + MAX(M, 2*N) + 30) or greater. RFFT2I needs to be called only once to initialize array WORK before calling RFFT2F and/or RFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:,:) :: A, B

SUBROUTINE FFT3B_64(PLACE, [M], [N], [K], A, [LDA], B, [LDB], WORK,
       LWORK)

CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N, K, LDA, LDB, LWORK
```

```
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void rfft3b(char place, int m, int n, int k, float  *a,  int
          lda, float *b, int ldb, float *work, int lwork);

void rfft3b_64(char place, long m, long n, long k, float *a,
          long  lda,  float  *b, long ldb, float *work, long
          lwork);
```

ARGUMENTS

PLACE (input)
Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. M >= 0; when M = 0, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. N >= 0; when N = 0, the subroutine returns immediately without changing any data.

K (input) Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. K >= 0; when K = 0, the subroutine returns immediately without changing any data.

A (input/output)
On entry, the three-dimensional array A(LDA,N,K) contains the data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N,1:K).

LDA (input)
Integer specifying the leading dimension of A. If an out-of-place transform is desired LDA >= M. Else if an in-place transform is desired LDA >= 2*(M/2+1).

B (input/output)
Real array of dimension B(2*LDB,N,K). On entry, if an out-of-place transform is requested B(1:2*(M/2+1),1:N,1:K) contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

LDB (input)
If an out-of-place transform is desired, 2*LDB is the leading dimension of the array B which contains the data to be transformed and 2*LDB >= 2*(M/2+1). Otherwise it is not referenced.

WORK (input/output)
One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by RFFT3I.

LWORK (input)
Integer. LWORK >= (M + 2*(N + K) + 4*K + 45).

       WORK, LWORK)

CHARACTER(LEN=1) :: PLACE, FULL
```

```
INTEGER(8) :: M, N, K, LDA, LDB, LWORK
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void rfft3f(char place, char full, int  m,  int  n,  int  k,
          float *a, int lda, float *b, int ldb, float *work,
          int lwork);

void rfft3f_64(char place, char full, long m, long  n,  long
          k,  float  *a, long lda, float *b, long ldb, float
          *work, long lwork);
```

ARGUMENTS

PLACE (input)
Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

FULL (input)
Select a full ('F' or 'f') or partial (' ') representation of the results. If the caller selects full representation then an MxNxK real array will transform to produce an MxNxK complex array. If the caller does not select full representation then an MxNxK real array will transform to a (M/2+1)xNxK complex array that takes advantage of the symmetry properties of a transformed real sequence.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. M >= 0; when M = 0, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. N >= 0; when N = 0, the subroutine returns immediately without changing any data.

K (input) Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. K >= 0; when K = 0, the subroutine returns immediately without changing any data.

```
A (input/output)
          On entry,  a  three-dimensional  array  A(LDA,N,K)
          that  contains  input  data to be transformed.  On
          exit, if an in-place transform is done and FULL is
          not  'F'  or 'f', A(1:2*(M/2+1),1:N,1:K) will con-
          tain the partial transformed results.  If  FULL  =
          'F' or 'f', A(1:2*M,1:N,1:K) will contain the com-
          plete transformed results.

LDA (input)
          Leading dimension of the array containing the data
          to  be  transformed.   LDA  must  be  even  if the
          transformed sequences are to be stored in A.
          If PLACE = ('O' or 'o') LDA >= M
          If PLACE = ('I' or 'i') LDA must be even.  If
          FULL = ('F' or 'f'), LDA >= 2*M
          FULL is not ('F' or 'f'), LDA >= 2*(M/2+1)

B (input/output)
          Upon exit, a three-dimensional array  B(2*LDB,N,K)
          that  contains  the transformed results if an out-
          of-place transform is done.  Otherwise, B  is  not
          used.
          If an out-of-place transform is done and  FULL  is
          not  'F'  or 'f', B(1:2*(M/2+1),1:N,1:K) will con-
          tain the partial transformed results.  If  FULL  =
          'F' or 'f', B(1:2*M,1:N,1:K) will contain the com-
          plete transformed results.

LDB (input)
          2*LDB is the leading dimension of the array B.  If
          an in-place transform is desired LDB is ignored.
          If PLACE is ('O' or 'o') and
          FULL is ('F' or 'f'), then LDB >= M
          FULL is not ('F' or 'f'), then LDB >= M/2 + 1
          Note that even though LDB is used in the  argument
          list, 2*LDB is the actual leading dimension of B.

WORK (input/output)
          One-dimensional real  array  of  length  at  least
          LWORK.  WORK must have been initialized by RFFT3I.

LWORK (input)
          Integer.  LWORK >= (M + 2*(N + K) + 4*K + 45).
```

Contents

NAME

```
rfft3i - initialize the array WSAVE, which is used  in  both
RFFT3F and RFFT3B.
```

SYNOPSIS

```
SUBROUTINE RFFT3I(M, N, K, WORK)

INTEGER M, N, K

NAME

```
rfftopt - compute the length of the closest fast FFT
```

SYNOPSIS

```
INTEGER FUNCTION RFFTOPT(LEN)

INTEGER LEN

INTEGER*8 FUNCTION RFFTOPT_64(LEN)

INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION RFFTOPT(LEN)

INTEGER :: LEN

INTEGER(8) FUNCTION RFFTOPT_64(LEN)

INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>

int rfftopt(int len);

long rfftopt_64(long len);
```

PURPOSE

```
rfftopt computes the length of the closest fast  FFT.   Fast
```

Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length 32=2**5 will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

RFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. RFFTOPT will return 16 for an input of N=16 and return 18=2*3*3 for an input of N=17.

Note that the length computed here is not guaranteed to be optimal, only to be a
product of small primes. Also, the value returned may change as the underlying
FFTs become capable of handling larger primes. For example, passing in N=51 to day will return 52=2*2*13 rather than 51=3*17 because the FFTs in Performance Li brary do not have fast radix 17 code. In the future, radix 17 code may be added
and then N=51 will return 51.

Contents

NAME

```
sasum - Return the sum of the absolute values of a vector x.
```

SYNOPSIS

```
REAL FUNCTION SASUM(N, X, INCX)

INTEGER N, INCX
REAL X(*)

REAL FUNCTION SASUM_64(N, X, INCX)

INTEGER*8 N, INCX
REAL X(*)
```

F95 INTERFACE

```
REAL FUNCTION ASUM([N], X, [INCX])

INTEGER :: N, INCX
REAL, DIMENSION(:) :: X

REAL FUNCTION ASUM_64([N], X, [INCX])

INTEGER(8) :: N, INCX
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>

float sasum(int n, float *x, int incx);

float sasum_64(long n, float *x, long incx);
```

PURPOSE

sasum Return the sum of the absolute values of x where x is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Contents

NAME

```
saxpy - compute y := alpha * x + y
```

SYNOPSIS

```
SUBROUTINE SAXPY(N, ALPHA, X, INCX, Y, INCY)

INTEGER N, INCX, INCY
REAL ALPHA
REAL X(*), Y(*)

SUBROUTINE SAXPY_64(N, ALPHA, X, INCX, Y, INCY)

INTEGER*8 N, INCX, INCY
REAL ALPHA
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE AXPY([N], ALPHA, X, [INCX], Y, [INCY])

INTEGER :: N, INCX, INCY
REAL :: ALPHA
REAL, DIMENSION(:) :: X, Y

SUBROUTINE AXPY_64([N], ALPHA, X, [INCX], Y, [INCY])

INTEGER(8) :: N, INCX, INCY
REAL :: ALPHA
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void saxpy(int n, float alpha, float *x, int incx, float *y,
          int incy);

void saxpy_64(long n, float  alpha,  float  *x,  long  incx,
          float *y, long incy);
```

PURPOSE

saxpy compute y := alpha * x + y where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
saxpyi - Compute y := alpha * x + y
```

SYNOPSIS

```
 SUBROUTINE SAXPYI(NZ, A, X, INDX, Y)

 REAL A
 REAL X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE SAXPYI_64(NZ, A, X, INDX, Y)

 REAL A
 REAL X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE AXPYI([NZ], [A], X, INDX, Y)

 REAL :: A
 REAL, DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE AXPYI_64([NZ], [A], X, INDX, Y)

 REAL :: A
 REAL, DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
SAXPYI Compute y := alpha * x + y where alpha is a scalar, x
is a sparse vector, and y is a vector in full storage form

 do i = 1, n
   y(indx(i)) = alpha * x(i) + y(indx(i))
 enddo
```

ARGUMENTS

```
NZ (input) - INTEGER
        Number of elements in the compressed form.
        Unchanged on exit.

A (input)
        On entry, A(LPHA) specifies the scaling value.
        Unchanged on exit.  A is defaulted to 1.0E0 for F95
        INTERFACE.
X (input)
        Vector containing the values of the compressed form.
        Unchanged on exit.

INDX (input) - INTEGER
        Vector containing the indices of the compressed
        form.  It is assumed that the elements in INDX are
        distinct and greater than zero.  Unchanged on exit.

Y (output)
        Vector on input which contains the vector Y in full
        storage form.  On exit, only the elements
        corresponding to the indices in INDX have been
        modified.
```

Contents

NAME

sbcomm - block coordinate matrix-matrix multiply

SYNOPSIS

```
 SUBROUTINE SBCOMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
*           VAL, BINDX, BJNDX, BNNZ, LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )

                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length LB*LB*BNNZ consisting of
                the non-zero block entries of A, in any order.
                Each block is stored in standard column-major form.

 BINDX()        integer array of length BNNZ consisting of the
                block row indices of the block entries of A.

 BJNDX()        integer array of length BNNZ consisting of the
                block column indices of the block entries of A.

 BNNZ           number of block entries

 LB             dimension of dense blocks composing A.

 B()            rectangular array with first dimension LDB.
 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block diagonal format
and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)

DV()          Array of length MB*LB*LB containing the elements of
              the diagonal blocks of the matrix D.  The size of each
              square block is LB-by-LB and each block
              is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-identity blocks on the main diagonal
                 1 : identity diagonal blocks
                 2 : diagonal blocks are dense matrices
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          Two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
               consisting of the NBDIAG non-zero block diagonal.
               Each dense block is stored in standard column-major form.

BLDA           Leading block dimension of VAL().  Should be greater
               than or equal to MB.

IBDIAG()       integer array of length NBDIAG consisting of the
               corresponding diagonal offsets of the non-zero block
               diagonals of A in VAL.  Lower triangular block diagonals
               have negative offsets, the main block diagonal has offset
               0, and upper triangular block diagonals have positive offset.
               Elements of IBDIAG  MUST be sorted in  increasing order.

NBDIAG         The number of non-zero block diagonals in A.

LB             Dimension of dense blocks composing A.

B()            Rectangular array with first dimension LDB.

LDB            Leading dimension of B.

BETA           Scalar parameter.

C()            Rectangular array with first dimension LDC.

LDC            Leading dimension of C.
```

```
WORK()        scratch array of length LWORK.
              On exit, if LWORK= -1, WORK(1) returns the optimum  size
              of LWORK.

LWORK        length of WORK array. LWORK should be at least
             MB*LB.

             For good performance, LWORK should generally be larger.
             For optimum performance on multiple processors, LWORK
             >=MB*LB*N_CPUS where N_CPUS is the maximum number of
             processors available to the program.

             If LWORK=0, the routine is to allocate workspace needed.

             If LWORK = -1, then a workspace query is assumed; the
             routine only calculates the optimum size of the WORK array,
             returns this value as the first entry of the WORK array,
             and no error message related to LWORK is issued by XERBLA.
```

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0, the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BDI representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block

number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

          ldvt, float *q, long *iq, long *info);
```

PURPOSE

sbdsdc computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = U * S * VT, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. SBDSDC can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLASD3 for details.

The code currently call SLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

ARGUMENTS

UPLO (input)
          = 'U': B is upper bidiagonal.
          = 'L': B is lower bidiagonal.

COMPQ (input)
Specifies whether singular vectors are to be computed as follows:
= 'N': Compute singular values only;
= 'P': Compute singular values and compute singular vectors in compact form; = 'I': Compute singular values and singular vectors.

N (input) The order of the matrix B. N >= 0.

D (input/output)
On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B.

E (input/output)
On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On exit, E has been destroyed.

U (output)
If COMPQ = 'I', then: On exit, if INFO = 0, U contains the left singular vectors of the bidiagonal matrix. For other values of COMPQ, U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= 1. If singular vectors are desired, then LDU >= max(1, N).

VT (output)
If COMPQ = 'I', then: On exit, if INFO = 0, VT' contains the right singular vectors of the bidiagonal matrix. For other values of COMPQ, VT is not referenced.

LDVT (input)
The leading dimension of the array VT. LDVT >= 1. If singular vectors are desired, then LDVT >= max(1, N).

Q (input) If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring O(N log N) space instead of 2*N**2. In particular, Q contains all the REAL data in LDQ >= N*(11 + 2*SMLSIZ + 8*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of

```
            the computation  tree  (usually  about  25).   For
            other values of COMPQ, Q is not referenced.

  IQ (output)
            If  COMPQ = 'P', then:  On exit, if INFO  =  0,  Q
            and IQ contain the left and right singular vectors
            in a compact form,  requiring  O(N  log  N)  space
            instead of 2*N**2.  In particular, IQ contains all
            INTEGER    data    in    LDIQ    >=     N*(3     +
            3*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where
            SMLSIZ is returned by ILAENV and is equal  to  the
            maximum  size  of the subproblems at the bottom of
            the computation  tree  (usually  about  25).   For
            other values of COMPQ, IQ is not referenced.

  WORK (workspace)
            If COMPQ = 'N' then LWORK >= (2 * N).  If COMPQ  =
            'P'  then  LWORK  >= (6 * N).  If COMPQ = 'I' then
            LWORK >= (3 * N**2 + 4 * N).

  IWORK (workspace)
            dimension(8*N)

  INFO (output)
            = 0:  successful exit.
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value.
            > 0:  The algorithm failed to compute an  singular
            value.   The  update process of divide and conquer
            failed.

```

PURPOSE

sbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = Q * S * P' (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes U * Q, P' * VT, or Q' * C, for given real input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

UPLO (input)
  = 'U': B is upper bidiagonal;
  = 'L': B is lower bidiagonal.

N (input) The order of the matrix B. N >= 0.

NCVT (input)
  The number of columns of the matrix VT. NCVT >= 0.

NRU (input)
The number of rows of the matrix U. NRU >= 0.

NCC (input)
The number of columns of the matrix C. NCC >= 0.

D (input/output)
On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

E (input/output)
On entry, the elements of E contain the offdiagonal elements of the bidiagonal matrix whose SVD is desired. On normal exit (INFO = 0), E is destroyed. If the algorithm does not converge (INFO > 0), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. E(N) is used for workspace.

VT (input/output)
On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by P' * VT. VT is not referenced if NCVT = 0.

LDVT (input)
The leading dimension of the array VT. LDVT >= max(1,N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U (input/output)
On entry, an NRU-by-N matrix U. On exit, U is overwritten by U * Q. U is not referenced if NRU = 0.

LDU (input)
The leading dimension of the array U. LDU >= max(1,NRU).

C (input/output)
On entry, an N-by-NCC matrix C. On exit, C is overwritten by Q' * C. C is not referenced if NCC = 0.

LDC (input)
The leading dimension of the array C. LDC >= max(1,N) if NCC > 0; LDC >=1 if NCC = 0.

WORK (workspace)
dimension(4*N)

INFO (output)
= 0: successful exit
< 0: If INFO = -i, the i-th argument had an illegal value
> 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

```

DESCRIPTION

```
         C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block Ellpack format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
```

```
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length LB*LB*BLDA*MAXBNZ containing
                matrix entries, stored column-major within each dense
                block.

 BINDX()        two-dimensional integer BLDA-by-MAXBNZ array such
                BINDX(i,:) consists of the block column indices of the
                nonzero blocks in block row i, padded by the integer
                value i if the number of nonzero blocks is less than
                MAXBNZ.

 BLDA           leading dimension of BINDX(:,:).

 MAXBNZ         max number of nonzeros blocks per row.
 LB             row and column dimension of the dense blocks composing
                VAL.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block Ellpack format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                    1 : symmetric (A=A')
                    2 : Hermitian (A= CONJG(A'))
                    3 : Triangular
                    4 : Skew(Anti)-Symmetric (A=-A')
                    5 : Diagonal
                    6 : Skew-Hermitian (A= -CONJG(A'))
                  Note: For the routine, DESCRA(1)=3 is only supported.

                  DESCRA(2) upper/lower triangular indicator
                    1 : lower
                    2 : upper
                  DESCRA(3) main diagonal type
                    0 : non-identity blocks on the main diagonal
                    1 : identity diagonal blocks
                    2 : diagonal blocks are dense matrices
                  DESCRA(4) Array base  (NOT IMPLEMENTED)
                    0 : C/C++ compatible
                    1 : Fortran compatible
                  DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                    0 : unknown
                    1 : no repeated indices
    VAL()         scalar array of length LB*LB*BLDA*MAXBNZ containing
                  matrix entries, stored column-major within each dense
                  block.

    BINDX()       two-dimensional integer BLDA-by-MAXBNZ array such
                  BINDX(i,:) consists of the block column indices of the
                  nonzero blocks in block row i, padded by the integer
                  value i if the number of nonzero blocks is less than
                  MAXBNZ.  The block column indices MUST be sorted
                  in increasing order for each block row.

    BLDA          leading dimension of BINDX(:,:).

    MAXBNZ        max number of nonzeros blocks per row.

    LB            row and column dimension of the dense blocks composing A.

    B()           rectangular array with first dimension LDB.

    LDB           leading dimension of B

    BETA          Scalar parameter

    C()           rectangular array with first dimension LDC.

    LDC           leading dimension of C

    WORK()        scratch array of length LWORK.
                  On exit, if LWORK= -1, WORK(1) returns the minimum
```

size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BEL representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block sparse column format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
```

```
                 DESCRA(3) main diagonal type
                   0 : non-unit
                   1 : unit
                 DESCRA(4) Array base  (NOT IMPLEMENTED)
                   0 : C/C++ compatible
                   1 : Fortran compatible
                 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                   0 : unknown
                   1 : no repeated indices

   VAL()         scalar array of length LB*LB*BNNZ consisting of
                 the block entries stored column-major within each
                 dense block.

   BINDX()       integer array of length BNNZ consisting of the
                 block row indices of the block entries of A.

   BPNTRB()      integer array of length KB such that
                 BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                 of the first block entry of the J-th block column
                 of A.
   BPNTRE()      integer array of length KB such that
                 BPNTRE(J)-BPNTRB(1) points to location in BINDX
                 of the last block entry of the J-th block column
                 of A.

   LB            dimension of dense blocks composing A.

   B()           rectangular array with first dimension LDB.

   LDB           leading dimension of B

   BETA          Scalar parameter

   C()           rectangular array with first dimension LDC.

   LDC           leading dimension of C

   WORK()        scratch array of length LWORK. WORK is not
                 referenced in the current version.

   LWORK         length of WORK array. LWORK is not referenced
                 in the current version.
```

NOTES/BUGS

It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
  CALL SBSCMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

 INTEGER*8, DIMENSION(:) ::    DESCRA, BINDX, BPNTRB, BPNTRE
 REAL    ALPHA, BETA
 REAL, DIMENSION(:) :: VAL, DV
 REAL, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block sparse column format
and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))

               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-identity blocks on the main diagonal
                 1 : identity diagonal blocks
                 2 : diagonal blocks are dense matrices
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          scalar array of length LB*LB*BNNZ consisting of the block
               entries stored column-major within each dense block.

BINDX()        integer array of length BNNZ consisting of the
               block row indices of the block entries of A.
               The block row indices MUST be sorted
               in increasing order for each block column.

BPNTRB()       integer array of length MB such that
               BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
               of the first block entry of the J-th block column of A.

BPNTRE()       integer array of length MB such that
               BPNTRE(J)-BPNTRB(1) points to location in BINDX
               of the last block entry of the J-th block column of A.

LB             dimension of dense blocks composing A.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C
```

```
 WORK()        scratch array of length LWORK.
               On exit, if LWORK= -1, WORK(1) returns the optimum
               size of LWORK.

 LWORK         length of WORK array. LWORK should be at least
               MB*LB.

               For good performance, LWORK should generally be larger.
               For optimum performance on multiple processors, LWORK
               >=MB*LB*N_CPUS where N_CPUS is the maximum number of
               processors available to the program.

               If LWORK=0, the routine is to allocate workspace needed.

               If LWORK = -1, then a workspace query is assumed; the
               routine only calculates the optimum size of the WORK
               array, returns this value as the first entry of the WORK
               array, and no error message related to LWORK is issued
               by XERBLA.
```

http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BSC representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed

successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

6. It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
  CALL SBSCSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

NAME

sbsrsm - block sparse row format triangular solve

SYNOPSIS

```
 SUBROUTINE SBSRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
*           VAL, BINDX, BPNTRB, BPNTRE, LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )
 INTEGER    TRANSA, MB, N, UNITD, DESCRA(5), LB,
*           LDB, LDC, LWORK
 INTEGER    BINDX(BNNZ), BPNTRB(MB), BPNTRE(MB)
 REAL       ALPHA, BETA
 REAL       DV(MB*LB*LB), VAL(LB*LB*BNNZ), B(LDB,*), C(LDC,*), WORK(LWORK)

 SUBROUTINE SBSRSM_64( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
*           VAL, BINDX, BPNTRB, BPNTRE, LB,
*           B, LDB, BETA, C, LDC, WORK, LWORK )
 INTEGER*8  TRANSA, MB, N, UNITD, DESCRA(5), LB,
*           LDB, LDC, LWORK
 INTEGER*8  BINDX(BNNZ), BPNTRB(MB), BPNTRE(MB)
 REAL       ALPHA, BETA
 REAL       DV(MB*LB*LB), VAL(LB*LB*BNNZ), B(LDB,*), C(LDC,*), WORK(LWORK)

 where: BNNZ = BPNTRE(MB)-BPNTRB(1)
```

F95 INTERFACE

```
 SUBROUTINE BSRSM(TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA, VAL, BINDX,
*     BPNTRB, BPNTRE, LB, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER    TRANSA, MB, N, UNITD, LB
 INTEGER, DIMENSION(:) ::    DESCRA, BINDX, BPNTRB, BPNTRE
 REAL    ALPHA, BETA
 REAL, DIMENSION(:) :: VAL, DV
 REAL, DIMENSION(:, :) ::  B, C
```

```
 SUBROUTINE BSRSM_64(TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA, VAL, BINDX,
*     BPNTRB, BPNTRE, LB, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, MB, N, UNITD, LB
 INTEGER*8, DIMENSION(:) ::    DESCRA, BINDX, BPNTRB, BPNTRE
 REAL    ALPHA, BETA
 REAL, DIMENSION(:) :: VAL, DV
 REAL, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block sparse row format
format and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-identity blocks on the main diagonal
                  1 : identity diagonal blocks
                  2 : diagonal blocks are dense matrices
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
  VAL()         scalar array of length LB*LB*BNNZ consisting of the block
                entries stored column-major within each dense block.

  BINDX()       integer array of length BNNZ consisting of the
                block column indices of the block entries of A.
                The block column indices MUST be sorted
                in increasing order for each block row.

  BPNTRB()      integer array of length MB such that
                BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                of the first block entry of the J-th block row of A.

  BPNTRE()      integer array of length MB such that
                BPNTRE(J)-BPNTRB(1) points to location in BINDX
                of the last block entry of the J-th block row of A.

  LB            dimension of dense blocks composing A.

  B()           rectangular array with first dimension LDB.

  LDB           leading dimension of B

  BETA          Scalar parameter

  C()           rectangular array with first dimension LDC.

  LDC           leading dimension of C
```

WORK()	scratch array of length LWORK. On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.
LWORK	length of WORK array. LWORK should be at least MB*LB. For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program. If LWORK=0, the routine is to allocate workspace needed. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

NIST FORTRAN Sparse Blas User's Guide available at:
http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BSR representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed

successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

2. It is known that there exists another representation of the block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse row format the following calling sequence should be used

```
  CALL SBSRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

NAME

```
scasum - Return the sum of the absolute values of  a  vector
x.
```

SYNOPSIS

```
REAL FUNCTION SCASUM(N, X, INCX)

COMPLEX X(*)
INTEGER N, INCX

REAL FUNCTION SCASUM_64(N, X, INCX)

COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL FUNCTION ASUM([N], X, [INCX])

COMPLEX, DIMENSION(:) :: X
INTEGER :: N, INCX

REAL FUNCTION ASUM_64([N], X, [INCX])

COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>

float scasum(int n, complex *x, int incx);

float scasum_64(long n, complex *x, long incx);
```

PURPOSE

scasum Return the sum of the absolute values of the elements of x where x is an n-vector. This is the sum of the absolute values of the real and complex elements and not the sum of the squares of the real and complex elements.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Contents

NAME

```
scnrm2 - Return the Euclidian norm of a vector.
```

SYNOPSIS

```
REAL FUNCTION SCNRM2(N, X, INCX)

COMPLEX X(*)
INTEGER N, INCX

REAL FUNCTION SCNRM2_64(N, X, INCX)

COMPLEX X(*)
INTEGER*8 N, INCX
```

F95 INTERFACE

```
REAL FUNCTION NRM2([N], X, [INCX])

COMPLEX, DIMENSION(:) :: X
INTEGER :: N, INCX

REAL FUNCTION NRM2_64([N], X, [INCX])

COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N, INCX
```

C INTERFACE

```
#include <sunperf.h>

float scnrm2(int n, complex *x, int incx);

float scnrm2_64(long n, complex *x, long incx);
```

PURPOSE

scnrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

              *work, int lwork);
    void scnvcor_64(char cnvcor, char four, long nx,  float  *x,
              long  ifx,  long incx, long ny, long npre, long m,
              float *y, long ify, long inc1y, long  inc2y,  long
              nz,  long  k, float *z, long ifz, long inc1z, long
              inc2z, float *work, long lwork);
```

PURPOSE

scnvcor computes the convolution or correlation of real vectors.

ARGUMENTS

CNVCOR (input)
'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

FOUR (input)
'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

NX (input)
Length of the filter vector. NX >= 0. SCNVCOR will return immediately if NX = 0.

X (input)
Filter vector.

IFX (input)
Index of the first element of X. NX >= IFX >= 1.

INCX (input)
Stride between elements of the filter vector in X. INCX > 0.

NY (input)
Length of the input vectors. NY >= 0. SCNVCOR will return immediately if NY = 0.

NPRE (input)
The number of implicit zeros prepended to the Y vectors. NPRE >= 0.

M (input)
Number of input vectors. M >= 0. SCNVCOR will return immediately if M = 0.

Y (input)
Input vectors.

IFY (input)
Index of the first element of Y. NY >= IFY >= 1.

INC1Y (input)
Stride between elements of the input vectors in Y. INC1Y > 0.

INC2Y (input)
Stride between the input vectors in Y. INC2Y > 0.

NZ (input)
Length of the output vectors. NZ >= 0. SCNVCOR will return immediately if NZ = 0. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

K (input)
Number of Z vectors. K >= 0. If K = 0 then SCNVCOR will return immediately. If K < M then only the first K input vectors will be processed. If K > M then M input vectors will be processed.

Z (output)
Result vectors.

IFZ (input)
Index of the first element of Z. NZ >= IFZ >= 1.

INC1Z (input)
Stride between elements of the output vectors in Z. INC1Z > 0.

INC2Z (input)
Stride between the output vectors in Z. INC2Z > 0.

WORK (input/output)
Scratch space. Before the first call to SCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to SCNVCOR or if SCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make SCNVCOR run faster.

LWORK (input)
Length of WORK. LWORK >= 4*max(NX,NPRE+NY,NZ)+15.

NOTES

If any vector overlaps a writable vector, either because of argument aliasing or ill-chosen values of the various INC arguments, the results are undefined and may vary from one run to the next.

The most common form of the computation, and the case that executes fastest, is applying a filter vector X to a series of vectors stored in the columns of Y with the result placed into the columns of Z. In that case, INCX = 1, INC1Y = 1, INC2Y >= NY, INC1Z = 1, INC2Z >= NZ. Another common form is applying a filter vector X to a series of vectors stored in the rows of Y and store the result in the row of Z, in which case INCX = 1, INC1Y >= NY, INC2Y = 1, INC1Z >= NZ, and INC2Z = 1.

          long nz, float *z, long ldz, complex *workin, long
          lwork);
```

PURPOSE

scnvcor2 computes the convolution or correlation of real matrices.

ARGUMENTS

CNVCOR (input)
'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

METHOD (input)
'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the

definition.

TRANSX (input)
'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

SCRATCHX (input)
'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

TRANSY (input)
'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

SCRATCHY (input)
'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

MX (input)
Number of rows in the filter matrix. MX >= 0.

NX (input)
Number of columns in the filter matrix. NX >= 0.

X (input) dimension(LDX,NX)
On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

LDX (input)
Leading dimension of the array that contains the filter matrix.

MY (input)
Number of rows in the input matrix. MY >= 0.

NY (input)
Number of columns in the input matrix. NY >= 0.

MPRE (input)
Number of implicit zeros to prepend to each row of the input matrix. MPRE >= 0.

NPRE (input)
Number of implicit zeros to prepend to each column of the input matrix. NPRE >= 0.

Y (input) dimension(LDY,*)
Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

LDY (input)
Leading dimension of the array that contains the input matrix.

MZ (input)
Number of rows in the output matrix. MZ >= 0. SCNVCOR2 will return immediately if MZ = 0.

NZ (input)
Number of columns in the output matrix. NZ >= 0. SCNVCOR2 will return immediately if NZ = 0.

Z (output)
dimension(LDZ,*)
Result matrix.

LDZ (input)
Leading dimension of the array that contains the result matrix. LDZ >= MAX(1,MZ).

WORKIN (input/output)
(input/scratch) dimension(LWORK)
On entry for the first call to SCNVCOR2, REAL(WORKIN(1)) must contain 0.0. After the first call, REAL(WORKIN(1)) must be set to 0.0 iff WORKIN has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

LWORK (input)
Length of the work vector. The upper bound of the workspace length requirement is 2 * (MYC + NYC) + 15, where MYC = MAX(MAX(MX,NX), MAX(MY,NY)+NPRE) and NYC = MAX(MAX(MX,NX), MAX(MY,NY)+MPRE). If LWORK indicates a workspace that is too small, the routine will allocate its own workspace. If the FFT is not used, the value of LWORK is unimportant.

DESCRIPTION

```
              C <- alpha op(A) B + beta C

      where ALPHA and BETA are scalar, C and B are dense matrices,
      A is a matrix represented in coordinate format and
      op( A )  is one  of
      op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                          ( ' indicates matrix transpose)
```

ARGUMENTS

```
      TRANSA        Indicates how to operate with the sparse matrix
                      0 : operate with matrix
                      1 : operate with transpose matrix
                      2 : operate with the conjugate transpose of matrix.
                          2 is equivalent to 1 if matrix is real.

      M             Number of rows in matrix A

      N             Number of columns in matrix C

      K             Number of columns in matrix A

      ALPHA         Scalar parameter

      DESCRA()      Descriptor argument.  Five element integer array
                    DESCRA(1) matrix structure
                      0 : general
                      1 : symmetric (A=A')
                      2 : Hermitian (A= CONJG(A'))
                      3 : Triangular
                      4 : Skew(Anti)-Symmetric (A=-A')
                      5 : Diagonal
                      6 : Skew-Hermitian (A= -CONJG(A'))
                    DESCRA(2) upper/lower triangular indicator
                      1 : lower
                      2 : upper
```

```
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length NNZ consisting of the
                non-zero entries of A, in any order.

 INDX()         integer array of length NNZ consisting of the
                corresponding row indices of the entries of A.

 JNDX()         integer array of length NNZ consisting of the
                corresponding column indices of the entries of A.

 NNZ            number of non-zero elements in A.
 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

NAME

```
scopy - Copy x to y
```

SYNOPSIS

```
SUBROUTINE SCOPY(N, X, INCX, Y, INCY)

INTEGER N, INCX, INCY
REAL X(*), Y(*)

SUBROUTINE SCOPY_64(N, X, INCX, Y, INCY)

INTEGER*8 N, INCX, INCY
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE COPY([N], X, [INCX], Y, [INCY])

INTEGER :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y

SUBROUTINE COPY_64([N], X, [INCX], Y, [INCY])

INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>

void scopy(int n, float *x, int incx, float *y, int incy);

void scopy_64(long n, float *x, long incx,  float  *y,  long
          incy);
```

PURPOSE

scopy Copy x to y where x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (output)
(1 + (m - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
  SUBROUTINE SCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,
 *           C, LDC, WORK, LWORK )
```

Contents

 REAL, DIMENSION(:) :: VAL, DV
 REAL, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in compressed sparse column
format and op( A )  is one  of
op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic column scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           scalar array of length NNZ consisting of nonzero entries
                of A.

INDX()          integer array of length NNZ consisting of the row indices
                of nonzero entries of A. (Row indices MUST be sorted in
                increasing order for each column).

PNTRB()         integer array of length M such that PNTRB(J)-PNTRB(1)+1
                points to location in VAL of the first nonzero element
                in column J.

PNTRE()         integer array of length M such that PNTRE(J)-PNTRB(1)
                points to location in VAL of the last nonzero element
                in column J.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.

                On exit,  if LWORK = -1, WORK(1) returns the optimum  LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the columns of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the columns have been scaled. UNITD=3 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the column number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the CSC representation

of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the CSC representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

5. It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
  SUBROUTINE SCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in compressed sparse row format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
```

```
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length NNZ consisting of nonzero
                entries of A.

 INDX()         integer array of length NNZ consisting of the
                column indices of nonzero entries of A.

 PNTRB()        integer array of length M such that PNTRB(J)-PNTRB(1)+1
                points to location in VAL of the first nonzero element
                in row J.
 PNTRE()        integer array of length M such that PNTRE(J)-PNTRB(1)
                points to location in VAL of the last nonzero element
                in row J.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each row in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of compressed sparse row format the following calling sequence should be used

```
  SUBROUTINE SCSRMM( TRANSA, M, N, K, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,
 *           C, LDC, WORK, LWORK )
```

```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in compressed sparse row format and op(A) is one of

op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of
              the scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))

               Note: For the routine, only DESCRA(1)=3 is supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          scalar array of length NNZ consisting of nonzero entries
               of A.

INDX()         integer array of length NNZ consisting of the column
               indices of nonzero entries of A (column indices MUST be
               sorted in increasing order for each row)

PNTRB()        integer array of length M such that PNTRB(J)-PNTRB(1)+1
               points to location in VAL of the first nonzero element
               in row J.

PNTRE()        integer array of length M such that PNTRE(J)-PNTRB(1)
               points to location in VAL of the last nonzero element
               in row J.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.

               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the CSR representation of a sparse matrix. They are not used anyway in these cases.

But if UNITD=4, the unit diagonal elements MUST be referenced in the CSR representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

5. It is known that there exists another representation of the compressed sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each row in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of compressed sparse row format the following calling sequence should be used

```
  SUBROUTINE SCSRSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA, C,
 *            LDC, WORK, LWORK )
```

                 2 : operate with the conjugate transpose of matrix.
                     2 is equivalent to 1 if matrix is real.

 M             Number of rows in matrix A

 N             Number of columns in matrix C

 K             Number of columns in matrix A

 ALPHA         Scalar parameter

 DESCRA()      Descriptor argument.  Five element integer array
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
```

```
VAL()          two-dimensional LDA-by-NDIAG array such that VAL(:,I)
               consists of non-zero elements on diagonal IDIAG(I)
               of A.  Diagonals in the lower triangular part of A
               are padded from the top, and those in the upper
               triangular part are padded from the bottom.

LDA            leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG()        integer array of length NDIAG consisting of the
               corresponding diagonal offsets of the non-zero
               diagonals of A in VAL.  Lower triangular diagonals
               have negative offsets, the main diagonal has offset
               0, and upper triangular diagonals have positive offset.

NDIAG          number of non-zero diagonals in A.

B()            rectangular array with first dimension LDB.
LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK. WORK is not
               referenced in the current version.

LWORK          length of WORK array. LWORK is not referenced
               in the current version.

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, only DESCRA(1)=3 is supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          two-dimensional LDA-by-NDIAG array such that VAL(:,I)
               consists of non-zero elements on diagonal IDIAG(I)
               of A.  Diagonals in the lower triangular part of A
               are padded from the top, and those in the upper
               triangular part are padded from the bottom.

LDA            leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG()        integer array of length NDIAG consisting of the
               corresponding diagonal offsets of the non-zero
               diagonals of A in VAL.  Lower triangular diagonals
               have negative offsets, the main diagonal has offset
               0, and upper triangular diagonals have positive offset.
               Elements of IDIAG of MUST be sorted in  increasing order.

NDIAG          number of non-zero diagonals in A.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.
               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the DIA representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the DIA representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

NAME

sdisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

SYNOPSIS

```
SUBROUTINE SDISNA(JOB, M, N, D, SEP, INFO)

CHARACTER * 1 JOB
INTEGER M, N, INFO
REAL D(*), SEP(*)

SUBROUTINE SDISNA_64(JOB, M, N, D, SEP, INFO)

CHARACTER * 1 JOB
INTEGER*8 M, N, INFO
REAL D(*), SEP(*)
```

F95 INTERFACE

```
SUBROUTINE DISNA(JOB, M, N, D, SEP, [INFO])

CHARACTER(LEN=1) :: JOB
INTEGER :: M, N, INFO
REAL, DIMENSION(:) :: D, SEP

SUBROUTINE DISNA_64(JOB, M, N, D, SEP, [INFO])

CHARACTER(LEN=1) :: JOB
INTEGER(8) :: M, N, INFO
REAL, DIMENSION(:) :: D, SEP
```

C INTERFACE

```
#include <sunperf.h>

void sdisna(char job, int m, int n, float  *d,  float  *sep,
          int *info);

void sdisna_64(char job, long m, long  n,  float  *d,  float
          *sep, long *info);
```

PURPOSE

sdisna computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix. The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the I-th computed vector is given by

```
SLAMCH( 'E' ) * ( ANORM / SEP( I ) )
```

where ANORM = 2-norm(A) = max(abs(D(j))). SEP(I) is not allowed to be smaller than SLAMCH('E')*ANORM in order to limit the size of the error bound.

SDISNA may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

ARGUMENTS

JOB (input)
Specifies for which problem the reciprocal condition numbers should be computed:
= 'E': the eigenvectors of a symmetric/Hermitian matrix;
= 'L': the left singular vectors of a general matrix;
= 'R': the right singular vectors of a general matrix.

M (input) The number of rows of the matrix. M >= 0.

N (input) If JOB = 'L' or 'R', the number of columns of the matrix, in which case N >= 0. Ignored if JOB = 'E'.

D (input) dimension (min(M,N)) if JOB = 'L' or 'R' The eigenvalues (if JOB = 'E') or singular values (if JOB = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

SEP (output)
dimension (min(M,N)) if JOB = 'L' or 'R' The reciprocal condition numbers of the vectors.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

Contents

NAME

```
sdot - compute the dot product of two vectors x and y.
```

SYNOPSIS

```
REAL FUNCTION SDOT(N, X, INCX, Y, INCY)

INTEGER N, INCX, INCY
REAL X(*), Y(*)

REAL FUNCTION SDOT_64(N, X, INCX, Y, INCY)

INTEGER*8 N, INCX, INCY
REAL X(*), Y(*)
```

F95 INTERFACE

```
REAL FUNCTION DOT([N], X, [INCX], Y, [INCY])

INTEGER :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y

REAL FUNCTION DOT_64([N], X, [INCX], Y, [INCY])

INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>

float sdot(int n, float *x, int incx, float *y, int incy);

float sdot_64(long n, float *x, long incx,  float  *y,  long
          incy);
```

PURPOSE

sdot compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

N (input)
: On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

X (input)
: (1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
: On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
: (1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

INCY (input)
: On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
sdoti - Compute the indexed dot product.
```

SYNOPSIS

```
 REAL FUNCTION SDOTI(NZ, X, INDX, Y)

 REAL X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 REAL FUNCTION SDOTI_64(NZ, X, INDX, Y)

 REAL X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 REAL FUNCTION DOTI([NZ], X, INDX, Y)

 REAL, DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 REAL FUNCTION DOTI_64([NZ], X, INDX, Y)

 REAL, DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
SDOTI Compute the indexed dot product of a real sparse
vector x stored in compressed form with a real vector y in
```

full storage form.

```
dot = 0
do i = 1, n
  dot = dot + x(i) * y(indx(i))
enddo
```

ARGUMENTS

NZ (input)
Number of elements in the compressed form. Unchanged on exit.

X (input)
Vector in compressed form. Unchanged on exit.

INDX (input)
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)
Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

Contents

NAME

```
sdsdot - compute a constant plus the  double  precision  dot
product of two single precision vectors x and y
```

SYNOPSIS

```
REAL FUNCTION SDSDOT(N, SB, SX, INCX, SY, INCY)

INTEGER N, INCX, INCY
REAL SB
REAL SX(*), SY(*)

REAL FUNCTION SDSDOT_64(N, SB, SX, INCX, SY, INCY)

INTEGER*8 N, INCX, INCY
REAL SB
REAL SX(*), SY(*)
```

F95 INTERFACE

```
REAL FUNCTION SDSDOT(N, SB, SX, INCX, SY, INCY)

INTEGER :: N, INCX, INCY
REAL :: SB
REAL, DIMENSION(:) :: SX, SY

REAL FUNCTION SDSDOT_64(N, SB, SX, INCX, SY, INCY)

INTEGER(8) :: N, INCX, INCY
REAL :: SB
REAL, DIMENSION(:) :: SX, SY
```

C INTERFACE

```
#include <sunperf.h>
```

```
float sdsdot(int n, float sb, float  *sx,  int  incx,  float
          *sy, int incy);

float sdsdot_64(long n, float  sb,  float  *sx,  long  incx,
          float *sy, long incy);
```

PURPOSE

sdsdot Computes a constant plus the double precision dot product of x and y where x and y are single precision n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

SB (input)
On entry, the constant that is added to the dot product before the result is returned. Unchanged on exit.

SX (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array SX must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of SX. INCX must not be zero. Unchanged on exit.

SY (input)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array SY must contain the vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of SY. INCY must not be zero. Unchanged on exit.

                 6 : Skew-Hermitian (A= -CONJG(A'))

               Note: For the routine, only DESCRA(1)=3 is supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          two-dimensional LDA-by-MAXNZ array such that VAL(I,:)
               consists of non-zero elements in row I of A, padded by
               zero values if the row contains less than MAXNZ.

INDX()         two-dimensional integer LDA-by-MAXNZ array such
               INDX(I,:) consists of the column indices of the
               nonzero elements in row I, padded by the integer
               value I if the number of nonzeros is less than MAXNZ.
               The column indices MUST be sorted in increasing order
               for each row.

LDA            leading dimension of VAL and INDX.

MAXNZ          max number of nonzeros elements per row.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.

               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the ELL representation of a sparse matrix. They are not used anyway in these cases.

But if UNITD=4, the unit diagonal elements MUST be referenced in the ELL representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>

void sfftc_ (int *iopt, int *n, float *scale, float *x, com-
          plex *y, float *trigs, int *ifac, float *work, int
          *lwork, int *ierr);

void sfftc_64_ (long *iopt, long *n, float *scale, float *x,
          complex *y, float *trigs, long *ifac, float *work,
          long *lwork, long *ierr);
```

PURPOSE

sfftc initializes the trigonometric weight and factor tables or computes the forward Fast Fourier Transform of a real sequence as follows:

```
               N-1
Y(k) = scale * SUM  W*X(j)
               j=0
```

where
k ranges from 0 to N-1
i = sqrt(-1)
isign = -1 for forward transform
W = exp(isign*i*j*k*2*pi/N)
In real-to-complex transform of length N, the (N/2+1) complex output data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:

```
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = -1 computes forward FFT

N (input)
          Integer specifying length of the input sequence X.
          N  is most efficient when it is a product of small
          primes.  N >= 0.  Unchanged on exit.

SCALE (input)
          Real scalar by which transform results are scaled.
          Unchanged  on exit.  SCALE is defaulted to 1.0 for
          F95 INTERFACE.

X (input) On entry, X is a real array whose first N elements
          contain the sequence to be transformed.

Y (output)
          Complex array whose first (N/2+1) elements contain
          the  transform  results.   X and Y may be the same
          array starting at the  same  memory  location,  in
          which  case  the  dimension  of X must be at least
          2*(N/2+1).  Otherwise, it is assumed that there is
          no overlap between X and Y in memory.

TRIGS (input/output)
          Real array of length 2*N that  contains  the  tri-
          gonometric weights.  The weights are computed when
          the routine is called with IOPT = 0 and  they  are
          used   in   subsequent   calls  when  IOPT  =  -1.
          Unchanged on exit.

IFAC (input/output)
          Integer array of dimension at least 128 that  con-
          tains  the factors of N.  The factors are computed
          when the routine is called with IOPT = 0 and  they
          are  used  in  subsequent  calls  where IOPT = -1.
          Unchanged on exit.

WORK (workspace)
          Real array of dimension at least N.  The user  can
          also  choose  to have the routine allocate its own
          workspace (see LWORK).

LWORK (input)
          Integer specifying workspace size.  If LWORK =  0,
          the routine will allocate its own workspace.

IERR (output)
          On exit, integer IERR has  one  of  the  following
```

```
values:
0 = normal return
-1 = IOPT is not 0 or -1
-2 = N < 0
-3 = (LWORK is not 0) and (LWORK is less than N)
-4 = memory allocation for workspace failed
```

IFAC, WORK, [LWORK], IERR)

     INTEGER(8), INTENT(IN) :: IOPT
     INTEGER(8), INTENT(IN), OPTIONAL :: N1, N2, LDX, LDY, LWORK
     REAL, INTENT(IN), OPTIONAL :: SCALE
     REAL, INTENT(IN), DIMENSION(:,:) :: X
     COMPLEX, INTENT(OUT), DIMENSION(:,:) :: Y
     REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS
     INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
     REAL, INTENT(OUT), DIMENSION(:) :: WORK
     INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
     #include <sunperf.h>
     void sfftc2_ (int *iopt, int *n1,  int  *n2,  float  *scale,
               float  *x,  int  *ldx, complex *y, int *ldy, float
               *trigs, int *ifac, float *work,  int  *lwork,  int
               *ierr);

     void sfftc2_64_ (long  *iopt,  long  *n1,  long  *n2,  float
               *scale,  float  *x,  long  *ldx,  complex *y, long
               *ldy, float *trigs, long *ifac, float *work,  long
               *lwork, long *ierr);
```

PURPOSE

sfftc2 initializes the trigonometric weight and factor tables or computes the two-dimensional forward Fast Fourier Transform of a two-dimensional real array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the columns of the input array. One-dimensional FFTs are then computed along the rows of the intermediate results.

```
                   N2-1  N1-1
Y(k1,k2) = scale * SUM   SUM   W2*W1*X(j1,j2)
                   j2=0  j1=0

where
k1 ranges from 0 to N1-1 and k2 ranges from 0 to N2-1
i = sqrt(-1)
isign = -1 for forward transform
W1 = exp(isign*i*j1*k1*2*pi/N1)
W2 = exp(isign*i*j2*k2*2*pi/N2)
```

In real-to-complex transform of length N1, the (N1/2+1) complex output data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N1 (input)
Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes N2 >= 0. Unchanged on exit.

SCALE (input)
Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains input data to be transformed. X and Y can be the same array.

LDX (input)
Leading dimension of X. LDX >= N1 if X is not the same array as Y. Else, LDX = 2*LDY. Unchanged on exit.

Y (output)
Y is a complex array of dimensions (LDY, N2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)

Leading dimension of Y. LDY >= N1/2+1 Unchanged on exit.

TRIGS (input/output)

Real array of length 2*(N1+N2) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least MAX(N1, 2*N2)*NCPUS, where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return
-1 = IOPT is not 0 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1) or (LDX not equal 2*LDY when X and Y are same array)
-5 = (LDY < N1/2+1)
-6 = (LWORK not equal 0) and (LWORK < MAX(N1,2*N2)*NCPUS)
-7 = memory allocation failed

SEE ALSO

fft

CAUTIONS

Y(N1/2+1:LDY,:) is used as scratch space. Upon returning, the original contents of Y(N1/2+1:LDY,:) will be lost, whereas Y(1:N1/2+1,1:N2) contains the transform results.

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = -1 computes forward FFT

N1 (input)
          Integer specifying length of the transform in  the
          first  dimension.  N1 is most efficient when it is
          a product of small primes.  N1 >= 0.  Unchanged on
          exit.

N2 (input)
          Integer specifying length of the transform in  the
          second dimension.  N2 is most efficient when it is
          a product of small primes.  N2 >= 0.  Unchanged on
          exit.
N3 (input)
          Integer specifying length of the transform in  the
          third  dimension.  N3 is most efficient when it is
          a product of small primes.  N3 >= 0.  Unchanged on
          exit.

SCALE (input)
          Real scalar by which transform results are scaled.
          Unchanged  on exit.  SCALE is defaulted to 1.0 for
          F95 INTERFACE.

X (input) X is a real array of dimensions (LDX1,  LDX2,  N3)
          that contains input data to be transformed.  X can
          be same array as Y.

LDX1 (input)
          first dimension of X.  If X is not same  array  as
          Y,  LDX1  >=  N1  Else, LDX1 = 2*LDY1 Unchanged on
          exit.

LDX2 (input)
          second dimension of X.  LDX2 >=  N2  Unchanged  on
          exit.

Y (output)
          Y is a complex array of  dimensions  (LDY1,  LDY2,
          N3)  that contains the transform results.  X and Y
```

can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)

first dimension of Y. LDY1 >= N1/2+1 Unchanged on exit.

LDY2 (input)

second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)

Real array of length 2*(N1+N2+N3) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 3*128 that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least (MAX(N,2*N2,2*N3) + 16*N3) * NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return

-1 = IOPT is not 0 or -1

-2 = N1 < 0

-3 = N2 < 0

-4 = N3 < 0

-5 = (LDX1 < N1) or (LDX not equal 2*LDY when X and Y are same array)

-6 = (LDX2 < N2)
-7 = (LDY1 < N1/2+1)
-8 = (LDY2 < N2) or (LDY2 not equal LDX2 when X and Y are same array)

CAUTIONS

This routine uses Y((N1/2+1)+1:LDY1,:,:) as scratch space. Therefore, the original contents of this subarray will be lost upon returning from routine while subarray Y(1:N1/2+1,1:N2,1:N3) contains the transform results.

Contents

NAME

sfftcm - initialize the trigonometric weight and factor tables or compute the one-dimensional forward Fast Fourier Transform of a set of real data sequences stored in a two-dimensional array.

SYNOPSIS

```
     SUBROUTINE SFFTCM(IOPT, N1, N2, SCALE, X, LDX, Y, LDY, TRIGS, IFAC, WORK,
LWORK, IERR)

     INTEGER IOPT, N1, N2, LDX, LDY, IFAC(*), LWORK, IERR
     REAL X(LDX, *), SCALE, TRIGS(*), WORK(*)
     COMPLEX Y(LDY, *)

     SUBROUTINE SFFTCM_64(IOPT, N1, N2, SCALE, X, LDX, Y, LDY, TRIGS, IFAC, WORK,
LWORK, IERR)

     INTEGER*8 IOPT, N1, N2, LDX, LDY, IFAC(*), LWORK, IERR
     REAL X(LDX, *), SCALE, TRIGS(*), WORK(*)
     COMPLEX Y(LDY, *)
```

F95 INTERFACE

```
     SUBROUTINE FFTM(IOPT, [N1], [N2], [SCALE], X, [LDX], Y, [LDY], TRIGS,
               IFAC, WORK, [LWORK], IERR)

     INTEGER*4, INTENT(IN) :: IOPT
     INTEGER*4, INTENT(IN), OPTIONAL :: N1, N2, LDX, LDY, LWORK
     REAL, INTENT(IN), OPTIONAL :: SCALE
     REAL, INTENT(IN), DIMENSION(:,:) :: X
     COMPLEX, INTENT(OUT), DIMENSION(:,:) :: Y
     REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS

IFAC, WORK, [LWORK], IERR)

     INTEGER(8), INTENT(IN) :: IOPT
     INTEGER(8), INTENT(IN), OPTIONAL :: N1, N2, LDX, LDY, LWORK
     REAL, INTENT(IN), OPTIONAL :: SCALE
     REAL, INTENT(IN), DIMENSION(:,:) :: X
     COMPLEX, INTENT(OUT), DIMENSION(:,:) :: Y
     REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS
     INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
     REAL, INTENT(OUT), DIMENSION(:) :: WORK
     INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
     #include <sunperf.h>
     void sfftcm_ (int *iopt, int *n1,  int  *n2,  float  *scale,
               float  *x,  int  *ldx, complex *y, int *ldy, float
               *trigs, int *ifac, float *work,  int  *lwork,  int
               *ierr);

     void sfftcm_64_ (long  *iopt,  long  *n1,  long  *n2,  float
               *scale,  float  *x,  long  *ldx,  complex *y, long
               *ldy, float *trigs, long *ifac, float *work,  long
               *lwork, long *ierr);
```

PURPOSE

sfftcm initializes the trigonometric weight and factor tables or computes the one-dimensional forward Fast Fourier Transform of a set of real data sequences stored in a two-dimensional array:

```
                 N1-1
Y(k,l) = scale * SUM  W*X(j,l)
                 j=0
```

where
k ranges from 0 to N1-1 and l ranges from 0 to N2-1
i = sqrt(-1)
isign = -1 for forward transform
W = exp(isign*i*j*k*2*pi/N1)
In real-to-complex transform of length N1, the (N1/2+1) complex output data points stored are the positive-frequency half of the spectrum of the discrete Fourier transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N1 (input)
Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)
Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a real array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns.

LDX (input)
Leading dimension of X. If X and Y are the same array, LDX = 2*LDY Else LDX >= N1 Unchanged on exit.

Y (output)
Y is a complex array of dimensions (LDY, N2) that contains the transform results of the input sequences. X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. LDY >= N1/2 + 1 Unchanged on exit.

TRIGS (input/output)
Real array of length 2*N1 that contains the trigonometric weights. The weights are computed when

the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)
Real array of dimension at least N1. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1) or (LDX not equal 2*LDY when X and Y are same array)
-4 = (LDY < N1/2 + 1)
-6 = (LWORK not equal 0) and (LWORK < N1)
-7 = memory allocation failed

```

C INTERFACE

```
#include <sunperf.h>

void sgbbrd(char vect, int m, int n, int ncc,  int  kl,  int
          ku, float *ab, int ldab, float *d, float *e, float
          *q, int ldq, float *pt, int ldpt,  float  *c,  int
          ldc, int *info);
void sgbbrd_64(char vect, long m, long n, long ncc, long kl,
          long ku, float *ab, long ldab, float *d, float *e,
          float *q, long ldq, float *pt,  long  ldpt,  float
          *c, long ldc, long *info);
```

PURPOSE

sgbbrd reduces a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation: Q' * A * P = B.

The routine computes B, and optionally forms Q or P', or computes Q'*C for a given matrix C.

ARGUMENTS

VECT (input)
Specifies whether or not the matrices Q and P' are to be formed. = 'N': do not form Q or P';
= 'Q': form Q only;
= 'P': form P' only;
= 'B': form both.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NCC (input)
The number of columns of the matrix C. NCC >= 0.

KL (input)
The number of subdiagonals of the matrix A. KL >= 0.

KU (input)
The number of superdiagonals of the matrix A. KU >= 0.

AB (input/output)
REAL array, dimension(LDAB,N) On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl). On exit, A is overwritten by values generated during the reduction.

LDAB (input)
The leading dimension of the array A. LDAB >= KL+KU+1.

D (output)
REAL array, dimension(min(M,N)) The diagonal elements of the bidiagonal matrix B.

E (output)
REAL array, dimension(min(M,N)-1) The superdiagonal elements of the bidiagonal matrix B.

Q (output)
REAL array, dimension(LDQ,M) If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT (output)
REAL array, dimension(LDPT,N) If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT (input)
The leading dimension of the array PT. LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C (input/output)
REAL array, dimension(LDC.NCC) On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q'*C. C is not referenced if NCC = 0.

LDC (input)

The leading dimension of the array C. LDC >= max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK (workspace)
REAL array, dimension(2*MAX(M,N))

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

Contents

NAME

sgbcon - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

SYNOPSIS

```
SUBROUTINE SGBCON(NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,
      RCOND, WORK, WORK2, INFO)

INTEGER N, NSUB, NSUPER, LDA, INFO
INTEGER IPIVOT(*), WORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)

SUBROUTINE SGBCON_64(NORM, N, NSUB, NSUPER, A, LDA, IPIVOT, ANORM,
      RCOND, WORK, WORK2, INFO)

CHARACTER * 1 NORM
INTEGER*8 N, NSUB, NSUPER, LDA, INFO
INTEGER*8 IPIVOT(*), WORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GBCON(NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT, ANORM,
       RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM
INTEGER :: N, NSUB, NSUPER, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT, WORK2
REAL :: ANORM, RCOND
```

```
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE GBCON_64(NORM, [N], NSUB, NSUPER, A, [LDA], IPIVOT, ANORM,
       RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, NSUB, NSUPER, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
void sgbcon(char norm, int n, int nsub,  int  nsuper,  float
          *a,  int  lda,  int  *ipivot,  float  anorm, float
          *rcond, int *info);

void sgbcon_64(char norm, long n, long  nsub,  long  nsuper,
          float  *a,  long  lda,  long *ipivot, float anorm,
          float *rcond, long *info);
```

PURPOSE

sgbcon estimates the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. N >= 0.

NSUB (input)
The number of subdiagonals within the band of A. NSUB >= 0.

```
NSUPER (input)
          The number of superdiagonals within the band of A.
          NSUPER >= 0.

A (input) Details of the LU factorization of the band matrix
          A, as computed by SGBTRF.  U is stored as an upper
          triangular band matrix with NSUB+NSUPER superdiag-
          onals  in  rows 1 to NSUB+NSUPER+1, and the multi-
          pliers used during the factorization are stored in
          rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          2*NSUB+NSUPER+1.

IPIVOT (input)
          The pivot indices; for 1 <= i <= N, row i  of  the
          matrix was interchanged with row IPIVOT(i).

ANORM (input)
          If NORM = '1' or 'O', the 1-norm of  the  original
          matrix A.  If NORM = 'I', the infinity-norm of the
          original matrix A.

RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix   A,  computed  as  RCOND  =  1/(norm(A)  *
          norm(inv(A))).

WORK (workspace)
          dimension(3*N)

WORK2 (workspace)
          dimension (N)

INFO (output)
          = 0:  successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
```

NAME

```
sgbequ - compute row and column scalings intended to equili-
brate  an  M-by-N  band  matrix  A  and reduce its condition
number
```

SYNOPSIS

```
SUBROUTINE SGBEQU(M, N, KL, KU, A, LDA, R, C, ROWCN,
      COLCN, AMAX, INFO)

INTEGER M, N, KL, KU, LDA, INFO
REAL ROWCN, COLCN, AMAX
REAL A(LDA,*), R(*), C(*)

SUBROUTINE SGBEQU_64(M, N, KL, KU, A, LDA, R, C, ROWCN,
      COLCN, AMAX, INFO)

INTEGER*8 M, N, KL, KU, LDA, INFO
REAL ROWCN, COLCN, AMAX
REAL A(LDA,*), R(*), C(*)
```

F95 INTERFACE

```
SUBROUTINE GBEQU([M], [N], KL, KU, A, [LDA], R, C,
       ROWCN, COLCN, AMAX, [INFO])

INTEGER :: M, N, KL, KU, LDA, INFO
REAL :: ROWCN, COLCN, AMAX
REAL, DIMENSION(:) :: R, C
REAL, DIMENSION(:,:) :: A

SUBROUTINE GBEQU_64([M], [N], KL, KU, A, [LDA], R, C,
       ROWCN, COLCN, AMAX, [INFO])
```

```
INTEGER(8) :: M, N, KL, KU, LDA, INFO
REAL :: ROWCN, COLCN, AMAX
REAL, DIMENSION(:) :: R, C
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgbequ(int m, int n, int kl, int ku, float *a, int lda,
          float  *r,  float  *c, float *rowcn, float *colcn,
          float *amax, int *info);

void sgbequ_64(long m, long n, long kl, long ku,  float  *a,
          long  lda, float *r, float *c, float *rowcn, float
          *colcn, float *amax, long *info);
```

PURPOSE

sgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

A (input) The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

R (output)
If INFO = 0, or INFO > M, R contains the row scale factors for A.

C (output)
If INFO = 0, C contains the column scale factors for A.

ROWCN (output)
If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest R(i) to the largest R(i). If ROWCN >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCN (output)
If INFO = 0, COLCN contains the ratio of the smallest C(i) to the largest C(i). If COLCN >= 0.1, it is not worth scaling by C.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

REAL A(LDA,*), X(*), Y(*)

SUBROUTINE SGBMV_64(TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,
      INCX, BETA, Y, INCY)

CHARACTER * 1 TRANSA
INTEGER*8 M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GBMV([TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA], X,
       [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A

SUBROUTINE GBMV_64([TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],
```

```
       X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgbmv(char transa, int m, int n, int nsub, int  nsuper,
          float  alpha,  float  *a,  int  lda, float *x, int
          incx, float beta, float *y, int incy);
void sgbmv_64(char transa, long m, long n, long  nsub,  long
          nsuper, float alpha, float *a, long lda, float *x,
          long incx, float beta, float *y, long incy);
```

PURPOSE

sgbmv performs one of the matrix-vector operations y := alpha*A*x + beta*y or y := alpha*A'*x + beta*y, where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with nsub sub-diagonals and nsuper super-diagonals.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   y := alpha*A*x + beta*y.

TRANSA = 'T' or 't'   y := alpha*A'*x + beta*y.

TRANSA = 'C' or 'c'   y := alpha*A'*x + beta*y.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

NSUB (input)
On entry, NSUB specifies the number of sub-diagonals of the matrix A. NSUB >= 0. Unchanged on exit.

NSUPER (input)
On entry, NSUPER specifies the number of super-diagonals of the matrix A. NSUPER >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry, the leading (nsub + nsuper + 1) by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (nsuper + 1) of the array, the first super-diagonal starting at position 2 in row nsuper, the first sub-diagonal starting at position 1 in row (nsuper + 2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left nsuper by nsuper triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     K = NSUPER + 1 - J
     DO 10, I = MAX( 1, J - NSUPER ), MIN( M, J  +
NSUB )
       A( K + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (nsub + nsuper + 1). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X

must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (m - 1)*abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

Contents

          long *ipivot, float *b, long ldb, float  *x,  long
          ldx, float *ferr, float *berr, long *info);
```

PURPOSE

sgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

KL (input)
```

The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input)
Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL*KU+1.

IPIVOT (input)
The pivot indices from SGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SGBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(3*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE GBSV_64([N], KL, KU, [NRHS], A, [LDA], IPIVOT, B,
       [LDB], [INFO])
```

```
INTEGER(8) :: N, KL, KU, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void sgbsv(int n, int kl, int ku, int nrhs,  float  *a,  int
          lda, int *ipivot, float *b, int ldb, int *info);

void sgbsv_64(long n, long kl, long ku, long nrhs, float *a,
          long  lda,  long *ipivot, float *b, long ldb, long
          *info);
```

PURPOSE

sgbsv computes the solution to a real system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as A = L * U, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the matrix A in band storage, in rows

KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: A(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL) On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDA (input)
The leading dimension of the array A. LDA >= 2*KL+KU+1.

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

On entry: On exit:

```
    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
```

```
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

C INTERFACE

```
#include <sunperf.h>

void sgbsvx(char fact, char transa, int n, int kl,  int  ku,
          int  nrhs, float *a, int lda, float *af, int ldaf,
          int *ipivot, char equed, float *r, float *c, float
          *b,  int  ldb,  float  *x,  int ldx, float *rcond,
          float *ferr, float *berr, int *info);

void sgbsvx_64(char fact, char transa, long n, long kl, long
          ku, long nrhs, float *a, long lda, float *af, long
          ldaf, long *ipivot, char equed,  float  *r,  float
          *c,  float *b, long ldb, float *x, long ldx, float
          *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

sgbsvx uses the LU factorization to compute the solution to a real system of linear equations A * X = B, A**T * X = B, or A**H * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to equilibrate

```
   the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X  =
diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X  =
diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X  =
diag(C)*B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(R)*A*diag(C) and B by  diag(R)*B  (if
TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU  decomposition  is  used  to
factor the
   matrix A (after equilibration if FACT = 'E') as
      A = L * U,
   where L is a product of permutation and unit  lower  tri-
angular
   matrices with KL subdiagonals, and U is upper  triangular
with
   KL+KU superdiagonals.

3. If some U(i,i)=0, so that U is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.

6. If equilibration was used, the matrix X is  premultiplied
by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS  =  'T'  or
```

```
'C') so
   that it solves the original system before equilibration.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored form of  the
          matrix A is supplied on entry, and if not, whether
          the matrix A should be equilibrated before  it  is
          factored.  = 'F':  On entry, AF and IPIVOT contain
          the factored form of A.  If EQUED is not 'N',  the
          matrix  A  has been equilibrated with scaling fac-
          tors given by R and C.  A, AF, and IPIVOT are  not
          modified.   = 'N':  The matrix A will be copied to
          AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.
TRANSA (input)
          Specifies the form of the system of equations.   =
          'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

KL (input)
          The number of subdiagonals within the band  of  A.
          KL >= 0.

KU (input)
          The number of superdiagonals within the band of A.
          KU >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the matrix A in band storage, in rows  1
          to KL+KU+1.  The j-th column of A is stored in the
          j-th column of the array A as follows:   A(KU+1+i-
          j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

          If FACT = 'F' and EQUED is not 'N',  then  A  must
          have been equilibrated by the scaling factors in R
          and/or C.  A is not modified if FACT = 'F' or 'N',
```

or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A
EQUED = 'C': A := A * diag(C)
EQUED = 'B': A := diag(R) * A * diag(C).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL+KU+1.

IPIVOT (input)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by SGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the equilibrated matrix A.

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input/output)
The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input/output)
The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)
On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))*X if TRANSA = 'N' and EQUED = 'C' or 'B', or inv(diag(R))*X if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(3*N) On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is

<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could

not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

SUBROUTINE GBTF2_64([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])

INTEGER(8) :: M, N, KL, KU, LDAB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:,:) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void sgbtf2(int m, int n, int kl, int  ku,  float  *ab,  int
          ldab, int *ipiv, int *info);

void sgbtf2_64(long m, long n, long kl, long ku, float  *ab,
          long ldab, long *ipiv, long *info);
```

PURPOSE

sgbtf2 computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

AB (input/output)
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input)
The leading dimension of the array AB. LDAB >=

```
          2*KL+KU+1.

IPIV (output)
          The pivot indices; for 1 <= i <= min(M,N),  row  i
          of the matrix was interchanged with row IPIV(i).

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          > 0: if INFO = +i, U(i,i)  is  exactly  zero.  The
          factorization has been completed, but the factor U
          is exactly singular, and  division  by  zero  will
          occur  if  it  is  used to solve a system of equa-
          tions.
```

FURTHER DETAILS

```
The band storage scheme  is  illustrated  by  the  following
example, when M = N = 6, KL = 2, KU = 1:

On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*

Array elements marked * are not used by  the  routine;  ele-
ments marked + need not be set on entry, but are required by
the routine to store  elements  of  U,  because  of  fill-in
resulting from the row
interchanges.

#include <sunperf.h>

void sgbtrf(int m, int n, int kl, int  ku,  float  *ab,  int
          ldab, int *ipivot, int *info);

void sgbtrf_64(long m, long n, long kl, long ku, float  *ab,
          long ldab, long *ipivot, long *info);
```

PURPOSE

sgbtrf computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

M (input) Integer
The number of rows of the matrix A. M >= 0.

N (input) Integer
The number of columns of the matrix A. N >= 0.

KL (input) Integer
The number of subdiagonals within the band of A. KL >= 0.

KU (input) Integer
The number of superdiagonals within the band of A. KU >= 0.

AB (input/output) Real array of dimension (LDAB, N).
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KL+KU+1+I-J,J) = A(I,J) for MAX(1,J-KU)<=I<=MIN(M,J+KL)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input) Integer
The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIVOT (output) Integer array of dimension MIN(M,N)
The pivot indices; for 1 <= I <= MIN(M,N), row I of the matrix was interchanged with row IPIVOT(I).

INFO (output) Integer
= 0: successful exit
< 0: if INFO = -I, the I-th argument had an illegal value
> 0: if INFO = +I, U(I,I) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

```
On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

INTEGER*8 IPIVOT(*)
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE GBTRS([TRANSA], [N], NSUB, NSUPER, [NRHS], A, [LDA],
       IPIVOT, B, [LDB], [INFO])

CHARACTER(LEN=1) :: TRANSA
INTEGER :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE GBTRS_64([TRANSA], [N], NSUB, NSUPER, [NRHS], A, [LDA],
```

```
          IPIVOT, B, [LDB], [INFO])

    CHARACTER(LEN=1) :: TRANSA
    INTEGER(8) :: N, NSUB, NSUPER, NRHS, LDA, LDB, INFO
    INTEGER(8), DIMENSION(:) :: IPIVOT
    REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
    #include <sunperf.h>

    void sgbtrs(char transa, int n, int nsub,  int  nsuper,  int
              nrhs,  float  *a,  int lda, int *ipivot, float *b,
              int ldb, int *info);
    void sgbtrs_64(char transa, long n, long nsub, long  nsuper,
              long nrhs, float *a, long lda, long *ipivot, float
              *b, long ldb, long *info);
```

PURPOSE

```
    sgbtrs solves a system of linear equations
       A * X = B  or  A' * X = B with a general  band  matrix  A
    using the LU factorization computed by SGBTRF.
```

ARGUMENTS

```
    TRANSA (input)
              Specifies the form of the system of equations.   =
              'N':  A * X = B  (No transpose)
              = 'T':  A'* X = B  (Transpose)
              = 'C':  A'* X = B  (Conjugate  transpose  =  Tran-
              spose)

              TRANSA is defaulted to 'N' for F95 INTERFACE.

    N (input) The order of the matrix A.  N >= 0.

    NSUB (input)
              The number of subdiagonals within the band  of  A.
              NSUB >= 0.

    NSUPER (input)
              The number of superdiagonals within the band of A.
              NSUPER >= 0.

    NRHS (input)
              The number of right hand sides, i.e.,  the  number
              of columns of the matrix B.  NRHS >= 0.
```

A (input) Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with NSUB+NSUPER superdiag- onals in rows 1 to NSUB+NSUPER+1, and the multi- pliers used during the factorization are stored in rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDA (input)
The leading dimension of the array A. LDA >= 2*NSUB+NSUPER+1.

IPIVOT (input)
The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value

CHARACTER * 1 JOB, SIDE
INTEGER N, ILO, IHI, M, LDV, INFO
REAL SCALE(*), V(LDV,*)

SUBROUTINE SGEBAK_64(JOB, SIDE, N, ILO, IHI, SCALE, M, V, LDV, INFO)

CHARACTER * 1 JOB, SIDE
INTEGER*8 N, ILO, IHI, M, LDV, INFO
REAL SCALE(*), V(LDV,*)
```

F95 INTERFACE

```
SUBROUTINE GEBAK(JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
       [INFO])

CHARACTER(LEN=1) :: JOB, SIDE
INTEGER :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:,:) :: V

SUBROUTINE GEBAK_64(JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
       [INFO])

CHARACTER(LEN=1) :: JOB, SIDE
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
```

```
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:,:) :: V
```

C INTERFACE

```
#include <sunperf.h>

void sgebak(char job, char side, int n, int  ilo,  int  ihi,
          float  *scale,  int  m,  float  *v,  int  ldv, int
          *info);

void sgebak_64(char job, char side, long n, long  ilo,  long
          ihi,  float  *scale,  long  m, float *v, long ldv,
          long *info);
```

PURPOSE

sgebak forms the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL.

ARGUMENTS

JOB (input)
Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to SGEBAL.

SIDE (input)
= 'R': V contains right eigenvectors;
= 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. N >= 0.

ILO (input)
The integers ILO and IHI determined by SGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description for ILO.

SCALE (input)
Details of the permutation and scaling factors, as

returned by SGEBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)
On entry, the matrix of right or left eigenvectors to be transformed, as returned by SHSEIN or STREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)
The leading dimension of the array V. LDV >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

Contents

NAME

```
sgebal - balance a general real matrix A
```

SYNOPSIS

```
SUBROUTINE SGEBAL(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)

CHARACTER * 1 JOB
INTEGER N, LDA, ILO, IHI, INFO
REAL A(LDA,*), SCALE(*)

SUBROUTINE SGEBAL_64(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)

CHARACTER * 1 JOB
INTEGER*8 N, LDA, ILO, IHI, INFO
REAL A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])

CHARACTER(LEN=1) :: JOB
INTEGER :: N, LDA, ILO, IHI, INFO
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:,:) :: A

SUBROUTINE GEBAL_64(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])

CHARACTER(LEN=1) :: JOB
INTEGER(8) :: N, LDA, ILO, IHI, INFO
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgebal(char job, int n, float *a, int  lda,  int  *ilo,
          int *ihi, float *scale, int *info);

void sgebal_64(char job, long n, float *a,  long  lda,  long
          *ilo, long *ihi, float *scale, long *info);
```

PURPOSE

sgebal balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input)
Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ILO (output)
ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I =

IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
See the description for ILO.

SCALE (output)
Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The permutations consist of row and column interchanges which put the matrix in the form

```
          ( T1   X   Y  )
  P A P = (  0   B   Z  )
          (  0   0   T2 )
```

where T1 and T2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ILO and IHI mark the starting and ending columns of the submatrix B. Balancing consists of applying a diagonal similarity transformation inv(D) * B * D to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

```
  ( T1     X*D          Y    )
  (  0  inv(D)*B*D  inv(D)*Z ).
  (  0      0           T2   )
```

Information about the permutations P and the diagonal matrix D is returned in the vector SCALE.

This subroutine is based on the EISPACK routine BALANC.

NAME

```
sgebrd - reduce a general real M-by-N matrix A to  upper  or
lower bidiagonal form B by an orthogonal transformation
```

SYNOPSIS

```
SUBROUTINE SGEBRD(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)

INTEGER M, N, LDA, LWORK, INFO
REAL A(LDA,*), D(*), E(*), TAUQ(*), TAUP(*), WORK(*)

SUBROUTINE SGEBRD_64(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,
      INFO)

INTEGER*8 M, N, LDA, LWORK, INFO
REAL A(LDA,*), D(*), E(*), TAUQ(*), TAUP(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEBRD([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK], [LWORK],
       [INFO])

INTEGER :: M, N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: D, E, TAUQ, TAUP, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE GEBRD_64([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],
       [LWORK], [INFO])

INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: D, E, TAUQ, TAUP, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgebrd(int m, int n, float *a, int lda, float *d, float
          *e, float *tauq, float *taup, int *info);

void sgebrd_64(long m, long n, float *a, long lda, float *d,
          float *e, float *tauq, float *taup, long *info);
```

PURPOSE

sgebrd reduces a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation: Q**T * A * P = B.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

ARGUMENTS

M (input) The number of rows in the matrix A. M >= 0.

N (input) The number of columns in the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

D (output)

The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E (output)

The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix Q. See Further Details.

TAUP (output)

The scalar factors of the elementary reflectors which represent the orthogonal matrix P. See Further Details.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of the array WORK. LWORK >= max(1,M,N). For optimum performance LWORK >= (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrices Q and P are represented as products of elementary reflectors:

If m >= n,

```
   Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)
```

Each H(i) and G(i) has the form:

```
   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'
```

```
where tauq and taup are real scalars, and v and u  are  real
vectors;  v(1:i-1)  = 0, v(i) = 1, and v(i+1:m) is stored on
exit in A(i+1:m,i); u(1:i) = 0, u(i+1) = 1, and u(i+2:n)  is
stored  on exit in A(i,i+2:n); tauq is stored in TAUQ(i) and
taup in TAUP(i).

If m < n,

   Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

Each H(i) and G(i) has the form:
   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

where tauq and taup are real scalars, and v and u  are  real
vectors;  v(1:i)  = 0, v(i+1) = 1, and v(i+2:m) is stored on
exit in A(i+2:m,i); u(1:i-1) = 0, u(i) = 1, and u(i+1:n)  is
stored  on exit in A(i,i+1:n); tauq is stored in TAUQ(i) and
taup in TAUP(i).

The contents of A on exit are illustrated by  the  following
examples:

m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

  (  d   e   u1  u1  u1 )           (  d   u1   u1   u1   u1
u1 )
  (  v1  d   e   u2  u2 )           (  e   d    u2   u2   u2
u2 )
  (  v1  v2  d   e   u3 )           (  v1  e    d    u3   u3
u3 )
  (  v1  v2  v3  d   e  )           (  v1  v2   e    d    u4
u4 )
  (  v1  v2  v3  v4  d  )           (  v1   v2   v3   e    d
u5 )
  (  v1  v2  v3  v4  v5 )

where d and e denote diagonal and off-diagonal  elements  of
B, vi denotes an element of the vector defining H(i), and ui
an element of the vector defining G(i).

void sgecon(char norm, int  n,  float  *a,  int  lda,  float
          anorm, float *rcond, int *info);

void sgecon_64(char norm, long n, float *a, long lda,  float
          anorm, float *rcond, long *info);
```

PURPOSE

sgecon estimates the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as
   RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I':   Infinity-norm.

N (input) The order of the matrix A. N >= 0.

A (input) The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(4*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

sgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE SGEEQU(M, N, A, LDA, R, C, ROWCN, COLCN, AMAX,
      INFO)

INTEGER M, N, LDA, INFO
REAL ROWCN, COLCN, AMAX
REAL A(LDA,*), R(*), C(*)

SUBROUTINE SGEEQU_64(M, N, A, LDA, R, C, ROWCN, COLCN, AMAX,
      INFO)

INTEGER*8 M, N, LDA, INFO
REAL ROWCN, COLCN, AMAX
REAL A(LDA,*), R(*), C(*)
```

F95 INTERFACE

```
SUBROUTINE GEEQU([M], [N], A, [LDA], R, C, ROWCN, COLCN,
       AMAX, [INFO])

INTEGER :: M, N, LDA, INFO
REAL :: ROWCN, COLCN, AMAX
REAL, DIMENSION(:) :: R, C
REAL, DIMENSION(:,:) :: A

SUBROUTINE GEEQU_64([M], [N], A, [LDA], R, C, ROWCN, COLCN,
       AMAX, [INFO])

INTEGER(8) :: M, N, LDA, INFO
```

```
REAL :: ROWCN, COLCN, AMAX
REAL, DIMENSION(:) :: R, C
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgeequ(int m, int n, float *a, int lda, float *r, float
          *c,  float  *rowcn, float *colcn, float *amax, int
          *info);

void sgeequ_64(long m, long n, float *a, long lda, float *r,
          float *c, float *rowcn, float *colcn, float *amax,
          long *info);
```

PURPOSE

sgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input) The M-by-N matrix whose equilibration factors are to be computed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

R (output)
If INFO = 0 or INFO > M, R contains the row scale factors for A.

C (output)

If INFO = 0, C contains the column scale factors for A.

ROWCN (output)
If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest R(i) to the largest R(i). If ROWCN >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCN (output)
If INFO = 0, COLCN contains the ratio of the smallest C(i) to the largest C(i). If COLCN >= 0.1, it is not worth scaling by C.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

void       sgees(char       jobz,        char        sortev,
          int(*select)(float,float),  int  n,  float *a, int
          lda, int *nout, float *wr, float  *wi,  float  *z,
          int ldz, int *info);

void      sgees_64(char       jobz,       char       sortev,
          long(*select)(float,float), long n, float *a, long
          lda, long *nout, float *wr, float *wi,  float  *z,
          long ldz, long *info);
```

PURPOSE

sgees computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z**T).

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

```
        [  a  b  ]
        [  c  a  ]
```

where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

ARGUMENTS

JOBZ (input)
= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

SORTEV (input)
Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO is set to N+2 (see INFO below).

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the N-by-N matrix A. On exit, A has been overwritten by its real Schur form T.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

NOUT (output)
If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR (output)
WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues will appear consecutively with the

eigenvalue having the positive imaginary part first.

WI (output)

See the description for WR.

Z (output)

If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1; if JOBZ = 'V', LDZ >= N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) contains the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK >= max(1,3*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK3 (workspace)

dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, and i is

<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

          *wi,  float  *z,  long  ldz,  float *srcone, float
          *rconv, long *info);
```

PURPOSE

sgeesx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z**T).

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A real matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

```
          [  a  b  ]
          [  c  a  ]
```

where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

ARGUMENTS

JOBZ (input)
  = 'N': Schur vectors are not computed;
  = 'V': Schur vectors are computed.

SORTEV (input)
  Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
  = 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
  SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both are. Note that a selected complex eigenvalue may no longer satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO may be set to N+3 (see INFO below).

```
SENSE (input)
          Determines which reciprocal condition numbers  are
          computed.  = 'N': None are computed;
          = 'E': Computed for  average  of  selected  eigen-
          values only;
          = 'V': Computed for selected right invariant  sub-
          space only;
          = 'B': Computed for both.  If SENSE = 'E', 'V'  or
          'B', SORTEV must equal 'S'.

N (input) The order of the matrix A. N >= 0.

A (input/output)
          On entry, the N-by-N matrix  A.   On  exit,  A  is
          overwritten by its real Schur form T.
LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

NOUT (output)
          If SORTEV = 'N', NOUT = 0.  If SORTEV = 'S',  NOUT
          =  number of eigenvalues (after sorting) for which
          SELECT is true. (Complex conjugate pairs for which
          SELECT is true for either eigenvalue count as 2.)

WR (output)
          WR and WI contain the real  and  imaginary  parts,
          respectively,  of the computed eigenvalues, in the
          same order that they appear on the diagonal of the
          output  Schur  form T.  Complex conjugate pairs of
          eigenvalues appear consecutively with  the  eigen-
          value having the positive imaginary part first.

WI (output)
          See the description for WR.

Z (output)
          If JOBZ = 'V', Z contains the orthogonal matrix  Z
          of  Schur vectors.  If JOBZ = 'N', Z is not refer-
          enced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= N.

SRCONE (output)
          If  SENSE  =  'E'  or  'B',  SRCONE  contains  the
          reciprocal condition number for the average of the
          selected eigenvalues.  Not referenced if  SENSE  =
          'N' or 'V'.
```

```
RCONV (output)
         If SENSE = 'V' or 'B', RCONV contains the recipro-
         cal   condition  number  for  the  selected  right
         invariant subspace.  Not referenced if SENSE = 'N'
         or 'E'.

WORK (workspace)
         On exit, if INFO = 0, WORK(1) returns the  optimal
         LDWORK.

LDWORK (input)
         The  dimension  of  the  array  WORK.   LDWORK  >=
         max(1,3*N).   Also,  if SENSE = 'E' or 'V' or 'B',
         LDWORK >= N+2*NOUT*(N-NOUT),  where  NOUT  is  the
         number  of  selected  eigenvalues computed by this
         routine.  Note that N+2*NOUT*(N-NOUT) <=  N+N*N/2.
         For  good  performance,  LDWORK  must generally be
         larger.

IWORK2 (workspace/output)
         Not referenced if SENSE = 'N' or 'E'.  On exit, if
         INFO = 0, IWORK2(1) returns the optimal LDWRK2.

LDWRK2 (input)
         The dimension of the array IWORK2.  LDWRK2  >=  1;
         if SENSE = 'V' or 'B', LDWRK2 >= NOUT*(N-NOUT).

BWORK3 (workspace)
         dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
         = 0: successful exit
         < 0: if INFO = -i, the i-th argument had an  ille-
         gal value.
         > 0: if INFO = i, and i is
         <= N: the QR algorithm failed to compute all the
         eigenvalues; elements 1:ILO-1 and i+1:N of WR  and
         WI contain those eigenvalues which have converged;
         if JOBZ = 'V', Z contains the transformation which
         reduces  A  to its partially converged Schur form.
         = N+1: the  eigenvalues  could  not  be  reordered
         because   some   eigenvalues  were  too  close  to
         separate (the problem is very ill-conditioned);  =
         N+2:  after reordering, roundoff changed values of
         some complex eigenvalues so  that  leading  eigen-
         values   in  the  Schur  form  no  longer  satisfy
         SELECT=.TRUE.  This could also be caused by under-
         flow due to scaling.

       VR, [LDVR], [WORK], [LDWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBVL, JOBVR
INTEGER(8) :: N, LDA, LDVL, LDVR, LDWORK, INFO
REAL, DIMENSION(:) :: WR, WI, WORK
REAL, DIMENSION(:,:) :: A, VL, VR
```

C INTERFACE

```
#include <sunperf.h>

void sgeev(char jobvl, char jobvr, int n, float *a, int lda,
          float  *wr,  float *wi, float *vl, int ldvl, float
          *vr, int ldvr, int *info);

void sgeev_64(char jobvl, char jobvr, long n, float *a, long
          lda,  float  *wr, float *wi, float *vl, long ldvl,
          float *vr, long ldvr, long *info);
```

PURPOSE

sgeev computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

```
The right eigenvector v(j) of A satisfies
                 A * v(j) = lambda(j) * v(j)
where lambda(j) is its eigenvalue.
The left eigenvector u(j) of A satisfies
              u(j)**H * A = lambda(j) * u(j)**H
where u(j)**H denotes the conjugate transpose of u(j).
```

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

JOBVL (input)
= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of A are computed.

JOBVR (input)
= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the N-by-N matrix A. On exit, A has been overwritten.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

WR (output)
WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)
See the description for WR.

VL (output)
If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL (input)
The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR (input)
If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR (input)
The leading dimension of the array VR. LDVR >= 1; if JOBVR = 'V', LDVR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >=

max(1,3*N), and if JOBVL = 'V' or JOBVR = 'V', LDWORK >= 4*N. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements i+1:N of WR and WI contain eigenvalues which have converged.

          ldvr,  long  *ilo,  long *ihi, float *scale, float
          *abnrm, float *rcone, float *rconv, long *info);
```

PURPOSE

sgeevx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right
eigenvectors (RCONDV).

The right eigenvector v(j) of A satisfies

```
                A * v(j) = lambda(j) * v(j)
```

```
where lambda(j) is its eigenvalue.
The left eigenvector u(j) of A satisfies
              u(j)**H * A = lambda(j) * u(j)**H
where u(j)**H denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to  have  Euclidean
norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and  columns  to
make  it more nearly upper triangular, and applying a diago-
nal similarity transformation D * A * D**(-1), where D is  a
diagonal matrix, to make its rows and columns closer in norm
and the condition numbers of its eigenvalues  and  eigenvec-
tors  smaller.   The  computed  reciprocal condition numbers
correspond to  the  balanced  matrix.   Permuting  rows  and
columns  will  not  change  the  condition numbers (in exact
arithmetic) but diagonal scaling will.  For further explana-
tion  of  balancing, see section 4.10.2 of the LAPACK Users'
Guide.
```

ARGUMENTS

```
BALANC (input)
          Indicates how the input matrix  should  be  diago-
          nally scaled and/or permuted to improve the condi-
          tioning of its eigenvalues.  = 'N': Do not  diago-
          nally scale or permute;
          = 'P': Perform permutations  to  make  the  matrix
          more  nearly  upper  triangular. Do not diagonally
          scale; = 'S': Diagonally scale  the  matrix,  i.e.
          replace  A  by  D*A*D**(-1), where D is a diagonal
          matrix chosen to make the rows and  columns  of  A
          more  equal  in  norm. Do not permute; = 'B': Both
          diagonally scale and permute A.

          Computed reciprocal condition numbers will be  for
          the  matrix after balancing and/or permuting. Per-
          muting does not change condition numbers (in exact
          arithmetic), but balancing does.

JOBVL (input)
          = 'N': left eigenvectors of A are not computed;
          = 'V': left eigenvectors of A  are  computed.   If
          SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input)
          = 'N': right eigenvectors of A are not computed;
          = 'V': right eigenvectors of A are  computed.   If
```

```
          SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE (input)
          Determines which reciprocal condition numbers  are
          computed.  = 'N': None are computed;
          = 'E': Computed for eigenvalues only;
          = 'V': Computed for right eigenvectors only;
          = 'B': Computed for eigenvalues and  right  eigen-
          vectors.

          If SENSE = 'E' or 'B', both left and right  eigen-
          vectors  must  also  be  computed (JOBVL = 'V' and
          JOBVR = 'V').

N (input) The order of the matrix A. N >= 0.
A (input/output)
          On entry, the N-by-N matrix A.   On  exit,  A  has
          been  overwritten.  If JOBVL = 'V' or JOBVR = 'V',
          A contains the real Schur  form  of  the  balanced
          version of the input matrix A.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

WR (output)
          WR and WI contain the real  and  imaginary  parts,
          respectively,  of  the computed eigenvalues.  Com-
          plex conjugate pairs of  eigenvalues  will  appear
          consecutively with the eigenvalue having the posi-
          tive imaginary part first.

WI (output)
          See the description for WR.

VL (output)
          If JOBVL = 'V', the  left  eigenvectors  u(j)  are
          stored  one after another in the columns of VL, in
          the same order as their eigenvalues.  If  JOBVL  =
          'N', VL is not referenced.  If the j-th eigenvalue
          is real, then u(j) = VL(:,j), the j-th  column  of
          VL.   If  the j-th and (j+1)-st eigenvalues form a
          complex conjugate pair,  then  u(j)  =  VL(:,j)  +
          i*VL(:,j+1) and
          u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL (input)
          The leading dimension of the array VL.  LDVL >= 1;
          if JOBVL = 'V', LDVL >= N.
```

VR (output)
If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR (input)
The leading dimension of the array VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO (output)
ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

IHI (output)
See the description of ILO.

SCALE (output)
Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)
The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONE (output)
RCONE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONV (output)
RCONV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V', LDWORK >= 3*N. If SENSE = 'V' or 'B', LDWORK >= N*(N+6). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

IWORK2 (workspace)

dimension(2*N-2) If SENSE = 'N' or 'E', not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of WR and WI contain eigenvalues which have converged.

          float *vsr, long ldvsr, long *info);
```

PURPOSE

sgegs routine is deprecated and has been replaced by routine SGGES.

SGEGS computes for a pair of N-by-N real nonsymmetric matrices A, B: the generalized eigenvalues (alphar +/- alphai*i, beta), the real Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver SGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one orthogonal matrix and both on the right by another orthogonal matrix, these two orthogonal matrices being chosen so as to bring the pair of matrices into (real) Schur form.

A pair of matrices A, B is in generalized real Schur form if B is upper triangular with non-negative diagonal and A is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues,

```
while 2-by-2 blocks of A will be  "standardized"  by  making
the corresponding elements of B have the form:
        [  a  0  ]
        [  0  b  ]

and the pair of corresponding 2-by-2 blocks in A and B  will
have a complex conjugate pair of generalized eigenvalues.

The left and right Schur vectors are the columns of VSL  and
VSR,  respectively,  where  VSL  and  VSR are the orthogonal
matrices which reduce A and B to Schur form:

Schur form of (A,B) = ( (VSL)**T A (VSR), (VSL)**T B (VSR) )
```

ARGUMENTS

```
JOBVSL (input)
          = 'N':  do not compute the left Schur vectors;
          = 'V':  compute the left Schur vectors.

JOBVSR (input)
          = 'N':  do not compute the right Schur vectors;
          = 'V':  compute the right Schur vectors.

N (input) The order of the matrices A, B, VSL, and  VSR.   N
          >= 0.

A (input/output)
          On entry, the first of the pair of matrices  whose
          generalized  eigenvalues  and  (optionally)  Schur
          vectors are to be computed.  On exit, the general-
          ized  Schur  form  of A.  Note: to avoid overflow,
          the Frobenius norm of the matrix A should be  less
          than the overflow threshold.

LDA (input)
          The leading dimension of A.  LDA >= max(1,N).

B (input/output)
          On entry, the second of the pair of matrices whose
          generalized  eigenvalues  and  (optionally)  Schur
          vectors are to be computed.  On exit, the general-
          ized  Schur  form  of B.  Note: to avoid overflow,
          the Frobenius norm of the matrix B should be  less
          than the overflow threshold.

LDB (input)
          The leading dimension of B.  LDB >= max(1,N).
```

ALPHAR (output)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, j=1,...,N and BETA(j),j=1,...,N are the diagonals of the complex Schur form (A,B) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)

See the description for ALPHAR.

BETA (output)

See the description for ALPHAR.

VSL (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal

LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,4*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: NB -- MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR The optimal LDWORK is 2*N + N*(NB+1).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from SGGBAL
=N+2: error return from SGEQRF
=N+3: error return from SORMQR
=N+4: error return from SORGQR
=N+5: error return from SGGHRD
=N+6: error return from SHGEQZ (other than failed iteration) =N+7: error return from SGGBAK (comput- ing VSL)
=N+8: error return from SGGBAK (computing VSR)
=N+9: error return from SLASCL (various places)

C INTERFACE

```
#include <sunperf.h>

void sgegv(char jobvl, char jobvr, int n, float *a, int lda,
          float  *b,  int ldb, float *alphar, float *alphai,
          float *beta, float *vl, int ldvl, float  *vr,  int
          ldvr, int *info);
void sgegv_64(char jobvl, char jobvr, long n, float *a, long
          lda,  float  *b,  long  ldb,  float *alphar, float
          *alphai, float *beta, float *vl, long ldvl,  float
          *vr, long ldvr, long *info);
```

PURPOSE

sgegv routine is deprecated and has been replaced by routine SGGEV.

SGEGV computes for a pair of n-by-n real nonsymmetric matrices A and B, the generalized eigenvalues (alphar +/- alphai*i, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that (A - w B) r = 0 . A left generalized eigenvector is a vector l such that l**H * (A - w B) = 0, where l**H is the
conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B -- see "Further Details", below.

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)

See the description of ALPHAR.

BETA (output)

See the description of ALPHAR.

VL (output)

If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVL = 'N'.

LDVL (input)

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (output)

If JOBVR = 'V', the right generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVR = 'N'.

LDVR (input)

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK >= max(1,8*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: NB -- MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR; The optimal LDWORK is: 2*N + MAX(6*N, N*(NB+1)).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from SGGBAL
=N+2: error return from SGEQRF
=N+3: error return from SORMQR
=N+4: error return from SORGQR
=N+5: error return from SGGHRD
=N+6: error return from SHGEQZ (other than failed iteration) =N+7: error return from STGEVC
=N+8: error return from SGGBAK (computing VL)
=N+9: error return from SGGBAK (computing VR)
=N+10: error return from SLASCL (various calls)

FURTHER DETAILS

Balancing

This driver calls SGGBAL to both permute and scale rows and columns of A and B. The permutations PL and PR are chosen so that PL*A*PR and PL*B*R will be upper triangular except for the diagonal blocks A(i:j,i:j) and B(i:j,i:j), with i and j as close together as possible. The diagonal scaling matrices DL and DR are chosen so that the pair DL*PL*A*PR*DR, DL*PL*B*PR*DR have elements close to one (except for the elements that start out zero.)

After the eigenvalues and eigenvectors of the balanced matrices have been computed, SGGBAK transforms the eigenvectors back to what they would have been (in perfect arithmetic) if they had not been balanced.

Contents of A and B on Exit
-------- -- - --- - -- ----

If any eigenvectors are computed (either JOBVL='V' or JOBVR='V' or both), then on exit the arrays A and B will contain the real Schur form[*] of the "balanced" versions of A and B. If no eigenvectors are computed, then only the diagonal blocks will be correct.

[*] See SHGEQZ, SGEGS, or read the book "Matrix Computations",
    by Golub & van Loan, pub. by Johns Hopkins U. Press.

Contents

NAME

```
sgehrd - reduce a real general matrix A to upper  Hessenberg
form H by an orthogonal similarity transformation
```

SYNOPSIS

```
SUBROUTINE SGEHRD(N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)

INTEGER N, ILO, IHI, LDA, LWORKIN, INFO
REAL A(LDA,*), TAU(*), WORKIN(*)

SUBROUTINE SGEHRD_64(N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)

INTEGER*8 N, ILO, IHI, LDA, LWORKIN, INFO
REAL A(LDA,*), TAU(*), WORKIN(*)
```

F95 INTERFACE

```
SUBROUTINE GEHRD([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
       [INFO])

INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO
REAL, DIMENSION(:) :: TAU, WORKIN
REAL, DIMENSION(:,:) :: A

SUBROUTINE GEHRD_64([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
       [INFO])

INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
REAL, DIMENSION(:) :: TAU, WORKIN
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgehrd(int n, int ilo, int  ihi,  float  *a,  int  lda,
          float *tau, int *info);

void sgehrd_64(long n, long ilo, long ihi,  float  *a,  long
          lda, float *tau, long *info);
```

PURPOSE

sgehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: Q' * A * Q = H .

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

IHI (input)
See the description of ILO.

A (input/output)
On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)
The length of the array WORKIN. LWORKIN >= max(1,N). For optimum performance LWORKIN >= N*NB, where NB is the optimal blocksize.

If LWORKIN = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of (ihi-ilo) elementary reflectors

```
   Q = H(ilo) H(ilo+1) . . . H(ihi-1).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with n = 7, ilo = 2 and ihi = 6:

```
on entry,                        on exit,

( a   a   a   a   a   a   a )    (  a   a   h    h    h    h
a  )  (      a   a   a   a   a   a )    (      a   h   h   h
h   a ) (     a   a   a   a   a   a )    (       h    h    h
h    h    h  ) (     a   a   a   a   a   a )    (      v2  h
h   h   h   h ) (     a   a   a   a   a   a )     (       v2
v3   h    h    h    h  )  (     a   a   a   a   a   a )    (
v2  v3  v4  h   h   h ) (                         a  )     (
a )
```

where a denotes an element of the original matrix A, h denotes a modified element of the upper Hessenberg matrix H, and vi denotes an element of the vector defining H(i).

          *info);

void sgelqf_64(long m, long n, float  *a,  long  lda,  float
          *tau, long *info);
```

PURPOSE

sgelqf computes an LQ factorization of a real M-by-N matrix A: A = L * Q.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(k) . . . H(2) H(1), where k = min(m,n).

Each H(i) has the form
   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is  stored  on  exit  in
A(i,i+1:n), and tau in TAU(i).

INTEGER :: M, N, NRHS, LDA, LDB, LDWORK, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE GELS_64([TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
       [WORK], LDWORK, [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void sgels (char, int, int, int, float*, int,  float*,  int,
          int*);

void sgels_64 (char, long, long, long, float*, long, float*,
          long, long*);
```

PURPOSE

sgels solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and m >= n: find the least squares solution of
   an overdetermined system, i.e., solve the least squares problem
                minimize || B - A*X ||.

2. If TRANS = 'N' and m < n: find the minimum norm solution of
   an underdetermined system A * X = B.

3. If TRANS = 'T' and m >= n: find the minimum norm solution of
   an undetermined system A**T * X = B.

4. If TRANS = 'T' and m < n: find the least squares solution of
   an overdetermined system, i.e., solve the least squares problem
                minimize || B - A**T * X ||.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

```
TRANSA (input)
          = 'N': the linear system involves A;
          = 'T': the linear system involves A**T.

          TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X. NRHS >=0.
A (input/output)
          On entry, the M-by-N matrix A.  On exit, if  M  >=
          N,  A is overwritten by details of its QR factori-
          zation as returned by SGEQRF; if  M  <   N,  A  is
          overwritten  by details of its LQ factorization as
          returned by SGELQF.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

B (input/output)
          On entry, the matrix B of right hand side vectors,
          stored columnwise; B is M-by-NRHS if TRANSA = 'N',
          or N-by-NRHS if TRANSA  =  'T'.   On  exit,  B  is
          overwritten   by   the  solution  vectors,  stored
          columnwise:  if TRANSA = 'N' and m >= n, rows 1 to
          n of B contain the least squares solution vectors;
          the residual sum of squares for  the  solution  in
          each column is given by the sum of squares of ele-
          ments N+1 to M in that column; if TRANSA = 'N' and
          m  <  n, rows 1 to N of B contain the minimum norm
          solution vectors; if TRANSA = 'T' and m >= n, rows
          1 to M of B contain the minimum norm solution vec-
          tors; if TRANSA = 'T' and m < n, rows 1 to M of  B
          contain  the  least  squares solution vectors; the
          residual sum of squares for the solution  in  each
          column  is given by the sum of squares of elements
          M+1 to N in that column.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          MAX(1,M,N).
```

```
WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (output)
          The dimension of the array WORK.  LDWORK  >=  max(
          1,  MN  +  max( MN, NRHS ) ).  For optimal perfor-
          mance, LDWORK >= max( 1, MN + max( MN,  NRHS  )*NB
          ).   where  MN  =  min(M,N)  and NB is the optimum
          block size.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

INTEGER(8), DIMENSION(:) :: IWORK
REAL :: RCOND
REAL, DIMENSION(:) :: S, WORK
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void sgelsd(int m, int n, int nrhs, float *a, int lda, float
          *b, int ldb, float *s, float rcond, int *rank, int
          *info);
void sgelsd_64(long m, long n, long  nrhs,  float  *a,  long
          lda,  float  *b,  long ldb, float *s, float rcond,
          long *rank, long *info);
```

PURPOSE

sgelsd computes the minimum-norm solution to a real linear least squares problem:

    minimize 2-norm(| b - A*x |)

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The problem is solved in three steps:
(1) Reduce the coefficient matrix A to bidiagonal form with
    Householder transformations, reducing the original prob-
lem
    into a "bidiagonal least squares problem" (BLS)
(2) Solve the BLS using a divide and conquer approach.
(3) Apply back all the Householder tranformations to solve
    the original least squares problem.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray

X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

M (input) The number of rows of A. M >= 0.

N (input) The number of columns of A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)
The leading dimension of the array B. LDB >= max(1,max(M,N)).

S (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND (input)
RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK (output)
The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. The exact minimum amount of workspace needed depends on M, N and NRHS. As long as LWORK is at least 12*N + 2*N*SMLSIZ + 8*N*NLVL + N*NRHS * (SMLSIZ+1)**2, if M is greater than or equal to N or 12*M + 2*M*SMLSIZ + 8*M*NLVL + M*NRHS + (SMLSIZ+1)**2, if M is less than N, the code will execute correctly. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1 For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
LIWORK >= 3 * MINMN * NLVL + 11 * MINMN, where MINMN = MIN(M,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

          long *irank, long *info);
```

PURPOSE

sgelss computes the minimum norm solution to a real linear least squares problem:

Minimize 2-norm(| b - A*x |).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the first min(m,n) rows of A are overwritten with its right

singular vectors, stored rowwise.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)
The leading dimension of the array B. LDB >= max(1,max(M,N)).

SING (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm = SING(1)/SING(min(m,n)).

RCOND (input)
RCOND is used to determine the effective rank of A. Singular values SING(i) <= RCOND*SING(1) are treated as zero. If RCOND < 0, machine precision is used instead.

IRANK (output)
The effective rank of A, i.e., the number of singular values which are greater than RCOND*SING(1).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= 1, and also: LDWORK >= 3*min(M,N) + max(2*min(M,N), max(M,N), NRHS) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

```
#include <sunperf.h>

void sgelsx(int m, int n, int nrhs, float *a, int lda, float
          *b, int ldb, int *jpivot, float rcond, int *irank,
          int *info);
void sgelsx_64(long m, long n, long  nrhs,  float  *a,  long
          lda,  float  *b,  long  ldb,  long  *jpivot, float
          rcond, long *irank, long *info);
```

PURPOSE

sgelsx routine is deprecated and has been replaced by routine SGELSY.

SGELSX computes the minimum-norm solution to a real linear least squares problem:

```
    minimize || A * X - B ||
```

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

```
    A * P = Q * [ R11 R12 ]
                [  0  R22 ]
```

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by orthogonal transformations from the right, arriving at the complete orthogonal factorization:

```
   A * P = Q * [ T11 0 ] * Z
               [  0  0 ]
```

The minimum-norm solution is then

```
   X = P * Z' [ inv(T11)*Q1'*B ]
```

```
                [        0       ]
where Q1 consists of the first RANK columns of Q.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of matrices B and X. NRHS >= 0.
A (input/output)
          On entry, the M-by-N matrix A.   On  exit,  A  has
          been   overwritten  by  details  of  its  complete
          orthogonal factorization.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

B (input/output)
          On entry, the M-by-NRHS right hand side matrix  B.
          On exit, the N-by-NRHS solution matrix X.  If m >=
          n and IRANK = n, the residual  sum-of-squares  for
          the  solution  in  the i-th column is given by the
          sum of squares of elements N+1:M in that column.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,M,N).

JPIVOT (input/output)
          On entry, if JPIVOT(i) .ne. 0, the i-th column  of
          A  is  an  initial  column, otherwise it is a free
          column.  Before the QR  factorization  of  A,  all
          initial  columns are permuted to the leading posi-
          tions; only the remaining free columns  are  moved
          as a result of column pivoting during the factori-
          zation.  On exit, if JPIVOT(i) = k, then the  i-th
          column of A*P was the k-th column of A.

RCOND (input)
          RCOND is used to determine the effective  rank  of
          A,  which  is  defined as the order of the largest
          leading triangular submatrix R11 in the QR factor-
          ization with pivoting of A, whose estimated condi-
          tion number < 1/RCOND.
```

```
IRANK (output)
          The effective rank of A, i.e., the  order  of  the
          submatrix  R11.   This is the same as the order of
          the submatrix T11 in the complete orthogonal  fac-
          torization of A.

WORK (workspace)
          (max( min(M,N)+3*N, 2*min(M,N)+NRHS )),
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

REAL, DIMENSION(:,:) :: A, B
```

```
SUBROUTINE GELSY_64([M], [N], [NRHS], A, [LDA], B, [LDB], JPVT,
       RCOND, RANK, [WORK], [LWORK], [INFO])

INTEGER(8) :: M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL :: RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void sgelsy(int m, int n, int nrhs, float *a, int lda, float
          *b,  int  ldb,  int *jpvt, float rcond, int *rank,
          int *info);
void sgelsy_64(long m, long n, long  nrhs,  float  *a,  long
          lda,  float *b, long ldb, long *jpvt, float rcond,
          long *rank, long *info);
```

PURPOSE

```
sgelsy computes the minimum-norm solution to a  real  linear
least squares problem:
    minimize || A * X - B ||
using a complete orthogonal factorization of A.  A is an  M-
by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can
be  handled in a single call; they are stored as the columns
of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
solution matrix X.

The routine first computes a QR  factorization  with  column
pivoting:
    A * P = Q * [ R11 R12 ]
                [  0  R22 ]
with R11 defined as  the  largest  leading  submatrix  whose
estimated  condition number is less than 1/RCOND.  The order
of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihi-
lated by orthogonal transformations from the right, arriving
at the complete orthogonal factorization:
   A * P = Q * [ T11 0 ] * Z
               [  0  0 ]
The minimum-norm solution is then
   X = P * Z' [ inv(T11)*Q1'*B ]
              [        0       ]
where Q1 consists of the first RANK columns of Q.
```

```
This routine is basically identical to the  original  xGELSX
except three differences:
  o The call to the subroutine xGEQPF has  been  substituted
by the
    the call to the subroutine xGEQP3. This subroutine is  a
Blas-3
    version of the QR factorization with column pivoting.
  o Matrix B (the right hand side) is updated with Blas-3.
  o The permutation of matrix B (the  right  hand  side)  is
faster and
    more simple.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.
N (input) The number of columns of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of matrices B and X. NRHS >= 0.

A (input/output)
          On entry, the M-by-N matrix A.   On  exit,  A  has
          been   overwritten  by  details  of  its  complete
          orthogonal factorization.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

B (input/output)
          On entry, the M-by-NRHS right hand side matrix  B.
          On exit, the N-by-NRHS solution matrix X.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,M,N).

JPVT (input/output)
          On entry, if JPVT(i) .ne. 0, the i-th column of  A
          is permuted to the front of AP, otherwise column i
          is a free column.  On exit, if JPVT(i) =  k,  then
          the i-th column of AP was the k-th column of A.

RCOND (input)
          RCOND is used to determine the effective  rank  of
          A,  which  is  defined as the order of the largest
```

leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

RANK (output)

The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. The unblocked strategy requires that: LWORK >= MAX(MN+3*N+1, 2*MN+NRHS), where MN = min(M, N). The block algorithm requires that: LWORK >= MAX(MN+2*N+NB*(N+1), 2*MN+NB*NRHS), where NB is an upper bound on the blocksize returned by ILAENV for the routines SGEQP3, STZRZF, STZRQF, SORMQR, and SORMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: If INFO = -i, the i-th argument had an illegal value.

       B, [LDB], BETA, C, [LDC])

CHARACTER(LEN=1) :: TRANSA, TRANSB
INTEGER :: M, N, K, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:,:) :: A, B, C

SUBROUTINE GEMM_64([TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],
       B, [LDB], BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: TRANSA, TRANSB
INTEGER(8) :: M, N, K, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>

void sgemm(char transa, char transb, int m, int  n,  int  k,
          float alpha, float *a, int lda, float *b, int ldb,
          float beta, float *c, int ldc);

void sgemm_64(char transa, char transb, long m, long n, long
          k, float alpha, float *a, long lda, float *b, long
          ldb, float beta, float *c, long ldc);
```

PURPOSE

sgemm performs one of the matrix-matrix operations C := alpha*op(A)*op(B) + beta*C where op(X) is one of

op(X) = X   or   op(X) = X',

alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', op(A) = A.

TRANSA = 'T' or 't', op(A) = A'.

TRANSA = 'C' or 'c', op(A) = A'.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

TRANSB (input)
On entry, TRANSB specifies the form of op(B) to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', op(B) = B.

TRANSB = 'T' or 't', op(B) = B'.

TRANSB = 'C' or 'c', op(B) = B'.

Unchanged on exit.

TRANSB is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix op(A) and of the matrix C. M must be at least zero. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry, K specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
REAL array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is m otherwise. Before entry with TRANSA = 'N' or 'n', the leading m by k part of the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA >= max(1, m), otherwise LDA >= max(1, k). Unchanged on exit.

B (input)
REAL array of DIMENSION (LDB, kb), where kb is n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the lead-

ing k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then LDB >= max(1, k), otherwise LDB >= max(1, n). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)
REAL array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta*C).

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC >= max(1, m). Unchanged on exit.

CHARACTER * 1 TRANSA
INTEGER*8 M, N, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GEMV([TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX], BETA,
       Y, [INCY])

CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A

SUBROUTINE GEMV_64([TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
       BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgemv(char transa, int m, int n, float alpha, float *a,
          int lda, float *x, int incx, float beta, float *y,
          int incy);
void sgemv_64(char transa, long  m,  long  n,  float  alpha,
          float  *a,  long  lda,  float *x, long incx, float
          beta, float *y, long incy);
```

PURPOSE

sgemv performs one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   y := alpha*A*x + beta*y.

TRANSA = 'T' or 't'   y := alpha*A'*x + beta*y.

TRANSA = 'C' or 'c'   y := alpha*A'*x + beta*y.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (m - 1)*abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

NAME

```
sgeqlf - compute a QL factorization of a real M-by-N  matrix
A
```

SYNOPSIS

```
SUBROUTINE SGEQLF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

INTEGER M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)

SUBROUTINE SGEQLF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

INTEGER*8 M, N, LDA, LDWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQLF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

INTEGER :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE GEQLF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgeqlf(int m, int n, float *a, int lda, float *tau, int
          *info);

void sgeqlf_64(long m, long n, float  *a,  long  lda,  float
          *tau, long *info);
```

PURPOSE

sgeqlf computes a QL factorization of a real M-by-N matrix A: A = Q * L.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK.   LDWORK >= max(1,N). For optimum performance LDWORK >= N*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(k) . . . H(2) H(1), where k = min(m,n).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in A(1:m-k+i-1,n-k+i), and tau in TAU(i).

       [INFO])

INTEGER :: M, N, LDA, LWORK, INFO
INTEGER, DIMENSION(:) :: JPVT
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE GEQP3_64([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
       [INFO])

INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
```

```
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgeqp3(int m, int n, float  *a,  int  lda,  int  *jpvt,
          float *tau, int *info);

void sgeqp3_64(long m, long n,  float  *a,  long  lda,  long
          *jpvt, float *tau, long *info);
```

PURPOSE

sgeqp3 computes a QR factorization with column pivoting of a matrix A: A*P = Q*R using Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M,N)-by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of min(M,N) elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

JPVT (input/output)
On entry, if JPVT(J).ne.0, the J-th column of A is permuted to the front of A*P (a leading column); if JPVT(J)=0, the J-th column of A is a free column.   On exit, if JPVT(J)=K, then the J-th column of A*P was the the K-th column of A.

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if INFO=0, WORK(1) returns the optimal

```
          LWORK.

LWORK (input)
          The dimension of the array WORK. LWORK  >=  3*N+1.
          For  optimal  performance LWORK >= 2*N+( N+1 )*NB,
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0: successful exit.
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value.
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real/complex scalar, and v is a  real/complex
vector with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on
exit in A(i+1:m,i), and tau in TAU(i).

void sgeqpf(int m, int n, float *a, int  lda,  int  *jpivot,
          float *tau, int *info);

void sgeqpf_64(long m, long n,  float  *a,  long  lda,  long
          *jpivot, float *tau, long *info);
```

PURPOSE

sgeqpf routine is deprecated and has been replaced by routine SGEQP3.

SGEQPF computes a QR factorization with column pivoting of a real M-by-N matrix A: A*P = Q*R.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M,N)-by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

JPIVOT (input/output)
On entry, if JPIVOT(i) .ne. 0, the i-th column of A is permuted to the front of A*P (a leading column); if JPIVOT(i) = 0, the i-th column of A is a free column. On exit, if JPIVOT(i) = k, then the i-th column of A*P was the k-th column of A.

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)

```
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(n)

Each H(i) has the form
   H = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is  stored  on  exit  in
A(i+1:m,i).

The matrix P is represented in jpvt as follows: If
   jpvt(j) = i
then the jth column of P is the ith canonical unit vector.

          *tau, long *info);
```

PURPOSE

```
sgeqrf computes a QR factorization of a real  M-by-N  matrix
A:  A = Q * R.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.
N (input) The number of columns of the matrix A.  N >= 0.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, the  ele-
          ments  on and above the diagonal of the array con-
          tain the min(M,N)-by-N upper trapezoidal matrix  R
          (R  is  upper  triangular if m >= n); the elements
          below the diagonal, with the array TAU,  represent
          the  orthogonal  matrix Q as a product of min(m,n)
          elementary reflectors (see Further Details).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

TAU (output)
          The scalar factors of  the  elementary  reflectors
          (see Further Details).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The  dimension  of  the  array  WORK.   LDWORK  >=
          max(1,N).  For optimum performance LDWORK >= N*NB,
          where NB is the optimal blocksize.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.
```

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form
   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is  stored  on  exit  in
A(i+1:m,i), and tau in TAU(i).
```

INTEGER*8 M, N, INCX, INCY, LDA
REAL ALPHA
REAL X(*), Y(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GER([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

INTEGER :: M, N, INCX, INCY, LDA
REAL :: ALPHA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A

SUBROUTINE GER_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

INTEGER(8) :: M, N, INCX, INCY, LDA
REAL :: ALPHA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sger(int m, int n, float alpha,  float  *x,  int  incx,
          float *y, int incy, float *a, int lda);

void sger_64(long m, long n, float  alpha,  float  *x,  long
          incx, float *y, long incy, float *a, long lda);
```

PURPOSE

sger performs the rank 1 operation A := alpha*x*y' + A, where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

Y (input)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

Contents

NAME

sgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

```
#include <sunperf.h>
void sgerfs(char transa, int n, int nrhs, float *a, int lda,
          float  *af,  int  ldaf, int *ipivot, float *b, int
          ldb, float *x, int ldx, float *ferr, float  *berr,
          int *info);

void sgerfs_64(char transa, long n,  long  nrhs,  float  *a,
          long  lda,  float  *af,  long  ldaf, long *ipivot,
          float *b, long ldb,  float  *x,  long  ldx,  float
          *ferr, float *berr, long *info);
```

PURPOSE

sgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations:
```
= 'N':  A * X = B     (No transpose)
= 'T':  A**T * X = B  (Transpose)
= 'C':  A**H * X = B  (Conjugate transpose = Tran-
spose)
```

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The original N-by-N matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

Contents

REAL, DIMENSION(:,:) :: A

SUBROUTINE GERQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgerqf(int m, int n, float *a, int lda, float *tau, int
          *info);

void sgerqf_64(long m, long n, float  *a,  long  lda,  float
          *tau, long *info);
```

PURPOSE

```
sgerqf computes an RQ factorization of a real M-by-N  matrix
A:  A = R * Q.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.
N (input) The number of columns of the matrix A.  N >= 0.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, if  m  <=
          n,  the  upper  triangle  of the subarray A(1:m,n-
          m+1:n) contains the M-by-M upper triangular matrix
          R;  if  m  >= n, the elements on and above the (m-
          n)-th subdiagonal contain the  M-by-N  upper  tra-
          pezoidal  matrix  R;  the remaining elements, with
          the array TAU, represent the orthogonal  matrix  Q
          as  a  product  of  min(m,n) elementary reflectors
          (see Further Details).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

TAU (output)
          The scalar factors of  the  elementary  reflectors
          (see Further Details).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The  dimension  of  the  array  WORK.   LDWORK  >=
          max(1,M).  For optimum performance LDWORK >= M*NB,
          where NB is the optimal blocksize.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
```

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(1) H(2) . . . H(k), where k = min(m,n).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(n-k+i+1:n) = 0 and v(n-k+i) = 1; v(1:n-k+i-1) is stored on exit in A(m-k+i,1:n-k+i-1), and tau in TAU(i).

#include <sunperf.h>

void sgesdd(char jobz, int m, int  n,  float  *a,  int  lda,
          float  *s, float *u, int ldu, float *vt, int ldvt,
          int *info);
void sgesdd_64(char jobz, long m, long  n,  float  *a,  long
          lda, float *s, float *u, long ldu, float *vt, long
          ldvt, long *info);
```

PURPOSE

sgesdd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm.

The SVD is written
 = U * SIGMA * transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V**T, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```
JOBZ (input)
          Specifies options for computing all or part of the
          matrix U:
          = 'A':  all M columns of U and all N rows of  V**T
          are  returned  in the arrays U and VT; = 'S':  the
          first min(M,N) columns of U and the first min(M,N)
          rows  of V**T are returned in the arrays U and VT;
          = 'O':  If M >= N, the first N columns  of  U  are
          overwritten  on  the  array A and all rows of V**T
          are returned  in  the  array  VT;  otherwise,  all
          columns  of  U are returned in the array U and the
          first M rows of V**T are overwritten in the  array
          VT;  =  'N':   no columns of U or rows of V**T are
          computed.

M (input) The number of rows of the input matrix A.  M >= 0.
N (input) The number of columns of the input matrix A.  N >=
          0.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, if JOBZ =
          'O',  A is overwritten with the first N columns of
          U (the left singular vectors,  stored  columnwise)
          if  M >= N; A is overwritten with the first M rows
          of V**T (the right singular vectors,  stored  row-
          wise)  otherwise.   if JOBZ .ne. 'O', the contents
          of A are destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

S (output)
          The singular values of A, sorted so that  S(i)  >=
          S(i+1).

U (output)
          UCOL = M if JOBZ = 'A' or JOBZ = 'O' and  M  <  N;
          UCOL  =  min(M,N) if JOBZ = 'S'.  If JOBZ = 'A' or
          JOBZ = 'O' and  M  <  N,  U  contains  the  M-by-M
          orthogonal matrix U; if JOBZ = 'S', U contains the
          first min(M,N) columns of  U  (the  left  singular
          vectors,  stored  columnwise); if JOBZ = 'O' and M
          >= N, or JOBZ = 'N', U is not referenced.

LDU (input)
          The leading dimension of the array U.  LDU  >=  1;
```

if JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT (output)

If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the N-by-N orthogonal matrix V**T; if JOBZ = 'S', VT contains the first min(M,N) rows of V**T (the right singular vectors, stored rowwise); if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT (input)

The leading dimension of the array VT. LDVT >= 1; if JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N; if JOBZ = 'S', LDVT >= min(M,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK;

LWORK (input)

The dimension of the array WORK. LWORK >= 1. If JOBZ = 'N', LWORK >= 3*min(M,N) + max(max(M,N),6*min(M,N)). If JOBZ = 'O', LWORK >= 3*min(M,N)*min(M,N) + max(max(M,N),5*min(M,N)* min(M,N)+4*min(M,N)). If JOBZ = 'S' or 'A' LWORK >= 3*min(M,N)*min(M,N) + max(max(M,N),4*min(M,N)* min(M,N)+4*min(M,N)). For good performance, LWORK should generally be larger. If LWORK < 0 but other input arguments are legal, WORK(1) returns optimal LWORK.

IWORK (workspace)

dimension(8*MIN(M,N))

INFO (output)

= 0: successful exit.

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: SBDSDC did not converge, updating process failed.

SUBROUTINE GESV_64([N], [NRHS], A, [LDA], IPIVOT, B, [LDB], [INFO])

INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgesv(int n, int nrhs, float *a, int lda, int  *ipivot,
          float *b, int ldb, int *info);

void sgesv_64(long n, long nrhs, float *a,  long  lda,  long
          *ipivot, float *b, long ldb, long *info);
```

PURPOSE

sgesv computes the solution to a real system of linear equations

A * X = B, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as

A = P * L * U,

where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the N-by-NRHS matrix of right hand side

matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

REAL, DIMENSION(:,:) :: A, U, VT
```

C INTERFACE

```
#include <sunperf.h>

void sgesvd(char jobu, char jobvt, int m, int n,  float  *a,
          int  lda,  float  *sing,  float *u, int ldu, float
          *vt, int ldvt, int *info);

void sgesvd_64(char jobu, char jobvt, long m, long n,  float
          *a,  long  lda,  float  *sing, float *u, long ldu,
          float *vt, long ldvt, long *info);
```

PURPOSE

sgesvd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written
 = U * SIGMA * transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**T, not V.

ARGUMENTS

JOBU (input)
Specifies options for computing all or part of the matrix U:
= 'A': all M columns of U are returned in array U:
= 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A;
= 'N': no columns of U (no left singular vectors) are computed.

```
JOBVT (input)
          Specifies options for computing all or part of the
          matrix V**T:
          = 'A':  all N rows of V**T  are  returned  in  the
          array VT;
          = 'S':  the first min(m,n) rows of V**T (the right
          singular  vectors) are returned in the array VT; =
          'O':  the first min(m,n) rows of V**T  (the  right
          singular  vectors) are overwritten on the array A;
          = 'N':  no rows of V**T (no  right  singular  vec-
          tors) are computed.

          JOBVT and JOBU cannot both be 'O'.

M (input) The number of rows of the input matrix A.  M >= 0.

N (input) The number of columns of the input matrix A.  N >=
          0.
A (input/output)
          On entry, the M-by-N matrix A.  On exit, if JOBU =
          'O',   A  is  overwritten  with the first min(m,n)
          columns of U (the left  singular  vectors,  stored
          columnwise); if JOBVT = 'O', A is overwritten with
          the first min(m,n) rows of V**T (the right  singu-
          lar vectors, stored rowwise); if JOBU .ne. 'O' and
          JOBVT .ne. 'O', the contents of A are destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

SING (output)
          The singular values of A, sorted so  that  SING(i)
          >= SING(i+1).

U (input) (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU  =
          'S'.  If JOBU = 'A', U contains the M-by-M orthog-
          onal matrix U; if JOBU = 'S', U contains the first
          min(m,n)  columns of U (the left singular vectors,
          stored columnwise); if JOBU = 'N' or 'O', U is not
          referenced.

LDU (input)
          The leading dimension of the array U.  LDU  >=  1;
          if JOBU = 'S' or 'A', LDU >= M.

VT (input)
          If JOBVT = 'A', VT contains the N-by-N  orthogonal
          matrix V**T; if JOBVT = 'S', VT contains the first
          min(m,n) rows of V**T (the right singular vectors,
```

stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT (input)
The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK; if INFO > 0, WORK(2:MIN(M,N)) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies A = U * B * VT, so it has the same singular values as A, and singular vectors related by U and VT.

LDWORK (input)
The dimension of the array WORK. LDWORK >= 1. LDWORK >= MAX(3*MIN(M,N)+MAX(M,N),5*MIN(M,N)). For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if SBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of WORK above for details.

```

PURPOSE

```
sgesvx uses the LU factorization to compute the solution  to
a real system of linear equations
   A * X = B, where A is an N-by-N matrix and X  and  B  are
N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X  =
diag(R)*B
```

```
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X  =
diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X  =
diag(C)*B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(R)*A*diag(C) and B by  diag(R)*B  (if
TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU  decomposition  is  used  to
factor the
   matrix A (after equilibration if FACT = 'E') as
      A = P * L * U,
   where P is a permutation matrix, L is a unit  lower  tri-
angular
   matrix, and U is upper triangular.
3. If some U(i,i)=0, so that U is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.

6. If equilibration was used, the matrix X is  premultiplied
by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS  =  'T'  or
'C') so
   that it solves the original system before equilibration.
```

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the N-by-N matrix A. If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A
EQUED = 'C': A := A * diag(C)
EQUED = 'B': A := diag(R) * A * diag(C).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the factors L and U from the factorization A = P*L*U as computed by SGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by SGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED (input/output)
Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input/output)
The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input/output)

The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))*X if TRANSA = 'N' and EQUED = 'C' or 'B', or inv(diag(R))*X if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)

The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(4*N) On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```
SUBROUTINE GETF2([M], [N], A, [LDA], IPIV, [INFO])

INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL, DIMENSION(:,:) :: A

SUBROUTINE GETF2_64([M], [N], A, [LDA], IPIV, [INFO])

INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sgetf2(int m, int n, float *a, int lda, int *ipiv,  int
          *info);

void sgetf2_64(long m, long n,  float  *a,  long  lda,  long
          *ipiv, long *info);
```

PURPOSE

sgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form
   A = P * L * U
where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

IPIV (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is

exactly singular, and division by zero will occur if it is used to solve a system of equations.

NAME

```
sgetri - compute the inverse of a matrix using the  LU  fac-
torization computed by SGETRF
```

SYNOPSIS

```
SUBROUTINE SGETRI(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)

INTEGER N, LDA, LDWORK, INFO
INTEGER IPIVOT(*)
REAL A(LDA,*), WORK(*)

SUBROUTINE SGETRI_64(N, A, LDA, IPIVOT, WORK, LDWORK, INFO)

INTEGER*8 N, LDA, LDWORK, INFO
INTEGER*8 IPIVOT(*)
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GETRI([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])

INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE GETRI_64([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])

INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sgetri(int n, float  *a,  int  lda,  int  *ipivot,  int
          *info);

void sgetri_64(long n, float *a,  long  lda,  long  *ipivot,
          long *info);
```

PURPOSE

sgetri computes the inverse of a matrix using the LU factor-
ization computed by SGETRF.

This method inverts U and then computes inv(A) by solving
the system inv(A)*L = inv(U) for inv(A).

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the factors L and U from the factoriza-
tion A = P*L*U as computed by SGETRF. On exit, if
INFO = 0, the inverse of the original matrix A.

LDA (input)
The leading dimension of the array A.   LDA >=
max(1,N).

IPIVOT (input)
The pivot indices from SGETRF; for 1<=i<=N, row i
of the matrix was interchanged with row IPIVOT(i).

WORK (workspace)
On exit, if INFO=0, then WORK(1) returns the
optimal LDWORK.

LDWORK (input)
The dimension of the array WORK.   LDWORK >=
max(1,N). For optimal performance LDWORK >= N*NB,
where NB is the optimal blocksize returned by
ILAENV.

If LDWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

```

PURPOSE

```
sgetrs solves a system of linear equations
   A * X = B  or  A' * X = B with a general N-by-N matrix  A
using the LU factorization computed by SGETRF.
```

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B  (No transpose)
          = 'T':  A'* X = B  (Transpose)
          = 'C':  A'* X = B  (Conjugate  transpose  =  Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input) The factors L and U from  the  factorization  A  =
          P*L*U as computed by SGETRF.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

IPIVOT (input)
          The pivot indices from SGETRF; for 1<=i<=N, row  i
```

of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

       [LDV], [INFO])

CHARACTER(LEN=1) :: JOB, SIDE
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE
REAL, DIMENSION(:,:) :: V
```

C INTERFACE

```
#include <sunperf.h>

void sggbak(char job, char side, int n, int  ilo,  int  ihi,
          float *lscale, float *rscale, int m, float *v, int
          ldv, int *info);

void sggbak_64(char job, char side, long n, long  ilo,  long
          ihi,  float  *lscale, float *rscale, long m, float
          *v, long ldv, long *info);
```

PURPOSE

sggbak forms the right or left eigenvectors of a real generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL.

ARGUMENTS

```
JOB (input)
          Specifies  the  type  of  backward  transformation
          required:
          = 'N':  do nothing, return immediately;
          = 'P':  do backward transformation for permutation
          only;
          = 'S':  do  backward  transformation  for  scaling
          only;
          = 'B':  do backward transformations for both  per-
          mutation and scaling.  JOB must be the same as the
          argument JOB supplied to SGGBAL.

SIDE (input)
          = 'R':  V contains right eigenvectors;
          = 'L':  V contains left eigenvectors.

N (input) The number of rows of the matrix V.  N >= 0.

ILO (input)
          The integers ILO and IHI determined by SGGBAL.   1
```

```
          <=  ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if
          N=0.

IHI (input)
          See the description for ILO.

LSCALE (input)
          Details of the permutations and/or scaling factors
          applied  to  the left side of A and B, as returned
          by SGGBAL.

RSCALE (input)
          Details of the permutations and/or scaling factors
          applied  to the right side of A and B, as returned
          by SGGBAL.

M (input) The number of columns of the matrix V.  M >= 0.

V (input/output)
          On entry, the matrix of right or left eigenvectors
          to  be  transformed,  as  returned  by STGEVC.  On
          exit, V is overwritten by the  transformed  eigen-
          vectors.

LDV (input)
          The leading dimension of  the  matrix  V.  LDV  >=
          max(1,N).

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
```

```
#include <sunperf.h>

void sggbal(char job, int n, float *a, int  lda,  float  *b,
          int  ldb, int *ilo, int *ihi, float *lscale, float
          *rscale, int *info);

void sggbal_64(char job, long n, float *a, long  lda,  float
          *b, long ldb, long *ilo, long *ihi, float *lscale,
          float *rscale, long *info);
```

PURPOSE

sggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem A*x = lambda*B*x.

ARGUMENTS

JOB (input)
Specifies the operations to be performed on A and B:
= 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i = 1,...,N. = 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced.

```
LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,N).

B (input) On entry, the input matrix  B.   On  exit,   B  is
          overwritten by the balanced matrix.  If JOB = 'N',
          B is not referenced.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

ILO (output)
          ILO and IHI are set to integers such that on  exit
          A(i,j)  =  0  and  B(i,j)  =  0  if  i > j and j =
          1,...,ILO-1 or i = IHI+1,...,N.  If JOB =  'N'  or
          'S', ILO = 1 and IHI = N.

IHI (output)
          See the description for ILO.

LSCALE (input)
          Details of the permutations  and  scaling  factors
          applied  to  the left side of A and B.  If P(j) is
          the index of the row interchanged with row j,  and
          D(j)  is the scaling factor applied to row j, then
          LSCALE(j) = P(j)    for J  =  1,...,ILO-1  =  D(j)
          for J = ILO,...,IHI = P(j)    for J = IHI+1,...,N.
          The order in which the interchanges are made is  N
          to IHI+1, then 1 to ILO-1.

RSCALE (input)
          Details of the permutations  and  scaling  factors
          applied  to the right side of A and B.  If P(j) is
          the index of the column interchanged  with  column
          j,  and  D(j)  is  the  scaling  factor applied to
          column  j,  then  LSCALE(j)  =  P(j)     for  J  =
          1,...,ILO-1  =  D(j)    for J = ILO,...,IHI = P(j)
          for J =  IHI+1,...,N.   The  order  in  which  the
          interchanges  are  made  is  N to IHI+1, then 1 to
          ILO-1.

WORK (workspace)
          dimension(6*N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
```

          *info);
```

PURPOSE

sgges computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

(A,B) = ((VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T)

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T.The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver SGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
        [  a  0  ]
        [  0  b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELCTG);

SELCTG (input)
SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j), BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2 in this case.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)
The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 8*N+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK (workspace)
dimension(N) Not referenced if SORT = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in

SHGEQZ.
=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

```

PURPOSE

sggesx computes for a pair of N-by-N real nonsymmetric

matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization
A,B) = ((VSL) S (VSR)**T, (VSL) T (VSR)**T)

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
[  a  0  ]
[  0  b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. =

'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELCTG).

SELCTG (input)
SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N' : None are computed;
= 'E' : Computed for average of selected eigenvalues only;
= 'V' : Computed for selected deflating subspaces only;
= 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

SDIM (output)

If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true. (Complex conjugate pairs for which SELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)

On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)

See the description for ALPHAR.

BETA (output)

See the description for ALPHAR.

VSL (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE (output)
If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV (output)
If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 8*(N+1)+16. If SENSE = 'E', 'V', or 'B', LWORK >= MAX(8*(N+1)+16, 2*SDIM*(N-SDIM)).

IWORK (workspace)
Not referenced if SENSE = 'N'.

LIWORK (input)
The dimension of the array WORK. LIWORK >= N+6.

BWORK (workspace)
dimension(N) Not referenced if SORT = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

Further details ===============

An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is

EPS * norm((A, B)) / RCONDE(1).

An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is

EPS * norm((A, B)) / RCONDV(2).

See LAPACK User's Guide, section 4.11 for more information.

REAL, DIMENSION(:) :: ALPHAR, ALPHAI, BETA, WORK
REAL, DIMENSION(:,:) :: A, B, VL, VR

SUBROUTINE GGEV_64(JOBVL, JOBVR, [N], A, [LDA], B, [LDB], ALPHAR,
       ALPHAI, BETA, VL, [LDVL], VR, [LDVR], [WORK], [LWORK], [INFO])
```

```
CHARACTER(LEN=1) :: JOBVL, JOBVR
INTEGER(8) :: N, LDA, LDB, LDVL, LDVR, LWORK, INFO
REAL, DIMENSION(:) :: ALPHAR, ALPHAI, BETA, WORK
REAL, DIMENSION(:,:) :: A, B, VL, VR
```

C INTERFACE

```
#include <sunperf.h>

void sggev(char jobvl, char jobvr, int n, float *a, int lda,
          float  *b,  int ldb, float *alphar, float *alphai,
          float *beta, float *vl, int ldvl, float  *vr,  int
          ldvr, int *info);
void sggev_64(char jobvl, char jobvr, long n, float *a, long
          lda,  float  *b,  long  ldb,  float *alphar, float
          *alphai, float *beta, float *vl, long ldvl,  float
          *vr, long ldvr, long *info);
```

PURPOSE

sggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

A * v(j) = lambda(j) * B * v(j).

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

u(j)**H * A = lambda(j) * u(j)**H * B .

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;

= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VL (input)
If JOBVL = 'V', the left eigenvectors u(j) are

stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part)+abs(imag. part)=1. Not referenced if JOBVL = 'N'.

LDVL (input)

The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (input)

If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part)+abs(imag. part)=1. Not referenced if JOBVR = 'N'.

LDVR (input)

The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,8*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an ille-

gal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ.
=N+2: error return from STGEVC.

```

PURPOSE

sggevx computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.
The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

A * v(j) = lambda(j) * B * v(j) .

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

u(j)**H * A = lambda(j) * u(j)**H * B.

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

BALANC (input)
Specifies the balance option to be performed. = 'N': do not diagonally scale or permute;
= 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized

eigenvectors;
= 'V': compute the right generalized eigenvectors.

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N': none are computed;
= 'E': computed for eigenvalues only;
= 'V': computed for eigenvectors only;
= 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the real Schur form of the "balanced" versions of the input A and B.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the real Schur form of the "balanced" versions of the input A and B.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description of ALPHAR.

BETA (output)
See the description of ALPHAR.

VL (output)
If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL (input)
The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (output)
If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR (input)
The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO (output)
ILO and IHI are integer values such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
See the description of ILO.

LSCALE (output)

Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1 = DL(j) for j = ILO,...,IHI = PL(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (output)

Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1 = DR(j) for j = ILO,...,IHI = PR(j) for j = IHI+1,...,N The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)

The one-norm of the balanced matrix A.

BBNRM (output)

The one-norm of the balanced matrix B.

RCONDE (output)

If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of RCONDE are set to the same value. Thus RCONDE(j), RCONDV(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If SENSE = 'V', RCONDE is not referenced.

RCONDV (output)

If SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of RCONDV are set to the same value. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal

LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,6*N). If SENSE = 'E', LWORK >= 12*N. If SENSE = 'V' or 'B', LWORK >= 2*N*N+12*N+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(N+6) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)
dimension(N) If SENSE = 'N', BWORK is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ.
=N+2: error return from STGEVC.

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue lambda is
hord(w, lambda) <= EPS * norm(ABNRM, BBNRM) / RCONDE(I)
An approximate error bound for the angle between the i-th computed eigenvector VL(i) or VR(i) is given by

PS * norm(ABNRM, BBNRM) / DIF(i).

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see section 4.11 of LAPACK User's Guide.

#include <sunperf.h>

void sggglm(int n, int m, int p, float *a,  int  lda,  float
          *b,  int  ldb,  float  *d, float *x, float *y, int
          *info);

void sggglm_64(long n, long m, long p, float *a,  long  lda,
          float  *b, long ldb, float *d, float *x, float *y,
          long *info);
```

PURPOSE

```
sggglm solves a  general  Gauss-Markov  linear  model  (GLM)
problem:
        minimize || y ||_2   subject to   d = A*x + B*y
            x

where A is an N-by-M matrix, B is an N-by-P matrix, and d is
a given N-vector. It is assumed that M <= N <= M+P, and

           rank(A) = M    and    rank( A B ) = N.

Under these assumptions, the constrained equation is  always
consistent,  and  there is a unique solution x and a minimal
2-norm solution y, which is obtained using a generalized  QR
factorization of A and B.

In particular, if matrix B is square nonsingular,  then  the
problem  GLM  is equivalent to the following weighted linear
least squares problem

             minimize || inv(B)*(d-A*x) ||_2
                 x

where inv(B) denotes the inverse of B.
```

ARGUMENTS

```
N (input) The number of rows of the matrices A and B.  N  >=
          0.

M (input) The number of columns of the matrix A.  0 <= M  <=
          N.

P (input) The number of columns of the matrix B.  P >= N-M.
```

A (input/output)
On entry, the N-by-M matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-P matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

D (input/output)
On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X (output)
On exit, X and Y are the solutions of the GLM problem.

Y (output)
See the description of X.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N+M+P). For optimum performance, LDWORK >= M+min(N,P)+max(N,P)*NB, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

```
SUBROUTINE GGHRD(COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB], Q,
       [LDQ], Z, [LDZ], [INFO])

CHARACTER(LEN=1) :: COMPQ, COMPZ
INTEGER :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
REAL, DIMENSION(:,:) :: A, B, Q, Z

SUBROUTINE GGHRD_64(COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB],
       Q, [LDQ], Z, [LDZ], [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ, COMPZ
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
REAL, DIMENSION(:,:) :: A, B, Q, Z
```

C INTERFACE

```
#include <sunperf.h>

void sgghrd(char compq, char compz, int n, int ilo, int ihi,
          float  *a,  int  lda, float *b, int ldb, float *q,
          int ldq, float *z, int ldz, int *info);

void sgghrd_64(char compq, char compz,  long  n,  long  ilo,
          long  ihi, float *a, long lda, float *b, long ldb,
          float *q, long  ldq,  float  *z,  long  ldz,  long
          *info);
```

PURPOSE

sgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular: Q' * A * Z = H and Q' * B * Z = T, where H is upper Hessenberg, T is upper triangular, and Q and Z are orthogonal, and ' means transpose.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that
1 * A * Z1' = (Q1*Q) * H * (Z1*Z)'

ARGUMENTS

COMPQ (input)
= 'N': do not compute Q;
= 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry, and the product Q1*Q is returned.

COMPZ (input)
= 'N': do not compute Z;
= 'I': Z is initialized to the unit matrix, and the orthogonal matrix Z is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry, and the product Z1*Z is returned.

N (input) The order of the matrices A and B. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description of ILO.

A (input/output)
On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q' B Z. The elements below the diagonal are set to zero.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

Q (input/output)
If COMPQ='N': Q is not referenced.
If COMPQ='I': on entry, Q need not be set, and on exit it contains the orthogonal matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain an orthogonal matrix Q1, and on exit this is overwritten by Q1*Q.

LDQ (input)
The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z (input/output)
If COMPZ='N': Z is not referenced.
If COMPZ='I': on entry, Z need not be set, and on exit it contains the orthogonal matrix Z, which is the product of the Givens transformations which

are applied to A and B on the right. If COMPZ='V': on entry, Z must contain an orthogonal matrix Z1, and on exit this is overwritten by Z1*Z.

LDZ (input)
The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in _Matrix_Computations_, by Golub and Van Loan (Johns Hopkins Press.)

REAL, DIMENSION(:) :: C, D, X, WORK
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE GGLSE_64([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],
       [LDWORK], [INFO])

INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
REAL, DIMENSION(:) :: C, D, X, WORK
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void sgglse(int m, int n, int p, float *a,  int  lda,  float
          *b,  int  ldb,  float  *c, float *d, float *x, int
          *info);

void sgglse_64(long m, long n, long p, float *a,  long  lda,
          float  *b, long ldb, float *c, float *d, float *x,
          long *info);
```

PURPOSE

```
sgglse solves the linear equality-constrained least  squares
(LSE) problem:
        minimize || c - A*x ||_2   subject to   B*x = d

where A is an M-by-N matrix, B is a P-by-N matrix,  c  is  a
given  M-vector,  and  d  is a given P-vector. It is assumed
that
P <= N <= M+P, and

         rank(B) = P and  rank( ( A ) ) = N.
                              ( ( B ) )

These conditions ensure that the LSE problem  has  a  unique
solution, which is obtained using a GRQ factorization of the
matrices B and A.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrices A and  B.  N
          >= 0.

P (input) The number of rows of the matrix B. 0 <= P <= N <=
          M+P.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, A is des-
          troyed.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).
```

B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

C (input/output)
On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D (input/output)
On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X (output)
On exit, X is the solution of the LSE problem.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M+N+P). For optimum performance LDWORK >= P+min(M,N)+max(M,N)*NB, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

       [WORK], [LWORK], [INFO])

INTEGER(8) :: N, M, P, LDA, LDB, LWORK, INFO
REAL, DIMENSION(:) :: TAUA, TAUB, WORK
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void sggqrf(int n, int m, int p, float *a,  int  lda,  float
          *taua, float *b, int ldb, float *taub, int *info);

void sggqrf_64(long n, long m, long p, float *a,  long  lda,
          float *taua, float *b, long ldb, float *taub, long
          *info);
```

PURPOSE

```
sggqrf computes a generalized QR factorization of an  N-by-M
matrix A and an N-by-P matrix B:
            A = Q*R,        B = Q*T*Z,

where Q is an  N-by-N  orthogonal  matrix,  Z  is  a  P-by-P
orthogonal matrix, and R and T assume one of the forms:

if N >= M,  R = ( R11 ) M  ,   or if N < M,  R = ( R11   R12
) N,
                (  0  ) N-M                         N   M-N
                   M

where R11 is upper triangular, and

if N <= P,  T = ( 0  T12 ) N,   or if N > P,  T =  (  T11  )
N-P,
                 P-N  N                           ( T21 ) P
                                                     P

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR  fac-
torization  of A and B implicitly gives the QR factorization
of inv(B)*A:

             inv(B)*A = Z'*(inv(T)*R)

where inv(B) denotes the inverse of the  matrix  B,  and  Z'
denotes the transpose of the matrix Z.
```

ARGUMENTS

```
N (input) The number of rows of the matrices A and B.  N  >=
          0.
```

M (input) The number of columns of the matrix A. M >= 0.

P (input) The number of columns of the matrix B. P >= 0.

A (input/output)
On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N,M)-by-M upper trapezoidal matrix R (R is upper triangular if N >= M); the elements below the diagonal, with the array TAUA, represent the orthogonal matrix Q as a product of min(N,M) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAUA (output)
The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B (input/output)
On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

TAUB (output)
The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,N,M,P). For optimum performance LWORK >=

max(N,M,P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of SORMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(n,m).

Each H(i) has the form

   H(i) = I - taua * v * v'

where taua is a real scalar, and v is a real vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is  stored  on  exit  in
A(i+1:n,i), and taua in TAUA(i).
To form Q explicitly, use LAPACK subroutine SORGQR.
To use Q to update another  matrix,  use  LAPACK  subroutine
SORMQR.

The matrix Z is  represented  as  a  product  of  elementary
reflectors

   Z = H(1) H(2) . . . H(k), where k = min(n,p).

Each H(i) has the form

   H(i) = I - taub * v * v'

where taub is a real scalar, and v is a real vector with
v(p-k+i+1:p) = 0 and v(p-k+i) = 1; v(1:p-k+i-1) is stored on
exit in B(n-k+i,1:p-k+i-1), and taub in TAUB(i).
To form Z explicitly, use LAPACK subroutine SORGRQ.
To use Z to update another  matrix,  use  LAPACK  subroutine
SORMRQ.

```

C INTERFACE

```
#include <sunperf.h>

void sggrqf(int m, int p, int n, float *a,  int  lda,  float
          *taua, float *b, int ldb, float *taub, int *info);

void sggrqf_64(long m, long p, long n, float *a,  long  lda,
          float *taua, float *b, long ldb, float *taub, long
          *info);
```

PURPOSE

```
sggrqf computes a generalized RQ factorization of an  M-by-N
matrix A and a P-by-N matrix B:
            A = R*Q,        B = Z*T*Q,

where Q is an  N-by-N  orthogonal  matrix,  Z  is  a  P-by-P
orthogonal matrix, and R and T assume one of the forms:

if M <= N,  R = ( 0  R12 ) M,   or if M > N,  R =  (  R11  )
M-N,
                 N-M  M                            ( R21 ) N
                                                      N

where R12 or R21 is upper triangular, and

if P >= N,  T = ( T11 ) N  ,   or if P < N,  T = ( T11   T12
) P,
                (  0  ) P-N                          P   N-P
                   N

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ  fac-
torization  of A and B implicitly gives the RQ factorization
of A*inv(B):

             A*inv(B) = (R*inv(T))*Z'

where inv(B) denotes the inverse of the  matrix  B,  and  Z'
denotes the transpose of the matrix Z.
```

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

```
P (input) The number of rows of the matrix B.  P >= 0.

N (input) The number of columns of the matrices A and  B.  N
          >= 0.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, if  M  <=
          N,  the  upper  triangle  of the subarray A(1:M,N-
          M+1:N) contains the M-by-M upper triangular matrix
          R;  if M > N, the elements on and above the (M-N)-
          th  subdiagonal  contain  the  M-by-N  upper  tra-
          pezoidal  matrix  R;  the remaining elements, with
          the array TAUA, represent the orthogonal matrix  Q
          as a product of elementary reflectors (see Further
          Details).
LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).

TAUA (output)
          The scalar factors of  the  elementary  reflectors
          which  represent  the  orthogonal  matrix  Q  (see
          Further Details).

B (input/output)
          On entry, the P-by-N matrix B.  On exit, the  ele-
          ments  on and above the diagonal of the array con-
          tain the min(P,N)-by-N upper trapezoidal matrix  T
          (T  is  upper  triangular if P >= N); the elements
          below the diagonal, with the array TAUB, represent
          the orthogonal matrix Z as a product of elementary
          reflectors (see Further Details).

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,P).

TAUB (output)

          which  represent  the  orthogonal  matrix  Z  (see
          Further Details).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  dimension  of  the  array  WORK.   LWORK   >=
          max(1,N,M,P).   For  optimum  performance LWORK >=
          max(N,M,P)*max(NB1,NB2,NB3),  where  NB1  is   the
```

```
            optimal  blocksize  for the RQ factorization of an
            M-by-N matrix, NB2 is the  optimal  blocksize  for
            the  QR  factorization of a P-by-N matrix, and NB3
            is the optimal blocksize for a call of SORMRQ.

            If LWORK = -1, then a workspace query is  assumed;
            the  routine  only  calculates the optimal size of
            the WORK array, returns this value  as  the  first
            entry  of  the  WORK  array,  and no error message
            related to LWORK is issued by XERBLA.
  INFO (output)
            = 0:  successful exit
            < 0:  if INF0= -i, the i-th argument had an  ille-
            gal value.
```

FURTHER DETAILS

```
  The matrix Q is  represented  as  a  product  of  elementary
  reflectors

     Q = H(1) H(2) . . . H(k), where k = min(m,n).

  Each H(i) has the form

     H(i) = I - taua * v * v'

  where taua is a real scalar, and v is a real vector with
  v(n-k+i+1:n) = 0 and v(n-k+i) = 1; v(1:n-k+i-1) is stored on
  exit in A(m-k+i,1:n-k+i-1), and taua in TAUA(i).
  To form Q explicitly, use LAPACK subroutine SORGRQ.
  To use Q to update another  matrix,  use  LAPACK  subroutine
  SORMRQ.

  The matrix Z is  represented  as  a  product  of  elementary
  reflectors

     Z = H(1) H(2) . . . H(k), where k = min(p,n).

  Each H(i) has the form

     H(i) = I - taub * v * v'

  where taub is a real scalar, and v is a real vector with
  v(1:i-1) = 0 and v(i) = 1; v(i+1:p) is  stored  on  exit  in
  B(i+1:p,i), and taub in TAUB(i).
  To form Z explicitly, use LAPACK subroutine SORGQR.
  To use Z to update another  matrix,  use  LAPACK  subroutine
  SORMQR.

          long ldq, long *iwork3, long *info);
```

PURPOSE

```
sggsvd computes the generalized singular value decomposition
(GSVD) of an M-by-N real matrix A and P-by-N real matrix B:

    U'*A*Q = D1*( 0 R ),    V'*B*Q = D2*( 0 R )

where U, V and Q are orthogonal  matrices,  and  Z'  is  the
transpose  of  Z.  Let K+L = the effective numerical rank of
the matrix (A',B')', then  R  is  a  K+L-by-K+L  nonsingular
upper  triangular matrix, D1 and D2 are M-by-(K+L) and P-by-
(K+L) "diagonal" matrices and of the  following  structures,
respectively:

If M-K-L >= 0,

                    K  L
       D1 =     K ( I  0 )
                L ( 0  C )
            M-K-L ( 0  0 )

                  K  L
```

```
       D2 =   L ( 0  S )
            P-L ( 0  0 )

                N-K-L  K    L
  ( 0 R ) = K (  0   R11  R12 )
            L (  0    0   R22 )
```

where

```
  C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
  S = diag( BETA(K+1),  ... , BETA(K+L) ),
  C**2 + S**2 = I.
```

R is stored in A(1:K+L,N-K-L+1:N) on exit.

If M-K-L < 0,

```
                  K M-K K+L-M
       D1 =   K ( I  0    0   )
            M-K ( 0  C    0   )

                    K M-K K+L-M
       D2 =   M-K ( 0  S    0  )
            K+L-M ( 0  0    I  )
              P-L ( 0  0    0  )

                   N-K-L  K   M-K  K+L-M
  ( 0 R ) =     K ( 0    R11  R12  R13  )
              M-K ( 0     0   R22  R23  )
            K+L-M ( 0     0    0   R33  )
```

where

```
  C = diag( ALPHA(K+1), ... , ALPHA(M) ),
  S = diag( BETA(K+1),  ... , BETA(M) ),
  C**2 + S**2 = I.
```

(R11 R12 R13) is stored in A(1:M, N-K-L+1:N), and R33 is stored
(0 R22 R23)
in B(M-K+1:L,N+M-K-L+1:N) on exit.

The routine computes C, S, R, and optionally the orthogonal transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):
A*inv(B) = U*(D1*inv(D2))*V'.
If (A',B')' has orthonormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Further-

more, the GSVD can be used to derive the solution of the eigenvalue problem:

```
                      A'*A x = lambda* B'*B x.
```

In some literature, the GSVD of A and B is presented in the form

```
                  U'*A*X = ( 0 D1 ),   V'*B*X = ( 0 D2 )
```

where U and V are orthogonal and X is nonsingular, D1 and D2 are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

```
                      X = Q*( I   0    )
                            ( 0 inv(R) ).
```

ARGUMENTS

JOBU (input)
  = 'U': Orthogonal matrix U is computed;
  = 'N': U is not computed.

JOBV (input)
  = 'V': Orthogonal matrix V is computed;
  = 'N': V is not computed.

JOBQ (input)
  = 'Q': Orthogonal matrix Q is computed;
  = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. P >= 0.

K (output)
  On exit, K and L specify the dimension of the sub-blocks described in the Purpose section. K + L = effective numerical rank of (A',B')'.

L (output)
  See the description of K.

A (input/output)
  On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)
  The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB (input)
The leading dimension of the array B. LDA >= max(1,P).

ALPHA (output)
On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1,
BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = C,
BETA(K+1:K+L) = S, or if M-K-L < 0,
ALPHA(K+1:M)=C, ALPHA(M+1:K+L)=0
BETA(K+1:M) =S, BETA(M+1:K+L) =1 and
ALPHA(K+L+1:N) = 0
BETA(K+L+1:N) = 0

BETA (output)
See the description of ALPHA.

U (output)
If JOBU = 'U', U contains the M-by-M orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (output)
If JOBV = 'V', V contains the P-by-P orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (output)
If JOBQ = 'Q', Q contains the N-by-N orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)
dimension (max(3*N,M,P)+N)

IWORK3 (output)
dimension(N) On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK3(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine STGSJA.

```

PURPOSE

```
sggsvp computes orthogonal matrices U, V and Q such that
              L ( 0     0   A23 )
          M-K-L ( 0     0    0  )

                 N-K-L  K    L
        =     K ( 0    A12  A13 )  if M-K-L < 0;
            M-K ( 0     0   A23 )

               N-K-L  K    L
 V'*B*Q =   L ( 0     0   B13 )
          P-L ( 0     0    0  )

where the K-by-K matrix A12 and L-by-L matrix B13  are  non-
singular upper triangular; A23 is L-by-L upper triangular if
M-K-L >= 0, otherwise A23 is (M-K)-by-L  upper  trapezoidal.
K+L  = the effective numerical rank of the (M+P)-by-N matrix
```

```
(A',B')'.  Z' denotes the transpose of Z.

This decomposition is the preprocessing step  for  computing
the  Generalized  Singular  Value  Decomposition (GSVD), see
subroutine SGGSVD.
```

ARGUMENTS

```
JOBU (input)
          = 'U':  Orthogonal matrix U is computed;
          = 'N':  U is not computed.

JOBV (input)
          = 'V':  Orthogonal matrix V is computed;
          = 'N':  V is not computed.
JOBQ (input)
          = 'Q':  Orthogonal matrix Q is computed;
          = 'N':  Q is not computed.

M (input) The number of rows of the matrix A.  M >= 0.

P (input) The number of rows of the matrix B.  P >= 0.

N (input) The number of columns of the matrices A and B.   N
          >= 0.

A (input/output)
          On entry, the M-by-N matrix A.  On  exit,  A  con-
          tains   the  triangular  (or  trapezoidal)  matrix
          described in the Purpose section.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).

B (input/output)
          On entry, the P-by-N matrix B.  On  exit,  B  con-
          tains  the triangular matrix described in the Pur-
          pose section.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,P).

TOLA (input)
          TOLA and TOLB are the thresholds to determine  the
          effective  numerical  rank  of matrix B and a sub-
          block of A. Generally, they  are  set  to  TOLA  =
```

MAX(M,N)*norm(A)*MACHEPS, TOLB = MAX(P,N)*norm(B)*MACHEPS. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
See the description of TOLA.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in Purpose. K + L = effective numerical rank of (A',B')'.

L (output)
See the description of K.

U (input) If JOBU = 'U', U contains the orthogonal matrix U.
If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) If JOBV = 'V', V contains the orthogonal matrix V.
If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) If JOBQ = 'Q', Q contains the orthogonal matrix Q.
If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

IWORK (workspace)
dimension(N)

TAU (workspace)
dimension(N)

WORK (workspace)
dimension(MAX(3*N,M,P))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine SGEQPF for the QR factorization with column pivoting to detect the effective numerical rank of the a matrix. It may be replaced by a better rank determination strategy.

Contents

NAME

sgssco - General sparse solver condition number estimate.

SYNOPSIS

```
SUBROUTINE SGSSCO ( COND, HANDLE, IER )

INTEGER            IER
REAL               COND
DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

SGSSCO - Condition number estimate.

PARAMETERS

```
COND      - REAL
        On exit, an estimate of the condition number of the
        factored matrix.  Must be called after the numerical
        factorization subroutine, SGSSFA().

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -700 : Invalid calling sequence - need to call SGSSFA first.
```

-710 : Condition number estimate not available (not implemented
       for this HANDLE's matix type).

Contents

NAME

```
sgssda - Deallocate working storage for the general sparse
solver.
```

SYNOPSIS

```
 SUBROUTINE SGSSDA ( HANDLE, IER )

 INTEGER           IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

SGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

```
HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         none
```

Contents

NAME

sgssfa - General sparse solver numeric factorization.

SYNOPSIS

```
 SUBROUTINE SGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )

 INTEGER            NEQNS, COLSTR(*), ROWIND(*), IER
 REAL               VALUES(*)
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

SGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

NEQNS   - INTEGER
        On entry, NEQNS specifies the number of equations in
        coefficient matrix. Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, *COLSTR*(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.

ROWIND(*) - INTEGER array
        On entry, *ROWIND*(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure. Unchanged on exit.

VALUES(*) - REAL array
        On entry, *VALUES*(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the numeric values of

```
        the sparse matrix to be factored.  Unchanged on
        exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER        - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -300 : Invalid calling sequence - need to call SGSSOR first.
         -301 : Failure to dynamically allocate memory.
         -666 : Internal error.
```

Contents

NAME

```
     sgssfs - General sparse solver one call interface.
```

SYNOPSIS

```
      SUBROUTINE SGSSFS ( MTXTYP, PIVOT , NEQNS, COLSTR, ROWIND,
                          VALUES, NRHS  , RHS   , LDRHS , ORDMTHD,
                          OUTUNT, MSGLVL, HANDLE, IER )

      CHARACTER*2        MTXTYP
      CHARACTER*1        PIVOT
      INTEGER            NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,
                         OUTUNT, MSGLVL, IER
      CHARACTER*3        ORDMTHD
      REAL               VALUES(*), RHS(*)
      DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

SGSSFS - General sparse solver one call interface.

PARAMETERS

```
     MTXTYP    - CHARACTER*2
             On entry, MTXTYP specifies the coefficient matrix
             type.  Specifically, the valid options are:

              'sp' or 'SP' - symmetric structure, positive-definite values
              'ss' or 'SS' - symmetric structure, symmetric values
              'su' or 'SU' - symmetric structure, unsymmetric values
              'uu' or 'UU' - unsymmetric structure, unsymmetric values

             Unchanged on exit.
```

```
PIVOT     - CHARACTER*1
        On entry, pivot specifies whether or not pivoting is
        used in the course of the numeric factorization.
        The valid options are:

         'n' or 'N' - no pivoting is used
         (Pivoting is not supported for this release).

        Unchanged on exit.

NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        the coefficient matrix.  NEQNS must be at least one.
        Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.
ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

VALUES(*) - REAL array
        On entry, VALUES(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the non-zero numeric
        values of the sparse matrix to be factored.
        Unchanged on exit.

NRHS      - INTEGER
        On entry, NRHS specifies the number of right hand
        sides to solve for.  Unchanged on exit.

RHS(*)    - REAL array
        On entry, RHS(LDRHS,NRHS) contains the NRHS right
        hand sides.  On exit, it contains the solutions.

LDRHS     - INTEGER
        On entry, LDRHS specifies the leading dimension of
        the RHS array. Unchanged on exit.

ORDMTHD   - CHARACTER*3
        On entry, ORDMTHD specifies the fill-reducing
        ordering to be used by the sparse solver.
        Specifically, the valid options are:

         'nat' or 'NAT' - natural ordering (no ordering)
         'mmd' or 'MMD' - multiple minimum degree
         'gnd' or 'GND' - general nested dissection
```

```
          'uso' or 'USO' - user specified ordering (see SGSSUO)

         Unchanged on exit.

OUTUNT    - INTEGER
         Output unit.  Unchanged on exit.

MSGLVL    - INTEGER
         Message level.

          0 - no output from solver.
          (No messages supported for this release.)

         Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
         On entry, HANDLE(*) is an array of containing
         information needed by the solver, and must be passed
         unchanged to each sparse solver subroutine.
         Modified on exit.
IER       - INTEGER
         Error number.  If no error encountered, unchanged on
         exit.  If error encountered, it is set to a non-zero
         integer.  Error numbers set by this subroutine:

          -101 : Failure to dynamically allocate memory.
          -102 : Invalid matrix type.
          -103 : Invalid pivot option.
          -104 : Number of nonzeros is less than NEQNS.
          -105 : NEQNS < 1
          -201 : Failure to dynamically allocate memory.
          -301 : Failure to dynamically allocate memory.
          -401 : Failure to dynamically allocate memory.
          -402 : NRHS < 1
          -403 : NEQNS > LDRHS

Contents

NAME

```
sgssin - Initialize the general sparse solver.
```

SYNOPSIS

```
 SUBROUTINE SGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,
                     MSGLVL, HANDLE, IER )

 CHARACTER*2       MTXTYP
 CHARACTER*1       PIVOT
 INTEGER           NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGLVL, IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

SGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

```
MTXTYP    - CHARACTER*2
        On entry, MTXTYP specifies the coefficient matrix
        type.  Specifically, the valid options are:

         'sp' or 'SP' - symmetric structure, positive-definite values
         'ss' or 'SS' - symmetric structure, symmetric values
         'su' or 'SU' - symmetric structure, unsymmetric values
         'uu' or 'UU' - unsymmetric structure, unsymmetric values

        Unchanged on exit.

PIVOT     - CHARACTER*1
        On entry, PIVOT specifies whether or not pivoting is
        used in the course of the numeric factorization.
```

```
        The valid options are:

         'n' or 'N' - no pivoting is used
         (Pivoting is not supported for this release).

        Unchanged on exit.

NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        the coefficient matrix.  NEQNS must be at least one.
        Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.

ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

OUTUNT    - INTEGER
        Output unit.  Unchanged on exit.

MSGLVL    - INTEGER
        Message level.

         0 - no output from solver.
         (No messages supported for this release.)

        Unchanged on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -101 : Failure to dynamically allocate memory.
         -102 : Invalid matrix type.
         -103 : Invalid pivot option.
         -104 : Number of nonzeros less than NEQNS.
         -105 : NEQNS < 1
```

Contents

NAME

```
sgssor - General sparse solver ordering and symbolic
factorization.
```

SYNOPSIS

```
 SUBROUTINE SGSSOR ( ORDMTHD, HANDLE, IER )

 CHARACTER*3       ORDMTHD
 INTEGER           IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

SGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

```
ORDMTHD   - CHARACTER*3
        On entry, ORDMTHD specifies the fill-reducing
        ordering to be used by the sparse solver.
        Specifically, the valid options are:

         'nat' or 'NAT' - natural ordering (no ordering)
         'mmd' or 'MMD' - multiple minimum degree
         'gnd' or 'GND' - general nested dissection
         'uso' or 'USO' - user specified ordering (see SGSSUO)

        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
```

```
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -200 : Invalid calling sequence - need to call SGSSIN first.
         -201 : Failure to dynamically allocate memory.
         -666 : Internal error.
```

Contents

NAME

```
sgssps - Print general sparse solver statics.
```

SYNOPSIS

```
 SUBROUTINE SGSSPS ( HANDLE, IER )

 INTEGER            IER
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

SGSSPS - Print solver statistics.

PARAMETERS

```
HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -800 : Invalid calling sequence - need to call SGSSSL first.
         -899 : Printed solver statistics not supported this release.
```

Contents

NAME

sgssrp - Return permutation used by the general sparse solver.

SYNOPSIS

```
SUBROUTINE SGSSRP ( PERM, HANDLE, IER )

INTEGER            PERM(*), IER
DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

SGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

```
PERM(NEQNS)  - INTEGER array
        Undefined on entry.  PERM(NEQNS) is the permutation
        array used by the sparse solver for the fill-
        reducing ordering.  Modified on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:
```

-600 : Invalid calling sequence - need to call SGSSOR first.

Contents

NAME

```
sgsssl - Solve routine for the general sparse solver.
```

SYNOPSIS

```
 SUBROUTINE SGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )

 INTEGER            NRHS, LDRHS, IER
 REAL               RHS(LDRHS,NRHS)
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

SGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

```
NRHS      - INTEGER
        On entry, NRHS specifies the number of right hand
        sides to solve for.  Unchanged on exit.

RHS(LDRHS,*) - REAL array
        On entry, RHS(LDRHS,NRHS) contains the NRHS right
        hand sides.  On exit, it contains the solutions.

LDRHS     - INTEGER
        On entry, LDRHS specifies the leading dimension of
        the RHS array. Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.
```

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-400 : Invalid calling sequence - need to call SGSSFA first.
-401 : Failure to dynamically allocate memory.
-402 : NRHS < 1
-403 : NEQNS > LDRHS

Contents

NAME

```
sgssuo - User supplied permutation for ordering used in the
general sparse solver.
```

SYNOPSIS

```
 SUBROUTINE SGSSUO ( PERM, HANDLE, IER )

 INTEGER            PERM(*), IER
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

SGSSUO - User supplied permutation for ordering. Must be
called after *SGSSIN*() (sparse solver initialization) and
before *SGSSOR*() (sparse solver ordering).

PARAMETERS

```
PERM(NEQNS)  - INTEGER array
        On entry, PERM(NEQNS) is a permutation array
        supplied by the user for the fill-reducing ordering.
        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER        - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:
```

-500 : Invalid calling sequence - need to call SGSSIN first.

Contents

NAME

```
sgtcon - estimate the reciprocal of the condition number  of
a  real  tridiagonal  matrix A using the LU factorization as
computed by SGTTRF
```

SYNOPSIS

```
SUBROUTINE SGTCON(NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM, RCOND,
      WORK, IWORK2, INFO)

CHARACTER * 1 NORM
INTEGER N, INFO
INTEGER IPIVOT(*), IWORK2(*)
REAL ANORM, RCOND
REAL LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)

SUBROUTINE SGTCON_64(NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
      RCOND, WORK, IWORK2, INFO)

CHARACTER * 1 NORM
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*), IWORK2(*)
REAL ANORM, RCOND
REAL LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GTCON(NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
       RCOND, [WORK], [IWORK2], [INFO])

CHARACTER(LEN=1) :: NORM
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
```

```
REAL, DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK

SUBROUTINE GTCON_64(NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
       RCOND, [WORK], [IWORK2], [INFO])

CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
```

C INTERFACE

```
#include <sunperf.h>
void sgtcon(char norm, int n, float *low, float *diag, float
          *up1,  float *up2, int *ipivot, float anorm, float
          *rcond, int *info);

void sgtcon_64(char norm, long n, float *low,  float  *diag,
          float *up1, float *up2, long *ipivot, float anorm,
          float *rcond, long *info);
```

PURPOSE

sgtcon estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I':   Infinity-norm.

N (input) The order of the matrix A. N >= 0.

LOW (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

DIAG (input)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input)
The (n-1) elements of the first superdiagonal of U.

UP2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

IWORK2 (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

Contents

NAME

```
sgthr - Gathers specified elements from y into x.
```

SYNOPSIS

```
 SUBROUTINE SGTHR(NZ, Y, X, INDX)

 REAL Y(*), X(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE SGTHR_64(NZ, Y, X, INDX)

 REAL Y(*), X(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE GTHR([NZ], Y, X, INDX)

 REAL, DIMENSION(:) :: Y, X
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE GTHR_64([NZ], Y, X, INDX)

 REAL, DIMENSION(:) :: Y, X
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
SGTHR - Gathers the specified elements from a vector y in
full storage form into a vector x in compressed form.  Only
```

the elements of y whose indices are listed in indx are referenced.

```
 do i = 1, n
   x(i) = y(indx(i))
 enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form. Unchanged on exit.

Y (input)
Vector in full storage form. Unchanged on exit.

X (output)
Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Contents

NAME

```
sgthrz - Gather and zero.
```

SYNOPSIS

```
 SUBROUTINE SGTHRZ(NZ, Y, X, INDX)

 REAL Y(*), X(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE SGTHRZ_64(NZ, Y, X, INDX)

 REAL Y(*), X(*)

 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE GTHRZ_64([NZ], Y, X, INDX)

 REAL, DIMENSION(:) :: Y, X
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
SGTHRZ - Gathers the specified elements from a vector y in
full storage form into a vector x in compressed form.  The
```

gathered elements of y are set to zero. Only the elements of y whose indices are listed in indx are referenced.

```
 do i = 1, n
   x(i) = y(indx(i))
   y(indx(i)) = 0
 enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form. Unchanged on exit.

Y (input/output)
Vector in full storage form. Gathered elements are set to zero.

X (output)
Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

```
#include <sunperf.h>

void sgtrfs(char transa, int n, int nrhs, float *low,  float
          *diag, float *up, float *lowf, float *diagf, float
          *upf1, float *upf2, int  *ipivot,  float  *b,  int
          ldb,  float *x, int ldx, float *ferr, float *berr,
          int *info);

void sgtrfs_64(char transa, long n, long nrhs,  float  *low,
          float *diag, float *up, float *lowf, float *diagf,
          float *upf1, float *upf2, long *ipivot, float  *b,
          long  ldb,  float *x, long ldx, float *ferr, float
          *berr, long *info);
```

PURPOSE

sgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)
```

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input)
The (n-1) subdiagonal elements of A.

DIAG (input)
The diagonal elements of A.

UP (input)
The (n-1) superdiagonal elements of A.

LOWF (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

DIAGF (input)
The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input)
The (n-1) elements of the first superdiagonal of U.

UPF2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SGTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE GTSV_64([N], [NRHS], LOW, DIAG, UP, B, [LDB], [INFO])

INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: LOW, DIAG, UP
REAL, DIMENSION(:,:) :: B
```

C INTERFACE

```
#include <sunperf.h>

void sgtsv(int n, int nrhs, float *low, float  *diag,  float
          *up, float *b, int ldb, int *info);
```

```
void sgtsv_64(long n, long nrhs, float  *low,  float  *diag,
          float *up, float *b, long ldb, long *info);
```

PURPOSE

sgtsv solves the equation

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation A'*X = B may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input/output)
On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-2) elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of U.

UP (input/output)
On entry, UP must contain the (n-1) super-diagonal elements of A.

On exit, UP is overwritten by the (n-1) elements of the first super-diagonal of U.

B (input/output)
On entry, the N by NRHS matrix of right hand side

matrix B. On exit, if INFO = 0, the N by NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

          *ipivot,  float  *b, long ldb, float *x, long ldx,
          float  *rcond,  float  *ferr,  float  *berr,  long
          *info);
```

PURPOSE

sgtsvx uses the LU factorization to compute the solution to a real system of linear equations A * X = B or A**T * X = B, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the

matrix A
as A = L * U, where L is a product of permutation and unit lower
bidiagonal matrices and U is upper triangular with nonzeros in
only the main diagonal and first two superdiagonals.

2. If some U(i,i)=0, so that U is exactly singular, then the routine
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A. If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.
3. The system of equations is solved for X using the factored form
of A.

4. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': LOWF, DIAGF, UPF1, UPF2, and IPIVOT contain the factored form of A; LOW, DIAG, UP, LOWF, DIAGF, UPF1, UPF2 and IPIVOT will not be modified. = 'N': The matrix will be copied to LOWF, DIAGF, and UPF1 and factored.

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input)
The (n-1) subdiagonal elements of A.

DIAG (input)
The n diagonal elements of A.

UP (input/output)
The (n-1) superdiagonal elements of A.

LOWF (input/output)
If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAGF (input/output)
If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input/output)
If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

UPF2 (input/output)
If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIVOT (input/output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each

solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: LOW, DIAG, UP1, UP2
```

C INTERFACE

```
#include <sunperf.h>

void sgttrf(int n, float  *low,  float  *diag,  float  *up1,
          float *up2, int *ipivot, int *info);

void sgttrf_64(long n, float *low, float *diag, float  *up1,
          float *up2, long *ipivot, long *info);
```

PURPOSE

sgttrf computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form
   A = L * U
where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)
On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)
On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)
On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

   sgttrs solves one of the systems of equations
      A*X = B  or  A'*X = B, with a tridiagonal matrix A  using
   the LU factorization computed by SGTTRF.
```

ARGUMENTS

```
   TRANSA (input)
             Specifies the form of the system of equations.   =
             'N':  A * X = B  (No transpose)
             = 'T':  A'* X = B  (Transpose)
             = 'C':  A'* X = B  (Conjugate  transpose  =  Tran-
             spose)

             TRANSA is defaulted to 'N' for F95 INTERFACE.

   N (input) The order of the matrix A.

   NRHS (input)
             The number of right hand sides, i.e.,  the  number
             of columns of the matrix B.  NRHS >= 0.

   LOW (input)
             The (n-1) multipliers that  define  the  matrix  L
             from the LU factorization of A.

   DIAG (input)
             The n diagonal elements of  the  upper  triangular
```

matrix U from the LU factorization of A.

UP1 (input)
The (n-1) elements of the first super-diagonal of U.

UP2 (input)
The (n-2) elements of the second super-diagonal of U.

IPIVOT (input)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input/output)
On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

```

PURPOSE

shgeqz implements a single-/double-shift version of the QZ method for finding the generalized eigenvalues B is upper triangular, and A is block upper triangular, where the diagonal blocks are either 1-by-1 or 2-by-2, the 2-by-2 blocks having complex generalized eigenvalues (see the description of the argument JOB.)

If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form by applying one orthogonal tranformation (usually called Q) on the left and another (usually called Z) on the right. The 2-by-2 upper-triangular diagonal blocks of B corresponding to 2-by-2 blocks of A will be reduced to positive diagonal matrices. (I.e., if A(j+1,j) is non-zero, then B(j+1,j)=B(j,j+1)=0 and B(j,j) and B(j+1,j+1) will be positive.)

If JOB='E', then at each iteration, the same transformations are computed, but they are only applied to those parts of A and B which are needed to compute ALPHAR, ALPHAI, and BETAR.

If JOB='S' and COMPQ and COMPZ are 'V' or 'I', then the orthogonal transformations used to reduce (A,B) are accumu-

lated into the arrays Q and Z s.t.:
(in) A(in) Z(in)* = Q(out) A(out) Z(out)*

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrixigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

JOB (input)
= 'E': compute only ALPHAR, ALPHAI, and BETA. A and B will not necessarily be put into generalized Schur form. = 'S': put A and B into generalized Schur form, as well as computing ALPHAR, ALPHAI, and BETA.

COMPQ (input)
= 'N': do not modify Q.
= 'V': multiply the array Q on the right by the transpose of the orthogonal tranformation that is applied to the left side of A and B to reduce them to Schur form. = 'I': like COMPQ='V', except that Q will be initialized to the identity first.

COMPZ (input)
= 'N': do not modify Z.
= 'V': multiply the array Z on the right by the orthogonal tranformation that is applied to the right side of A and B to reduce them to Schur form. = 'I': like COMPZ='V', except that Z will be initialized to the identity first.

N (input) The order of the matrices A, B, Q, and Z. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description of ILO.

A (input) On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to generalized Schur form. If JOB='E', then on exit A will have been destroyed. The diagonal blocks will be correct, but the off-diagonal portion will be meaningless.

LDA (input)
The leading dimension of the array A. LDA >= max(1, N).

B (input) On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. 2-by-2 blocks in B corresponding to 2-by-2 blocks in A will be reduced to positive diagonal form. (I.e., if A(j+1,j) is non-zero, then B(j+1,j)=B(j,j+1)=0 and B(j,j) and B(j+1,j+1) will be positive.) If JOB='S', then on exit A and B will have been simultaneously reduced to Schur form. If JOB='E', then on exit B will have been destroyed. Elements corresponding to diagonal blocks of A will be correct, but the off-diagonal portion will be meaningless.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

ALPHAR (output)
ALPHAR(1:N) will be set to real parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then ALPHAR(j)=A(j,j). Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB.

ALPHAI (output)
ALPHAI(1:N) will be set to imaginary parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then ALPHAR(j)=0. Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB.

BETA (output)

BETA(1:N) will be set to the (real) diagonal elements of B that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then BETA(j)=B(j,j). Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB. (Note that BETA(1:N) will always be non-negative, and no BETAI is necessary.)

Q (input/output)

If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the transpose of the orthogonal transformations which are applied to A and B on the left will be applied to the array Q on the right.

LDQ (input)

The leading dimension of the array Q. LDQ >= 1. If COMPQ='V' or 'I', then LDQ >= N.

Z (input/output)

If COMPZ='N', then Z will not be referenced. If COMPZ='V' or 'I', then the orthogonal transformations which are applied to A and B on the right will be applied to the array Z on the right.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1. If COMPZ='V' or 'I', then LDZ >= N.

WORK (workspace)

On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an ille-

gal value
= 1,...,N: the QZ iteration did not converge. (A,B) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (A,B) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO-N+1,...,N should be correct. > 2*N: various "impossible" errors.

FURTHER DETAILS

```
Iteration counters:

C INTERFACE

```
#include <sunperf.h>
void shsein(char side, char eigsrc, char initv, int *select,
          int  n,  float  *h, int ldh, float *wr, float *wi,
          float *vl, int ldvl, float *vr, int ldvr, int  mm,
          int *m, int *ifaill, int *ifailr, int *info);

void shsein_64(char side,  char  eigsrc,  char  initv,  long
          *select,  long  n,  float *h, long ldh, float *wr,
          float *wi, float *vl, long ldvl, float  *vr,  long
          ldvr,   long  mm,  long  *m,  long  *ifaill,  long
          *ifailr, long *info);
```

PURPOSE

shsein uses inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

```
             H * x = w * x,     y**h * H = w * y**h
```

where y**h denotes the conjugate transpose of the vector y.

ARGUMENTS

```
SIDE (input)
          = 'R': compute right eigenvectors only;
          = 'L': compute left eigenvectors only;
          = 'B': compute both right and left eigenvectors.

EIGSRC (input)
          Specifies the source of  eigenvalues  supplied  in
```

(WR,WI):
= 'Q': the eigenvalues were found using SHSEQR; thus, if H has zero subdiagonal elements, and so is block-triangular, then the j-th eigenvalue can be assumed to be an eigenvalue of the block containing the j-th row/column. This property allows SHSEIN to perform inverse iteration on just one diagonal block. = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, SHSEIN must always perform inverse iteration using the whole matrix H.

INITV (input)
= 'N': no initial vectors are supplied;
= 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT (input/output)
Specifies the eigenvectors to be computed. To select the real eigenvector corresponding to a real eigenvalue WR(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex eigenvalue (WR(j),WI(j)), with complex conjugate (WR(j+1),WI(j+1)), either SELECT(j) or SELECT(j+1) or both must be set to

N (input) The order of the matrix H. N >= 0.

H (input) The upper Hessenberg matrix H.

LDH (input)
The leading dimension of the array H. LDH >= max(1,N).

WR (input/output)
On entry, the real and imaginary parts of the eigenvalues of H; a complex conjugate pair of eigenvalues must be stored in consecutive elements of WR and WI. On exit, WR may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

WI (input)
See the description of WR.

VL (input/output)
On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same

column(s) in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR required to store the eigenvectors; each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)
dimension((N+2)*N)

IFAILL (output)
If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the

left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VL hold a complex eigenvector, then IFAILL(i) and IFAILL(i+1) are set to the same value. If SIDE = 'R', IFAILL is not referenced.

IFAILR (output)

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VR hold a complex eigenvector, then IFAILR(i) and IFAILR(i+1) are set to the same value. If SIDE = 'L', IFAILR is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

FURTHER DETAILS

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x|+|y|.

    REAL, DIMENSION(:,:) :: H, Z
```

C INTERFACE

```
    #include <sunperf.h>

    void shseqr(char job, char compz, int n, int ilo,  int  ihi,
              float *h, int ldh, float *wr, float *wi, float *z,
              int ldz, int *info);
    void shseqr_64(char job, char compz, long n, long ilo,  long
              ihi,  float  *h,  long  ldh, float *wr, float *wi,
              float *z, long ldz, long *info);
```

PURPOSE

shseqr computes the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition H = Z T Z**T, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q, so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q: A = Q*H*Q**T = (QZ)*T*(QZ)**T.

ARGUMENTS

JOB (input)
= 'E': compute eigenvalues only;
= 'S': compute eigenvalues and the Schur form T.

COMPZ (input)
= 'N': no Schur vectors are computed;
= 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an orthogonal matrix Q on entry, and the product Q*Z is returned.

N (input) The order of the matrix H. N >= 0.

ILO (input)

It is assumed that H is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL, and then passed to SGEHRD when the matrix output by SGEBAL is reduced to Hessenberg form. Otherwise ILO and IHI should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description of ILO.

H (input/output)
On entry, the upper Hessenberg matrix H. On exit, if JOB = 'S', H contains the upper quasi-triangular matrix T from the Schur decomposition (the Schur form); 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1) < 0. If JOB = 'E', the contents of H are unspecified on exit.

LDH (input)
The leading dimension of the array H. LDH >= max(1,N).

WR (output)
The real and imaginary parts, respectively, of the computed eigenvalues. If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of WR and WI, say the i-th and (i+1)th, with WI(i) > 0 and WI(i+1) < 0. If JOB = 'S', the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in H, with WR(i) = H(i,i) and, if H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) = sqrt(H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

WI (output)
See the description of WR.

Z (input) If COMPZ = 'N': Z is not referenced.
If COMPZ = 'I': on entry, Z need not be set, and on exit, Z contains the orthogonal matrix Z of the Schur vectors of H. If COMPZ = 'V': on entry Z must contain an N-by-N matrix Q, which is assumed to be equal to the unit matrix except for the submatrix Z(ILO:IHI,ILO:IHI); on exit Z contains Q*Z. Normally Q is the orthogonal matrix generated by SORGHR after the call to SGEHRD which formed the

Hessenberg matrix H.

LDZ (input)
The leading dimension of the array Z. LDZ >= max(1,N) if COMPZ = 'I' or 'V'; LDZ >= 1 otherwise.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, SHSEQR failed to compute all of the eigenvalues in a total of 30*(IHI-ILO+1) iterations; elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed.

Contents

NAME

```
sinqb - synthesize a Fourier sequence from  its  representa-
tion  in  terms of a sine series with odd wave numbers.  The
SINQ operations are unnormalized inverses of themselves,  so
a  call  to  SINQF followed by a call to SINQB will multiply
the input sequence by 4 * N.
```

SYNOPSIS

```
SUBROUTINE SINQB(N, X, WSAVE)

INTEGER N
REAL X(*), WSAVE(*)

SUBROUTINE SINQB_64(N, X, WSAVE)

INTEGER*8 N
REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQB(N, X, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE SINQB_64(N, X, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void sinqb(int n, float *x, float *wsave);
```

```
void sinqb_64(long n, float *x, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. On exit, the quarter-wave sine synthesis of the input.

WSAVE (input)
On entry, an array with dimension of at least (3 * N + 15) for scalar subroutines, initialized by SINQI.

Contents

NAME

```
sinqf - compute the Fourier coefficients in  a  sine  series
representation  with only odd wave numbers.  The SINQ opera-
tions are unnormalized inverses of themselves, so a call  to
SINQF  followed  by  a call to SINQB will multiply the input
sequence by 4 * N.
```

SYNOPSIS

```
SUBROUTINE SINQF(N, X, WSAVE)

INTEGER N
REAL X(*), WSAVE(*)

SUBROUTINE SINQF_64(N, X, WSAVE)

INTEGER*8 N
REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQF(N, X, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE SINQF_64(N, X, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void sinqf(int n, float *x, float *wsave);
```

```
void sinqf_64(long n, float *x, float *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence   to   be   transformed.   On  exit,  the
          quarter-wave sine transform of the input.
WSAVE (input)
          On entry, an array with dimension of at least   (3
          *  N  + 15) for scalar subroutines, initialized by
          SINQI.
```

Contents

NAME

```
sinqi - initialize the array xWSAVE, which is used  in  both
SINQF and SINQB.
```

SYNOPSIS

```
SUBROUTINE SINQI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE SINQI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE SINQI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void sinqi(int n, float *wsave);

void sinqi_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array of dimension (3 * N + 15) or greater. SINQI needs to be called only once to initialize WSAVE before calling SINQF and/or SINQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

```
sint - compute the discrete Fourier sine transform of an odd
sequence.   The SINT transforms are unnormalized inverses of
themselves, so a call of SINT followed by  another  call  of
SINT will multiply the input sequence by 2 * (N+1).
```

SYNOPSIS

```
SUBROUTINE SINT(N, X, WSAVE)

INTEGER N
REAL X(*), WSAVE(*)

SUBROUTINE SINT_64(N, X, WSAVE)

INTEGER*8 N
REAL X(*), WSAVE(*)
```

F95 INTERFACE

REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void sint(int n, float *x, float *wsave);
```

```
void sint_64(long n, float *x, float *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines  are most efficient when N+1 is a pro-
          duct of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence  to  be  transformed.   On exit, the sine
          transform of the input.
WSAVE (input/output)
          On entry, an array  with  dimension  of  at  least
          int(2.5 * N + 15) initialized by SINTI.
```

Contents

NAME

```
sinti - initialize the array WSAVE, which is used in subrou-
tine SINT.
```

SYNOPSIS

```
SUBROUTINE SINTI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE SINTI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINTI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE SINTI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void sinti(int n, float *wsave);

void sinti_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input/output)
On entry, an array of dimension (2N + N/2 + 15) or greater. SINTI is called once to initialize WSAVE before calling SINT and need not be called again between calls to SINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

 INTEGER*8     TRANSA, M, K, MAXNZ
 INTEGER*8, DIMENSION(:) ::  DESCRA, INDX, PNTR, IPERM
 REAL    ALPHA, BETA
 REAL, DIMENSION(:) ::  VAL
 REAL, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in jagged-diagonal format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
```

```
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

VAL()           array of length NNZ consisting of entries of A.
                VAL can be viewed as a column major ordering of a
                row permutation of the Ellpack representation of A,
                where the Ellpack representation is permuted so that
                the rows are non-increasing in the number of nonzero
                entries.  Values added for padding in Ellpack are
                not included in the Jagged-Diagonal format.

INDX()          array of length NNZ consisting of the column indices
                of the corresponding entries in VAL.
PNTR()          array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
                points to the location in VAL of the first element
                in the row-permuted Ellpack represenation of A.

MAXNZ           max number of nonzeros elements per row.

IPERM()         integer array of length M such that I = IPERM(I'),
                where row I in the original Ellpack representation
                corresponds to row I' in the permuted representation.
                If IPERM(1) = 0, it is assumed by convention that
                IPERM(I) = I. IPERM is used to determine the order
                in which rows of C are updated.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK. WORK is not
                referenced in the current version.

LWORK           length of WORK array. LWORK is not referenced
                in the current version.

NAME

sjadrp - right permutation of a jagged diagonal matrix

SYNOPSIS

```
 SUBROUTINE SJADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, WORK, LWORK )
 INTEGER    TRANSP, M, K, MAXNZ, LWORK
 INTEGER    INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
 REAL       VAL(*)

 SUBROUTINE SJADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, WORK, LWORK )
 INTEGER*8  TRANSP, M, K, MAXNZ, LWORK
 INTEGER*8  INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
 REAL       VAL(*)
```

F95 INTERFACE

```
 SUBROUTINE JADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
 INTEGER TRANSP, M, K,  MAXNZ
 INTEGER, DIMENSION(:) :: INDX, PNTR, IPERM
 REAL, DIMENSION(:) :: VAL

 SUBROUTINE JADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
 INTEGER*8 TRANSP, M, K,  MAXNZ
 INTEGER*8, DIMENSION(:) :: INDX, PNTR, IPERM
 REAL, DIMENSION(:) :: VAL
```

DESCRIPTION

```
A <- A P
A <- A P'
                                   ( ' indicates matrix transpose)
```

where permutation P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symetrically permuted jagged diagonal matrix P A P', one can explicitly permute the columns P A by calling

```
   SJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP — Indicates how to operate with the permutation matrix
  0 : operate with matrix
  1 : operate with transpose matrix

M — Number of rows in matrix A

K — Number of columns in matrix A

VAL() — array of length PNTR(MAXNZ+1)-PNTR(1) consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format.

INDX() — array of length PNTR(MAXNZ+1)-PNTR(1) consisting of the column indices of the corresponding entries in VAL.

PNTR() — array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack represenation of A.

MAXNZ — max number of nonzeros elements per row.

IPERM() — integer array of length K such that I = IPERM(I').

```
                 Array IPERM represents a permutation P, such that
                 IPERM(I) is equal to the position of the only nonzero
                 element in row I of permutation matrix P.
                 For example, if
                                | 0 0 1 |
                            P  =| 1 0 0 |
                                | 0 1 0 |
                 then IPERM = (3, 1, 2).

   WORK()        scratch array of length LWORK.  LWORK should be at
                 least K.

   LWORK         length of WORK array

                 If LWORK = -1, then a workspace query is assumed;
                 the routine only calculates the optimal size of the
                 WORK array, returns this value as the first entry of
                 the WORK array, and no error message related to LWORK
                 is issued by XERBLA.
```

 INTEGER*8    TRANSA, M, MAXNZ
 INTEGER*8, DIMENSION(:) ::  DESCRA, INDX, PNTR, IPERM
 REAL    ALPHA, BETA
 REAL, DIMENSION(:) ::  VAL, DV
 REAL, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in jagged-diagonal format and op(A) is one of

op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          array of length NNZ consisting of entries of A.
               VAL can be viewed as a column major ordering of a
               row permutation of the Ellpack representation of A,
               where the Ellpack representation is permuted so that
               the rows are non-increasing in the number of nonzero
               entries.  Values added for padding in Ellpack are
               not included in the Jagged-Diagonal format.

INDX()         array of length NNZ consisting of the column indices
               of the corresponding entries in VAL.

PNTR()         array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
               points to the location in VAL of the first element
               in the row-permuted Ellpack represenation of A.

MAXNZ          max number of nonzeros elements per row.

IPERM()        integer array of length M such that I = IPERM(I'),
               where row I in the original Ellpack representation
               corresponds to row I' in the permuted representation.
               If IPERM(1)=0,   it's assumed by convention that
               IPERM(I)=I. IPERM is used to determine the order
               in which rows of C are updated.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter
```

```
C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.
               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK          length of WORK array.  LWORK should be at least 2*M.

               For good performance, LWORK should generally be larger.
               For optimum performance on multiple processors, LWORK
               >=2*M*N_CPUS where N_CPUS is the maximum number of
               processors available to the program.

               If LWORK=0, the routine is to allocate workspace needed.

               If LWORK = -1, then a workspace query is assumed; the
               routine only calculates the optimum size of the WORK
               array, returns this value as the first entry of the WORK
               array, and no error message related to LWORK is issued
               by XERBLA.
```

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the JAD representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the JAD representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

NAME

```
slagtf - factorize the matrix (T-lambda*I), where T is an  n
by  n  tridiagonal  matrix  and  lambda  is  a scalar, as T-
lambda*I = PLU
```

SYNOPSIS

```
SUBROUTINE SLAGTF(N, A, LAMBDA, B, C, TOL, D, IN, INFO)

INTEGER N, INFO
INTEGER IN(*)
REAL LAMBDA, TOL
REAL A(*), B(*), C(*), D(*)

SUBROUTINE SLAGTF_64(N, A, LAMBDA, B, C, TOL, D, IN, INFO)

INTEGER*8 N, INFO
INTEGER*8 IN(*)
REAL LAMBDA, TOL
REAL A(*), B(*), C(*), D(*)
```

F95 INTERFACE

```
SUBROUTINE LAGTF([N], A, LAMBDA, B, C, TOL, D, IN, [INFO])

INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IN
REAL :: LAMBDA, TOL
REAL, DIMENSION(:) :: A, B, C, D

SUBROUTINE LAGTF_64([N], A, LAMBDA, B, C, TOL, D, IN, [INFO])

INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IN
```

```
REAL :: LAMBDA, TOL
REAL, DIMENSION(:) :: A, B, C, D
```

C INTERFACE

```
#include <sunperf.h>

void slagtf(int n, float *a, float lambda, float  *b,  float
          *c, float tol, float *d, int *in, int *info);

void slagtf_64(long n, float *a,  float  lambda,  float  *b,
          float  *c,  float  tol,  float  *d, long *in, long
          *info);
```

PURPOSE

slagtf factorizes the matrix (T - lambda*I), where T is an n by n tridiagonal matrix and lambda is a scalar, as where P is a permutation matrix, L is a unit lower tridiagonal matrix with at most one non-zero sub-diagonal elements per column and U is an upper triangular matrix with at most two non-zero super-diagonal elements per column.

The factorization is obtained by Gaussian elimination with partial pivoting and implicit row scaling.

The parameter LAMBDA is included in the routine so that SLAGTF may be used, in conjunction with SLAGTS, to obtain eigenvectors of T by inverse iteration.

ARGUMENTS

N (input) The order of the matrix T.

A (input/output)
On entry, A must contain the diagonal elements of T.

On exit, A is overwritten by the n diagonal elements of the upper triangular matrix U of the factorization of T.

LAMBDA (input)
On entry, the scalar lambda.

B (input/output)
On entry, B must contain the (n-1) super-diagonal elements of T.

On exit, B is overwritten by the (n-1) super-diagonal elements of the matrix U of the factorization of T.

C (input/output)

On entry, C must contain the (n-1) sub-diagonal elements of T.

On exit, C is overwritten by the (n-1) sub-diagonal elements of the matrix L of the factorization of T.

TOL (input/output)

On entry, a relative tolerance used to indicate whether or not the matrix (T - lambda*I) is nearly singular. TOL should normally be chose as approximately the largest relative error in the elements of T. For example, if the elements of T are correct to about 4 significant figures, then TOL should be set to about 5*10**(-4). If TOL is supplied as less than eps, where eps is the relative machine precision, then the value eps is used in place of TOL.

D (output)

On exit, D is overwritten by the (n-2) second super-diagonal elements of the matrix U of the factorization of T.

IN (output)

On exit, IN contains details of the permutation matrix P. If an interchange occurred at the kth step of the elimination, then IN(k) = 1, otherwise IN(k) = 0. The element IN(n) returns the smallest positive integer j such that

abs(u(j,j)).le. norm((T - lambda*I)(j))*TOL,

where norm(A(j)) denotes the sum of the absolute values of the jth row of the matrix A. If no such j exists then IN(n) is returned as zero. If IN(n) is returned as positive, then a diagonal element of U is small, indicating that (T - lambda*I) is singular or nearly singular,

INFO (output)

= 0 : successful exit

INTEGER*8 N1, N2, TRD1, TRD2
INTEGER*8 INDEX(*)
REAL A(*)
```

F95 INTERFACE

```
SUBROUTINE LAMRG(N1, N2, A, TRD1, TRD2, INDEX)

INTEGER :: N1, N2, TRD1, TRD2
INTEGER, DIMENSION(:) :: INDEX
REAL, DIMENSION(:) :: A

SUBROUTINE LAMRG_64(N1, N2, A, TRD1, TRD2, INDEX)

INTEGER(8) :: N1, N2, TRD1, TRD2
INTEGER(8), DIMENSION(:) :: INDEX
REAL, DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void slamrg(int n1, int n2, float *a, int  trd1,  int  trd2,
          int *index);

void slamrg_64(long n1, long n2, float *a, long  trd1,  long
          trd2, long *index);
```

PURPOSE

slamrg will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order.

ARGUMENTS

N1 (input)
Length of the first sequence to be merged.

N2 (input)
Length of the second sequence to be merged.

A (input) On entry, the first N1 elements of A contain a list of numbers which are sorted in either ascending or descending order. Likewise for the final N2 elements.

TRD1 (input)
Describes the stride to be taken through the array A for the first N1 elements.
= -1 subset is sorted in descending order.
= 1 subset is sorted in ascending order.

TRD2 (input)
Describes the stride to be taken through the array A for the first N1 elements.
= -1 subset is sorted in descending order.
= 1 subset is sorted in ascending order.

INDEX (output)
On exit this array will contain a permutation such that if B(I) = A(INDEX(I)) for I=1,N1+N2, then B will be sorted in ascending order.

NAME

slarz - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right

SYNOPSIS

```
SUBROUTINE SLARZ(SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)

CHARACTER * 1 SIDE
INTEGER M, N, L, INCV, LDC
REAL TAU
REAL V(*), C(LDC,*), WORK(*)

SUBROUTINE SLARZ_64(SIDE, M, N, L, V, INCV, TAU, C, LDC, WORK)

CHARACTER * 1 SIDE
INTEGER*8 M, N, L, INCV, LDC
REAL TAU
REAL V(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE LARZ(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])

CHARACTER(LEN=1) :: SIDE
INTEGER :: M, N, L, INCV, LDC
REAL :: TAU
REAL, DIMENSION(:) :: V, WORK
REAL, DIMENSION(:,:) :: C

SUBROUTINE LARZ_64(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])

CHARACTER(LEN=1) :: SIDE
```

```
INTEGER(8) :: M, N, L, INCV, LDC
REAL :: TAU
REAL, DIMENSION(:) :: V, WORK
REAL, DIMENSION(:,:) :: C
```

C INTERFACE

```
#include <sunperf.h>

void slarz(char side, int m, int n, int  l,  float  *v,  int
          incv, float tau, float *c, int ldc);

void slarz_64(char side, long m, long n, long l,  float  *v,
          long incv, float tau, float *c, long ldc);
```

PURPOSE

slarz applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right. H is represented in the form

H = I - tau * v * v'

where tau is a real scalar and v is a real vector.

If tau = 0, then H is taken to be the unit matrix.

H is a product of k elementary reflectors as returned by STZRZF.

ARGUMENTS

SIDE (input)
= 'L': form H * C
= 'R': form C * H

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

L (input) The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V (input) The vector v in the representation of H as returned by STZRZF. V is not used if TAU = 0.

INCV (input)
The increment between elements of v. INCV <> 0.

TAU (input)
The value tau in the representation of H.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
(N) if SIDE = 'L' or (M) if SIDE = 'R'

FURTHER DETAILS

Based on contributions by
A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

Contents

NAME

```
slarzb - applies a real block reflector H or  its  transpose
H**T  to  a  real  distributed M-by-N C from the left or the
right
```

SYNOPSIS

```
SUBROUTINE SLARZB(SIDE, TRANS, DIRECT, STOREV, M, N, K, L, V, LDV, T,
      LDT, C, LDC, WORK, LDWORK)

```

```
CHARACTER(LEN=1) :: SIDE, TRANS, DIRECT, STOREV
INTEGER(8) :: M, N, K, L, LDV, LDT, LDC, LDWORK
REAL, DIMENSION(:,:) :: V, T, C, WORK
```

C INTERFACE

```
#include <sunperf.h>

void slarzb(char side, char trans, char direct, char storev,
          int  m,  int  n,  int k, int l, float *v, int ldv,
          float *t, int ldt, float *c, int ldc, int ldwork);

void slarzb_64(char side,  char  trans,  char  direct,  char
          storev,  long m, long n, long k, long l, float *v,
          long ldv, float *t, long ldt, float *c, long  ldc,
          long ldwork);
```

PURPOSE

slarzb applies a real block reflector H or its transpose H**T to a real distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

SIDE (input)
= 'L': apply H or H' from the Left
= 'R': apply H or H' from the Right

TRANS (input)
= 'N': apply H (No transpose)
= 'C': apply H' (Transpose)

DIRECT (input)
Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet)
= 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV (input)
Indicates how the vectors which define the elementary reflectors are stored:
= 'C': Columnwise (not supported yet)
= 'R': Rowwise

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

K (input) The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L (input) The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V (input) If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV (input)
The leading dimension of the array V. If STOREV = 'C', LDV >= L; if STOREV = 'R', LDV >= K.

T (input) The triangular K-by-K matrix T in the representation of the block reflector.

LDT (input)
The leading dimension of the array T. LDT >= K.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by H*C or H'*C or C*H or C*H'.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
dimension(MAX(M,N),K)

LDWORK (input)
The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1,N); if SIDE = 'R', LDWORK >= max(1,M).

NAME

slarzt - form the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors

SYNOPSIS

```
SUBROUTINE SLARZT(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)

CHARACTER * 1 DIRECT, STOREV
INTEGER N, K, LDV, LDT
REAL V(LDV,*), TAU(*), T(LDT,*)

SUBROUTINE SLARZT_64(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)

CHARACTER * 1 DIRECT, STOREV
INTEGER*8 N, K, LDV, LDT
REAL V(LDV,*), TAU(*), T(LDT,*)
```

F95 INTERFACE

```
SUBROUTINE LARZT(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])

CHARACTER(LEN=1) :: DIRECT, STOREV
INTEGER :: N, K, LDV, LDT
REAL, DIMENSION(:) :: TAU
REAL, DIMENSION(:,:) :: V, T

SUBROUTINE LARZT_64(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])

CHARACTER(LEN=1) :: DIRECT, STOREV
INTEGER(8) :: N, K, LDV, LDT
REAL, DIMENSION(:) :: TAU
```

```
REAL, DIMENSION(:,:) :: V, T
```

C INTERFACE

```
#include <sunperf.h>

void slarzt(char direct, char storev, int n,  int  k,  float
          *v, int ldv, float *tau, float *t, int ldt);

void slarzt_64(char direct, char storev,  long  n,  long  k,
          float  *v,  long  ldv,  float *tau, float *t, long
          ldt);
```

PURPOSE

slarzt forms the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

H = I - V * T * V'

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

H = I - V' * T * V

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

DIRECT (input)
Specifies the order in which the elementary reflectors are multiplied to form the block reflector:
= 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet)
= 'B': H = H(k) . . . H(2) H(1) (Backward)

```
STOREV (input)
          Specifies how the vectors which define the elemen-
          tary  reflectors  are  stored  (see  also  Further
          Details):
          = 'R': rowwise

N (input) The order of the block reflector H. N >= 0.

K (input) The order of the triangular factor T (= the number
          of elementary reflectors). K >= 1.

V (input) (LDV,K) if STOREV = 'C' (LDV,N) if  STOREV  =  'R'
          The matrix V. See further details.

LDV (input)
          The leading dimension of the array V.  If STOREV =
          'C', LDV >= max(1,N); if STOREV = 'R', LDV >= K.

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i).

T (input) The k by  k  triangular  factor  T  of  the  block
          reflector.   If  DIRECT = 'F', T is upper triangu-
          lar; if DIRECT = 'B', T is lower  triangular.  The
          rest of the array is not used.

LDT (input)
          The leading dimension of the array T. LDT >= K.
```

FURTHER DETAILS

```
Based on contributions by
  A. Petitet, Computer Science Dept., Univ. of Tenn.,  Knox-
ville, USA

The shape of the matrix V and the  storage  of  the  vectors
which  define  the H(i) is best illustrated by the following
example with n = 5 and k = 3. The elements equal  to  1  are
not  stored;  the  corresponding array elements are modified
but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV =  'C':          DIRECT  =  'F'  and
STOREV = 'R':

                                                    ______V_____
       (    v1    v2    v3    )                                /
( v1 v2 v3 )                        ( v1 v1 v1 v1 v1 . . . . 1
)
   V = ( v1 v2 v3 )                        ( v2 v2 v2 v2 v2  .
```

```
. . 1   )
       ( v1 v2 v3 )                       ( v3 v3 v3 v3 v3  .
. 1     )
       ( v1 v2 v3 )
          .  .  .
          1  .  .
             1  .
                1

DIRECT = 'B' and STOREV =  'C':          DIRECT  =  'B'  and
STOREV = 'R':

                                                    ______V_____
          1                                              /
.  1                          ( 1 . . . . v1 v1 v1 v1 v1 )
          .  .  1                         ( . 1 . . .  v2  v2
v2 v2 v2 )
          .  .  .                         ( . . 1 . .  v3  v3
v3 v3 v3 )
          .  .  .
       ( v1 v2 v3 )
    V = ( v1 v2 v3 )
       ( v1 v2 v3 )

```

C INTERFACE

```
#include <sunperf.h>
```

```
void slasrt(char id, int n, float *d, int *info);

void slasrt_64(char id, long n, float *d, long *info);
```

PURPOSE

```
slasrt the numbers in D in increasing order (if ID = 'I') or
in decreasing order (if ID = 'D' ).

Use Quick Sort, reverting to Insertion sort on arrays of
size <= 20. Dimension of STACK limits N to about 2**32.
```

ARGUMENTS

```
ID (input)
          = 'I': sort D in increasing order;
          = 'D': sort D in decreasing order.

N (input) The length of the array D.

D (input/output)
          On entry, the array to be sorted.  On exit, D  has
          been  sorted into increasing order (D(1) <= ... <=
          D(N) ) or into decreasing order (D(1)  >=  ...  >=
          D(N) ), depending on ID.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

          float tau, float *c1, float *c2, int ldc);

void slatzm_64(char side, long m, long  n,  float  *v,  long
          incv, float tau, float *c1, float *c2, long ldc);
```

PURPOSE

```
slatzm routine is deprecated and has been replaced  by  rou-
tine SORMRZ.

SLATZM applies a Householder matrix generated by STZRQF to a
matrix.

Let P = I - tau*u*u',   u = ( 1 ),
                            ( v )
where v is an (m-1) vector if SIDE = 'L', or a (n-1)  vector
if SIDE = 'R'.

If SIDE equals 'L', let
       C = [ C1 ] 1
           [ C2 ] m-1
             n
Then C is overwritten by P*C.

If SIDE equals 'R', let
       C = [ C1, C2 ] m
              1  n-1
Then C is overwritten by C*P.
```

ARGUMENTS

```
SIDE (input)
          = 'L': form P * C
          = 'R': form C * P

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.
```

V (input) (1 + (M-1)*abs(INCV)) if SIDE = 'L' (1 + (N-1)*abs(INCV)) if SIDE = 'R' The vector v in the representation of P. V is not used if TAU = 0.

INCV (input)
The increment between elements of v. INCV <> 0

TAU (input)
The value tau in the representation of P.

C1 (input/output)
(LDC,N) if SIDE = 'L' (M,1) if SIDE = 'R' On entry, the n-vector C1 if SIDE = 'L', or the m-vector C1 if SIDE = 'R'.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

C2 (input/output)
(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

LDC (input)
The leading dimension of the arrays C1 and C2. LDC >= (1,M).

WORK (workspace)
(N) if SIDE = 'L' (M) if SIDE = 'R'

Contents

NAME

```
snrm2 - Return the Euclidian norm of a vector.
```

SYNOPSIS

```
REAL FUNCTION SNRM2(N, X, INCX)

INTEGER N, INCX
REAL X(*)

REAL FUNCTION SNRM2_64(N, X, INCX)

INTEGER*8 N, INCX
REAL X(*)
```

F95 INTERFACE

```
REAL FUNCTION NRM2([N], X, [INCX])

INTEGER :: N, INCX
REAL, DIMENSION(:) :: X

REAL FUNCTION NRM2_64([N], X, [INCX])

INTEGER(8) :: N, INCX
REAL, DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>

float snrm2(int n, float *x, int incx);

float snrm2_64(long n, float *x, long incx);
```

PURPOSE

snrm2 Return the Euclidian norm of a vector x where x is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must be positive. Unchanged on exit.

REAL, DIMENSION(:,:) :: C
```

C INTERFACE

```
#include <sunperf.h>

void sopmtr(char side, char uplo, char trans, int m, int  n,
          float  *ap,  float  *tau,  float  *c, int ldc, int
          *info);

void sopmtr_64(char side, char uplo,  char  trans,  long  m,
          long n, float *ap, float *tau, float *c, long ldc,
          long *info);
```

PURPOSE

sopmtr overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by SSPTRD using packed storage:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

UPLO (input)
= 'U': Upper triangular packed storage used in previous call to SSPTRD; = 'L': Lower triangular packed storage used in previous call to SSPTRD.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

AP (input)
(M*(M+1)/2) if SIDE = 'L' (N*(N+1)/2) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SSPTRD. AP is modified by the routine but restored on exit.

TAU (input)
or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SSPTRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
(N) if SIDE = 'L' (M) if SIDE = 'R'

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
#include <sunperf.h>

void sorg2l(int m, int n, int k, float *a,  int  lda,  float
```

```
          *tau, int *info);

void sorg2l_64(long m, long n, long k, float *a,  long  lda,
          float *tau, long *info);
```

PURPOSE

sorg2l L generates an m by n real matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

```
      Q  =  H(k) . . . H(2) H(1)
```

as returned by SGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)
On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGEQLF in the last k columns of its array argument A. On exit, the m by n matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument has an illegal value

```

F95 INTERFACE

```
SUBROUTINE ORGBR(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: VECT
INTEGER :: M, N, K, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE ORGBR_64(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: VECT
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

```
    REAL, DIMENSION(:) :: TAU, WORK
    REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
    #include <sunperf.h>

    void sorgbr(char vect, int m, int n, int k,  float  *a,  int
              lda, float *tau, int *info);

    void sorgbr_64(char vect, long m, long n, long k, float  *a,
              long lda, float *tau, long *info);
```

PURPOSE

```
    sorgbr generates one of the real orthogonal  matrices  Q  or
    P**T  determined  by SGEBRD when reducing a real matrix A to
    bidiagonal form: A = Q * B * P**T.  Q and P**T  are  defined
    as  products  of  elementary reflectors H(i) or G(i) respec-
    tively.

    If VECT = 'Q', A is assumed to have been an  M-by-K  matrix,
    and Q is of order M:
    if m >= k, Q = H(1) H(2) . . . H(k) and SORGBR  returns  the
    first n columns of Q, where m >= n >= k;
    if m < k, Q = H(1) H(2) . . . H(m-1) and SORGBR returns Q as
    an M-by-M matrix.

    If VECT = 'P', A is assumed to have been  a  K-by-N  matrix,
    and P**T is of order N:
    if k < n, P**T = G(k) . . . G(2) G(1) and SORGBR returns the
    first m rows of P**T, where n >= m >= k;
    if k >= n, P**T = G(n-1) . . . G(2) G(1) and SORGBR  returns
    P**T as an N-by-N matrix.
```

ARGUMENTS

```
    VECT (input)
              Specifies whether the matrix Q or the matrix  P**T
              is  required,  as  defined  in  the transformation
              applied by SGEBRD:
              = 'Q':  generate Q;
              = 'P':  generate P**T.

    M (input) The number of rows of the matrix Q or P**T  to  be
              returned.  M >= 0.

    N (input) The number of columns of the matrix Q or  P**T  to
```

be returned. N >= 0. If VECT = 'Q', M >= N >= min(M,K); if VECT = 'P', N >= M >= min(N,K).

K (input) If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by SGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by SGEBRD. K >= 0.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by SGEBRD. On exit, the M-by-N matrix Q or P**T.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (input)
(min(M,K)) if VECT = 'Q' (min(N,K)) if VECT = 'P' TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P**T, as returned by SGEBRD in its array argument TAUQ or TAUP.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,min(M,N)). For optimum performance LWORK >= min(M,N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

sorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD

SYNOPSIS

```
SUBROUTINE SORGHR(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER N, ILO, IHI, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)

SUBROUTINE SORGHR_64(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORGHR([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK], [INFO])

INTEGER :: N, ILO, IHI, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE ORGHR_64([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorghr(int n, int ilo, int  ihi,  float  *a,  int  lda,
          float *tau, int *info);

void sorghr_64(long n, long ilo, long ihi,  float  *a,  long
          lda, float *tau, long *info);
```

PURPOSE

sorghr generates a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

ARGUMENTS

N (input) The order of the matrix Q. N >= 0.

ILO (input)
ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description of ILO.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by SGEHRD. On exit, the N-by-N orthogonal matrix Q.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= IHI-ILO. For optimum performance LWORK >= (IHI-ILO)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

sorgl2 generates an m by n real matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

      Q = H(k) . . . H(2) H(1)

as returned by SGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)
On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGELQF in the first k rows of its array argument A. On exit, the m-by-n matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

PURPOSE

sorglq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the first M rows of a product of K elementary reflectors of order N

```
      Q  =  H(k) . . . H(2) H(1)
```

as returned by SGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)
On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGELQF in the first k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB,

```
          where NB is the optimal blocksize.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.

REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE ORGRQ_64(M, [N], [K], A, [LDA], TAU, [WORK], [LDWORK],
       [INFO])

INTEGER(8) :: M, N, K, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sorgrq(int m, int n, int k, float *a,  int  lda,  float
          *tau, int *info);

void sorgrq_64(long m, long n, long k, float *a,  long  lda,
          float *tau, long *info);
```

PURPOSE

sorgrq generates an M-by-N real matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

      Q = H(1) H(2) . . . H(k)

as returned by SGERQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)
On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB,

where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument has an illegal value

REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE ORGTR_64(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void sorgtr(char uplo, int n, float *a, int lda, float *tau,
          int *info);

void sorgtr_64(char uplo, long n, float *a, long lda,  float
          *tau, long *info);
```

PURPOSE

```
sorgtr generates a real orthogonal matrix Q which is defined
as  the  product of n-1 elementary reflectors of order N, as
returned by SSYTRD:
if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).
```

ARGUMENTS

```
UPLO (input)
          = 'U': Upper triangle  of  A  contains  elementary
          reflectors from SSYTRD; = 'L': Lower triangle of A
          contains elementary reflectors from SSYTRD.

N (input) The order of the matrix Q. N >= 0.

A (input/output)
          On entry, the vectors which define the  elementary
          reflectors,  as  returned by SSYTRD.  On exit, the
          N-by-N orthogonal matrix Q.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,N).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by SSYTRD.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  dimension  of  the  array  WORK.   LWORK   >=
```

max(1,N-1). For optimum performance LWORK >= (N-1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER*8 M, N, K, LDA, LDC, LWORK, INFO
REAL A(LDA,*), TAU(*), C(LDC,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ORMBR(VECT, SIDE, [TRANS], [M], [N], K, A, [LDA], TAU, C,
       [LDC], [WORK], [LWORK], [INFO])

CHARACTER(LEN=1) :: VECT, SIDE, TRANS
INTEGER :: M, N, K, LDA, LDC, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A, C

SUBROUTINE ORMBR_64(VECT, SIDE, [TRANS], [M], [N], K, A, [LDA], TAU,
       C, [LDC], [WORK], [LWORK], [INFO])

CHARACTER(LEN=1) :: VECT, SIDE, TRANS
```

```
INTEGER(8) :: M, N, K, LDA, LDC, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A, C
```

C INTERFACE

```
#include <sunperf.h>

void sormbr(char vect, char side, char trans, int m, int  n,
          int  k,  float  *a, int lda, float *tau, float *c,
          int ldc, int *info);

void sormbr_64(char vect, char side,  char  trans,  long  m,
          long  n,  long  k, float *a, long lda, float *tau,
          float *c, long ldc, long *info);
```

PURPOSE

```
sormbr VECT = 'Q', SORMBR overwrites the general real M-by-N
matrix C with
                SIDE = 'L'      SIDE  =  'R'  TRANS  =  'N':
Q  *  C           C * Q TRANS = 'T':      Q**T * C       C *
Q**T

If VECT = 'P', SORMBR overwrites  the  general  real  M-by-N
matrix C with
                SIDE = 'L'     SIDE = 'R'
TRANS = 'N':      P * C          C * P
TRANS = 'T':      P**T * C       C * P**T
```

Here Q and P**T are the orthogonal matrices determined by SGEBRD when reducing a real matrix A to bidiagonal form: A = Q * B * P**T. Q and P**T are defined as products of elementary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Thus nq is the order of the orthogonal matrix Q or P**T that is applied.

```
If VECT = 'Q', A is assumed to have been an NQ-by-K  matrix:
if nq >= k, Q = H(1) H(2) . . . H(k);
if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a  K-by-NQ  matrix:
if k < nq, P = G(1) G(2) . . . G(k);
if k >= nq, P = G(1) G(2) . . . G(nq-1).
```

ARGUMENTS

```
VECT (input)
          = 'Q': apply Q or Q**T;
          = 'P': apply P or P**T.

SIDE (input)
          = 'L': apply Q, Q**T, P or P**T from the Left;
          = 'R': apply Q, Q**T, P or P**T from the Right.

TRANS (input)
          = 'N':  No transpose, apply Q  or P;
          = 'T':  Transpose, apply Q**T or P**T.

          TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.
N (input) The number of columns of the matrix C. N >= 0.

K (input) If VECT = 'Q', the number of columns in the origi-
          nal  matrix reduced by SGEBRD.  If VECT = 'P', the
          number of rows in the original matrix  reduced  by
          SGEBRD.  K >= 0.

A (input) (LDA,min(nq,K)) if VECT = 'Q'  (LDA,nq)         if
          VECT = 'P' The vectors which define the elementary
          reflectors H(i) and G(i), whose products determine
          the matrices Q and P, as returned by SGEBRD.

LDA (input)
          The leading dimension of the array A.  If  VECT  =
          'Q',  LDA  >=  max(1,nq);  if  VECT  = 'P', LDA >=
          max(1,min(nq,K)).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary  reflector H(i) or G(i) which determines Q
          or P, as returned by SGEBRD in the array  argument
          TAUQ or TAUP.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten  by  Q*C or Q**T*C or C*Q**T or C*Q or
          P*C or P**T*C or C*P or C*P**T.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
```

LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

C INTERFACE

```
#include <sunperf.h>

void sormhr(char side, char trans, int m, int  n,  int  ilo,
          int  ihi, float *a, int lda, float *tau, float *c,
          int ldc, int *info);

void sormhr_64(char side, char trans, long m, long  n,  long
          ilo,  long  ihi,  float  *a, long lda, float *tau,
          float *c, long ldc, long *info);
```

PURPOSE

sormhr overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by SGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

ARGUMENTS

SIDE (input)
- = 'L': apply Q or Q**T from the Left;
- = 'R': apply Q or Q**T from the Right.

TRANS (input)
- = 'N': No transpose, apply Q;
- = 'T': Transpose, apply Q**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

ILO (input)
ILO and IHI must have the same values as in the previous call of SGEHRD. Q is equal to the unit matrix except in the submatrix

Q(ilo+1:ihi,ilo+1:ihi). If SIDE = 'L', then 1 <= ILO <= IHI <= M, if M > 0, and ILO = 1 and IHI = 0, if M = 0; if SIDE = 'R', then 1 <= ILO <= IHI <= N, if N > 0, and ILO = 1 and IHI = 0, if N = 0.

IHI (input)
See the description of ILO.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by SGEHRD.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M) if SIDE = 'L'; LDA >= max(1,N) if SIDE = 'R'.

TAU (input)
(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEHRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value

```

PURPOSE

sormlq overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

      Q = H(k) . . . H(2) H(1)

as returned by SGELQF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGELQF in the first k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)
The leading dimension of the array A. LDA >= max(1,K).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGELQF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGEQLF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

          k,  float *a, long lda, float *tau, float *c, long
          ldc, long *info);
```

PURPOSE

sormqr overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix defined as the product of k elementary reflectors

      Q = H(1) H(2) . . . H(k)

as returned by SGEQRF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

```
A (input) The i-th column  must  contain  the  vector  which
          defines  the  elementary  reflector  H(i), for i =
          1,2,...,k, as returned by SGEQRF in  the  first  k
          columns of its array argument A.  A is modified by
          the routine but restored on exit.

LDA (input)
          The leading dimension of the array A.  If  SIDE  =
          'L',  LDA  >=  max(1,M);  if  SIDE  =  'R', LDA >=
          max(1,N).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by SGEQRF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

```

PURPOSE

sormrq overwrites the general real M-by-N matrix C with
TRANS = 'T':   Q**T * C   C * Q**T

where Q is a real orthogonal matrix defined as the product
of k elementary reflectors

      Q = H(1) H(2) . . . H(k)

as returned by SGERQF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**T from the Left;
= 'R': apply Q or Q**T from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'T': Transpose, apply Q**T.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', M >= K >= 0;
if SIDE = 'R', N >= K >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by SGERQF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)
The leading dimension of the array A. LDA >= max(1,K).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by SGERQF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**T*C or C*Q**T or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void spbcon(char uplo, int n, int kd,  float  *a,  int  lda,
          float anorm, float *rcond, int *info);

void spbcon_64(char uplo, long n, long kd,  float  *a,  long
          lda, float anorm, float *rcond, long *info);
```

PURPOSE

spbcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangular factor stored in A;
= 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO ='U', A(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', A(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

ANORM (input)
The 1-norm (or infinity-norm) of the symmetric band matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

spbequ computes row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

```
    UPLO (input)
              = 'U':  Upper triangular of A is stored;
              = 'L':  Lower triangular of A is stored.

    N (input) The order of the matrix A.  N >= 0.

    KD (input)
              The number of superdiagonals of the  matrix  A  if
              UPLO  = 'U', or the number of subdiagonals if UPLO
              = 'L'.  KD >= 0.

    A (input) The upper or lower triangle of the symmetric  band
              matrix  A,  stored  in  the first KD+1 rows of the
              array.  The j-th column of A is stored in the j-th
              column  of the array A as follows:  if UPLO = 'U',
```

A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          ldb, float *x, long ldx, float *ferr, float *berr,
          long *info);
```

PURPOSE

spbrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
```

A (input) The upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the band matrix A as computed by SPBTRF, in the same storage format as A (see A).

LDAF (input)
The leading dimension of the array AF. LDAF >= KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative

```
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(3*N)
WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

REAL, DIMENSION(:,:) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void spbstf(char uplo, int n, int kd, float *ab,  int  ldab,
          int *info);

void spbstf_64(char uplo, long n, long kd, float  *ab,  long
          ldab, long *info);
```

PURPOSE

```
spbstf computes a split Cholesky  factorization  of  a  real
symmetric positive definite band matrix A.

This routine is designed to  be  used  in  conjunction  with
SSBGST.
The factorization has the form  A = S**T*S   where  S  is  a
band  matrix  of  the  same bandwidth as A and the following
structure:

  S = ( U    )
      ( M  L )

where U is upper triangular of order m = (n+kd)/2, and L  is
lower triangular of order n-m.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

AB (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band  matrix  A,  stored in the first kd+1
          rows of the array.  The j-th column of A is stored
          in the j-th column of the array AB as follows:  if
          UPLO = 'U', AB(kd+1+i-j,j) = A(i,j)  for  max(1,j-
          kd)<=i<=j;  if UPLO = 'L', AB(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+kd).
```

On exit, if INFO = 0, the factor S from the split Cholesky factorization A = S**T*S. See Further Details.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 7, KD = 2:

```
S = ( s11  s12  s13                     )
    (      s22  s23  s24                )
    (           s33  s34                )
    (                s44                )
    (           s53  s54  s55           )
    (                s64  s65  s66      )
    (                     s75  s76  s77 )
```

If UPLO = 'U', the array AB holds:

```
on entry:                          on exit:

 *    *   a13  a24  a35  a46  a57   *    *   s13   s24   s53
s64  s75
 *   a12  a23  a34  a45  a56  a67   *   s12  s23   s34   s54
s65   s76  a11   a22  a33  a44  a55  a66  a77  s11  s22  s33
s44  s55  s66  s77
```

If UPLO = 'L', the array AB holds:

```
on entry:                          on exit:

a11  a22  a33  a44  a55  a66  a77  s11  s22  s33   s44   s55
s66   s77  a21   a32  a43  a54  a65  a76   *   s12  s23  s34
s54  s65  s76   * a31  a42  a53  a64   a64    *     *    s13
s24  s53  s64  s75   *    *
```

#include <sunperf.h>

void spbsv(char uplo, int n, int ndiag, int nrhs, float  *a,
          int lda, float *b, int ldb, int *info);

void spbsv_64(char uplo, long  n,  long  ndiag,  long  nrhs,
          float  *a,  long  lda,  float  *b,  long ldb, long
          *info);
```

PURPOSE

spbsv computes the solution to a real system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.
The Cholesky decomposition is used to factor A as
   A = U**T * U, if UPLO = 'U', or
   A = L * L**T, if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
  = 'U': Upper triangle of A is stored;
  = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NDIAG (input)
  The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG >= 0.

NRHS (input)
  The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
  On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if

UPLO = 'U', A(NDIAG+1+i-j,j) = A(i,j) for max(1,j-NDIAG)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(N,j+NDIAG). See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the band matrix A, in the same storage format as A.

LDA (input)
The leading dimension of the array A. LDA >= NDIAG+1.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, NDIAG = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
```

```
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

Array elements marked * are not used by the routine.

#include <sunperf.h>

void spbsvx(char fact, char uplo,  int  n,  int  ndiag,  int
          nrhs, float *a, int lda, float *af, int ldaf, char
          equed, float *s, float *b, int ldb, float *x,  int
          ldx,  float  *rcond, float *ferr, float *berr, int
          *info);

void spbsvx_64(char fact, char uplo,  long  n,  long  ndiag,
          long  nrhs,  float  *a,  long lda, float *af, long
          ldaf, char equed, float *s, float  *b,  long  ldb,
          float  *x,  long  ldx,  float *rcond, float *ferr,
          float *berr, long *info);
```

PURPOSE

spbsvx uses the Cholesky factorization A = U**T*U or A = L*L**T to compute the solution to a real system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to

```
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is  used
to
   factor the matrix A (after equilibration if FACT  =  'E')
as
      A = U**T * U,  if UPLO = 'U', or
      A = L * L**T,  if UPLO = 'L',
   where U is an upper triangular band matrix, and  L  is  a
lower
   triangular band matrix.
3. If the leading i-by-i principal  minor  is  not  positive
definite,
   then the routine returns with INFO =  i.  Otherwise,  the
factored
   form of A is used to estimate the condition number of the
matrix
   A.  If the reciprocal of the  condition  number  is  less
than machine
   precision, INFO = N+1 is returned as a warning,  but  the
routine
   still goes on to solve for X and compute error bounds as
   described below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.

6. If equilibration was used, the matrix X is  premultiplied
by
   diag(S) so that it solves the original system before
   equilibration.
```

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NDIAG (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG >= 0.

NRHS (input)
The number of right-hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first NDIAG+1 rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(NDIAG+1+i-j,j) = A(i,j) for max(1,j-NDIAG)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(N,j+NDIAG). See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA (input)
The leading dimension of the array A. LDA >= NDIAG+1.

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U**T*U or A =

L*L**T of the band matrix A, in the same storage format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= NDIAG+1.

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would

suggest.

FURTHER DETAILS

```
The band storage scheme  is  illustrated  by  the  following
example, when N = 6, NDIAG = 2, and UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:
   a11  a12  a13
        a22  a23  a24
             a33  a34  a35
                  a44  a45  a46
                       a55  a56
   (aij=conjg(aji))         a66

Band storage of the upper triangle of A:

    *    *   a13  a24  a35  a46
    *   a12  a23  a34  a45  a56
   a11  a22  a33  a44  a55  a66

Similarly, if UPLO = 'L' the format of A is as follows:

   a11  a22  a33  a44  a55  a66
   a21  a32  a43  a54  a65   *
   a31  a42  a53  a64   *    *

Array elements marked * are not used by the routine.
```

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, KD, LDAB, INFO
REAL, DIMENSION(:,:) :: AB

SUBROUTINE PBTF2_64(UPLO, [N], KD, AB, [LDAB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, KD, LDAB, INFO
REAL, DIMENSION(:,:) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void spbtf2(char uplo, int n, int kd, float *ab,  int  ldab,
          int *info);

void spbtf2_64(char uplo, long n, long kd, float  *ab,  long
          ldab, long *info);
```

PURPOSE

spbtf2 computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

```
   A = U' * U ,  if UPLO = 'U', or
   A = L  * L',  if UPLO = 'L',
```

where U is an upper triangular matrix, U' is the transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j)   = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L

from the Cholesky factorization A = U'*U or A = L*L' of the band matrix A, in the same storage format as A.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

Array elements marked * are not used by the routine.

          lda, long *info);
```

PURPOSE

spbtrf computes the Cholesky factorization of a real symmetric positive definite band matrix A.

The factorization has the form

```
   A = U**T * U,  if UPLO = 'U', or
   A = L  * L**T,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)
: = 'U': Upper triangle of A is stored;
: = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
: The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input/output)
: On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

: On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T of the band matrix A, in the same storage format as A.

LDA (input)

The leading dimension of the array A. LDA >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

          anorm, float *rcond, long *info);
```

PURPOSE

spocon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPOTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ANORM (input)
The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(3*N)

NAME

```
spoequ - compute row and column scalings intended to equili-
brate  a symmetric positive definite matrix A and reduce its
condition number (with respect to the two-norm)
```

SYNOPSIS

```
SUBROUTINE SPOEQU(N, A, LDA, SCALE, SCOND, AMAX, INFO)

INTEGER N, LDA, INFO
REAL SCOND, AMAX
REAL A(LDA,*), SCALE(*)

SUBROUTINE SPOEQU_64(N, A, LDA, SCALE, SCOND, AMAX, INFO)

INTEGER*8 N, LDA, INFO
REAL SCOND, AMAX
REAL A(LDA,*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])

INTEGER :: N, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:,:) :: A

SUBROUTINE POEQU_64([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])

INTEGER(8) :: N, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void spoequ(int n, float *a, int lda,  float  *scale,  float
          *scond, float *amax, int *info);

void spoequ_64(long n, float *a,  long  lda,  float  *scale,
          float *scond, float *amax, long *info);
```

PURPOSE

spoequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

A (input) The N-by-N symmetric positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          float *x, long ldx, float *ferr, float *berr, long
          *info);
```

PURPOSE

sporfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular

part of the matrix A, and the strictly upper tri-
angular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPOTRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPOTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)

```
            dimension(N)

INFO (output)
            = 0:  successful exit
            < 0:  if INFO =  -i,  the  i-th  argument  had  an
            illegal value
```

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE POSV_64(UPLO, [N], [NRHS], A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sposv(char uplo, int n, int nrhs, float  *a,  int  lda,
          float *b, int ldb, int *info);

void sposv_64(char uplo, long n, long nrhs, float  *a,  long
          lda, float *b, long ldb, long *info);
```

PURPOSE

sposv computes the solution to a real system of linear equations
   A * X = B, where A is an N-by-N symmetric positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as
   A = U**T* U, if UPLO = 'U', or
   A = L * L**T, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
          = 'U': Upper triangle of A is stored;
          = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
          The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
          On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

          On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

          int  lda,  float  *af, int ldaf, char equed, float
          *s, float *b, int ldb, float *x,  int  ldx,  float
          *rcond, float *ferr, float *berr, int *info);

void sposvx_64(char fact, char  uplo,  long  n,  long  nrhs,
          float  *a,  long  lda,  float *af, long ldaf, char
          equed, float *s, float *b,  long  ldb,  float  *x,
          long  ldx, float *rcond, float *ferr, float *berr,
          long *info);
```

PURPOSE

```
sposvx uses the Cholesky factorization A =  U**T*U  or  A  =
L*L**T  to  compute  the solution to a real system of linear
equations
   A * X = B, where A is an N-by-N symmetric positive defin-
ite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
the
```

scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
factor the matrix A (after equilibration if FACT = 'E') as
A = U**T* U, if UPLO = 'U', or
A = L * L**T, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.

3. If the leading i-by-i principal minor is not positive definite,
then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.

4. The system of equations is solved for X using the factored form
of A.

5. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

6. If equilibration was used, the matrix X is premultiplied by
diag(S) so that it solves the original system before
equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is

```
            factored.   = 'F':  On entry, AF contains the fac-
            tored form of A.  If EQUED = 'Y', the matrix A has
            been equilibrated with scaling factors given by S.
            A and AF will not be modified.  = 'N':  The matrix
            A will be copied to AF and factored.
            = 'E':  The  matrix  A  will  be  equilibrated  if
            necessary, then copied to AF and factored.

UPLO (input)
            = 'U':  Upper triangle of A is stored;
            = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
            the matrix A.  N >= 0.

NRHS (input)
            The number of right hand sides, i.e.,  the  number
            of columns of the matrices B and X.  NRHS >= 0.
A (input/output)
            On entry, the symmetric matrix A, except if FACT =
            'F'  and  EQUED  =  'Y',  then  A must contain the
            equilibrated matrix diag(S)*A*diag(S).  If UPLO  =
            'U', the leading N-by-N upper triangular part of A
            contains the upper triangular part of  the  matrix
            A,  and the strictly lower triangular part of A is
            not referenced.  If UPLO = 'L', the leading N-by-N
            lower triangular part of A contains the lower tri-
            angular part of the matrix  A,  and  the  strictly
            upper  triangular  part of A is not referenced.  A
            is not modified if FACT = 'F' or 'N', or if FACT =
            'E' and EQUED = 'N' on exit.

            On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
            overwritten by diag(S)*A*diag(S).

LDA (input)
            The leading dimension of  the  array  A.   LDA  >=
            max(1,N).

AF (input/output)
            If FACT = 'F', then AF is an input argument and on
            entry  contains  the triangular factor U or L from
            the Cholesky factorization  A  =  U**T*U  or  A  =
            L*L**T, in the same storage format as A.  If EQUED
            .ne. 'N', then AF is  the  factored  form  of  the
            equilibrated matrix diag(S)*A*diag(S).

            If FACT = 'N', then AF is an output  argument  and
            on  exit returns the triangular factor U or L from
            the Cholesky factorization  A  =  U**T*U  or  A  =
```

```
          L*L**T of the original matrix A.

          If FACT = 'E', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
          the Cholesky factorization  A  =  U**T*U  or  A  =
          L*L**T  of  the  equilibrated  matrix  A  (see the
          description of A for the form of the  equilibrated
          matrix).

LDAF (input)
          The leading dimension of the array  AF.   LDAF  >=
          max(1,N).

EQUED (input)
          Specifies the form of equilibration that was done.
          =  'N':   No  equilibration (always true if FACT =
          'N').
          = 'Y':  Equilibration was done, i.e., A  has  been
          replaced  by  diag(S)  * A * diag(S).  EQUED is an
          input argument if FACT = 'F'; otherwise, it is  an
          output argument.

S (input/output)
          The scale factors for A; not accessed if  EQUED  =
          'N'.  S is an input argument if FACT = 'F'; other-
          wise, S is an output argument.  If FACT = 'F'  and
          EQUED = 'Y', each element of S must be positive.

B (input/output)
          On entry, the N-by-NRHS right hand side matrix  B.
          On  exit,  if  EQUED  = 'N', B is not modified; if
          EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (output)
          If INFO = 0 or INFO = N+1, the N-by-NRHS  solution
          matrix  X  to  the  original  system of equations.
          Note that if EQUED = 'Y', A and B are modified  on
          exit,  and the solution to the equilibrated system
          is inv(diag(S))*X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

RCOND (output)
          The estimate of the reciprocal condition number of
```

the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

void spotf2_64(char uplo, long n, float *a, long  lda,  long
          *info);
```

PURPOSE

spotf2 computes the Cholesky factorization of a real symmetric positive definite matrix A.

The factorization has the form
   A = U' * U , if UPLO = 'U', or
   A = L * L', if UPLO = 'L',
where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U'*U or A = L*L'.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

```
INFO (output)
          = 0: successful exit
          < 0: if INFO = -k, the k-th argument had an  ille-
          gal value
          > 0: if INFO = k, the leading minor of order k  is
          not positive definite, and the factorization could
          not be completed.

          *info);
```

PURPOSE

spotri computes the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPOTRF.   On exit, the upper or lower triangle of the (symmetric) inverse of A, overwriting the input factor U or L.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

#include <sunperf.h>

void spotrs(char uplo, int n, int nrhs, float *a,  int  lda,
          float *b, int ldb, int *info);

void spotrs_64(char uplo, long n, long nrhs, float *a,  long
          lda, float *b, long ldb, long *info);
```

PURPOSE

spotrs solves a system of linear equations A*X = B with a symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPOTRF.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B.   LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

sppcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF

SYNOPSIS

```
SUBROUTINE SPPCON(UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)

CHARACTER * 1 UPLO
INTEGER N, INFO
INTEGER WORK2(*)
REAL ANORM, RCOND
REAL A(*), WORK(*)

SUBROUTINE SPPCON_64(UPLO, N, A, ANORM, RCOND, WORK, WORK2, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, INFO
INTEGER*8 WORK2(*)
REAL ANORM, RCOND
REAL A(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE PPCON(UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: A, WORK
```

```
SUBROUTINE PPCON_64(UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>

void sppcon(char uplo, int n, float *a, float  anorm,  float
          *rcond, int *info);
void sppcon_64(char uplo, long n,  float  *a,  float  anorm,
          float *rcond, long *info);
```

PURPOSE

sppcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

ANORM (input)
The 1-norm (or infinity-norm) of the symmetric matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

sppequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE SPPEQU(UPLO, N, A, SCALE, SCOND, AMAX, INFO)

CHARACTER * 1 UPLO
INTEGER N, INFO
REAL SCOND, AMAX
REAL A(*), SCALE(*)

SUBROUTINE SPPEQU_64(UPLO, N, A, SCALE, SCOND, AMAX, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, INFO
REAL SCOND, AMAX
REAL A(*), SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PPEQU(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: A, SCALE

SUBROUTINE PPEQU_64(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])

CHARACTER(LEN=1) :: UPLO
```

```
INTEGER(8) :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: A, SCALE
```

C INTERFACE

```
#include <sunperf.h>

void sppequ(char uplo, int n, float *a, float *scale,  float
          *scond, float *amax, int *info);

void sppequ_64(char uplo, long n, float  *a,  float  *scale,
          float *scond, float *amax, long *info);
```

PURPOSE

sppequ computes row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i)=1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j)=S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input) The upper  or  lower  triangle  of  the  symmetric
          matrix  A,  packed  columnwise  in a linear array.
          The j-th column of A is stored in the array  A  as
          follows:  if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j)
          for 1<=i<=j; if UPLO = 'L', A(i +  (j-1)*(2n-j)/2)
          = A(i,j) for j<=i<=n.

SCALE (output)
          If INFO = 0, SCALE contains the scale factors  for
          A.

SCOND (output)
          If INFO = 0, SCALE contains the ratio of the smal-
          lest  SCALE(i)  to the largest SCALE(i).  If SCOND
```

>= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

REAL, DIMENSION(:) :: A, AF, FERR, BERR, WORK
REAL, DIMENSION(:,:) :: B, X
```

C INTERFACE

```
#include <sunperf.h>
void spprfs(char uplo, int n, int nrhs, float *a, float *af,
          float *b, int ldb, float *x, int ldx, float *ferr,
          float *berr, int *info);

void spprfs_64(char uplo, long n, long nrhs, float *a, float
          *af, float *b, long ldb, float *x, long ldx, float
          *ferr, float *berr, long *info);
```

PURPOSE

spprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see A).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE PPSV_64(UPLO, N, [NRHS], A, B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: A
REAL, DIMENSION(:,:) :: B
```

C INTERFACE

```
#include <sunperf.h>

void sppsv(char uplo, int n, int nrhs, float *a,  float  *b,
          int ldb, int *info);

void sppsv_64(char uplo, long n, long nrhs, float *a,  float
          *b, long ldb, long *info);
```

PURPOSE

```
sppsv computes the solution to a real system of linear equa-
tions
   A * X = B, where A is an N-by-N symmetric positive defin-
ite matrix stored in packed format and X and B are N-by-NRHS
matrices.

The Cholesky decomposition is used to factor A as
   A = U**T* U,  if UPLO = 'U', or
   A = L * L**T,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower  tri-
angular  matrix.   The  factored  form  of A is then used to
solve the system of equations A * X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  A  as  follows:   if  UPLO = 'U', A(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i +
          (j-1)*(2n-j)/2)  =  A(i,j) for j<=i<=n.  See below
          for further details.
```

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, in the same storage format as A.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

#include <sunperf.h>

void sppsvx(char fact, char uplo, int n, int nrhs, float *a,
          float  *af,  char  equed,  float *s, float *b, int
          ldb, float *x, int ldx, float *rcond, float *ferr,
          float *berr, int *info);

void sppsvx_64(char fact, char  uplo,  long  n,  long  nrhs,
          float  *a,  float *af, char equed, float *s, float
          *b, long ldb, float *x, long  ldx,  float  *rcond,
          float *ferr, float *berr, long *info);
```

PURPOSE

```
sppsvx uses the Cholesky factorization A =  U**T*U  or  A  =
L*L**T  to  compute  the solution to a real system of linear
equations
   A * X = B, where A is an N-by-N symmetric positive defin-
ite matrix stored in packed format and X and B are N-by-NRHS
matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
```

is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
factor the matrix A (after equilibration if FACT = 'E') as
A = U**T* U, if UPLO = 'U', or
A = L * L**T, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular
matrix.

3. If the leading i-by-i principal minor is not positive definite,
then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.

4. The system of equations is solved for X using the factored form
of A.

5. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

6. If equilibration was used, the matrix X is premultiplied by
diag(S) so that it solves the original system before
equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the fac-

```
          tored form of A.  If EQUED = 'Y', the matrix A has
          been equilibrated with scaling factors given by S.
          A and AF will not be modified.  = 'N':  The matrix
          A will be copied to AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  matrix  A,  packed  columnwise in a linear
          array, except if FACT = 'F' and EQUED = 'Y',  then
          A    must    contain   the   equilibrated   matrix
          diag(S)*A*diag(S).  The j-th column of A is stored
          in  the  array A as follows:  if UPLO = 'U', A(i +
          (j-1)*j/2) = A(i,j) for 1<=i<=j; if  UPLO  =  'L',
          A(i  +  (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.  See
          below for further details.  A is not  modified  if
          FACT  =  'F'  or 'N', or if FACT = 'E' and EQUED =
          'N' on exit.

          On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
          overwritten by diag(S)*A*diag(S).

AF (input/output)
          (N*(N+1)/2) If FACT = 'F', then  AF  is  an  input
          argument and on entry contains the triangular fac-
          tor U or L from the  Cholesky  factorization  A  =
          U'*U or A = L*L', in the same storage format as A.
          If EQUED .ne. 'N', then AF is the factored form of
          the equilibrated matrix A.

          If FACT = 'N', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
          the Cholesky factorization A = U'*U or A = L*L' of
          the original matrix A.

          If FACT = 'E', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
          the Cholesky factorization A = U'*U or A = L*L' of
          the  equilibrated matrix A (see the description of
```

A for the form of the equilibrated matrix).

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest ele-

ment in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

```

C INTERFACE

```
#include <sunperf.h>

void spptrf(char uplo, int n, float *a, int *info);

void spptrf_64(char uplo, long n, float *a, long *info);
```

PURPOSE

spptrf computes the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format.

The factorization has the form
```
   A = U**T * U,  if UPLO = 'U', or
   A = L  * L**T,  if UPLO = 'L',
```
where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**T*U or A = L*L**T, in the same storage format as A.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

```
The packed storage scheme is illustrated  by  the  following
example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44

Packed storage of the upper triangle of A:

A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

#include <sunperf.h>

void sptcon(int n, float *diag, float  *offd,  float  anorm,
          float *rcond, int *info);

void sptcon_64(long  n,  float  *diag,  float  *offd,  float
          anorm, float *rcond, long *info);
```

PURPOSE

sptcon computes the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization A = L*D*L**T or A = U**T*D*U computed by SPTTRF.
Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

DIAG (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by SPTTRF.

OFFD (input)
The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by SPTTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(N)

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The method used is described in Nicholas J. Higham, "Efficient Algorithms for Computing the Condition Number of a Tridiagonal Matrix", SIAM J. Sci. Stat. Comput., Vol. 7, No. 1, January 1986.

```

F95 INTERFACE

```
SUBROUTINE PTEQR(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
INTEGER :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:,:) :: Z

SUBROUTINE PTEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, INFO
```

```
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void spteqr(char compz, int n, float *d, float *e, float *z,
          int ldz, int *info);

void spteqr_64(char compz, long n, float *d, float *e, float
          *z, long ldz, long *info);
```

PURPOSE

spteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band symmetric positive definite matrix can also be found if SSYTRD, SSPTRD, or SSBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvectors of original symmetric matrix also. Array Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', the orthogonal matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original symmetric matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK (workspace)
dimension(4*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

          *info);
```

PURPOSE

sptrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input)
The n diagonal elements of the tridiagonal matrix A.

OFFD (input)
The (n-1) subdiagonal elements of the tridiagonal matrix A.

DIAGF (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization computed by SPTTRF.

OFFDF (input)
The (n-1) subdiagonal elements of the unit bidiag-

onal factor L from the factorization computed by SPTTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SPTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

REAL, DIMENSION(:,:) :: B

SUBROUTINE PTSV_64([N], [NRHS], DIAG, SUB, B, [LDB], [INFO])

INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: DIAG, SUB
REAL, DIMENSION(:,:) :: B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sptsv(int n, int nrhs, float *diag, float  *sub,  float
          *b, int ldb, int *info);

void sptsv_64(long n, long nrhs, float  *diag,  float  *sub,
          float *b, long ldb, long *info);
```

PURPOSE

sptsv computes the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as A = L*D*L**T, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the factorization A = L*DIAG*L**T.

SUB (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**T factorization of A. (SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U**T*DIAG*U factorization of A.)

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >=

max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

PURPOSE

```
sptsvx uses the factorization A = L*D*L**T  to  compute  the
solution to a real system of linear equations A*X = B, where
A is  an  N-by-N  symmetric  positive  definite  tridiagonal
matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'N', the matrix A is factored as A =  L*D*L**T,
where L
   is a unit lower bidiagonal matrix and D is diagonal.  The
   factorization can also be regarded as having the form
   A = U**T*D*U.

2. If the leading i-by-i principal  minor  is  not  positive
definite,
   then the routine returns with INFO =  i.  Otherwise,  the
factored
   form of A is used to estimate the condition number of the
```

```
matrix
   A.  If the reciprocal of the  condition  number  is  less
than machine
   precision, INFO = N+1 is returned as a warning,  but  the
routine
   still goes on to solve for X and compute error bounds as
   described below.

3. The system of equations is solved for X  using  the  fac-
tored form
   of A.

4. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored  form  of  A
          has  been  supplied  on  entry.  = 'F':  On entry,
          DIAGF and SUBF contain the  factored  form  of  A.
          DIAG,  SUB,  DIAGF, and SUBF will not be modified.
          = 'N':  The matrix A will be copied to  DIAGF  and
          SUBF and factored.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

DIAG (input)
          The n diagonal elements of the tridiagonal  matrix
          A.

SUB (input)
          The (n-1) subdiagonal elements of the  tridiagonal
          matrix A.

DIAGF (input/output)
          If FACT = 'F', then DIAGF is an input argument and
          on  entry  contains the n diagonal elements of the
          diagonal matrix DIAG from the L*DIAG*L**T factori-
          zation of A.  If FACT = 'N', then DIAGF is an out-
          put argument and on exit contains the  n  diagonal
```

elements of the diagonal matrix DIAG from the L*DIAG*L**T factorization of A.

SUBF (input/output)
If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**T factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**T factorization of A.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 of INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is

<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

NAME

```
spttrf - compute the L*D*L' factorization  of  a  real  sym-
metric positive definite tridiagonal matrix A
```

SYNOPSIS

```
SUBROUTINE SPTTRF(N, DIAG, OFFD, INFO)

INTEGER N, INFO
REAL DIAG(*), OFFD(*)

SUBROUTINE SPTTRF_64(N, DIAG, OFFD, INFO)

INTEGER*8 N, INFO
REAL DIAG(*), OFFD(*)
```

F95 INTERFACE

```
SUBROUTINE PTTRF([N], DIAG, OFFD, [INFO])

INTEGER :: N, INFO
REAL, DIMENSION(:) :: DIAG, OFFD

SUBROUTINE PTTRF_64([N], DIAG, OFFD, [INFO])

INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: DIAG, OFFD
```

C INTERFACE

```
#include <sunperf.h>

void spttrf(int n, float *diag, float *offd, int *info);

void  spttrf_64(long  n,  float  *diag,  float  *offd,  long
```

```
            *info);
```

PURPOSE

spttrf computes the L*D*L' factorization of a real symmetric positive definite tridiagonal matrix A. The factorization may also be regarded as having the form A = U'*D*U.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

DIAG (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the L*DIAG*L' factorization of A.

OFFD (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L' factorization of A. OFFD can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U'*DIAG*U factorization of A.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite; if k < N, the factorization could not be completed, while if k = N, the factorization was completed, but DIAG(N) = 0.

```

```
          *b, int ldb, int *info);

void spttrs_64(long n, long nrhs, float *diag, float  *offd,
          float *b, long ldb, long *info);
```

PURPOSE

spttrs solves a tridiagonal system of the form
   A * X = B using the L*D*L' factorization of A computed by
SPTTRF. D is a diagonal matrix specified in the vector D, L
is a unit bidiagonal matrix whose subdiagonal is specified
in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

N (input) The order of the tridiagonal matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. NRHS >= 0.

DIAG (input)
The n diagonal elements of the diagonal matrix
DIAG from the L*DIAG*L' factorization of A.

OFFD (input/output)
The (n-1) subdiagonal elements of the unit bidiag-
onal factor L from the L*DIAG*L' factorization of
A. OFFD can also be regarded as the superdiagonal
of the unit bidiagonal factor U from the factori-
zation A = U'*DIAG*U.

B (input/output)
On entry, the right hand side vectors B for the
system of linear equations. On exit, the solution
vectors, X.

LDB (input)
The leading dimension of the array B.   LDB >=
max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an ille-
gal value

```
          int ldb);

void sptts2_64(long n, long nrhs, float *d, float *e,  float
          *b, long ldb);
```

PURPOSE

sptts2 solves a tridiagonal system of the form
A * X = B using the L*D*L' factorization of A computed by SPTTRF. D is a diagonal matrix specified in the vector D, L is a unit bidiagonal matrix whose subdiagonal is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

N (input) The order of the tridiagonal matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D (input) The n diagonal elements of the diagonal matrix D from the L*D*L' factorization of A.

E (input) The (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*D*L' factorization of A. E can also be regarded as the superdiagonal of the unit bidiagonal factor U from the factorization A = U'*D*U.

B (input/output)
On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INTEGER :: N, INCX, INCY
REAL :: C, S
REAL, DIMENSION(:) :: X, Y

SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)

INTEGER(8) :: N, INCX, INCY
REAL :: C, S
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void srot(int n, float *x, int incx,  float  *y,  int  incy,
          float c, float s);

void srot_64(long n, float *x, long  incx,  float  *y,  long
          incy, float c, float s);
```

PURPOSE

srot Apply a Given's rotation constructed by SROTG.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

C (input) On entry, the C rotation value constructed by SROTG. Unchanged on exit.

S (input) On entry, the S rotation value constructed by SROTG. Unchanged on exit.

Contents

NAME

```
srotg - Construct a Given's plane rotation
```

SYNOPSIS

```
SUBROUTINE SROTG(A, B, C, S)

REAL A, B, C, S

SUBROUTINE SROTG_64(A, B, C, S)

REAL A, B, C, S
```

F95 INTERFACE

```
SUBROUTINE ROTG(A, B, C, S)

REAL :: A, B, C, S

SUBROUTINE ROTG_64(A, B, C, S)

REAL :: A, B, C, S
```

C INTERFACE

```
#include <sunperf.h>

void srotg(float *a, float *b, float *c, float *s);

void srotg_64(float *a, float *b, float *c, float *s);
```

PURPOSE

srotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

A (input/output)
On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

B (input/output)
On entry, B contains the entry to be annihilated in the second vector. On exit, contains either S or 1/C depending on which of the input values of A and B is larger.

C (output)
On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

S (output)
See the description of C.

NAME

```
sroti -  Apply an indexed Givens rotation.
```

SYNOPSIS

```
 SUBROUTINE SROTI(NZ, X, INDX, Y, C, S)

 INTEGER NZ
 INTEGER INDX(*)
 REAL C, S
 REAL X(*), Y(*)

 SUBROUTINE SROTI_64(NZ, X, INDX, Y, C, S)

 INTEGER*8 NZ
 INTEGER*8 INDX(*)
 REAL C, S
 REAL X(*), Y(*)

F95 INTERFACE
 SUBROUTINE ROTI([NZ], X, INDX, Y, C, S)

 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX
 REAL :: C, S
 REAL, DIMENSION(:) :: X, Y

 SUBROUTINE ROTI_64([NZ], X, INDX, Y, C, S)

 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
 REAL :: C, S
 REAL, DIMENSION(:) :: X, Y
```

PURPOSE

```
SROTI - Applies a Givens rotation to a sparse vector x
stored in compressed form and another vector y in full
storage form

 do i = 1, n
   temp = -s * x(i) + c * y(indx(i))
   x(i) = c * x(i) + s * y(indx(i))
   y(indx(i)) = temp
 enddo
```

ARGUMENTS

```
NZ (input) - INTEGER
        Number of elements in the compressed form.
        Unchanged on exit.
X (input)
        Vector containing the values of the compressed form.

INDX (input) - INTEGER
        Vector containing the indices of the compressed
        form.  It is assumed that the elements in INDX are
        distinct and greater than zero.  Unchanged on exit.

Y (input/output)
        Vector on input which contains the vector Y in full
        storage form.  On exit, only the elements
        corresponding to the indices in INDX have been
        modified.

C (input)
        Scalar defining the Givens rotation

S (input)
        Scalar defining the Givens rotation
```

SUBROUTINE ROTM_64([N], X, [INCX], Y, [INCY], PARAM)

INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y, PARAM
```

C INTERFACE

```
#include <sunperf.h>

void srotm(int n, float *x, int incx, float  *y,  int  incy,
          float *param);
```

```
void srotm_64(long n, float *x, long incx,  float  *y,  long
          incy, float *param);
```

PURPOSE

srotm Apply a Given's rotation constructed by SROTMG.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, X is overwritten by the updated vector x.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

PARAM (input)
On entry, the rotation values constructed by SROTMG. Unchanged on exit.

REAL :: D1, D2, B1, B2
REAL, DIMENSION(:) :: PARAM
```

C INTERFACE

```
#include <sunperf.h>

void srotmg(float d1, float d2, float b1,  float  b2,  float
          *param);
```

```
void srotmg_64(float d1, float d2, float b1, float b2, float
          *param);
```

PURPOSE

srotmg Construct Gentleman's modified a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

D1 (input/output)
On entry, the first diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

D2 (input/output)
On entry, the second diagonal entry in the H matrix. On exit, changed to reflect the effect of the transformation.

B1 (input/output)
On entry, the first element of the vector to which the H matrix is applied. On exit, changed to reflect the effect of the transformation.

B2 (input)
On entry, the second element of the vector to which the H matrix is applied. Unchanged on exit.

PARAM (output)
On exit, PARAM(1) describes the form of the rotation matrix H, and PARAM(2..5) contain the H matrix.

If PARAM(1) = -2 then H = I and no elements of PARAM are modified.

If PARAM(1) = -1 then PARAM(2) = h11, PARAM(3) = h21, PARAM(4) = h12, and PARAM(5) = h22.

If PARAM(1) = 0 then h11 = h22 = 1, PARAM(3) = h21, and PARAM(4) = h12.

If PARAM(1) = 1 then h12 = 1, h21 = -1, PARAM(2) = h11, and PARAM(5) = h22.

```
SUBROUTINE SBEV(JOBZ, UPLO, [N], KD, A, [LDA], W, Z, [LDZ], [WORK],
       [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, KD, LDA, LDZ, INFO
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:,:) :: A, Z

SUBROUTINE SBEV_64(JOBZ, UPLO, [N], KD, A, [LDA], W, Z, [LDZ],
       [WORK], [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, KD, LDA, LDZ, INFO
```

```
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:,:) :: A, Z
```

C INTERFACE

```
#include <sunperf.h>

void ssbev(char jobz, char uplo, int n, int  kd,  float  *a,
          int lda, float *w, float *z, int ldz, int *info);

void ssbev_64(char jobz, char uplo, long n, long  kd,  float
          *a,  long  lda, float *w, float *z, long ldz, long
          *info);
```

PURPOSE

ssbev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

LDA (input)
The leading dimension of the array A. LDA >= KD + 1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(MAX(1,3*N-2))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

       [WORK], [LWORK], [IWORK], [LIWORK], [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, KD, LDAB, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:,:) :: AB, Z
```

C INTERFACE

```
#include <sunperf.h>

void ssbevd(char jobz, char uplo, int n, int kd, float  *ab,
          int ldab, float *w, float *z, int ldz, int *info);
void ssbevd_64(char jobz, char uplo, long n, long kd,  float
          *ab, long ldab, float *w, float *z, long ldz, long
          *info);
```

PURPOSE

ssbevd computes all the eigenvalues and, optionally, eigen- vectors of a real symmetric band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.
```

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB (input)

The leading dimension of the array AB. LDAB >= KD + 1.

W (output)

If INFO = 0, the eigenvalues in ascending order.

Z (output)

If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 2, LWORK must be at least 2*N. If JOBZ = 'V' and N > 2, LWORK must be at least (1 + 5*N + 2*N**2).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

```
            entry  of  the  WORK  array,  and no error message
            related to LWORK is issued by XERBLA.

IWORK (workspace/output)
            On exit, if INFO = 0, IWORK(1) returns the optimal
            LIWORK.
LIWORK (input)
            The dimension of the array LIWORK.  If JOBZ  = 'N'
            or  N <= 1, LIWORK must be at least 1.  If JOBZ  =
            'V' and N > 2, LIWORK must be at least 3 + 5*N.

            If LIWORK = -1, then a workspace query is assumed;
            the  routine  only  calculates the optimal size of
            the IWORK array, returns this value as  the  first
            entry  of  the  IWORK  array, and no error message
            related to LIWORK is issued by XERBLA.

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  if INFO = i, the algorithm  failed  to  con-
            verge;  i off-diagonal elements of an intermediate
            tridiagonal form did not converge to zero.

          long  *nfound,  float *w, float *z, long ldz, long
          *ifail, long *info);
```

PURPOSE

ssbevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found;
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be  found; = 'I': the IL-th through
          IU-th eigenvalues will be found.
```

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band  matrix  A,  stored in the first KD+1
          rows of the array.  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
          UPLO = 'U', A(kd+1+i-j,j) =  A(i,j)  for  max(1,j-
          kd)<=i<=j;  if  UPLO = 'L', A(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+kd).

          On exit, A is overwritten by values generated dur-
          ing  the reduction to tridiagonal form.  If UPLO =
          'U', the first superdiagonal and the  diagonal  of
          the  tridiagonal  matrix T are returned in rows KD
          and KD+1 of A, and if UPLO = 'L', the diagonal and
          first  subdiagonal  of T are returned in the first
          two rows of A.

LDA (input)
          The leading dimension of the array A.  LDA >= KD +
          1.

Q (output)
          If JOBZ = 'V', the N-by-N orthogonal  matrix  used
          in  the  reduction to tridiagonal form.  If JOBZ =
          'N', the array Q is not referenced.

LDQ (input)
          The leading dimension of the array Q.  If  JOBZ  =
          'V', then LDQ >= max(1,N).

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

VU (input)
          See the description of VL.

IL (input)
```

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input)
If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in

```
            IFAIL.  If JOBZ = 'N', then Z is  not  referenced.
            Note:   the   user   must  ensure  that  at  least
            max(1,NFOUND) columns are supplied in the array Z;
            if  RANGE  = 'V', the exact value of NFOUND is not
            known in advance and an upper bound must be used.
LDZ (input)
            The leading dimension of the array Z.  LDZ  >=  1,
            and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
            dimension(7*N)

IWORK2 (workspace)

IFAIL (output)
            If JOBZ = 'V', then if INFO = 0, the first  NFOUND
            elements  of  IFAIL  are  zero.  If INFO > 0, then
            IFAIL contains the  indices  of  the  eigenvectors
            that  failed  to  converge.   If  JOBZ = 'N', then
            IFAIL is not referenced.

INFO (output)
            = 0:  successful exit.
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value.
            > 0:  if INFO = i, then i eigenvectors  failed  to
            converge.   Their  indices  are  stored  in  array
            IFAIL.

REAL, DIMENSION(:,:) :: AB, BB, X
```

C INTERFACE

```
#include <sunperf.h>

void ssbgst(char vect, char uplo, int n,  int  ka,  int  kb,
          float  *ab,  int  ldab, float *bb, int ldbb, float
          *x, int ldx, int *info);

void ssbgst_64(char vect, char uplo, long n, long  ka,  long
          kb,  float  *ab,  long ldab, float *bb, long ldbb,
          float *x, long ldx, long *info);
```

PURPOSE

ssbgst reduces a real symmetric-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y, such that C has the same bandwidth as A.

B must have been previously factorized as S**T*S by SPBSTF, using a split Cholesky factorization. A is overwritten by C = X**T*A*X, where X = S**(-1)*Q and Q is an orthogonal matrix chosen to preserve the bandwidth of A.

ARGUMENTS

```
VECT (input)
          = 'N':  do not form the transformation matrix X;
          = 'V':  form X.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrices A and B.  N >= 0.

KA (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KA >= 0.

KB (input)
          The number of superdiagonals of the  matrix  B  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
```

= 'L'. KA >= KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the transformed matrix X**T*A*X, stored in the same format as A.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input)
The banded factor S from the split Cholesky factorization of B, as returned by SPBSTF, stored in the first KB+1 rows of the array.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

X (output)
If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N) if VECT = 'V'; LDX >= 1 otherwise.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

          kb,  float  *ab,  long ldab, float *bb, long ldbb,
          float *w, float *z, long ldz, long *info);
```

PURPOSE

ssbgv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB (input/output)

On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S**T*S, as returned by SPBSTF.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z**T*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:

<= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then SPBSTF
returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:,:) :: AB, BB, Z
```

C INTERFACE

```
#include <sunperf.h>

void ssbgvd(char jobz, char uplo, int n,  int  ka,  int  kb,
          float  *ab,  int  ldab, float *bb, int ldbb, float
          *w, float *z, int ldz, int *info);

void ssbgvd_64(char jobz, char uplo, long n, long  ka,  long
          kb,  float  *ab,  long ldab, float *bb, long ldbb,
          float *w, float *z, long ldz, long *info);
```

PURPOSE

ssbgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
```

```
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

KA (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KA >= 0.

KB (input)
          The number of superdiagonals of the  matrix  B  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KB >= 0.

AB (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band  matrix  A,  stored in the first ka+1
          rows of the array.  The j-th column of A is stored
          in the j-th column of the array AB as follows:  if
          UPLO = 'U', AB(ka+1+i-j,j) = A(i,j)  for  max(1,j-
          ka)<=i<=j;  if UPLO = 'L', AB(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+ka).

          On exit, the contents of AB are destroyed.

LDAB (input)
          The leading dimension of the array  AB.   LDAB  >=
          KA+1.

BB (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band  matrix  B,  stored in the first kb+1
          rows of the array.  The j-th column of B is stored
          in the j-th column of the array BB as follows:  if
          UPLO = 'U', BB(ka+1+i-j,j) = B(i,j)  for  max(1,j-
          kb)<=i<=j;  if UPLO = 'L', BB(1+i-j,j)    = B(i,j)
          for j<=i<=min(n,j+kb).

          On exit, the factor S from the split Cholesky fac-
          torization B = S**T*S, as returned by SPBSTF.

LDBB (input)
          The leading dimension of the array  BB.   LDBB  >=
          KB+1.

W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          matrix  Z of eigenvectors, with the i-th column of
```

Z holding the eigenvector associated with W(i). The eigenvectors are normalized so Z**T*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 3*N. If JOBZ = 'V' and N > 1, LWORK >= 1 + 5*N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if LIWORK > 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:
<= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then SPBSTF
returned INFO = i: B is not positive definite. The factorization of B could not be completed and

no eigenvalues or eigenvectors were computed.

```

PURPOSE

ssbgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be symmetric and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)
On entry, the upper or lower triangle of the symmetric band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(ka+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S**T*S, as returned by SPBSTF.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

Q (output)
If JOBZ = 'V', the n-by-n matrix used in the reduction of A*x = (lambda)*B*x to standard form, i.e. C*x = (lambda)*x, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so Z**T*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(7*N)

IWORK (workspace/output)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvalues that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0 : successful exit
< 0 : if INFO = -i, the i-th argument had an illegal value
<= N: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in IFAIL. > N : SPBSTF returned an error code; i.e., if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

NAME

ssbmv - perform the matrix-vector operation   y := alpha*A*x + beta*y

SYNOPSIS

```
SUBROUTINE SSBMV(UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y,
      INCY)

CHARACTER * 1 UPLO
INTEGER N, K, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)

SUBROUTINE SSBMV_64(UPLO, N, K, ALPHA, A, LDA, X, INCX, BETA, Y,
      INCY)

CHARACTER * 1 UPLO
INTEGER*8 N, K, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SBMV(UPLO, [N], K, ALPHA, A, [LDA], X, [INCX], BETA,
       Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, K, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A

SUBROUTINE SBMV_64(UPLO, [N], K, ALPHA, A, [LDA], X, [INCX],
```

```
        BETA, Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, K, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssbmv(char uplo, int n, int k, float alpha,  float  *a,
          int lda, float *x, int incx, float beta, float *y,
          int incy);
void ssbmv_64(char uplo, long n, long k, float alpha,  float
          *a,  long  lda,  float  *x, long incx, float beta,
          float *y, long incy);
```

PURPOSE

ssbmv performs the matrix-vector operation y := alpha*A*x + beta*y, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric band matrix, with k super-diagonals.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is being supplied.

UPLO = 'L' or 'l'   The lower triangular part of A is being supplied.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry, K specifies the number of super-diagonals of the matrix A. K >= 0. Unchanged on

exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the symmetric matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a symmetric band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (

k + 1). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>

void ssbtrd(char vect, char uplo, int n, int kd, float  *ab,
          int  ldab,  float *d, float *e, float *q, int ldq,
          int *info);

void ssbtrd_64(char vect, char uplo, long n, long kd,  float
          *ab, long ldab, float *d, float *e, float *q, long
          ldq, long *info);
```

PURPOSE

ssbtrd reduces a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: Q**T * A * Q = T.

ARGUMENTS

```
VECT (input)
          = 'N':  do not form Q;
          = 'V':  form Q;
          = 'U':  update a matrix X, by forming X*Q.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

AB (input/output)
          On entry, the upper or lower triangle of the  sym-
          metric  band  matrix  A,  stored in the first KD+1
          rows of the array.  The j-th column of A is stored
          in the j-th column of the array AB as follows:  if
          UPLO = 'U', AB(kd+1+i-j,j) = A(i,j)  for  max(1,j-
```

kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if KD > 0, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

D (output)
The diagonal elements of the tridiagonal matrix T.

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = T(i,i+1) if UPLO = 'U'; E(i) = T(i+1,i) if UPLO = 'L'.

Q (input/output)
On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N orthogonal matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

sscal Compute y := alpha * y where alpha is a scalar and y is an n-vector.

ARGUMENTS

N (input)
: On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
: On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

Y (input/output)
: (1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
: On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
ssctr - Scatters elements from x into y.
```

SYNOPSIS

```
 SUBROUTINE SSCTR(NZ, X, INDX, Y)

 REAL X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE SSCTR_64(NZ, X, INDX, Y)

 REAL X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE SCTR([NZ], X, INDX, Y)

 REAL, DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE SCTR_64([NZ], X, INDX, Y)

 REAL, DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
SSCTR - Scatters the components of a sparse vector x stored
in compressed form into specified components of a vector y
```

in full storage form.

```
 do i = 1, n
   y(indx(i)) = x(i)
 enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form.
Unchanged on exit.

X (input)
Vector containing the values to be scattered from compressed form into full storage form. Unchanged on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (output)
Vector whose elements specified by indx have been set to the corresponding entries of x. Only the elements corresponding to the indices in indx have been modified.

 INTEGER*8    TRANSA, M, K
 INTEGER*8, DIMENSION(:) ::  DESCRA,  PNTR
 REAL    ALPHA, BETA
 REAL, DIMENSION(:) ::  VAL
 REAL, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C
where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in skyline format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general (NOT SUPPORTED)
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
```

```
                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          array contain the nonzeros of A in skyline profile form.
                Row-oriented if DESCRA(2) = 1 (lower triangular),
                column oriented if DESCRA(2) = 2 (upper triangular).
 PNTR()         integer array of length M+1 (lower triangular) or
                K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
                points to the location in VAL of the first element of
                the skyline profile in row (column) I.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in skyline format and
op( A )  is one  of

 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' )).
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row or column scaling (see section
                    NOTES for further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter
```

```
DESCRA()        Descriptor argument.  Five element integer array
                DESCRA(1) matrix structure
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.
                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

VAL()           array contain the nonzeros of A in skyline profile form.
                Row-oriented if DESCRA(2) = 1 (lower triangular),
                column oriented if DESCRA(2) = 2 (upper triangular).

PNTR()          integer array of length M+1 (lower triangular) or
                K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
                points to the location in VAL of the first element of
                the skyline profile in row (column) I.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.
                On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK           length of WORK array.  LWORK should be at least M.

                For good performance, LWORK should generally be larger.
```

For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

NIST FORTRAN Sparse Blas User's Guide available at:

http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. Also not supported:
   a. lower triangular matrix A of size m by n where m > n
   b. upper triangular matrix A of size m by n where m < n

2. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

3. If UNITD =4, the routine scales the rows of A if *DESCRA*(2)=1 and the columns of A if *DESCRA*(2)=2 such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in this particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows (columns) have been scaled. UNITD=2 if *DESCRA*(2)=1 and UNITD=3 if *DESCRA*(2)=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row (column) number which 2-norm is exactly zero.

4. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements

might or might not be referenced in the SKY representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the SKY representation.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

C INTERFACE

```
#include <sunperf.h>
void sspcon(char uplo, int n, float *ap, int *ipivot,  float
          anorm, float *rcond, int *info);

void sspcon_64(char uplo, long n, float *ap,  long  *ipivot,
          float anorm, float *rcond, long *info);
```

PURPOSE

sspcon estimates the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

AP (input)
Real array, dimension (N*(N+1)/2) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
Real array, dimension(2*N)

IWORK2 (workspace)
Integer array, dimension (2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

Contents

NAME

```
sspev - compute all the eigenvalues and, optionally,  eigen-
vectors of a real symmetric matrix A in packed storage
```

SYNOPSIS

```
SUBROUTINE SSPEV(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, INFO)

CHARACTER * 1 JOBZ, UPLO
INTEGER N, LDZ, INFO
REAL AP(*), W(*), Z(LDZ,*), WORK(*)

SUBROUTINE SSPEV_64(JOBZ, UPLO, N, AP, W, Z, LDZ, WORK, INFO)

CHARACTER * 1 JOBZ, UPLO
INTEGER*8 N, LDZ, INFO
REAL AP(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SPEV(JOBZ, UPLO, N, AP, W, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, LDZ, INFO
REAL, DIMENSION(:) :: AP, W, WORK
REAL, DIMENSION(:,:) :: Z

SUBROUTINE SPEV_64(JOBZ, UPLO, N, AP, W, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDZ, INFO
REAL, DIMENSION(:) :: AP, W, WORK
REAL, DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void sspev(char jobz, char uplo, int n, float *ap, float *w,
          float *z, int ldz, int *info);

void sspev_64(char jobz, char uplo, long n, float *ap, float
          *w, float *z, long ldz, long *info);
```

PURPOSE

sspev computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

AP (input/output)
          Real array, dimension (N*(N+1)/2)  On  entry,  the
          upper or lower triangle of the symmetric matrix A,
          packed columnwise in a  linear  array.   The  j-th
          column  of A is stored in the array AP as follows:
          if UPLO = 'U', AP(i  +  (j-1)*j/2)  =  A(i,j)  for
          1<=i<=j;  if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) =
          A(i,j) for j<=i<=n.

          On exit, AP is  overwritten  by  values  generated
          during the reduction to tridiagonal form.  If UPLO
          = 'U', the diagonal and first superdiagonal of the
          tridiagonal  matrix  T overwrite the corresponding
          elements of A, and if UPLO = 'L', the diagonal and
          first subdiagonal of T overwrite the corresponding
          elements of A.

W (output)
          Real array, dimension (N) If INFO = 0, the  eigen-
          values in ascending order.
```

```
Z (output)
          Real array, dimension (LDZ, N) If JOBZ = 'V', then
          if  INFO = 0, Z contains the orthonormal eigenvec-
          tors of the matrix A, with the i-th  column  of  Z
          holding  the eigenvector associated with W(i).  If
          JOBZ = 'N', then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          Real array, dimension(3*N)
INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  if INFO = i, the algorithm  failed  to  con-
          verge;  i off-diagonal elements of an intermediate
          tridiagonal form did not converge to zero.
```

REAL, DIMENSION(:) :: AP, W, WORK
REAL, DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void sspevd(char jobz, char uplo, int n,  float  *ap,  float
          *w, float *z, int ldz, int *info);
void sspevd_64(char jobz, char  uplo,  long  n,  float  *ap,
          float *w, float *z, long ldz, long *info);
```

PURPOSE

sspevd computes all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
          = 'N': Compute eigenvalues only;
          = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U': Upper triangle of A is stored;
          = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
          Real array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array.   The j-th

```
          column  of A is stored in the array AP as follows:
          if UPLO = 'U', AP(i  +  (j-1)*j/2)  =  A(i,j)  for
          1<=i<=j;  if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) =
          A(i,j) for j<=i<=n.

          On exit, AP is  overwritten  by  values  generated
          during the reduction to tridiagonal form.  If UPLO
          = 'U', the diagonal and first superdiagonal of the
          tridiagonal  matrix  T overwrite the corresponding
          elements of A, and if UPLO = 'L', the diagonal and
          first subdiagonal of T overwrite the corresponding
          elements of A.
W (output)
          Real array, dimension (N) If INFO = 0, the  eigen-
          values in ascending order.

Z (input) Real array, dimension (LDZ, N) If JOBZ = 'V', then
          if  INFO = 0, Z contains the orthonormal eigenvec-
          tors of the matrix A, with the i-th  column  of  Z
          holding  the eigenvector associated with W(i).  If
          JOBZ = 'N', then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          Real array, dimension (LWORK) On exit, if  INFO  =
          0, WORK(1) returns the optimal LWORK.

LWORK (input)
          The dimension of the  array  WORK.   If  N  <=  1,
          LWORK  must  be at least 1.  If JOBZ = 'N' and N >
          1, LWORK must be at least 2*N.  If JOBZ = 'V'  and
          N > 1, LWORK must be at least 1 + 6*N + N**2.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace/output)
          Integer array, dimension (LIWORK) On exit, if INFO
          = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
          The dimension of the array IWORK.  If JOBZ  =  'N'
          or  N <= 1, LIWORK must be at least 1.  If JOBZ  =
          'V' and N > 1, LIWORK must be at least 3 + 5*N.
```

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

C INTERFACE

```
#include <sunperf.h>
void sspevx(char jobz, char range, char uplo, int  n,  float
          *ap,  float  vl,  float  vu, int il, int iu, float
          abtol, int *nfound, float *w, float *z,  int  ldz,
          int *ifail, int *info);

void sspevx_64(char jobz, char range,  char  uplo,  long  n,
          float  *ap,  float vl, float vu, long il, long iu,
          float abtol, long *nfound,  float  *w,  float  *z,
          long ldz, long *ifail, long *info);
```

PURPOSE

sspevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found;
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)

Real array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)

Real array, dimension (N) If INFO = 0, the selected eigenvalues in ascending order.

Z (output)

Real array, dimension (LDZ, max(1,M)) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

Real array, dimension(8*N)

IWORK2 (workspace)

Integer array, dimension (5*N)

IFAIL (output)

Integer array, dimension (N) If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: ITYPE, N, INFO
REAL, DIMENSION(:) :: AP, BP
```

C INTERFACE

```
#include <sunperf.h>
```

```
void sspgst(int itype, char uplo, int n,  float  *ap,  float
          *bp, int *info);

void sspgst_64(long itype, char uplo,  long  n,  float  *ap,
          float *bp, long *info);
```

PURPOSE

sspgst reduces a real symmetric-definite generalized eigen-problem to standard form, using packed storage.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T)
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U**T or L**T*A*L.

B must have been previously factorized as U**T*U or L*L**T by SPPTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T);
= 2 or 3: compute U*A*U**T or L**T*A*L.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as U**T*U; = 'L': Lower triangle of A is stored and B is factored as L*L**T.

N (input) The order of the matrices A and B. N >= 0.

AP (input/output)
Real array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP (input)
Real array, dimension (N*(N+1)/2) The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by SPPTRF.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

Contents

C INTERFACE

```
#include <sunperf.h>

void sspgv(int itype, char jobz, char  uplo,  int  n,  float
          *ap,  float  *bp, float *w, float *z, int ldz, int
          *info);

void sspgv_64(long itype, char  jobz,  char  uplo,  long  n,
          float  *ap,  float  *bp,  float *w, float *z, long
          ldz, long *info);
```

PURPOSE

sspgv computes all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

AP (input/output)
          Real array, dimension (N*(N+1)/2)  On  entry,  the
          upper or lower triangle of the symmetric matrix A,
          packed columnwise in a  linear  array.   The  j-th
          column  of A is stored in the array AP as follows:
```

if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of AP are destroyed.

BP (input/output)

Real array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array BP as follows: if UPLO = 'U', BP(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T, in the same storage format as B.

W (output)

Real array, dimension (N) If INFO = 0, the eigenvalues in ascending order.

Z (output)

Real array, dimension (LDZ, N) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

Real array, dimension(3*N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: SPPTRF or SSPEV returned an error code:

<= N: if INFO = i, SSPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero. > N: if INFO = n + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

          float  *ap,  float  *bp,  float *w, float *z, long
          ldz, long *info);
```

PURPOSE

sspgvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed format, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x
```

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

AP (input/output)
          Real array, dimension (N*(N+1)/2)  On  entry,  the
          upper or lower triangle of the symmetric matrix A,
          packed columnwise in a  linear  array.   The  j-th
          column  of A is stored in the array AP as follows:
          if UPLO = 'U', AP(i  +  (j-1)*j/2)  =  A(i,j)  for
          1<=i<=j;  if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) =
          A(i,j) for j<=i<=n.

          On exit, the contents of AP are destroyed.

BP (input/output)
          Real array, dimension (N*(N+1)/2)  On  entry,  the
          upper or lower triangle of the symmetric matrix B,
          packed columnwise in a  linear  array.   The  j-th
          column  of B is stored in the array BP as follows:
          if UPLO = 'U', BP(i  +  (j-1)*j/2)  =  B(i,j)  for
          1<=i<=j;  if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) =
          B(i,j) for j<=i<=n.

          On exit, the triangular factor U  or  L  from  the
          Cholesky  factorization  B = U**T*U or B = L*L**T,
          in the same storage format as B.

W (output)
          Real array, dimension (N) If INFO = 0, the  eigen-
          values in ascending order.

Z (output)
          Real array, dimension (LDZ, N) If JOBZ = 'V', then
          if  INFO = 0, Z contains the matrix Z of eigenvec-
          tors.  The eigenvectors are normalized as follows:
          if  ITYPE  =  1  or 2, Z**T*B*Z = I; if ITYPE = 3,
          Z**T*inv(B)*Z = I.  If JOBZ = 'N', then Z  is  not
          referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).
```

WORK (workspace/output)
Real array, dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 2*N. If JOBZ = 'V' and N > 1, LWORK >= 1 + 6*N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
Integer array, dimension (LIWORK) On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPPTRF or SSPEVD returned an error code:
<= N: if INFO = i, SSPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

void sspgvx_64(long itype, char jobz, char range, char uplo,
          long  n, float *ap, float *bp, float vl, float vu,
          long il, long iu, float abstol, long *m, float *w,
          float *z, long ldz, long *ifail, long *info);
```

PURPOSE

sspgvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric, stored in packed storage, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
```

```
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangle of A and B are stored;
          = 'L':  Lower triangle of A and B are stored.

N (input) The order of the matrix pencil (A,B).  N >= 0.
AP (input/output)
          Real array, dimension (N*(N+1)/2)  On  entry,  the
          upper or lower triangle of the symmetric matrix A,
          packed columnwise in a  linear  array.   The  j-th
          column  of A is stored in the array AP as follows:
          if UPLO = 'U', AP(i  +  (j-1)*j/2)  =  A(i,j)  for
          1<=i<=j;  if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) =
          A(i,j) for j<=i<=n.

          On exit, the contents of AP are destroyed.

BP (input/output)
          Real array, dimension (N*(N+1)/2)  On  entry,  the
          upper or lower triangle of the symmetric matrix B,
          packed columnwise in a  linear  array.   The  j-th
          column  of B is stored in the array BP as follows:
          if UPLO = 'U', BP(i  +  (j-1)*j/2)  =  B(i,j)  for
          1<=i<=j;  if UPLO = 'L', BP(i + (j-1)*(2*n-j)/2) =
          B(i,j) for j<=i<=n.

          On exit, the triangular factor U  or  L  from  the
          Cholesky  factorization  B = U**T*U or B = L*L**T,
          in the same storage format as B.

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

VU (input)
          See the description of VL.

IL (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
```

and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tri- diagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)

Real array, dimension (N) On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (output)

Real array, dimension (LDZ, max(1,M)) If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector asso- ciated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
Real array, dimension(8*N)

IWORK (workspace)
INTEGER array, dimension(5*N)

IFAIL (output)
INTEGER array, dimension (N) If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPPTRF or SSPEVX returned an error code:
<= N: if INFO = i, SSPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

SUBROUTINE SPMV(UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: A, X, Y

SUBROUTINE SPMV_64(UPLO, N, ALPHA, A, X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INCX, INCY
REAL :: ALPHA, BETA
```

```
REAL, DIMENSION(:) :: A, X, Y
```

C INTERFACE

```
#include <sunperf.h>

void sspmv(char uplo, int n, float alpha,  float  *a,  float
          *x, int incx, float beta, float *y, int incy);

void sspmv_64(char uplo, long  n,  float  alpha,  float  *a,
          float  *x,  long  incx, float beta, float *y, long
          incy);
```

PURPOSE

sspmv performs the matrix-vector operation y := alpha*A*x + beta*y, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l'   The lower triangular part of A is supplied in A.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

          float *a);

void sspr_64(char uplo, long n, float alpha, float *x,  long
          incx, float *a);
```

PURPOSE

sspr performs the symmetric rank 1 operation A := alpha*x*x' + A, where alpha is a real scalar, x is an n element vector and A is an n by n symmetric matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l'   The lower triangular part of A is supplied in A.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

A (input/output)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the symmetric matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix.

          ldx, float *ferr, float *berr, int *info);

void ssprfs_64(char uplo, long  n,  long  nrhs,  float  *ap,
          float *af, long *ipivot, float *b, long ldb, float
          *x, long ldx,  float  *ferr,  float  *berr,  float
          *work, long *iwork, long *info);
```

PURPOSE

ssprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) Real array, dimension (N*(N+1)/2) The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if

UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AF (input)
Real array, dimension (N*(N+1)/2) The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

B (input) Real array, dimension (LDB,NRHS) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
Real array, dimension (LDX,NRHS) On entry, the solution matrix X, as computed by SSPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
Real array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Real array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

```
WORK (workspace)
          Real array, dimension(3*N)

WORK2 (workspace)
          Integer array, dimension(N)
INFO (output) Integer

```

C INTERFACE

```
#include <sunperf.h>

void sspsv(char uplo,  int  n,  int  nrhs,  float  *ap,  int
          *ipivot, float *b, int ldb, int *info);

void sspsv_64(char uplo, long n, long nrhs, float *ap,  long
          *ipivot, float *b, long ldb, long *info);
```

PURPOSE

sspsv computes the solution to a real system of linear equations
   A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
   A = U * D * U**T, if UPLO = 'U', or
   A = L * D * L**T, if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
  = 'U': Upper triangle of A is stored;
  = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
  The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP (input/output)
  Real array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th

column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D, as determined by SSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)

Real array, dimension (LDB,NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44

Packed storage of the upper triangle of A:

AP = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

          ldb, float  *x,  long  ldx,  float  *rcond,  float
          *ferr, float *berr, long *info);
```

PURPOSE

SSPSVX uses the diagonal pivoting factorization A = U*D*U**T or A = L*D*L**T to compute the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
```

where U (or L) is a product of permutation and unit upper (lower)

triangular matrices and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the routine
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A. If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form
of A.
4. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. AP, AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

AP (input)
Real array, dimension (N*(N+1)/2) The upper or lower triangle of the symmetric matrix A, packed

columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AF (input/output)
Real array, dimension (N*(N+1)/2) If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)
Integer array, dimension (N) If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSPTRF.

B (input) Real array, dimension (LDB,NRHS) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)

Real array, dimension (LDX,NRHS) If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
Real array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Real array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
Real array, dimension(3*N)

WORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine

precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':
Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44
```

Packed storage of the upper triangle of A:

AP = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

```

C INTERFACE

```
#include <sunperf.h>

void ssptrd(char uplo, int n, float *ap, float *d, float *e,
          float *tau, int *info);

void ssptrd_64(char uplo, long n, float *ap, float *d, float
          *e, float *tau, long *info);
```

PURPOSE

ssptrd reduces a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation: Q**T * A * Q = T.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input)
Real array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are over- written by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

D (output)
Real array, dimension (N) The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E (output)
Real array, dimension (N-1) The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU (output)
Real array, dimension (N-1) The scalar factors of the elementary reflectors (see Further Details).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

```
   Q = H(n-1) . . . H(2) H(1).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in AP, overwriting A(1:i-1,i+1), and tau is stored in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

```
   Q = H(1) H(2) . . . H(n-1).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is stored on exit in AP, overwriting A(i+2:n,i), and tau is stored in TAU(i).

#include <sunperf.h>

void ssptrf(char uplo, int n, float *ap,  int  *ipivot,  int
          *info);

void ssptrf_64(char uplo, long n, float *ap,  long  *ipivot,
          long *info);
```

PURPOSE

ssptrf computes the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Real array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array.   The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)
Integer array, dimension (N) Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

```
5-96 - Based on modifications by J. Lewis,  Boeing  Computer
Services
       Company

If UPLO = 'U', then A = U*D*U', where
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where  k  decreases
from  n  to  1 in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation matrix as defined by IPIVOT(k), and U(k) is a
unit upper triangular matrix,  such  that  if  the  diagonal
block D(k) is of order s (s = 1 or 2), then

           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k

If s = 1, D(k) overwrites A(k,k), and  v  overwrites  A(1:k-
1,k).   If s = 2, the upper triangle of D(k) overwrites A(k-
1,k-1), A(k-1,k), and A(k,k), and  v  overwrites  A(1:k-2,k-
1:k).

If UPLO = 'L', then A = L*D*L', where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
```

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

```

F95 INTERFACE

```
SUBROUTINE SPTRI(UPLO, N, AP, IPIVOT, [WORK], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: AP, WORK

SUBROUTINE SPTRI_64(UPLO, N, AP, IPIVOT, [WORK], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, INFO
```

```
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: AP, WORK
```

C INTERFACE

```
#include <sunperf.h>

void ssptri(char uplo, int n, float  *a,  int  *ipivot,  int
          *info);

void ssptri_64(char uplo, long n, float  *a,  long  *ipivot,
          long *info);
```

PURPOSE

ssptri computes the inverse of a real symmetric indefinite matrix A in packed storage using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Real array, dimension (N*(N+1)/2) On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

WORK (workspace)

```
          Real array, dimension(N)

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          > 0: if INFO = i, D(i,i) = 0; the matrix is singu-
          lar and its inverse could not be computed.
```

NAME

SSPTRS - solve a system of linear equations A*X = B with a real symmetric matrix A stored in packed format using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF

SYNOPSIS

```
SUBROUTINE SSPTRS(UPLO, N, NRHS, AP, IPIVOT, B, LDB, INFO)

CHARACTER * 1 UPLO
INTEGER N, NRHS, LDB, INFO
INTEGER IPIVOT(*)
REAL AP(*), B(LDB,*)

SUBROUTINE SSPTRS_64(UPLO, N, NRHS, AP, IPIVOT, B, LDB, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDB, INFO
INTEGER*8 IPIVOT(*)
REAL AP(*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE SPTRS(UPLO, N, [NRHS], AP, IPIVOT, B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDB, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: AP
REAL, DIMENSION(:,:) :: B

SUBROUTINE SPTRS_64(UPLO, N, [NRHS], AP, IPIVOT, B, [LDB], [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL, DIMENSION(:) :: AP
REAL, DIMENSION(:,:) :: B
```

C INTERFACE

```
#include <sunperf.h>

void ssptrs(char uplo, int  n,  int  nrhs,  float  *ap,  int
          *ipivot, float *b, int ldb, int *info);

void ssptrs_64(char uplo, long n, long nrhs, float *ap, long
          *ipivot, float *b, long ldb, long *info);
```

PURPOSE

ssptrs solves a system of linear equations A*X = B with a real symmetric matrix A stored in packed format using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP (input)
Real array, dimension (N*(N+1)/2) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by SSPTRF.

B (input/output)
Real array, dimension (LDB, NRHS) On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

CHARACTER(LEN=1) :: RANGE, ORDER
INTEGER(8) :: N, IL, IU, M, NSPLIT, INFO
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK
REAL :: VL, VU, ABSTOL
REAL, DIMENSION(:) :: D, E, W, WORK
```

C INTERFACE

```
#include <sunperf.h>

void sstebz(char range, char order, int n, float  vl,  float
          vu,  int il, int iu, float abstol, float *d, float
          *e, int *m, int *nsplit, float  *w,  int  *iblock,
          int *isplit, int *info);

void sstebz_64(char range, char order,  long  n,  float  vl,
          float  vu,  long  il, long iu, float abstol, float
          *d, float *e, long *m,  long  *nsplit,  float  *w,
          long *iblock, long *isplit, long *info);
```

PURPOSE

sstebz computes the eigenvalues of a symmetric tridiagonal matrix T. The user may ask for all eigenvalues, all eigenvalues in the half-open interval (VL, VU], or the IL-th through IU-th eigenvalues.

To avoid overflow, the matrix must be scaled so that its largest element is no greater than overflow**(1/2) * underflow**(1/4) in absolute value, and for greatest accuracy, it should not be much smaller than that.

See W. Kahan "Accurate Eigenvalues of a Symmetric Tridiagonal Matrix", Report CS41, Computer Science Dept., Stanford University, July 21, 1966.

ARGUMENTS

RANGE (input)
= 'A': ("All")   all eigenvalues will be found.
= 'V': ("Value") all eigenvalues in the half-open interval (VL, VU] will be found. = 'I': ("Index") the IL-th through IU-th eigenvalues (of the entire matrix) will be found.

ORDER (input)
= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see IBLOCK, ISPLIT) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.

N (input) The order of the tridiagonal matrix T. N >= 0.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to VL, or greater than VU, will not be returned. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute tolerance for the eigenvalues. An eigenvalue (or cluster) is considered to be located if it has been determined to lie in an interval whose width is ABSTOL or less. If ABSTOL is less than or equal to zero, then ULP*|T| will be used, where |T| means the 1-norm of T.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) off-diagonal elements of the tridiagonal matrix T.

M (output)

The actual number of eigenvalues found. 0 <= M <= N. (See also the description of INFO=2,3.)

NSPLIT (output)
The number of diagonal blocks in the matrix T. 1 <= NSPLIT <= N.

W (output)
On exit, the first M elements of W will contain the eigenvalues. (SSTEBZ may use the remaining N-M elements as workspace.)

IBLOCK (output)
At each row/column j where E(j) is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if INFO = 0, IBLOCK(i) specifies to which block (from 1 to the number of blocks) the eigenvalue W(i) belongs. (SSTEBZ may use the remaining N-M elements as workspace.)

ISPLIT (output)
The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc., and the NSPLIT-th consists of rows/columns ISPLIT(NSPLIT-1)+1 through ISPLIT(NSPLIT)=N. (Only the first NSPLIT elements will actually be used, but since the user cannot know a priori what value NSPLIT will have, N words must be reserved for ISPLIT.)

WORK (workspace)
dimension(4*N)

IWORK (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: some or all of the eigenvalues failed to converge or
were not computed:
=1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. This is generally caused

by unexpectedly inaccurate arithmetic. =2 or 3: RANGE='I' only: Not all of the eigenvalues IL:IU were found.
Effect: M < IU+1-IL
Cause: non-monotonic arithmetic, causing the Sturm sequence to be non-monotonic. Cure: recalculate, using RANGE='A', and pick
out eigenvalues IL:IU. = 4: RANGE='I', and the Gershgorin interval initially used was too small. No eigenvalues were computed.

NAME

```
sstedc - compute all eigenvalues and, optionally,  eigenvec-
tors  of a symmetric tridiagonal matrix using the divide and
conquer method
```

SYNOPSIS

```
SUBROUTINE SSTEDC(COMPZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK, LIWORK,
      INFO)

CHARACTER * 1 COMPZ
INTEGER N, LDZ, LWORK, LIWORK, INFO
INTEGER IWORK(*)
REAL D(*), E(*), Z(LDZ,*), WORK(*)

SUBROUTINE SSTEDC_64(COMPZ, N, D, E, Z, LDZ, WORK, LWORK, IWORK,
      LIWORK, INFO)

CHARACTER * 1 COMPZ
INTEGER*8 N, LDZ, LWORK, LIWORK, INFO
INTEGER*8 IWORK(*)
REAL D(*), E(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEDC(COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],
       [LIWORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
INTEGER :: N, LDZ, LWORK, LIWORK, INFO
INTEGER, DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:,:) :: Z
```

```
SUBROUTINE STEDC_64(COMPZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],
       [LIWORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void sstedc(char compz, int n, float *d, float *e, float *z,
          int ldz, int *info);
void sstedc_64(char compz, long n, float *d, float *e, float
          *z, long ldz, long *info);
```

PURPOSE

sstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band real symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'I': Compute eigenvectors of tridiagonal matrix also.
= 'V': Compute eigenvectors of original dense symmetric matrix also. On entry, Z contains the orthogonal matrix used to reduce the original matrix to tridiagonal form.

N (input) The dimension of the symmetric tridiagonal matrix.

```
          N >= 0.

D (input/output)
          On entry, the diagonal elements of the tridiagonal
          matrix.   On exit, if INFO = 0, the eigenvalues in
          ascending order.

E (input/output)
          On entry, the subdiagonal elements of the tridiag-
          onal matrix.  On exit, E has been destroyed.

Z (input) On entry, if COMPZ =  'V',  then  Z  contains  the
          orthogonal  matrix used in the reduction to tridi-
          agonal form.  On exit, if INFO = 0, then if  COMPZ
          =  'V', Z contains the orthonormal eigenvectors of
          the original symmetric matrix, and if COMPZ = 'I',
          Z  contains  the  orthonormal  eigenvectors of the
          symmetric tridiagonal matrix.  If   COMPZ  =  'N',
          then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1.
          If eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
          dimension (LWORK) On exit, if INFO  =  0,  WORK(1)
          returns the optimal LWORK.

LWORK (input)
          The dimension of the array WORK.  If COMPZ  =  'N'
          or N <= 1 then LWORK must be at least 1.  If COMPZ
          = 'V' and N > 1 then LWORK must be at least ( 1  +
          3*N  +  2*N*lg N + 3*N**2 ), where lg( N ) = smal-
          lest integer k such that 2**k >= N.   If  COMPZ  =
          'I'  and  N  > 1 then LWORK must be at least ( 1 +
          4*N + N**2 ).

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LIWORK.

LIWORK (input)
          The dimension of the array IWORK.  If COMPZ =  'N'
          or  N  <=  1  then  LIWORK must be at least 1.  If
```

```
           COMPZ = 'V' and N > 1 then LIWORK must be at least
           (  6 + 6*N + 5*N*lg N ).  If COMPZ = 'I' and N > 1
           then LIWORK must be at least ( 3 + 5*N ).

           If LIWORK = -1, then a workspace query is assumed;
           the  routine  only  calculates the optimal size of
           the IWORK array, returns this value as  the  first
           entry  of  the  IWORK  array, and no error message
           related to LIWORK is issued by XERBLA.

 INFO (output)
           = 0:  successful exit.
           < 0:  if INFO = -i, the i-th argument had an ille-
           gal value.
           > 0:  The algorithm failed to  compute  an  eigen-
           value while working on the submatrix lying in rows
           and columns INFO/(N+1) through mod(INFO,N+1).
```

```
#include <sunperf.h>
void sstegr(char jobz, char range, int n,  float  *d,  float
          *e,  float  vl,  float  vu,  int il, int iu, float
          abstol, int *m, float *w, float *z, int  ldz,  int
          *isuppz, int *info);

void sstegr_64(char jobz, char  range,  long  n,  float  *d,
          float  *e,  float  vl, float vu, long il, long iu,
          float abstol, long *m, float *w,  float  *z,  long
          ldz, long *isuppz, long *info);
```

PURPOSE

```
sstegr b) Compute the  eigenvalues,  lambda_j,  of  L_i  D_i
L_i^T to high
       relative accuracy by the dqds algorithm,
   (c) If there is a cluster of close eigenvalues,  "choose"
sigma_i
       close to the cluster, and go to step (a),
   (d) Given the approximate eigenvalue lambda_j of L_i  D_i
L_i^T,
       compute the corresponding eigenvector by forming a
       rank-revealing twisted factorization.
The desired accuracy of the output can be specified  by  the
input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for  the  sym-
metric   tridiagonal   eigenvalue/eigenvector  problem",  by
Inderjit Dhillon, Computer Science Division Technical Report
No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently SSTEGR is only set up to find ALL  the  n
eigenvalues and eigenvectors of T in O(n^2) time
Note 2 : Currently the routine  SSTEIN  is  called  when  an
appropriate  sigma_i  cannot  be  chosen  in step (c) above.
```

SSTEIN invokes modified Gram-Schmidt when eigenvalues are close.
Note 3 : SSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E; E(N) need not be set. On exit, E is overwritten.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues/eigenvectors. IF JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than N*EPS*|T|, then N*EPS*|T| will be used in its place, where EPS is the machine precision and |T| is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of EPS*|T| irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input)
If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,18*N)
If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= max(1,10*N)

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = 1, internal error in SLARRE, if INFO = 2, internal error in SLARRV.

agonal  matrix  T  corresponding  to  specified eigenvalues,
using inverse iteration
```

SYNOPSIS

```
SUBROUTINE SSTEIN(N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK, IWORK,
      IFAIL, INFO)

INTEGER N, M, LDZ, INFO
INTEGER IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
REAL D(*), E(*), W(*), Z(LDZ,*), WORK(*)

SUBROUTINE SSTEIN_64(N, D, E, M, W, IBLOCK, ISPLIT, Z, LDZ, WORK,
      IWORK, IFAIL, INFO)

INTEGER*8 N, M, LDZ, INFO
INTEGER*8 IBLOCK(*), ISPLIT(*), IWORK(*), IFAIL(*)
REAL D(*), E(*), W(*), Z(LDZ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEIN(N, D, E, M, W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],
       [IWORK], IFAIL, [INFO])

INTEGER :: N, M, LDZ, INFO
INTEGER, DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL, DIMENSION(:) :: D, E, W, WORK
REAL, DIMENSION(:,:) :: Z

SUBROUTINE STEIN_64(N, D, E, M, W, IBLOCK, ISPLIT, Z, [LDZ], [WORK],
       [IWORK], IFAIL, [INFO])
```

```
INTEGER(8) :: N, M, LDZ, INFO
INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
REAL, DIMENSION(:) :: D, E, W, WORK
REAL, DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void sstein(int n, float *d, float *e, int m, float *w,  int
          *iblock,  int  *isplit,  float  *z,  int  ldz, int
          *ifail, int *info);

void sstein_64(long n, float *d, float *e, long m, float *w,
          long  *iblock,  long  *isplit, float *z, long ldz,
          long *ifail, long *info);
```

PURPOSE

sstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

ARGUMENTS

N (input) The order of the matrix. N >= 0.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix T, in elements 1 to N-1. E(N) need not be set.

M (input) The number of eigenvectors to be found. 0 <= M <= N.

W (input) The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBZ with ORDER = 'B' is expected here.)

IBLOCK (input)
The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBZ is expected here.)

ISPLIT (input)
The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBZ is expected here.)

Z (output)
The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations.

LDZ (input)
The leading dimension of the array Z. LDZ >= max(1,N).

WORK (workspace)
dimension(5*N)

IWORK (workspace)
dimension(N)

IFAIL (output)
On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:,:) :: Z

SUBROUTINE STEQR_64(COMPZ, N, D, E, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
INTEGER(8) :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void ssteqr(char compz, int n, float *d, float *e, float *z,
          int ldz, int *info);

void ssteqr_64(char compz, long n, float *d, float *e, float
          *z, long ldz, long *info);
```

PURPOSE

ssteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band symmetric matrix can also be found if SSYTRD or SSPTRD or SSBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors of the original symmetric matrix. On entry, Z must contain the orthogonal matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the orthogonal matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original symmetric matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
dimension(max(1,2*N-2)) If COMPZ = 'N', then WORK is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value
> 0: the algorithm has failed to find all the eigenvalues in a total of 30*N iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is orthogonally similar to the original matrix.

SUBROUTINE STEVD_64(JOBZ, N, D, E, Z, [LDZ], [WORK], [LWORK], [IWORK],
```

```
       [LIWORK], [INFO])

CHARACTER(LEN=1) :: JOBZ
INTEGER(8) :: N, LDZ, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: D, E, WORK
REAL, DIMENSION(:,:) :: Z
```

C INTERFACE

```
#include <sunperf.h>

void sstevd(char jobz, int n, float *d, float *e, float  *z,
          int ldz, int *info);
void sstevd_64(char jobz, long n, float *d, float *e,  float
          *z, long ldz, long *info);
```

PURPOSE

sstevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A, stored in elements 1 to N-1 of E; E(N) need not be set, but is used by the

```
          routine.   On  exit,  the  contents  of E are des-
          troyed.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          orthonormal eigenvectors of the matrix A, with the
          i-th column of Z holding the  eigenvector  associ-
          ated  with  D(i).   If  JOBZ  = 'N', then Z is not
          referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).
WORK (workspace)
          dimension (LWORK) On exit, if INFO  =  0,  WORK(1)
          returns the optimal LWORK.

LWORK (input)
          The dimension of the array WORK.  If JOBZ   =  'N'
          or  N <= 1 then LWORK must be at least 1.  If JOBZ
          = 'V' and N > 1 then LWORK must be at least ( 1  +
          4*N + N**2 ).

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LIWORK.

LIWORK (input)
          The dimension of the array IWORK.  If JOBZ  =  'N'
          or N <= 1 then LIWORK must be at least 1.  If JOBZ
          = 'V' and N > 1  then  LIWORK  must  be  at  least
          3+5*N.

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, the algorithm  failed  to  con-
          verge;  i  off-diagonal elements of E did not con-
```

verge to zero.

```
#include <sunperf.h>
void sstevr(char jobz, char range, int n,  float  *d,  float
          *e,  float  vl,  float  vu,  int il, int iu, float
          abstol, int *m, float *w, float *z, int  ldz,  int
          *isuppz, int *info);

void sstevr_64(char jobz, char  range,  long  n,  float  *d,
          float  *e,  float  vl, float vu, long il, long iu,
          float abstol, long *m, float *w,  float  *z,  long
          ldz, long *isuppz, long *info);
```

PURPOSE

sstevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSTEVR calls SSTEGR to compute the eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

```
   (a) Compute T - sigma_i = L_i D_i L_i^T,  such  that  L_i
D_i L_i^T
        is a relatively robust representation,
   (b) Compute the eigenvalues, lambda_j, of L_i  D_i  L_i^T
to high
       relative accuracy by the dqds algorithm,
   (c) If there is a cluster of close eigenvalues,  "choose"
```

sigma_i
close to the cluster, and go to step (a),
(d) Given the approximate eigenvalue lambda_j of L_i D_i L_i^T,
compute the corresponding eigenvector by forming a
rank-revealing twisted factorization.
The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : SSTEVR calls SSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSTEVR calls SSTEBZ and SSTEIN on non-ieee machines and
when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, D may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of E;

E(N) need not be set. On exit, E may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

See the description of VL.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)

See the description of IL.

ABSTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but future releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input)
If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 20*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= 10*N.

```
            If LIWORK = -1, then a workspace query is assumed;
            the  routine  only  calculates the optimal size of
            the IWORK array, returns this value as  the  first
            entry  of  the  IWORK  array, and no error message
            related to LIWORK is issued by XERBLA.
  INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  Internal error
```

```

C INTERFACE

```
#include <sunperf.h>
void sstevx(char jobz, char range, int n, float *diag, float
          *offd,  float  vl, float vu, int il, int iu, float
          abtol, int *nfound, float *w, float *z,  int  ldz,
          int *ifail, int *info);

void sstevx_64(char jobz, char range, long n,  float  *diag,
          float *offd, float vl, float vu, long il, long iu,
          float abtol, long *nfound,  float  *w,  float  *z,
          long ldz, long *ifail, long *info);
```

PURPOSE

sstevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. N >= 0.

DIAG (input/output)

On entry, the n diagonal elements of the tridiagonal matrix A. On exit, DIAG may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

OFFD (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A in elements 1 to N-1 of OFFD; OFFD(N) need not be set. On exit, OFFD may be multiplied by a constant factor chosen to avoid over/underflow in computing the eigenvalues.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal

Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
: The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
: The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input)
: If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge (INFO > 0), then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
: The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
: dimension(5*N)

IWORK2 (workspace)

IFAIL (output)
: If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
: = 0: successful exit
: < 0: if INFO = -i, the i-th argument had an illegal value
: > 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:) :: L, D, SUBL
REAL, DIMENSION(:,:) :: B
```

C INTERFACE

```
#include <sunperf.h>

void sstsv(int n, int nrhs, float *l, float *d, float *subl,
          float *b, int ldb, int *ipiv, int *info);

void sstsv_64(long n, long nrhs, float *l, float  *d,  float
          *subl,  float  *b,  long  ldb,  long  *ipiv,  long
          *info);
```

PURPOSE

sstsv computes the solution to a system of linear equations A * X = B where A is a symmetric tridiagonal matrix.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides in B.

L (input/output)
REAL array, dimension (N)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
REAL array, dimension (N)
On exit, part of the factorization of A.

B (input/output)
The columns of B contain the right hand sides.

LDB (input)
The leading dimension of B as specified in a type or DIMENSION statement.

IPIV (output)

INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

C INTERFACE

```
#include <sunperf.h>
```

```
void ssttrf(int n, float *l,  float  *d,  float  *subl,  int
          *ipiv, int *info);

void ssttrf_64(long n, float *l, float *d, float *subl, long
          *ipiv, long *info);
```

PURPOSE

ssttrf computes the factorization of a complex Hermitian tridiagonal matrix A.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. N >= 0.

L (input/output)
REAL array, dimension (N)
On entry, the n-1 subdiagonal elements of the tri- diagonal matrix A. On exit, part of the factori- zation of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiago- nal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the L*D*L**H factoriza- tion of A.

SUBL (output)
REAL array, dimension (N)
On exit, part of the factorization of A.

IPIV (output)
INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value
> 0: if INFO = i, D(k,k) is exactly zero.   The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system

of equations.

C INTERFACE

```
#include <sunperf.h>

void ssttrs(int n, int  nrhs,  float  *l,  float  *d,  float
          *subl, float *b, int ldb, int *ipiv, int *info);

void ssttrs_64(long n, long nrhs, float *l, float *d,  float
          *subl,  float  *b,  long  ldb,  long  *ipiv,  long
          *info);
```

PURPOSE

ssttrs computes the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. N >= 0.

NRHS (input)
INTEGER
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

L (input) REAL array, dimension (N-1)
On entry, the subdiagonal elements of LL and DD.

D (input) REAL array, dimension (N)
On entry, the diagonal elements of DD.

SUBL (input)
REAL array, dimension (N-2)
On entry, the second subdiagonal elements of LL.

B (input/output)
REAL array, dimension
(LDB, NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
INTEGER
The leading dimension of the array B. LDB >= max(1, N)

```
IPIV (output)
           INTEGER array, dimension (N)
          Details of the interchanges and block  pivot.   If
          IPIV(K)  > 0, 1 by 1 pivot, and if IPIV(K) = K + 1
          an interchange done;  If  IPIV(K)  <  0,  2  by  2
          pivot, no interchange required.

INFO (output)
           INTEGER
          = 0:  successful exit
          < 0:  if INFO = -k, the k-th argument had an ille-
          gal value
```

Contents

NAME

```
sswap - Exchange vectors x and y.
```

SYNOPSIS

```
SUBROUTINE SSWAP(N, X, INCX, Y, INCY)

INTEGER N, INCX, INCY
REAL X(*), Y(*)

SUBROUTINE SSWAP_64(N, X, INCX, Y, INCY)

INTEGER*8 N, INCX, INCY
REAL X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SWAP([N], X, [INCX], Y, [INCY])

INTEGER :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y

SUBROUTINE SWAP_64([N], X, [INCX], Y, [INCY])

INTEGER(8) :: N, INCX, INCY
REAL, DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>

void sswap(int n, float *x, int incx, float *y, int incy);

void sswap_64(long n, float *x, long incx,  float  *y,  long
          incy);
```

PURPOSE

sswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, the y vector.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

ssycon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF

SYNOPSIS

```
SUBROUTINE SSYCON(UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,
      IWORK2, INFO)

CHARACTER * 1 UPLO
INTEGER N, LDA, INFO
INTEGER IPIVOT(*), IWORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)

SUBROUTINE SSYCON_64(UPLO, N, A, LDA, IPIVOT, ANORM, RCOND, WORK,
      IWORK2, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INFO
INTEGER*8 IPIVOT(*), IWORK2(*)
REAL ANORM, RCOND
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYCON(UPLO, N, A, [LDA], IPIVOT, ANORM, RCOND, [WORK],
       [IWORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
```

```
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE SYCON_64(UPLO, N, A, [LDA], IPIVOT, ANORM, RCOND, [WORK],
       [IWORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
void ssycon(char  uplo,  int  n,  float  *a,  int  lda,  int
          *ipivot, float anorm, float *rcond, int *info);

void ssycon_64(char uplo, long n, float *a, long  lda,  long
          *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

```
ssycon estimates the reciprocal of the condition number  (in
the  1-norm) of a real symmetric matrix A using the factori-
zation A = U*D*U**T or A = L*D*L**T computed by SSYTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal
of  the condition number is computed as RCOND = 1 / (ANORM *
norm(inv(A))).
```

ARGUMENTS

```
UPLO (input)
          Specifies whether the details of the factorization
          are stored as an upper or lower triangular matrix.
          = 'U':  Upper triangular, form is A = U*D*U**T;
          = 'L':  Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A.  N >= 0.

A (input) The block diagonal matrix D  and  the  multipliers
          used  to  obtain  the factor U or L as computed by
          SSYTRF.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
```

max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by SSYTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

IWORK2 (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

REAL A(LDA,*), W(*), WORK(*)

SUBROUTINE SSYEV_64(JOBZ, UPLO, N, A, LDA, W, WORK, LDWORK, INFO)

CHARACTER * 1 JOBZ, UPLO
INTEGER*8 N, LDA, LDWORK, INFO
REAL A(LDA,*), W(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYEV(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK], [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER :: N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE SYEV_64(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LDWORK],
       [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDA, LDWORK, INFO
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssyev(char jobz, char uplo, int n, float *a,  int  lda,
          float *w, int *info);

void ssyev_64(char jobz, char uplo, long n, float  *a,  long
          lda, float *w, long *info);
```

PURPOSE

```
ssyev computes all eigenvalues and, optionally, eigenvectors
of a real symmetric matrix A.
```

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the  matrix  A.   On  exit, if JOBZ = 'V', then if
          INFO = 0, A contains the orthonormal  eigenvectors
          of  the matrix A.  If JOBZ = 'N', then on exit the
          lower triangle (if UPLO='L') or the upper triangle
          (if  UPLO='U')  of  A,  including the diagonal, is
          destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

W (output)
          If INFO = 0, the eigenvalues in ascending order.
```

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,3*N-1). For optimal efficiency, LDWORK >= (NB+2)*N, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```
SUBROUTINE SYEVD_64(JOBZ, UPLO, N, A, [LDA], W, [WORK], [LWORK],
       [IWORK], [LIWORK], [INFO])

CHARACTER(LEN=1) :: JOBZ, UPLO
INTEGER(8) :: N, LDA, LWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: W, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssyevd(char jobz, char uplo, int n, float *a, int  lda,
          float *w, int *info);
void ssyevd_64(char jobz, char uplo, long n, float *a,  long
          lda, float *w, long *info);
```

PURPOSE

ssyevd computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

Because of large use of BLAS of level 3, SSYEVD needs N**2 more workspace than SSYEVX.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
```

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
dimension (LWORK) On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least 2*N+1. If JOBZ = 'V' and N > 1, LWORK must be at least 1 + 6*N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If N <= 1, LIWORK must be at least 1. If JOBZ = 'N' and N > 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message

```
            related to LIWORK is issued by XERBLA.

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  if INFO = i, the algorithm  failed  to  con-
            verge;  i off-diagonal elements of an intermediate
            tridiagonal form did not converge to zero.

```

PURPOSE

ssyevr computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, SSYEVR calls SSTEGR to compute the eigenspectrum using Relatively Robust Representations. SSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

(a) Compute T - sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T is a relatively robust representation,

(b) Compute the eigenvalues, lambda_j, of L_i D_i L_i^T to high

relative accuracy by the dqds algorithm,
(c) If there is a cluster of close eigenvalues, "choose" sigma_i
close to the cluster, and go to step (a),
(d) Given the approximate eigenvalue lambda_j of L_i D_i L_i^T,
compute the corresponding eigenvector by forming a
rank-revealing twisted factorization.
The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.
Note 1 : SSYEVR calls SSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. SSYEVR calls SSTEBZ and SSTEIN on non-ieee machines and
when partial spectrum requests are made.

Normal execution of SSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A.

If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tri-diagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but furu- tre releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diago- nally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigen- values in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,26*N). For optimal efficiency, LWORK >= (NB+6)*N, where NB is the max of the blocksize for SSYTRD and SORMTR returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

```
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.
IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LWORK.

LIWORK (input)
          The dimension  of  the  array  IWORK.   LIWORK  >=
          max(1,10*N).

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  Internal error
```

          float *z, long ldz, long *ifail, long *info);
```

PURPOSE

ssyevx computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
```

= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when

```
          ABTOL  is  set  to  twice  the underflow threshold
          2*SLAMCH('S'), not zero.  If this routine  returns
          with INFO>0, indicating that some eigenvectors did
          not converge, try setting ABTOL to 2*SLAMCH('S').

          See "Computing Small Singular Values of Bidiagonal
          Matrices  with Guaranteed High Relative Accuracy,"
          by Demmel and Kahan, LAPACK Working Note #3.
NFOUND (output)
          The total  number  of  eigenvalues  found.   0  <=
          NFOUND  <=  N.  If RANGE = 'A', NFOUND = N, and if
          RANGE = 'I', NFOUND = IU-IL+1.

W (output)
          On normal exit, the first NFOUND elements  contain
          the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first  NFOUND
          columns  of Z contain the orthonormal eigenvectors
          of the matrix  A  corresponding  to  the  selected
          eigenvalues, with the i-th column of Z holding the
          eigenvector associated with W(i).  If an eigenvec-
          tor  fails to converge, then that column of Z con-
          tains the latest approximation to the eigenvector,
          and  the  index  of the eigenvector is returned in
          IFAIL.  If JOBZ = 'N', then Z is  not  referenced.
          Note:   the   user   must  ensure  that  at  least
          max(1,NFOUND) columns are supplied in the array Z;
          if  RANGE  = 'V', the exact value of NFOUND is not
          known in advance and an upper bound must be used.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The  length  of  the  array   WORK.   LDWORK   >=
          max(1,8*N).   For  optimal  efficiency,  LDWORK >=
          (NB+3)*N, where NB is the max of the blocksize for
          SSYTRD and SORMTR returned by ILAENV.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.
```

IWORK2 (workspace)
IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

CHARACTER * 1 UPLO
INTEGER ITYPE, N, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)

SUBROUTINE SSYGS2_64(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)

CHARACTER * 1 UPLO
INTEGER*8 ITYPE, N, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE SYGS2(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: ITYPE, N, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE SYGS2_64(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: ITYPE, N, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssygs2(int itype, char uplo, int n, float *a, int  lda,
          float *b, int ldb, int *info);

void ssygs2_64(long itype, char uplo, long n, float *a, long
          lda, float *b, long ldb, long *info);
```

PURPOSE

ssygs2 reduces a real symmetric-definite generalized eigen-problem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U')*A*inv(U) or inv(L)*A*inv(L')
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U` or L'*A*L.

B must have been previously factorized as U'*U or L*L' by SPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U')*A*inv(U) or inv(L)*A*inv(L');
= 2 or 3: compute U*A*U' or L'*A*L.

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored, and how B has been factorized. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by SPOTRF.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

INTEGER ITYPE, N, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)

SUBROUTINE SSYGST_64(ITYPE, UPLO, N, A, LDA, B, LDB, INFO)

CHARACTER * 1 UPLO
INTEGER*8 ITYPE, N, LDA, LDB, INFO
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE SYGST(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: ITYPE, N, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE SYGST_64(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: ITYPE, N, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ssygst(int itype, char uplo, int n, float *a, int  lda,
          float *b, int ldb, int *info);

void ssygst_64(long itype, char uplo, long n, float *a, long
          lda, float *b, long ldb, long *info);
```

PURPOSE

ssygst reduces a real symmetric-definite generalized eigen-problem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T)
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U**T or L**T*A*L.

B must have been previously factorized as U**T*U or L*L**T by SPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U**T)*A*inv(U) or inv(L)*A*inv(L**T);
= 2 or 3: compute U*A*U**T or L**T*A*L.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as U**T*U; = 'L': Lower triangle of A is stored and B is factored as L*L**T.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix,

```
          stored in the same format as A.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input) The triangular factor from the Cholesky factoriza-
          tion of B, as returned by SPOTRF.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void ssygv(int itype, char jobz, char uplo, int n, float *a,
          int lda, float *b, int ldb, float *w, int *info);

void ssygv_64(long itype, char  jobz,  char  uplo,  long  n,
          float  *a, long lda, float *b, long ldb, float *w,
          long *info);
```

PURPOSE

ssygv computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also
positive definite.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
```

If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the symmetric positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,3*N-1). For optimal efficiency, LDWORK >= (NB+2)*N, where NB is the blocksize for SSYTRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPOTRF or SSYEV returned an error code:
<= N: if INFO = i, SSYEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

void ssygvd(int itype, char jobz, char uplo,  int  n,  float
          *a,  int  lda,  float  *b,  int ldb, float *w, int
          *info);

void ssygvd_64(long itype, char jobz,  char  uplo,  long  n,
          float  *a, long lda, float *b, long ldb, float *w,
          long *info);
```

PURPOSE

ssygvd computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigen-problem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

Specifies the problem type to be solved:
= 1: A*x = (lambda)*B*x
= 2: A*B*x = (lambda)*x
= 3: B*A*x = (lambda)*x

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the symmetric matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U**T*U or B = L*L**T.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= 2*N+1. If JOBZ = 'V' and N > 1, LWORK >= 1 + 6*N + 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If N <= 1, LIWORK >= 1. If JOBZ = 'N' and N > 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPOTRF or SSYEVD returned an error code:
<= N: if INFO = i, SSYEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

```

PURPOSE

ssygvx computes selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be symmetric and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangle of A and B are stored;
          = 'L':  Lower triangle of A and B are stored.

N (input) The order of the matrix pencil (A,B).  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the matrix A.

          On exit, the lower triangle (if UPLO='L')  or  the
          upper  triangle  (if UPLO='U') of A, including the
          diagonal, is destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input/output)
          On entry, the symmetric matrix B.  If UPLO =  'U',
          the leading N-by-N upper triangular part of B con-
          tains the upper triangular part of the  matrix  B.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of B contains the lower  triangular  part  of
          the matrix B.

          On exit, if INFO <= N, the part  of  B  containing
          the matrix is overwritten by the triangular factor
          U or L from the Cholesky factorization B =  U**T*U
          or B = L*L**T.
```

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
See the description of VL.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
See the description of IL.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tri-diagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*DLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
On normal exit, the first M elements contain the selected eigenvalues in ascending order.

```
Z (input) If JOBZ = 'N', then Z is not referenced.  If  JOBZ
          =  'V', then if INFO = 0, the first M columns of Z
          contain the orthonormal eigenvectors of the matrix
          A  corresponding to the selected eigenvalues, with
          the i-th column of Z holding the eigenvector asso-
          ciated with W(i).  The eigenvectors are normalized
          as follows:  if ITYPE = 1 or 2, Z**T*B*Z =  I;  if
          ITYPE = 3, Z**T*inv(B)*Z = I.
          If an eigenvector fails  to  converge,  then  that
          column  of  Z contains the latest approximation to
          the eigenvector, and the index of the  eigenvector
          is  returned in IFAIL.  Note: the user must ensure
          that at least max(1,M) columns are supplied in the
          array  Z;  if RANGE = 'V', the exact value of M is
          not known in advance and an upper  bound  must  be
          used.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  length  of  the   array   WORK.    LWORK   >=
          max(1,8*N).   For  optimal  efficiency,  LWORK  >=
          (NB+3)*N, where NB is  the  blocksize  for  SSYTRD
          returned by ILAENV.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace)
          dimension(5*N)

IFAIL (output)
          If JOBZ = 'V', then if INFO = 0, the first M  ele-
          ments  of IFAIL are zero.  If INFO > 0, then IFAIL
          contains the  indices  of  the  eigenvectors  that
          failed  to converge.  If JOBZ = 'N', then IFAIL is
          not referenced.

INFO (output)
          = 0:  successful exit
```

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: SPOTRF or SSYEVX returned an error code:
<= N: if INFO = i, SSYEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

FURTHER DETAILS

NAME

```
ssymm - perform one of the matrix-matrix operations    C  :=
alpha*A*B + beta*C or C := alpha*B*A + beta*C
```

SYNOPSIS

```
SUBROUTINE SSYMM(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
      LDC)

CHARACTER * 1 SIDE, UPLO
INTEGER M, N, LDA, LDB, LDC
REAL ALPHA, BETA
REAL A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE SSYMM_64(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
      LDC)

CHARACTER * 1 SIDE, UPLO
INTEGER*8 M, N, LDA, LDB, LDC
REAL ALPHA, BETA
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYMM(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])

CHARACTER(LEN=1) :: SIDE, UPLO
INTEGER :: M, N, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:,:) :: A, B, C

SUBROUTINE SYMM_64(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO
INTEGER(8) :: M, N, LDA, LDB, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>

void ssymm(char side, char uplo, int m, int n, float  alpha,
          float  *a, int lda, float *b, int ldb, float beta,
          float *c, int ldc);

void ssymm_64(char side, char uplo, long m,  long  n,  float
          alpha,  float  *a,  long  lda, float *b, long ldb,
          float beta, float *c, long ldc);
```

PURPOSE

ssymm performs one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of the symmetric matrix is to be referenced.

```
           Unchanged on exit.

  M (input)
           On entry,  M  specifies the number of rows of  the
           matrix  C.  M >= 0.  Unchanged on exit.

  N (input)
           On entry, N specifies the number of columns of the
           matrix C.  N >= 0.  Unchanged on exit.

  ALPHA (input)
           On  entry,  ALPHA  specifies  the  scalar   alpha.
           Unchanged on exit.
  A (input)
           REAL array of DIMENSION ( LDA, ka ), where ka is m
           when  SIDE = 'L' or 'l'  and is  n otherwise.

           Before entry  with  SIDE = 'L' or 'l',  the  m  by
           m   part  of  the array  A  must contain the  sym-
           metric matrix,  such that when  UPLO = 'U' or 'u',
           the  leading  m  by m upper triangular part of the
           array  A  must contain the upper  triangular  part
           of  the  symmetric matrix and the  strictly  lower
           triangular part of  A   is  not  referenced,   and
           when   UPLO  =  'L'  or  'l',  the leading  m by m
           lower triangular part  of the  array  A must  con-
           tain   the   lower  triangular  part  of the  sym-
           metric matrix and the  strictly  upper  triangular
           part of  A  is not referenced.

           Before entry  with  SIDE = 'R' or 'r',  the  n  by
           n   part  of  the array  A  must contain the  sym-
           metric matrix,  such that when  UPLO = 'U' or 'u',
           the  leading  n  by n upper triangular part of the
           array  A  must contain the upper  triangular  part
           of  the  symmetric matrix and the  strictly  lower
           triangular part of  A   is  not  referenced,   and
           when   UPLO  =  'L'  or  'l',  the leading  n by n
           lower triangular part  of the  array  A must  con-
           tain   the   lower  triangular  part  of the  sym-
           metric matrix and the  strictly  upper  triangular
           part of  A  is not referenced.

           Unchanged on exit.

  LDA (input)
           On entry, LDA specifies the first dimension  of  A
           as  declared  in  the calling (sub) program.  When
           SIDE = 'L' or 'l'  then LDA >= max( 1, m ), other-
```

wise LDA >= max(1, n). Unchanged on exit.

B (input)
REAL array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB >= max(1, m). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)
REAL array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC >= max(1, m). Unchanged on exit.

SUBROUTINE SSYMV_64(UPLO, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)

CHARACTER * 1 UPLO
INTEGER*8 N, LDA, INCX, INCY
REAL ALPHA, BETA
REAL A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE SYMV(UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A

SUBROUTINE SYMV_64(UPLO, [N], ALPHA, A, [LDA], X, [INCX], BETA, Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO
```

```
INTEGER(8) :: N, LDA, INCX, INCY
REAL :: ALPHA, BETA
REAL, DIMENSION(:) :: X, Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssymv(char uplo, int n, float alpha, float *a, int lda,
          float  *x,  int  incx,  float  beta, float *y, int
          incy);

void ssymv_64(char uplo, long n, float alpha, float *a, long
          lda,  float  *x,  long incx, float beta, float *y,
          long incy);
```

PURPOSE

ssymv performs the matrix-vector operation y := alpha*A*x + beta*y, where alpha and beta are scalars, x and y are n element vectors and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading

n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

REAL, DIMENSION(:) :: X
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssyr(char uplo, int n, float alpha, float *x, int incx,
          float *a, int lda);

void ssyr_64(char uplo, long n, float alpha, float *x,  long
          incx, float *a, long lda);
```

PURPOSE

ssyr performs the symmetric rank 1 operation A := alpha*x*x' + A, where alpha is a real scalar, x is an n element vector and A is an n by n symmetric matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

```
          [LDB], BETA, C, [LDC])

   CHARACTER(LEN=1) :: UPLO, TRANSA
   INTEGER(8) :: N, K, LDA, LDB, LDC
   REAL :: ALPHA, BETA
   REAL, DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
   #include <sunperf.h>

   void ssyr2k(char uplo, char transa,  int  n,  int  k,  float
             alpha, float *a, int lda, float *b, int ldb, float
             beta, float *c, int ldc);
   void ssyr2k_64(char uplo, char transa, long n, long k, float
             alpha,  float  *a,  long  lda, float *b, long ldb,
             float beta, float *c, long ldc);
```

PURPOSE

ssyr2k performs one of the symmetric rank 2k operations C := alpha*A*B' + alpha*B*A' + beta*C or C := alpha*A'*B + alpha*B'*A + beta*C where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' C := alpha*A*B' + alpha*B*A' + beta*C.

TRANSA = 'T' or 't'   C := alpha*A'*B + alpha*B'*A + beta*C.

TRANSA = 'C' or 'c'   C := alpha*A'*B + alpha*B'*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

REAL array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

B (input)

REAL array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

REAL array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

```

PURPOSE

ssyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not refer-

enced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSYTRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by SSYTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SSYTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

ssyrk - perform one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C

SYNOPSIS

```
SUBROUTINE SSYRK(UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)

CHARACTER * 1 UPLO, TRANSA
INTEGER N, K, LDA, LDC
REAL ALPHA, BETA
REAL A(LDA,*), C(LDC,*)

SUBROUTINE SSYRK_64(UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)

CHARACTER * 1 UPLO, TRANSA
INTEGER*8 N, K, LDA, LDC
REAL ALPHA, BETA
REAL A(LDA,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE SYRK(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA, C,
       [LDC])

CHARACTER(LEN=1) :: UPLO, TRANSA
INTEGER :: N, K, LDA, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:,:) :: A, C

SUBROUTINE SYRK_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
       C, [LDC])

CHARACTER(LEN=1) :: UPLO, TRANSA
```

```
INTEGER(8) :: N, K, LDA, LDC
REAL :: ALPHA, BETA
REAL, DIMENSION(:,:) :: A, C
```

C INTERFACE

```
#include <sunperf.h>

void ssyrk(char uplo, char  transa,  int  n,  int  k,  float
          alpha,  float  *a,  int lda, float beta, float *c,
          int ldc);

void ssyrk_64(char uplo, char transa, long n, long k,  float
          alpha,  float  *a, long lda, float beta, float *c,
          long ldc);
```

PURPOSE

ssyrk performs one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' C := alpha*A*A' + beta*C.

TRANSA = 'T' or 't' C := alpha*A'*A + beta*C.

TRANSA = 'C' or 'c' C := alpha*A'*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)
On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't' or 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
REAL array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)
REAL array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated

matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

NAME

ssysv - compute the solution to a real system of linear equations A * X = B,

SYNOPSIS

```
SUBROUTINE SSYSV(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK, LWORK,
      INFO)

CHARACTER * 1 UPLO
INTEGER N, NRHS, LDA, LDB, LWORK, INFO
INTEGER IPIV(*)
REAL A(LDA,*), B(LDB,*), WORK(*)

SUBROUTINE SSYSV_64(UPLO, N, NRHS, A, LDA, IPIV, B, LDB, WORK,
      LWORK, INFO)

CHARACTER * 1 UPLO
INTEGER*8 N, NRHS, LDA, LDB, LWORK, INFO
INTEGER*8 IPIV(*)
REAL A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE SYSV(UPLO, [N], [NRHS], A, [LDA], IPIV, B, [LDB], [WORK],
       [LWORK], [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, NRHS, LDA, LDB, LWORK, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE SYSV_64(UPLO, [N], [NRHS], A, [LDA], IPIV, B, [LDB], [WORK],
```

```
          [LWORK], [INFO])

   CHARACTER(LEN=1) :: UPLO
   INTEGER(8) :: N, NRHS, LDA, LDB, LWORK, INFO
   INTEGER(8), DIMENSION(:) :: IPIV
   REAL, DIMENSION(:) :: WORK
   REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
   #include <sunperf.h>

   void ssysv(char uplo, int n, int nrhs, float  *a,  int  lda,
             int *ipivot, float *b, int ldb, int *info);
   void ssysv_64(char uplo, long n, long nrhs, float  *a,  long
             lda,  long  *ipivot,  float  *b,  long  ldb,  long
             *info);
```

PURPOSE

```
   ssysv computes the solution to a real system of linear equa-
   tions
      A * X = B, where A is an N-by-N symmetric  matrix  and  X
   and B are N-by-NRHS matrices.

   The diagonal pivoting method is used to factor A as
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation  and  unit  upper
   (lower)  triangular  matrices,  and D is symmetric and block
   diagonal with 1-by-1 and 2-by-2 diagonal blocks.   The  fac-
   tored  form  of  A is then used to solve the system of equa-
   tions A * X = B.
```

ARGUMENTS

```
   UPLO (input)
             = 'U':  Upper triangle of A is stored;
             = 'L':  Lower triangle of A is stored.

   N (input) The number of linear equations, i.e., the order of
             the matrix A.  N >= 0.

   NRHS (input)
             The number of right hand sides, i.e.,  the  number
             of columns of the matrix B.  NRHS >= 0.

   A (input/output)
```

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSYTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)
Details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of WORK. LWORK >= 1, and for best performance LWORK >= N*NB, where NB is the optimal blocksize for SSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

              *b, int ldb, float  *x,  int  ldx,  float  *rcond,
              float *ferr, float *berr, int *info);

    void ssysvx_64(char fact, char  uplo,  long  n,  long  nrhs,
              float  *a,  long  lda,  float *af, long ldaf, long
              *ipivot, float *b, long ldb, float *x,  long  ldx,
              float  *rcond,  float  *ferr,  float  *berr,  long
              *info);
```

PURPOSE

```
    ssysvx uses the diagonal pivoting factorization  to  compute
    the solution to a real system of linear equations A * X = B,
    where A is an N-by-N symmetric matrix and X and B are  N-by-
    NRHS matrices.

    Error bounds on the solution and a  condition  estimate  are
    also provided.

    The following steps are performed:

    1. If FACT = 'N', the diagonal pivoting method  is  used  to
    factor A.
       The form of the factorization is
          A = U * D * U**T,  if UPLO = 'U', or
          A = L * D * L**T,  if UPLO = 'L',
       where U (or L) is a product of permutation and unit upper
    (lower)
       triangular matrices, and D is symmetric and block  diago-
```

nal with
1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the routine returns with INFO = i. Otherwise, the factored form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than machine precision, INFO = N+1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form of A.

4. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not refer-

enced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by SSYTRF.
If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by SSYTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by SSYTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >= 3*N, and for best performance LDWORK >= N*NB, where NB is the optimal blocksize for SSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

REAL, DIMENSION(:,:) :: A

SUBROUTINE SYTD2_64(UPLO, N, A, [LDA], D, E, TAU, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
REAL, DIMENSION(:) :: D, E, TAU
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssytd2(char uplo, int n, float *a, int lda,  float  *d,
          float *e, float *tau, int *info);

void ssytd2_64(char uplo, long n, float *a, long lda,  float
          *d, float *e, float *tau, long *info);
```

PURPOSE

ssytd2 reduces a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation: Q' * A * Q = T.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input) On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

D (output)
The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

```
   Q = H(n-1) . . . H(2) H(1).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in A(1:i-1,i+1), and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a product of elementary reflectors

```
   Q = H(1) H(2) . . . H(n-1).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is stored on exit in A(i+2:n,i), and tau in TAU(i).

The contents of A on exit are illustrated by the following examples with n = 5:

```
if UPLO = 'U':                       if UPLO = 'L':

  (  d   e   v2  v3  v4 )              (  d
)
  (      d   e   v3  v4 )              (  e   d
)
  (          d   e   v4 )              (  v1  e   d
)
  (              d   e  )              (  v1  v2  e   d
)
  (                  d  )              (  v1  v2  v3  e   d
)
```

where d and e denote diagonal and off-diagonal elements of T, and vi denotes an element of the vector defining H(i).

INTEGER*8 IPIV(*)
REAL A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE SYTF2(UPLO, [N], A, [LDA], IPIV, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL, DIMENSION(:,:) :: A

SUBROUTINE SYTF2_64(UPLO, [N], A, [LDA], IPIV, [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, INFO
```

```
INTEGER(8), DIMENSION(:) :: IPIV
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssytf2(char uplo, int n, float *a, int lda, int  *ipiv,
          int *info);

void ssytf2_64(char uplo, long n, float *a, long  lda,  long
          *ipiv, long *info);
```

PURPOSE

ssytf2 computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

```
   A = U*D*U'  or  A = L*D*L'
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

```
          tipliers  used  to  obtain  the factor U or L (see
          below for further details).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

IPIV (output)
          Details of the interchanges and the  block  struc-
          ture  of D.  If IPIV(k) > 0, then rows and columns
          k and IPIV(k) were interchanged and  D(k,k)  is  a
          1-by-1  diagonal block.  If UPLO = 'U' and IPIV(k)
          = IPIV(k-1) < 0, then rows  and  columns  k-1  and
          -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a
          2-by-2 diagonal block.  If UPLO = 'L' and  IPIV(k)
          =  IPIV(k+1)  <  0,  then rows and columns k+1 and
          -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a
          2-by-2 diagonal block.

INFO (output)
          = 0: successful exit
          < 0: if INFO = -k, the k-th argument had an  ille-
          gal value
          > 0: if INFO = k, D(k,k)  is  exactly  zero.   The
          factorization  has  been  completed, but the block
          diagonal matrix D is exactly singular,  and  divi-
          sion  by  zero will occur if it is used to solve a
          system of equations.
```

FURTHER DETAILS

```
1-96 - Based on modifications by J. Lewis,  Boeing  Computer
Services
       Company

If UPLO = 'U', then A = U*D*U', where
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where  k  decreases
from  n  to  1 in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation  matrix  as defined by IPIV(k), and U(k) is a
unit upper triangular matrix,  such  that  if  the  diagonal
block D(k) is of order s (s = 1 or 2), then

           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k

If s = 1, D(k) overwrites A(k,k), and  v  overwrites  A(1:k-
```

1,k).   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where

```
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
```

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

CHARACTER(LEN=1) :: UPLO
INTEGER :: N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: D, E, TAU, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE SYTRD_64(UPLO, N, A, [LDA], D, E, TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: UPLO
INTEGER(8) :: N, LDA, LWORK, INFO
```

```
REAL, DIMENSION(:) :: D, E, TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void ssytrd(char uplo, int n, float *a, int lda,  float  *d,
          float *e, float *tau, int *info);

void ssytrd_64(char uplo, long n, float *a, long lda,  float
          *d, float *e, float *tau, long *info);
```

PURPOSE

ssytrd reduces a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation: Q**T * A * Q = T.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

D (output)
The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

```
Q = H(n-1) . . . H(2) H(1).
```

Each H(i) has the form

```
H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(i+1:n) = 0 and v(i) = 1; v(1:i-1) is stored on exit in

```
A(1:i-1,i+1), and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i) = 0 and v(i+1) = 1; v(i+2:n) is  stored  on  exit  in
A(i+2:n,i), and tau in TAU(i).
The contents of A on exit are illustrated by  the  following
examples with n = 5:

if UPLO = 'U':                       if UPLO = 'L':

  (  d   e   v2  v3  v4 )              (  d
)
  (      d   e   v3  v4 )              (  e   d
)
  (          d   e   v4 )              (  v1  e   d
)
  (              d   e  )              (  v1  v2  e   d
)
  (                  d  )              (  v1  v2  v3  e   d
)

where d and e denote diagonal and off-diagonal  elements  of
T, and vi denotes an element of the vector defining H(i).

```

C INTERFACE

```
#include <sunperf.h>

void ssytrf(char  uplo,  int  n,  float  *a,  int  lda,  int
          *ipivot, int *info);

void ssytrf_64(char uplo, long n, float *a, long  lda,  long
          *ipivot, long *info);
```

PURPOSE

ssytrf computes the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
   A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the symmetric matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A,
          and the strictly lower triangular part of A is not
          referenced.  If UPLO =  'L',  the  leading  N-by-N
          lower triangular part of A contains the lower tri-
          angular part of the matrix  A,  and  the  strictly
          upper triangular part of A is not referenced.
```

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >=1. For best performance LDWORK >= N*NB, where NB is the block size returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If UPLO = 'U', then A = U*D*U', where

```
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
```

i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where

```
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
```

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

```

PURPOSE

ssytrs solves a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by SSYTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by SSYTRF.

B (input/output)
On entry, the right hand side matrix B. On exit,

the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

REAL A(LDA,*), WORK(*)

SUBROUTINE STBCON_64(NORM, UPLO, DIAG, N, KD, A, LDA, RCOND, WORK,
      WORK2, INFO)

CHARACTER * 1 NORM, UPLO, DIAG
INTEGER*8 N, KD, LDA, INFO
INTEGER*8 WORK2(*)
REAL RCOND
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TBCON(NORM, UPLO, DIAG, N, KD, A, [LDA], RCOND, [WORK],
       [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER :: N, KD, LDA, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL :: RCOND
```

```
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE TBCON_64(NORM, UPLO, DIAG, N, KD, A, [LDA], RCOND,
       [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, KD, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
void stbcon(char norm, char uplo, char diag, int n, int  kd,
          float *a, int lda, float *rcond, int *info);

void stbcon_64(char norm, char uplo, char diag, long n, long
          kd, float *a, long lda, float *rcond, long *info);
```

PURPOSE

stbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
   RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.
```

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

A (input) The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A

SUBROUTINE TBMV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, K, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void stbmv(char uplo, char transa, char diag, int n, int  k,
          float *a, int lda, float *y, int incy);

void stbmv_64(char uplo, char transa,  char  diag,  long  n,
          long k, float *a, long lda, float *y, long incy);
```

PURPOSE

stbmv performs one of the matrix-vector operations x := A*x, or x := A'*x, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := A'*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit

triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit tri-angular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K >= 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coef-ficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coef-ficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower

triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tran- formed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

Contents

NAME

```
stbrfs - provide error bounds and backward  error  estimates
for the solution to a system of linear equations with a tri-
angular band coefficient matrix
```

SYNOPSIS

C INTERFACE

```
#include <sunperf.h>

void stbrfs(char uplo, char transa, char diag,  int  n,  int
          kd,  int  nrhs,  float  *a, int lda, float *b, int
          ldb, float *x, int ldx, float *ferr, float  *berr,
          int *info);

void stbrfs_64(char uplo, char transa, char  diag,  long  n,
          long  kd, long nrhs, float *a, long lda, float *b,
          long ldb, float *x, long ldx, float  *ferr,  float
          *berr, long *info);
```

PURPOSE

stbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by STBTRS or some other means before entering this routine. STBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

UPLO (input)
  = 'U': A is upper triangular;
  = 'L': A is lower triangular.

TRANSA (input)
  Specifies the form of the system of equations:
  = 'N': A * X = B (No transpose)
  = 'T': A**T * X = B (Transpose)
  = 'C': A**H * X = B (Conjugate transpose = Transpose)

  TRANSA is defaulted to 'N' for F95 INTERFACE.

```
DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals  or  subdiagonals  of
          the triangular band matrix A.  KD >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
A (input) The upper  or  lower  triangular  band  matrix  A,
          stored  in  the  first kd+1 rows of the array. The
          j-th column of A is stored in the j-th  column  of
          the  array A as follows:  if UPLO = 'U', A(kd+1+i-
          j,j) = A(i,j) for  max(1,j-kd)<=i<=j;  if  UPLO  =
          'L', A(1+i-j,j)    = A(i,j) for j<=i<=min(n,j+kd).
          If DIAG = 'U', the diagonal elements of A are  not
          referenced and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          KD+1.

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.
```

```
BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(3*N)
WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

SUBROUTINE TBSV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, K, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void stbsv(char uplo, char transa, char diag, int n, int  k,
          float *a, int lda, float *y, int incy);

void stbsv_64(char uplo, char transa,  char  diag,  long  n,
          long k, float *a, long lda, float *y, long incy);
```

PURPOSE

stbsv solves one of the systems of equations A*x = b, or A'*x = b, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   A'*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

          long  kd, long nrhs, float *a, long lda, float *b,
          long ldb, long *info);
```

PURPOSE

stbtrs solves a triangular system of the form

where A is a triangular band matrix of order N, and B is an N-by NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)
- = 'U': A is upper triangular;
- = 'L': A is lower triangular.

TRANSA (input)
Specifies the form the system of equations:
- = 'N': A * X = B (No transpose)
- = 'T': A**T * X = B (Transpose)
- = 'C': A**H * X = B (Conjugate transpose = Transpose)

DIAG (input)
- = 'N': A is non-unit triangular;
- = 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

```
A (input) The upper  or  lower  triangular  band  matrix  A,
          stored  in  the  first  kd+1  rows of A.  The j-th
          column of A is stored in the j-th  column  of  the
          array  A as follows:  if UPLO = 'U', A(kd+1+i-j,j)
          = A(i,j) for max(1,j-kd)<=i<=j;  if  UPLO  =  'L',
          A(1+i-j,j)     = A(i,j) for j<=i<=min(n,j+kd).  If
          DIAG = 'U', the diagonal elements  of  A  are  not
          referenced and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          KD+1.

B (input/output)
          On entry, the right hand side matrix B.  On  exit,
          if INFO = 0, the solution matrix X.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, the i-th diagonal element of  A
          is  zero,  indicating  that the matrix is singular
          and the solutions X have not been computed.

       [LDVL], VR, [LDVR], MM, M, [WORK], [INFO])

CHARACTER(LEN=1) :: SIDE, HOWMNY
INTEGER(8) :: N, LDA, LDB, LDVL, LDVR, MM, M, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A, B, VL, VR
```

C INTERFACE

```
#include <sunperf.h>

void stgevc(char side, char  howmny,  int  *select,  int  n,
          float  *a,  int lda, float *b, int ldb, float *vl,
          int ldvl, float *vr, int ldvr, int mm, int *m, int
          *info);

void stgevc_64(char side, char howmny, long *select, long n,
          float *a, long lda, float *b, long ldb, float *vl,
          long ldvl, float *vr, long ldvr, long mm, long *m,
          long *info);
```

PURPOSE

stgevc computes some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

```
        (A - wB) * x = 0  and  y**H * (A - wB) = 0
```

where y**H denotes the conjugate tranpose of y.

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products Z*X and/or Q*Y, where Z and Q are input orthogonal matrices. If (A,B) was obtained from the generalized real-Schur factorization of an original pair of matrices
   (A0,B0) = (Q*A*Z**H,Q*B*Z**H),
then Z*X and Q*Y are the matrices of right or left eigenvec-

tors of A.

A must be block upper triangular, with 1-by-1 and 2-by-2 diagonal blocks. Corresponding to each 2-by-2 diagonal block is a complex conjugate pair of eigenvalues and eigen- vectors; only one
eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

SIDE (input)
= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)
= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input)
If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the real eigenvector corresponding to the real eigenvalue w(j), SELECT(j) must be set to .TRUE. To select the complex eigenvector corresponding to a complex conjugate pair w(j) and w(j+1), either SELECT(j) or SELECT(j+1) must be set to .TRUE..

N (input) The order of the matrices A and B. N >= 0.

A (input) The upper quasi-triangular matrix A.

LDA (input)
The leading dimension of array A. LDA >= max(1, N).

B (input) The upper triangular matrix B. If A has a 2-by-2 diagonal block, then the corresponding 2-by-2 block of B must be diagonal with positive ele- ments.

LDB (input)

The leading dimension of array B. LDB >= max(1,N).

VL (input/output)

On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the orthogonal matrix Q of left Schur vectors returned by SHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part.

LDVL (input)

The leading dimension of array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Z of right Schur vectors returned by SHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part.

LDVR (input)

The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)

The number of columns in the arrays VL and/or VR.

```
          MM >= M.

M (output)
          The number of columns in the arrays VL  and/or  VR
          actually  used  to  store  the  eigenvectors.   If
          HOWMNY = 'A' or 'B', M is set to N.  Each selected
          real  eigenvector  occupies  one  column  and each
          selected complex eigenvector occupies two columns.
WORK (workspace)
          dimension(6*N)

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  the 2-by-2 block (INFO:INFO+1) does not have
          a complex eigenvalue.
```

FURTHER DETAILS

```
Allocation of workspace:
---------- -- ---------

   WORK( j ) = 1-norm of j-th column of A, above the  diago-
nal
   WORK( N+j ) = 1-norm of j-th column of B, above the diag-
onal
   WORK( 2*N+1:3*N ) = real part of eigenvector
   WORK( 3*N+1:4*N ) = imaginary part of eigenvector
   WORK( 4*N+1:5*N ) = real part of back-transformed  eigen-
vector
   WORK( 5*N+1:6*N ) = imaginary  part  of  back-transformed
eigenvector

Rowwise vs. columnwise solution methods:
------- --  ---------- -------- -------

Finding a  generalized  eigenvector  consists  basically  of
solving the singular triangular system

 (A - w B) x = 0     (for right) or:   (A - w B)**H  y  =  0
(for left)

Consider finding the  i-th  right  eigenvector  (assume  all
eigenvalues are real). The equation to be solved is:
0 = sum  C(j,k) v(k)  = sum  C(j,k) v(k)     for j =  i,.  .
.,1
    k=j                 k=j

where  C = (A - w B)  (The components v(i+1:n) are 0.)
```

The "rowwise" method is:

```
(1)  v(i) := 1
for j = i-1,. . .,1:
                        i
    (2) compute  s = - sum C(j,k) v(k)   and
                      k=j+1

    (3) v(j) := s / C(j,j)
```

Step 2 is sometimes called the "dot product" step, since it is an inner product between the j-th row and the portion of the eigenvector that has been computed so far.

The "columnwise" method consists basically in doing the sums for all the rows in parallel. As each v(j) is computed, the contribution of v(j) times the j-th column of C is added to the partial sums. Since FORTRAN arrays are stored column-wise, this has the advantage that at each step, the elements of C that are accessed are adjacent to one another, whereas with the rowwise method, the elements accessed at a step are spaced LDA (and LDB) words apart.

When finding left eigenvectors, the matrix in question is the transpose of the one in storage, so the rowwise method then actually accesses columns of A and B at each step, and so is the preferred method.

REAL, DIMENSION(:,:) :: A, B, Q, Z
```

C INTERFACE

```
#include <sunperf.h>

void stgexc(int wantq, int wantz, int n, float *a, int  lda,
          float  *b,  int  ldb, float *q, int ldq, float *z,
          int ldz, int *ifst, int *ilst, int *info);

void stgexc_64(long wantq, long wantz,  long  n,  float  *a,
          long  lda, float *b, long ldb, float *q, long ldq,
          float *z, long ldz, long *ifst, long  *ilst,  long
          *info);
```

PURPOSE

stgexc reorders the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation

so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)' = Q(out) * A(out) * Z(out)'
Q(in) * B(in) * Z(in)' = Q(out) * B(out) * Z(out)'
```

ARGUMENTS

WANTQ (input)

WANTZ (input)

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the matrix A in generalized real Schur

canonical form. On exit, the updated matrix A, again in generalized real Schur canonical form.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the matrix B in generalized real Schur canonical form (A,B). On exit, the updated matrix B, again in generalized real Schur canonical form (A,B).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

Q (input/output)
On entry, if WANTQ = .TRUE., the orthogonal matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1. If WANTQ = .TRUE., LDQ >= N.

Z (input/output)
On entry, if WANTZ = .TRUE., the orthogonal matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

IFST (input/output)
Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST, ILST <= N.

ILST (input/output)
See the description of IFST.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal

LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 4*N + 16.
If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
=0: successful exit.
<0: if INFO = -i, the i-th argument had an illegal value.
=1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill- conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

          *info);
```

PURPOSE

stgsen reorders the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence trans- formation Q' * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B. The leading columns of Q and Z form orthonormal bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in generalized real Schur canonical form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

STGSEN also computes the generalized eigenvalues

w(j) = (ALPHAR(j) + i*ALPHAI(j))/BETA(j)

of the reordered matrix pair (A, B).

Optionally, STGSEN computes the estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

IJOB (input)
Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):
=0: Only reorder w.r.t. SELECT. No extras.
=1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate
(DIF(1:2)).
=3: Estimate of Difu and Difl. 1-norm-based estimate
(DIF(1:2)). About 5 times as expensive as IJOB = 2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Compute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ (input)

WANTZ (input)

SELECT (input)
SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue w(j), SELECT(j) must be set to w(j) and w(j+1), corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to either both included in the cluster or both excluded.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the upper quasi-triangular matrix A, with (A, B) in generalized real Schur canonical form. On exit, A is overwritten by the reordered matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the upper triangular matrix B, with (A, B) in generalized real Schur canonical form. On exit, B is overwritten by the reordered matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (A,B) were further reduced to triangular form using complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

ALPHAI (output)
See the description of ALPHAR.

BETA (output)
See the description of ALPHAR.

Q (input/output)

On entry, if WANTQ = .TRUE., Q is an N-by-N matrix. On exit, Q has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Q form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTQ = .FALSE., Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1; and if WANTQ = .TRUE., LDQ >= N.

Z (input/output)
On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left orthogonal transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

M (output)
The dimension of the specified pair of left and right eigen- spaces (deflating subspaces). 0 <= M <= N.

PL (output)
If IJOB = 1, 4 or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspaces with respect to the selected cluster. 0 < PL, PR <= 1. If M = 0 or M = N, PL = PR = 1. If IJOB = 0, 2 or 3, PL and PR are not referenced.

PR (output)
See the description of PL.

DIF (output)
If IJOB >= 2, DIF(1:2) store the estimates of Difu and Difl.
If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on
Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK (workspace)
If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 4*N+16. If IJOB = 1, 2 or 4, LWORK >= MAX(4*N+16, 2*M*(N-M)). If IJOB = 3 or 5, LWORK >= MAX(4*N+16, 4*M*(N-M)).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+6. If IJOB = 3 or 5, LIWORK >= MAX(2*M*(N-M), N+6).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
=0: Successful exit.
<0: If INFO = -i, the i-th argument had an illegal value.
=1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

FURTHER DETAILS

STGSEN first collects the selected eigenvalues by computing orthogonal U and W that move them to the top left corner of (A, B). In other words, the selected eigenvalues are the eigenvalues of (A11, B11) in:

```
              U'*(A, B)*W = (A11 A12) (B11 B12) n1
                            ( 0  A22),( 0  B22) n2
                              n1  n2    n1  n2
```

where N = n1+n2 and U' means the transpose of U. The first n1 columns of U and W span the specified pair of left and right eigenspaces (deflating subspaces) of (A, B).

If (A, B) has been obtained from the generalized real Schur decomposition of a matrix pair (C, D) = Q*(A, B)*Z', then the reordered generalized real Schur form of (C, D) is given by

```
         (C, D) = (Q*U)*(U'*(A, B)*W)*(Z*W)',
```

and the first n1 columns of Q*U and Z*W span the corresponding deflating subspaces of (C, D) (Q and Z store Q*U and Z*W, resp.).

Note that if the selected eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

The reciprocal condition numbers of the left and right eigenspaces spanned by the first n1 columns of U and W (or Q*U and Z*W) may be returned in DIF(1:2), corresponding to Difu and Difl, resp.

The Difu and Difl are defined as:
ifu[(A11, B11), (A22, B22)] = sigma-min(Zu)
and

where sigma-min(Zu) is the smallest singular value of the (2*n1*n2)-by-(2*n1*n2) matrix

```
u = [ kron(In2, A11)  -kron(A22', In1) ]
          [ kron(In2, B11)  -kron(B22', In1) ].
```

Here, Inx is the identity matrix of size nx and A22' is the transpose of A22. kron(X, Y) is the Kronecker product between the matrices X and Y.

When DIF(2) is small, small changes in (A, B) can cause large changes in the deflating subspace. An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is PS * norm((A, B)) / DIF(2),

where EPS is the machine precision.

The reciprocal norm of the projectors on the left and right eigenspaces associated with (A11, B11) may be returned in PL and PR. They are computed as follows. First we compute L and R so that P*(A, B)*Q is block diagonal, where

```
 = ( I -L ) n1           Q = ( I R ) n1
        ( 0  I ) n2    and        ( 0 I ) n2
          n1 n2                    n1 n2
```

and (L, R) is the solution to the generalized Sylvester equation 11*R - L*A22 = -A12

Then PL = (F-norm(L)**2+1)**(-1/2) and PR = (F-norm(R)**2+1)**(-1/2). An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is
PS * norm((A, B)) / PL.

There are also global error bounds which valid for perturbations up to a certain restriction: A lower bound (x) on the smallest F-norm(E,F) for which an eigenvalue of (A11, B11) may move and coalesce with an eigenvalue of (A22, B22) under perturbation (E,F), (i.e. (A + E, B + F), is

x = min(Difu,Difl)/((1/(PL*PL)+1/(PR*PR))**(1/2)+2*max(1/PL,1/PR)).

An approximate bound on x can be computed from DIF(1:2), PL and PR.

If y = (F-norm(E,F) / x) <= 1, the angles between the perturbed (L', R') and unperturbed (L, R) left and right deflating subspaces associated with the selected cluster in the (1,1)-blocks can be bounded as

max-angle(L, L') <= arctan(y * PL / (1 - y * (1 - PL * PL)**(1/2))
max-angle(R, R') <= arctan(y * PR / (1 - y * (1 - PR * PR)**(1/2))

See LAPACK User's Guide section 4.11 or the following references for more information.

Note that if the default method for computing the Frobenius-norm- based estimate DIF is not wanted (see SLATDF), then the parameter IDIFJB (see below) should be changed from 3 to 4 (routine SLATDF (IJOB = 2 will be used)). See STGSYL for more details.

Based on contributions by

```

PURPOSE

stgsja computes the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine SGGSVP from a general M-by-N matrix A and P-by-N matrix B:

```
             N-K-L  K    L
   A =    K ( 0    A12  A13 ) if M-K-L >= 0;
          L ( 0     0   A23 )
      M-K-L ( 0     0    0  )
```

```
           N-K-L  K    L
   A =  K ( 0    A12  A13 ) if M-K-L < 0;
      M-K ( 0     0   A23 )

           N-K-L  K    L
   B =  L ( 0     0   B13 )
      P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,

```
            U'*A*Q = D1*( 0 R ),    V'*B*Q = D2*( 0 R ),
```

where U, V and Q are orthogonal matrices, Z' denotes the transpose of Z, R is a nonsingular upper triangular matrix, and D1 and D2 are ``diagonal'' matrices, which are of the following structures:
If M-K-L >= 0,

```
                    K  L
       D1 =     K ( I  0 )
                L ( 0  C )
            M-K-L ( 0  0 )

                  K  L
       D2 = L   ( 0  S )
            P-L ( 0  0 )

               N-K-L  K    L
  ( 0 R ) = K (  0   R11  R12 ) K
            L (  0    0   R22 ) L
```

where

```
  C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
  S = diag( BETA(K+1),  ... , BETA(K+L) ),
  C**2 + S**2 = I.

  R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
               K M-K K+L-M
    D1 =   K ( I  0    0   )
         M-K ( 0  C    0   )

                 K M-K K+L-M
```

```
    D2 =   M-K ( 0  S    0   )
         K+L-M ( 0  0    I   )
           P-L ( 0  0    0   )

               N-K-L  K   M-K  K+L-M

          M-K ( 0     0   R22  R23  )
        K+L-M ( 0     0    0   R33  )
```

where
C = diag(ALPHA(K+1), ... , ALPHA(M)),
S = diag(BETA(K+1), ... , BETA(M)),
C**2 + S**2 = I.

R = (R11 R12 R13) is stored in A(1:M, N-K-L+1:N) and R33 is stored
(0 R22 R23)
in B(M-K+1:L,N+M-K-L+1:N) on exit.

The computation of the orthogonal transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices U1, V1, or Q1.
STGSJA essentially uses a variant of Kogbetliantz algorithm to reduce min(L,M-K)-by-L triangular (or trapezoidal) matrix A23 and L-by-L matrix B13 to the form:
U1'*A13*Q1 = C1*R1; V1'*B13*Q1 = S1*R1,
where U1, V1 and Q1 are orthogonal matrix, and Z' is the transpose of Z. C1 and S1 are diagonal matrices satisfying
C1**2 + S1**2 = I,
and R1 is an L-by-L nonsingular upper triangular matrix.

ARGUMENTS

JOBU (input)
= 'U': U must contain an orthogonal matrix U1 on entry, and the product U1*U is returned; = 'I': U is initialized to the unit matrix, and the orthogonal matrix U is returned; = 'N': U is not computed.

JOBV (input)
= 'V': V must contain an orthogonal matrix V1 on entry, and the product V1*V is returned; = 'I': V is initialized to the unit matrix, and the orthogonal matrix V is returned; = 'N': V is not computed.

JOBQ (input)

= 'Q': Q must contain an orthogonal matrix Q1 on entry, and the product Q1*Q is returned; = 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

K (input) K and L specify the subblocks in the input matrices A and B:
A23 = A(K+1:MIN(K+L,M),N-L+1:N) and B13 = B(1:L,N-L+1:N) of A and B, whose GSVD is going to be computed by STGSJA. See Further details.
L (input) See the description of K.

A (input/output)
On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L,M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

TOLA (input)
TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say TOLA = max(M,N)*norm(A)*MACHEPS, TOLB = max(P,N)*norm(B)*MACHEPS.

TOLB (input)
See the description of TOLA.

ALPHA (output)
On exit, ALPHA and BETA contain the generalized

```
           singular value pairs of A and B; ALPHA(1:K) = 1,
           BETA(1:K)  = 0, and if M-K-L >= 0,  ALPHA(K+1:K+L)
           = diag(C),
           BETA(K+1:K+L)   =  diag(S),  or  if  M-K-L  <   0,
           ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0
           BETA(K+1:M) = S, BETA(M+1:K+L) = 1.   Furthermore,
           if K+L < N, ALPHA(K+L+1:N) = 0 and
           BETA(K+L+1:N)  = 0.

 BETA (output)
           See the description of ALPHA.
 U (input) On entry, if JOBU = 'U', U must contain  a  matrix
           U1  (usually  the  orthogonal  matrix  returned by
           SGGSVP).  On exit, if JOBU = 'I', U  contains  the
           orthogonal matrix U; if JOBU = 'U', U contains the
           product U1*U.  If JOBU = 'N', U is not referenced.

 LDU (input)
           The leading dimension  of  the  array  U.  LDU  >=
           max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

 V (input) On entry, if JOBV = 'V', V must contain  a  matrix
           V1  (usually  the  orthogonal  matrix  returned by
           SGGSVP).  On exit, if JOBV = 'I', V  contains  the
           orthogonal matrix V; if JOBV = 'V', V contains the
           product V1*V.  If JOBV = 'N', V is not referenced.

 LDV (input)
           The leading dimension  of  the  array  V.  LDV  >=
           max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

 Q (input) On entry, if JOBQ = 'Q', Q must contain  a  matrix
           Q1  (usually  the  orthogonal  matrix  returned by
           SGGSVP).  On exit, if JOBQ = 'I', Q  contains  the
           orthogonal matrix Q; if JOBQ = 'Q', Q contains the
           product Q1*Q.  If JOBQ = 'N', Q is not referenced.

 LDQ (input)
           The leading dimension  of  the  array  Q.  LDQ  >=
           max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

 WORK (workspace)
           dimension(2*N)

 NCYCLE (output)
           The number of cycles required for convergence.

 INFO (output)
           = 0:  successful exit
           < 0:  if INFO = -i, the i-th argument had an ille-
```

gal value.
= 1: the procedure does not converge after MAXIT cycles.

               *dif, long mm, long *m, long *info);
```

PURPOSE

stgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q*A*Z', Q*B*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z.

(A, B) must be in generalized real Schur form (as returned by SGGES), i.e. A is block upper triangular with 1-by-1 and 2-by-2 diagonal blocks. B is upper triangular.

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):
= 'E': for eigenvalues only (S);
= 'V': for eigenvectors only (DIF);
= 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNT (input)
= 'A': compute condition numbers for all eigenpairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

N (input) The order of the square matrix pair (A, B). N >= 0.

A (input) The upper quasi-triangular matrix A in the pair (A,B).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The upper triangular matrix B in the pair (A,B).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

VL (input)
If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by STGEVC. If JOB = 'V', VL is not referenced.

LDVL (input)

The leading dimension of the array VL. LDVL >= 1.
If JOB = 'E' or 'B', LDVL >= N.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigen- vectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns ov VR, as returned by STGEVC. If JOB = 'V', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= 1.
If JOB = 'E' or 'B', LDVR >= N.

S (output)
If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive ele- ments of S are set to the same value. Thus S(j), DIF(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in gen- eral the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

DIF (output)
If JOB = 'V' or 'B', the estimated reciprocal con- dition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of DIF are set to the same value. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', DIF is not referenced.

MM (input)
The number of elements in the arrays S and DIF. MM >= M.

M (output)
The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected real eigenvalue one element is used, and for each selected complex conjugate pair of eigenvalues, two elements are used. If HOWMNT = 'A', M is set to N.

WORK (workspace)
If JOB = 'E', WORK is not referenced. Otherwise,

on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= N. If JOB = 'V' or 'B' LWORK >= 2*N*(N+2)+16.
If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(N+6) If JOB = 'E', IWORK is not referenced.

INFO (output)
=0: Successful exit
<0: If INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of a generalized eigenvalue w = (a, b) is defined as
(w) = (|u'Av|**2 + |u'Bv|**2)**(1/2) / (norm(u)*norm(v))

where u and v are the left and right eigenvectors of (A, B) corresponding to w; |z| denotes the absolute value of the complex number, and norm(u) denotes the 2-norm of the vector u.
The pair (a, b) corresponds to an eigenvalue w = a/b (= u'Av/u'Bv) of the matrix pair (A, B). If both a and b equal zero, then (A B) is singular and S(I) = -1 is returned.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue lambda is
hord(w, lambda) <= EPS * norm(A, B) / S(I)

where EPS is the machine precision.

The reciprocal of the condition number DIF(i) of right eigenvector u and left eigenvector v corresponding to the generalized eigenvalue w is defined as follows:

a) If the i-th eigenvalue w = (a,b) is real

Suppose U and V are orthogonal transformations such that

```
              U'*(A, B)*V  = (S, T) = ( a   *  ) ( b   *   )
1
                                        ( 0  S22 ),( 0  T22  )
n-1
                                          1  n-1     1 n-1

   Then the reciprocal condition number DIF(i) is
              Difl((a, b), (S22, T22)) = sigma-min( Zl ),

   where sigma-min(Zl) denotes the smallest  singular  value
of the
   2(n-1)-by-2(n-1) matrix

       Zl = [ kron(a, In-1)  -kron(1, S22) ]
            [ kron(b, In-1)  -kron(1, T22) ] .

   Here In-1 is the identity matrix of size n-1. kron(X,  Y)
is the
   Kronecker product between the matrices X and Y.

   Note that if the default method for computing  DIF(i)  is
wanted
   (see SLATDF),  then  the  parameter  DIFDRI  (see  below)
should be
   changed from 3 to 4 (routine  SLATDF(IJOB  =  2  will  be
used)).
   See STGSYL for more details.

b) If the i-th and (i+1)-th eigenvalues are  complex  conju-
gate pair,

   Suppose U and V are orthogonal transformations such that

              U'*(A, B)*V = (S, T) = ( S11  *   ) (  T11   *
)  2
                                       (  0     S22   ),(   0
T22) n-2
                                         2    n-2     2    n-2

   and (S11,  T11)  corresponds  to  the  complex  conjugate
eigenvalue
   pair (w, conjg(w)). There exist unitary matrices  U1  and
V1 such
   that

       U1'*S11*V1 = ( s11 s12 )   and U1'*T11*V1 = ( t11 t12
)
                    (  0  s22 )                    (  0  t22
)
```

where the generalized eigenvalues w = s11/t11 and
conjg(w) = s22/t22.

Then the reciprocal condition number DIF(i) is bounded by

min(d1, max(1, |real(s11)/real(s22)|)*d2)

where, d1 = Difl((s11, t11), (s22, t22)) = sigma-min(Z1), where
Z1 is the complex 2-by-2 matrix

```
Z1 =  [ s11  -s22 ]
      [ t11  -t22 ],
```

This is done by computing (using real arithmetic) the roots of the characteristical polynomial det(Z1' * Z1 - lambda I),
where Z1' denotes the conjugate transpose of Z1 and det(X) denotes
the determinant of X.

and d2 is an upper bound on Difl((S11, T11), (S22, T22)), i.e. an
upper bound on sigma-min(Z2), where Z2 is (2n-2)-by-(2n-2)

```
Z2 = [ kron(S11', In-2)  -kron(I2, S22) ]
     [ kron(T11', In-2)  -kron(I2, T22) ]
```

Note that if the default method for computing DIF is wanted (see
SLATDF), then the parameter DIFDRI (see below) should be changed
from 3 to 4 (routine SLATDF(IJOB = 2 will be used)). See STGSYL
for more details.

For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of Difl.

An approximate error bound for the i-th computed eigenvector VL(i) or VR(i) is given by

EPS * norm(A, B) / DIF(i).

See ref. [2-3] for more details and further references.

```

PURPOSE

stgsyl solves the generalized Sylvester equation:

```
            A * R - L * B = scale * C                 (1)
            D * R - L * E = scale * F
```

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with real entries. (A, D) and (B, E) must be in generalized (real) Schur canonical form, i.e. A, B are upper quasi triangular and D, E are upper triangular.

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve Zx = scale b, where Z is defined as

```
           Z = [ kron(In, A)  -kron(B', Im) ]         (2)
               [ kron(In, D)  -kron(E', Im) ].
```

Here Ik is the identity matrix of size k and X' is the transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'T', STGSYL solves the transposed system Z'*y = scale*b, which is equivalent to solve for R and L in

```
            A' * R  + D' * L   = scale *  C           (3)
            R  * B' + L  * E'  = scale * (-F)
```

This case (TRANS = 'T') is used to compute an one-norm-based estimate of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D) and (B,E), using SLACON.

If IJOB >= 1, STGSYL computes a Frobenius norm-based estimate of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z. See [1-2] for more information.

This is a level 3 BLAS algorithm.

ARGUMENTS

TRANS (input)
= 'N', solve the generalized Sylvester equation (1). = 'T', solve the 'transposed' system (3).

IJOB (input)
Specifies what kind of functionality to be performed. =0: solve (1) only.
=1: The functionality of 0 and 3.
=2: The functionality of 0 and 4.
=3: Only an estimate of Dif[(A,D), (B,E)] is computed. (look ahead strategy IJOB = 1 is used).
=4: Only an estimate of Dif[(A,D), (B,E)] is computed. (SGECON on sub-systems is used). Not referenced if TRANS = 'T'.

M (input) The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N (input) The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A (input) The upper quasi triangular matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1, M).

B (input) The upper quasi triangular matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

C (input/output)
On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC (input)
The leading dimension of the array C. LDC >= max(1, M).

D (input) The upper triangular matrix D.

LDD (input)
The leading dimension of the array D. LDD >= max(1, M).

E (input) The upper triangular matrix E.

LDE (input)
The leading dimension of the array E. LDE >= max(1, N).

F (input/output)
On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF (input)
The leading dimension of the array F. LDF >= max(1, M).

DIF (output)
On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of Dif[(A,D), (B,E)] = sigma_min(Z), where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

SCALE (output)
On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of Dif[(A,D), (B,E)] = sigma_min(Z), where Z as in (2). If IJOB = 0 or TRANS = 'T', SCALE is not touched.

WORK (workspace)
If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK > = 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(M+N+2)

INFO (output)
=0: successful exit
<0: If INFO = -i, the i-th argument had an illegal value.
>0: (A, D) and (B, E) have common or close eigen- values.

REAL, DIMENSION(:) :: A, WORK
```

C INTERFACE

```
#include <sunperf.h>

void stpcon(char norm, char uplo, char diag,  int  n,  float
          *a, float *rcond, int *info);
void stpcon_64(char norm, char  uplo,  char  diag,  long  n,
          float *a, float *rcond, long *info);
```

PURPOSE

stpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.
```

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

Contents

NAME

```
stpmv - perform one of the  matrix-vector  operations  x  :=
A*x, or x := A'*x
```

SYNOPSIS

```
SUBROUTINE STPMV(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, INCY
REAL A(*), Y(*)

SUBROUTINE STPMV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, INCY
REAL A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPMV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, INCY
REAL, DIMENSION(:) :: A, Y

SUBROUTINE TPMV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, INCY
REAL, DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stpmv(char uplo, char transa, char diag, int  n,  float
          *a, float *y, int incy);

void stpmv_64(char uplo, char transa,  char  diag,  long  n,
          float *a, float *y, long incy);
```

PURPOSE

stpmv performs one of the matrix-vector operations x := A*x, or x := A'*x, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := A'*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit tri-

angular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tranformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>

void stprfs(char uplo, char transa, char diag,  int  n,  int
          nrhs,  float  *a, float *b, int ldb, float *x, int
          ldx, float *ferr, float *berr, int *info);
void stprfs_64(char uplo, char transa, char  diag,  long  n,
          long nrhs, float *a, float *b, long ldb, float *x,
          long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

stprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by STPTRS or some other means before entering this routine. STPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B  (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
          = 'N':  A is non-unit triangular;
```

```
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The upper or lower  triangular  matrix  A,  packed
          columnwise  in a linear array.  The j-th column of
          A is stored in the array A as follows:  if UPLO  =
          'U',  A(i  +  (j-1)*j/2)  = A(i,j) for 1<=i<=j; if
          UPLO = 'L', A(i + (j-1)*(2*n-j)/2)  =  A(i,j)  for
          j<=i<=n.   If DIAG = 'U', the diagonal elements of
          A are not referenced and are assumed to be 1.

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(3*N)

WORK2 (workspace)
          dimension(N)
```

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

NAME

```
stpsv - solve one of the systems of equations A*x  =  b,  or
A'*x = b
```

SYNOPSIS

```
SUBROUTINE STPSV(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, INCY
REAL A(*), Y(*)

SUBROUTINE STPSV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, INCY
REAL A(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TPSV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, INCY
REAL, DIMENSION(:) :: A, Y

SUBROUTINE TPSV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, INCY
REAL, DIMENSION(:) :: A, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stpsv(char uplo, char transa, char diag, int  n,  float
          *a, float *y, int incy);

void stpsv_64(char uplo, char transa,  char  diag,  long  n,
          float *a, float *y, long incy);
```

PURPOSE

stpsv solves one of the systems of equations A*x = b, or A'*x = b, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   A'*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

Contents

NAME

```
stptri - compute the inverse of a real upper or  lower  tri-
angular matrix A stored in packed format
```

SYNOPSIS

```
SUBROUTINE STPTRI(UPLO, DIAG, N, A, INFO)

CHARACTER * 1 UPLO, DIAG

REAL A(*)

SUBROUTINE STPTRI_64(UPLO, DIAG, N, A, INFO)

CHARACTER * 1 UPLO, DIAG
INTEGER*8 N, INFO
REAL A(*)
```

F95 INTERFACE

```
SUBROUTINE TPTRI(UPLO, DIAG, N, A, [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER :: N, INFO
REAL, DIMENSION(:) :: A

SUBROUTINE TPTRI_64(UPLO, DIAG, N, A, [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER(8) :: N, INFO
REAL, DIMENSION(:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void stptri(char uplo, char  diag,  int  n,  float  *a,  int
          *info);

void stptri_64(char uplo, char diag, long n, float *a,  long
          *info);
```

PURPOSE

stptri computes the inverse of a real upper or lower triangular matrix A stored in packed format.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the upper or lower triangular matrix  A,
          stored  columnwise  in  a  linear array.  The j-th
          column of A is stored in the array A  as  follows:
          if  UPLO  =  'U',  A(i  +  (j-1)*j/2) = A(i,j) for
          1<=i<=j; if UPLO = 'L', A(i + (j-1)*((2*n-j)/2)  =
          A(i,j)   for   j<=i<=n.   See  below  for  further
          details.  On exit, the (triangular) inverse of the
          original  matrix,  in the same packed storage for-
          mat.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, A(i,i) is  exactly  zero.   The
          triangular  matrix is singular and its inverse can
          not be computed.
```

FURTHER DETAILS

A triangular matrix A can be transferred to packed storage using one of the following program segments:

UPLO = 'U':

```
      JC = 1
      DO 2 J = 1, N
         DO 1 I = 1, J
            A(JC+I-1)  =  A(I,J)
    1    CONTINUE
         JC = JC + J
    2 CONTINUE
```

UPLO = 'L':

```
      JC = 1
      DO 2 J = 1, N
         DO 1 I = J, N
            A(JC+I-J)   =  A(I,J)
    1    CONTINUE
         JC = JC + N - J  + 1
    2 CONTINUE
```

INTEGER(8) :: N, NRHS, LDB, INFO
REAL, DIMENSION(:) :: A
REAL, DIMENSION(:,:) :: B
```

C INTERFACE

```
#include <sunperf.h>

void stptrs(char uplo, char transa, char diag,  int  n,  int
          nrhs, float *a, float *b, int ldb, int *info);

void stptrs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs,  float  *a,  float  *b, long ldb, long
          *info);
```

PURPOSE

stptrs solves a triangular system of the form

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B  (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input) The upper or lower  triangular  matrix  A,  packed
          columnwise  in a linear array.  The j-th column of
          A is stored in the array A as follows:  if UPLO  =
          'U',  A(i  +  (j-1)*j/2)  = A(i,j) for 1<=i<=j; if
          UPLO = 'L', A(i + (j-1)*(2*n-j)/2)  =  A(i,j)  for
          j<=i<=n.
```

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

```
strans - transpose and scale source matrix
```

SYNOPSIS

```
SUBROUTINE STRANS(PLACE, SCALE, SOURCE, M, N, DEST)

CHARACTER * 1 PLACE
INTEGER M, N
REAL SCALE
REAL SOURCE(*), DEST(*)

SUBROUTINE STRANS_64(PLACE, SCALE, SOURCE, M, N, DEST)

CHARACTER * 1 PLACE
INTEGER*8 M, N
REAL SCALE
REAL SOURCE(*), DEST(*)
```

F95 INTERFACE

```
SUBROUTINE TRANS([PLACE], SCALE, SOURCE, M, N, [DEST])

CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N
REAL :: SCALE
REAL, DIMENSION(:) :: SOURCE, DEST

SUBROUTINE TRANS_64([PLACE], SCALE, SOURCE, M, N, [DEST])

CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N
REAL :: SCALE
REAL, DIMENSION(:) :: SOURCE, DEST
```

C INTERFACE

```
#include <sunperf.h>

void strans(char place, float scale, float *source,  int  m,
          int n, float *dest);

void strans_64(char place, float scale, float *source,  long
          m, long n, float *dest);
```

PURPOSE

strans scales and transposes the source matrix. The N2 x N1 result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE'

PLACE = 'O' or 'o': DEST = SCALE * SOURCE'

ARGUMENTS

PLACE (input)
Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place. 'I' is default.

SCALE (input)
Scale factor on the SOURCE matrix.

SOURCE (input/output)
(M, N) on input. Array of (N, M) on output if in-place transpose.

M (input)
Number of rows in the SOURCE matrix on input.

N (input)
Number of columns in the SOURCE matrix on input.

DEST (output)
Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

REAL A(LDA,*), WORK(*)

SUBROUTINE STRCON_64(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,
      INFO)

CHARACTER * 1 NORM, UPLO, DIAG
INTEGER*8 N, LDA, INFO
INTEGER*8 WORK2(*)
REAL RCOND
REAL A(LDA,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON(NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK], [WORK2],
       [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER :: N, LDA, INFO
INTEGER, DIMENSION(:) :: WORK2
REAL :: RCOND
```

```
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE TRCON_64(NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],
       [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL :: RCOND
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
void strcon(char norm, char uplo, char diag,  int  n,  float
          *a, int lda, float *rcond, int *info);

void strcon_64(char norm, char  uplo,  char  diag,  long  n,
          float *a, long lda, float *rcond, long *info);
```

PURPOSE

strcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.
```

N (input) The order of the matrix A. N >= 0.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)

INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: T, VL, VR
```

C INTERFACE

```
#include <sunperf.h>

void strevc(char side, char  howmny,  int  *select,  int  n,
          float *t, int ldt, float *vl, int ldvl, float *vr,
          int ldvr, int mm, int *m, int *info);
void strevc_64(char side, char howmny, long *select, long n,
          float  *t,  long  ldt, float *vl, long ldvl, float
          *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

strevc computes some or all of the right and/or left eigen-vectors of a real upper quasi-triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
T*x = w*x,     y'*T = w*y'
```

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input orthogonal
matrix. If T was obtained from the real-Schur factorization of an original matrix A = Q*T*Q', then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diag-onal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign. Corresponding to each 2-by-2 diagonal block is a com-plex conjugate pair of eigenvalues and eigenvectors; only one eigenvector of the pair is computed, namely the one corresponding to the eigenvalue with positive imaginary part.

ARGUMENTS

```
SIDE (input)
          = 'R':  compute right eigenvectors only;
          = 'L':  compute left eigenvectors only;
          = 'B':  compute both right and left eigenvectors.

HOWMNY (input)
          = 'A':  compute all right  and/or  left  eigenvec-
          tors;
          = 'B':  compute all right  and/or  left  eigenvec-
          tors,  and  backtransform  them  using  the  input
          matrices supplied in VR and/or VL; = 'S':  compute
          selected right and/or left eigenvectors, specified
          by the logical array SELECT.
SELECT (input/output)
          If HOWMNY = 'S', SELECT specifies the eigenvectors
          to be computed.  If HOWMNY = 'A' or 'B', SELECT is
          not referenced.  To select  the  real  eigenvector
          corresponding to a real eigenvalue w(j), SELECT(j)
          must be set to  .TRUE..   To  select  the  complex
          eigenvector  corresponding  to a complex conjugate
          pair  w(j)  and  w(j+1),   either   SELECT(j)   or
          SELECT(j+1)  must  be  set to .TRUE.; then on exit
          SELECT(j) is .TRUE. and SELECT(j+1) is .FALSE..

N (input) The order of the matrix T. N >= 0.

T (input/output)
          The  upper  quasi-triangular  matrix  T  in  Schur
          canonical form.

LDT (input)
          The leading dimension  of  the  array  T.  LDT  >=
          max(1,N).

VL (input/output)
          On entry, if SIDE = 'L' or 'B' and HOWMNY  =  'B',
          VL  must  contain  an N-by-N matrix Q (usually the
          orthogonal matrix Q of Schur vectors  returned  by
          SHSEQR).   On  exit, if SIDE = 'L' or 'B', VL con-
          tains:  if HOWMNY = 'A',  the  matrix  Y  of  left
          eigenvectors  of  T;  VL  has the same quasi-lower
          triangular form as T'. If T(i,i) is a real  eigen-
          value,  then  the  i-th column VL(i) of VL  is its
          corresponding eigenvector. If T(i:i+1,i:i+1) is  a
          2-by-2   block   whose  eigenvalues  are  complex-
          conjugate  eigenvalues  of  T,  then  VL(i)+sqrt(-
```

1)*VL(i+1) is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part, and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the orthogonal matrix Q of Schur vectors returned by SHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR has the same quasi-upper triangular form as T. If T(i,i) is a real eigenvalue, then the i-th column VR(i) of VR is its corresponding eigenvector. If T(i:i+1,i:i+1) is a 2-by-2 block whose eigenvalues are complex-conjugate eigenvalues of T, then VR(i)+sqrt(-1)*VR(i+1) is the complex eigenvector corresponding to the eigenvalue with positive real part. if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR

actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The algorithm used in this program is basically backward (forward) substitution, with scaling to make the the code robust against possible overflow.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|.

NAME

```
strexc - reorder the real  Schur  factorization  of  a  real
matrix  A  =  Q*T*Q**T, so that the diagonal block of T with
row index IFST is moved to row ILST
```

SYNOPSIS

```
SUBROUTINE STREXC(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK, INFO)

CHARACTER * 1 COMPQ
INTEGER N, LDT, LDQ, IFST, ILST, INFO
REAL T(LDT,*), Q(LDQ,*), WORK(*)

SUBROUTINE STREXC_64(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, WORK,
      INFO)

CHARACTER * 1 COMPQ
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
REAL T(LDT,*), Q(LDQ,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TREXC(COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],
       [INFO])

CHARACTER(LEN=1) :: COMPQ
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: T, Q

SUBROUTINE TREXC_64(COMPQ, N, T, [LDT], Q, [LDQ], IFST, ILST, [WORK],
       [INFO])

CHARACTER(LEN=1) :: COMPQ
```

```
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
REAL, DIMENSION(:) :: WORK
REAL, DIMENSION(:,:) :: T, Q
```

C INTERFACE

```
#include <sunperf.h>

void strexc(char compq, int n, float *t, int ldt, float  *q,
          int ldq, int *ifst, int *ilst, int *info);

void strexc_64(char compq, long n, float *t, long ldt, float
          *q, long ldq, long *ifst, long *ilst, long *info);
```

PURPOSE

strexc reorders the real Schur factorization of a real matrix A = Q*T*Q**T, so that the diagonal block of T with row index IFST is moved to row ILST.

The real Schur form T is reordered by an orthogonal similarity transformation Z**T*T*Z, and optionally the matrix Q of Schur vectors is updated by postmultiplying it with Z.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

COMPQ (input)
= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q.

N (input) The order of the matrix T. N >= 0.

T (input/output)
On entry, the upper quasi-triangular matrix T, in Schur Schur canonical form. On exit, the reordered upper quasi-triangular matrix, again in Schur canonical form.

LDT (input)
The leading dimension of the array T. LDT >= max(1,N).

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N).

IFST (input/output)
Specify the reordering of the diagonal blocks of T. The block with row index IFST is moved to row ILST, by a sequence of transpositions between adjacent blocks. On exit, if IFST pointed on entry to the second row of a 2-by-2 block, it is changed to point to the first row; ILST always points to the first row of the block in its final position (which may differ from its input value by +1 or -1). 1 <= IFST <= N; 1 <= ILST <= N.

ILST (input/output)
See the description of IFST.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1: two adjacent blocks were too close to swap (the problem is very ill-conditioned); T may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

NAME

```
strmm - perform one of the matrix-matrix operations    B  :=
alpha*op( A )*B, or B := alpha*B*op( A )
```

SYNOPSIS

```
SUBROUTINE STRMM(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
      LDB)

CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER M, N, LDA, LDB
REAL ALPHA
REAL A(LDA,*), B(LDB,*)

SUBROUTINE STRMM_64(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
      LDB)

CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER*8 M, N, LDA, LDB
REAL ALPHA
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRMM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],
       B, [LDB])

CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE TRMM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
       [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void strmm(char side, char uplo, char transa, char diag, int
          m,  int  n,  float alpha, float *a, int lda, float
          *b, int ldb);

void strmm_64(char side, char uplo, char transa, char  diag,
          long  m,  long n, float alpha, float *a, long lda,
          float *b, long ldb);
```

PURPOSE

strmm performs one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A) where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

op(A) = A   or   op(A) = A'.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether op(A) multiplies B from the left or right as follows:

SIDE = 'L' or 'l'   B := alpha*op(A)*B.

SIDE = 'R' or 'r'   B := alpha*B*op(A).

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n'   op(A) = A.

TRANSA = 'T' or 't'   op(A) = A'.

TRANSA = 'C' or 'c'   op(A) = A'.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

M (input)
On entry, M specifies the number of rows of B. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of B. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)
REAL array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not refer-

enced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1, m), when SIDE = 'R' or 'r' then LDA >= max(1, n). Unchanged on exit.

B (input/output)

REAL array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB >= max(1, m). Unchanged on exit.

```
#include <sunperf.h>

void strmv(char uplo, char transa, char diag, int  n,  float
          *a, int lda, float *y, int incy);

void strmv_64(char uplo, char transa,  char  diag,  long  n,
          float *a, long lda, float *y, long incy);
```

PURPOSE

strmv performs one of the matrix-vector operations x := A*x, or x := A'*x, where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

```
UPLO (input)
          On entry, UPLO specifies whether the matrix is  an
          upper or lower triangular matrix as follows:

          UPLO = 'U' or  'u'    A  is  an  upper  triangular
          matrix.

          UPLO = 'L'  or  'l'    A  is  a  lower  triangular
          matrix.

          Unchanged on exit.

TRANSA (input)
          On entry, TRANSA specifies  the  operation  to  be
          performed as follows:

          TRANSA = 'N' or 'n'   x := A*x.

          TRANSA = 'T' or 't'   x := A'*x.

          TRANSA = 'C' or 'c'   x := A'*x.

          Unchanged on exit.

          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
          On entry, DIAG specifies whether or not A is  unit
          triangular as follows:
```

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tranformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

INTEGER, DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: FERR, BERR, WORK
REAL, DIMENSION(:,:) :: A, B, X
```

```
SUBROUTINE TRRFS_64(UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B, [LDB],
       X, [LDX], FERR, BERR, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDA, LDB, LDX, INFO
INTEGER(8), DIMENSION(:) :: WORK2
REAL, DIMENSION(:) :: FERR, BERR, WORK
REAL, DIMENSION(:,:) :: A, B, X
```

C INTERFACE

```
#include <sunperf.h>

void strrfs(char uplo, char transa, char diag,  int  n,  int
          nrhs,  float *a, int lda, float *b, int ldb, float
          *x, int ldx, float *ferr, float *berr, int *info);
void strrfs_64(char uplo, char transa, char  diag,  long  n,
          long nrhs, float *a, long lda, float *b, long ldb,
          float *x, long ldx, float *ferr, float *berr, long
          *info);
```

PURPOSE

strrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by STRTRS or some other means before entering this routine. STRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B  (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
```

```
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The triangular matrix A.  If UPLO = 'U', the lead-
          ing  N-by-N  upper  triangular part of the array A
          contains the  upper  triangular  matrix,  and  the
          strictly  lower triangular part of A is not refer-
          enced.  If UPLO = 'L', the  leading  N-by-N  lower
          triangular  part of the array A contains the lower
          triangular matrix, and the strictly upper triangu-
          lar  part  of A is not referenced.  If DIAG = 'U',
          the diagonal elements of A are also not referenced
          and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
```

change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void strsen(char job, char compq, int *select, int n,  float
          *t,  int  ldt, float *q, int ldq, float *wr, float
          *wi, int *m, float *s, float *sep, int *info);

void strsen_64(char job, char compq, long *select,  long  n,
          float *t, long ldt, float *q, long ldq, float *wr,
          float *wi, long *m, float  *s,  float  *sep,  long
          *info);
```

PURPOSE

strsen reorders the real Schur factorization of a real matrix A = Q*T*Q**T, so that a selected cluster of eigen-values appears in the leading diagonal blocks of the upper quasi-triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diag-onal blocks; each 2-by-2 diagonal block has its diagonal elemnts equal and its off-diagonal elements of opposite sign.

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):
= 'N': none;
= 'E': for eigenvalues only (S);
= 'V': for invariant subspace only (SEP);
= 'B': for both eigenvalues and invariant subspace (S and SEP).

COMPQ (input)
= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q.

SELECT (input)
SELECT specifies the eigenvalues in the selected cluster. To select a real eigenvalue w(j), SELECT(j) must be set to w(j) and w(j+1), corresponding to a 2-by-2 diagonal block, either SELECT(j) or SELECT(j+1) or both must be set to either both included in the cluster or both excluded.

N (input) The order of the matrix T. N >= 0.

T (input/output)
On entry, the upper quasi-triangular matrix T, in Schur canonical form. On exit, T is overwritten by the reordered matrix T, again in Schur canonical form, with the selected eigenvalues in the leading diagonal blocks.

LDT (input)
The leading dimension of the array T. LDT >= max(1,N).

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the orthogonal transformation matrix which reorders T; the leading M columns of Q form an orthonormal basis for the specified invariant subspace. If COMPQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1;

```
           and if COMPQ = 'V', LDQ >= N.

 WR (output)
           The real and imaginary parts, respectively, of the
           reordered  eigenvalues  of  T. The eigenvalues are
           stored in the same order as on the diagonal of  T,
           with  WR(i)  =  T(i,i) and, if T(i:i+1,i:i+1) is a
           2-by-2 diagonal block, WI(i) >  0  and  WI(i+1)  =
           -WI(i).  Note that if a complex eigenvalue is suf-
           ficiently  ill-conditioned,  then  its  value  may
           differ  significantly from its value before reord-
           ering.

 WI (output)
           See the description of WR.
 M (output)
           The dimension of the specified invariant subspace.
           0 < = M <= N.

 S (output)
           If JOB = 'E' or 'B', S is a  lower  bound  on  the
           reciprocal condition number for the selected clus-
           ter of eigenvalues.  S  cannot  underestimate  the
           true  reciprocal  condition  number by more than a
           factor of sqrt(N). If M = 0 or N, S = 1.  If JOB =
           'N' or 'V', S is not referenced.

 SEP (output)
           If JOB = 'V' or 'B', SEP is the estimated recipro-
           cal  condition  number  of the specified invariant
           subspace. If M = 0 or N, SEP = norm(T).  If JOB  =
           'N' or 'E', SEP is not referenced.

 WORK (workspace)
           On exit, if INFO = 0, WORK(1) returns the  optimal
           LWORK.

 LWORK (input)
           The dimension of the array WORK.  If  JOB  =  'N',
           LWORK >= max(1,N); if JOB = 'E', LWORK >= M*(N-M);
           if JOB = 'V' or 'B', LWORK >= 2*M*(N-M).

           If LWORK = -1, then a workspace query is  assumed;
           the  routine  only  calculates the optimal size of
           the WORK array, returns this value  as  the  first
           entry  of  the  WORK  array,  and no error message
           related to LWORK is issued by XERBLA.

 IWORK (workspace/output)
           If JOB = 'N' or 'E', IWORK is not referenced.
```

```
LIWORK (input)
          The dimension of the array IWORK.  If JOB = 'N' or
          'E',  LIWORK  >= 1; if JOB = 'V' or 'B', LIWORK >=
          M*(N-M).

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.
INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          = 1: reordering of T failed  because  some  eigen-
          values  are  too close to separate (the problem is
          very ill-conditioned); T may have  been  partially
          reordered,  and  WR and WI contain the eigenvalues
          in  the  same  order  as  in  T;  S  and  SEP  (if
          requested) are set to zero.
```

FURTHER DETAILS

```
STRSEN first collects the selected eigenvalues by  computing
an  orthogonal transformation Z to move them to the top left
corner of T.  In other words, the selected  eigenvalues  are
the eigenvalues of T11 in:

              Z'*T*Z = ( T11 T12 ) n1
                       (  0  T22 ) n2
                          n1  n2

where N = n1+n2 and Z' means the transpose of Z.  The  first
n1 columns of Z span the specified invariant subspace of T.

If T has been obtained from the real Schur factorization  of
a  matrix A = Q*T*Q', then the reordered real Schur factori-
zation of A is given by A = (Q*Z)*(Z'*T*Z)*(Q*Z)',  and  the
first  n1  columns  of  Q*Z span the corresponding invariant
subspace of A.

The reciprocal condition number of the average of the eigen-
values  of  T11 may be returned in S. S lies between 0 (very
badly conditioned) and 1 (very well conditioned). It is com-
puted as follows. First we compute R so that

                       P = ( I  R ) n1
                           ( 0  0 ) n2
                             n1 n2
```

is the projector on the invariant subspace associated with T11. R is the solution of the Sylvester equation:

T11*R - R*T22 = T12.

Let F-norm(M) denote the Frobenius-norm of M and 2-norm(M) denote the two-norm of M. Then S is computed as the lower bound

(1 + F-norm(R)**2)**(-1/2)

on the reciprocal of 2-norm(P), the true reciprocal condition number. S cannot underestimate 1 / 2-norm(P) by more than a factor of sqrt(N).

An approximate error bound for the computed average of the eigenvalues of T11 is

EPS * norm(T) / S

where EPS is the machine precision.

The reciprocal condition number of the right invariant subspace spanned by the first n1 columns of Z (or of Q*Z) is returned in SEP. SEP is defined as the separation of T11 and T22:

sep(T11, T22) = sigma-min(C)

where sigma-min(C) is the smallest singular value of the n1*n2-by-n1*n2 matrix

C = kprod(I(n2), T11) - kprod(transpose(T22), I(n1))

I(m) is an m by m identity matrix, and kprod denotes the Kronecker product. We estimate sigma-min(C) by the reciprocal of an estimate of the 1-norm of inverse(C). The true reciprocal 1-norm of inverse(C) cannot differ from sigma-min(C) by more than a factor of sqrt(n1*n2).

When SEP is small, small changes in T can cause large changes in the invariant subspace. An approximate bound on the maximum angular error in the computed right invariant subspace is

EPS * norm(T) / SEP

Contents

NAME

strsm - solve one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B

SYNOPSIS

```
SUBROUTINE STRSM(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
      LDB)

CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG

REAL A(LDA,*), B(LDB,*)

SUBROUTINE STRSM_64(SIDE, UPLO, TRANSA, DIAG, M, N, ALPHA, A, LDA, B,
      LDB)

CHARACTER * 1 SIDE, UPLO, TRANSA, DIAG
INTEGER*8 M, N, LDA, LDB
REAL ALPHA
REAL A(LDA,*), B(LDB,*)
```

F95 INTERFACE

```
SUBROUTINE TRSM(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A, [LDA],
       B, [LDB])

CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:,:) :: A, B

SUBROUTINE TRSM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
       [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
INTEGER(8) :: M, N, LDA, LDB
REAL :: ALPHA
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void strsm(char side, char uplo, char transa, char diag, int
          m,  int  n,  float alpha, float *a, int lda, float
          *b, int ldb);

void strsm_64(char side, char uplo, char transa, char  diag,
          long  m,  long n, float alpha, float *a, long lda,
          float *b, long ldb);
```

PURPOSE

strsm solves one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

op(A) = A or op(A) = A'.

The matrix X is overwritten on B.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l'   op(A)*X = alpha*B.

SIDE = 'R' or 'r'   X*op(A) = alpha*B.

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = A'.

Unchanged on exit.
TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit tri- angular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N >= 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

REAL array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.
Before entry with UPLO = 'U' or 'u', the lead- ing k by k upper triangular part of the array A must contain the upper triangular matrix and the

strictly lower triangular part of A is not referenced.
Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.
Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be one. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1, m), when SIDE = 'R' or 'r' then LDA >= max(1, n). Unchanged on exit.

B (input/output)
REAL array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB >= max(1, m). Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>

void strsna(char job, char howmny, int *select, int n, float
          *t,  int  ldt, float *vl, int ldvl, float *vr, int
          ldvr, float *s, float *sep, int mm,  int  *m,  int
          ldwork, int *info);

void strsna_64(char job, char howmny, long *select, long  n,
          float  *t,  long  ldt, float *vl, long ldvl, float
          *vr, long ldvr, float *s,  float  *sep,  long  mm,
          long *m, long ldwork, long *info);
```

PURPOSE

strsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix Q*T*Q**T with Q orthogonal).

T must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):

= 'E': for eigenvalues only (S);
= 'V': for eigenvectors only (SEP);
= 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY (input)
= 'A': compute condition numbers for all eigenpairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
If HOWMNY = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the eigenpair corresponding to a real eigenvalue w(j), SELECT(j) must be set to .TRUE.. To select condition numbers corresponding to a complex conjugate pair of eigenvalues w(j) and w(j+1), either SELECT(j) or SELECT(j+1) or both, must be set to .TRUE.. If HOWMNY = 'A', SELECT is not referenced.

N (input) The order of the matrix T. N >= 0.

T (input) The upper quasi-triangular matrix T, in Schur canonical form.

LDT (input)
The leading dimension of the array T. LDT >= max(1,N).

VL (input)
If JOB = 'E' or 'B', VL must contain left eigenvectors of T (or of any Q*T*Q**T with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by SHSEIN or STREVC. If JOB = 'V', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= 1; and if JOB = 'E' or 'B', LDVL >= N.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigenvectors of T (or of any Q*T*Q**T with Q orthogonal), corresponding to the eigenpairs specified by HOWMNY and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by

SHSEIN or STREVC. If JOB = 'V', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= 1; and if JOB = 'E' or 'B', LDVR >= N.

S (output)
If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of S are set to the same value. Thus S(j), SEP(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of SEP are set to the same value. If the eigenvalues cannot be reordered to compute SEP(j), SEP(j) is set to 0; this can only occur when the true value would be very small anyway. If JOB = 'E', SEP is not referenced.

MM (input)
The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M (output)
The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK (workspace)
dimension(LDWORK,N+1) If JOB = 'E', WORK is not referenced.

LDWORK (input)
The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

WORK1 (workspace)
dimension(N) If JOB = 'E', WORK1 is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of an eigenvalue lambda is defined as

S(lambda) = |v'*u| / (norm(u)*norm(v))

where u and v are the right and left eigenvectors of T corresponding to lambda; v' denotes the conjugate-transpose of v, and norm(u) denotes the Euclidean norm. These reciprocal condition numbers always lie between zero (very badly conditioned) and one (very well conditioned). If n = 1, S(lambda) is defined to be 1.

An approximate error bound for a computed eigenvalue W(i) is given by

EPS * norm(T) / S(i)

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u corresponding to lambda is defined as follows. Suppose

```
T = ( lambda  c  )
    (   0    T22 )
```

Then the reciprocal condition number is

SEP(lambda, T22) = sigma-min(T22 - lambda*I)

where sigma-min denotes the smallest singular value. We approximate the smallest singular value by the reciprocal of an estimate of the one-norm of the inverse of T22 - lambda*I. If n = 1, SEP(1) is defined to be abs(T(1,1)).

An approximate error bound for a computed right eigenvector VR(i) is given by

EPS * norm(T) / SEP(i)

NAME

strsv - solve one of the systems of equations A*x = b, or
A'*x = b

SYNOPSIS

```
SUBROUTINE STRSV(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER N, LDA, INCY
REAL A(LDA,*), Y(*)

SUBROUTINE STRSV_64(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
INTEGER*8 N, LDA, INCY
REAL A(LDA,*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE TRSV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER :: N, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A

SUBROUTINE TRSV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, LDA, INCY
REAL, DIMENSION(:) :: Y
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void strsv(char uplo, char transa, char diag, int  n,  float
          *a, int lda, float *y, int incy);

void strsv_64(char uplo, char transa,  char  diag,  long  n,
          float *a, long lda, float *y, long incy);
```

PURPOSE

strsv solves one of the systems of equations A*x = b, or A'*x = b, where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.
No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   A'*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

Contents

NAME

strsyl - solve the real Sylvester matrix equation

SYNOPSIS

```
SUBROUTINE STRSYL(TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C, LDC,
      SCALE, INFO)

INTEGER ISGN, M, N, LDA, LDB, LDC, INFO
REAL SCALE
REAL A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE STRSYL_64(TRANA, TRANB, ISGN, M, N, A, LDA, B, LDB, C,
      LDC, SCALE, INFO)

CHARACTER * 1 TRANA, TRANB
INTEGER*8 ISGN, M, N, LDA, LDB, LDC, INFO
REAL SCALE
REAL A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE TRSYL(TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB], C,
       [LDC], SCALE, [INFO])

CHARACTER(LEN=1) :: TRANA, TRANB
INTEGER :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL :: SCALE
REAL, DIMENSION(:,:) :: A, B, C

SUBROUTINE TRSYL_64(TRANA, TRANB, ISGN, M, N, A, [LDA], B, [LDB], C,
       [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB
INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL :: SCALE
REAL, DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>

void strsyl(char trana, char tranb, int isgn, int m, int  n,
          float  *a,  int  lda, float *b, int ldb, float *c,
          int ldc, float *scale, int *info);

void strsyl_64(char trana, char tranb, long  isgn,  long  m,
          long  n,  float  *a, long lda, float *b, long ldb,
          float *c, long ldc, float *scale, long *info);
```

PURPOSE

strsyl solves the real Sylvester matrix equation:

```
op(A)*X + X*op(B) = scale*C or
op(A)*X - X*op(B) = scale*C,
```

where op(A) = A or A**T, and A and B are both upper quasi-triangular. A is M-by-M and B is N-by-N; the right hand side C and the solution X are M-by-N; and scale is an output scale factor, set <= 1 to avoid overflow in X.

A and B must be in Schur canonical form (as returned by SHSEQR), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks; each 2-by-2 diagonal block has its diagonal elements equal and its off-diagonal elements of opposite sign.

ARGUMENTS

```
TRANA (input)
          Specifies the option op(A):
          = 'N': op(A) = A    (No transpose)
          = 'T': op(A) = A**T (Transpose)
          = 'C': op(A) = A**H (Conjugate transpose  =  Tran-
          spose)

TRANB (input)
          Specifies the option op(B):
          = 'N': op(B) = B    (No transpose)
          = 'T': op(B) = B**T (Transpose)
```

```
          = 'C': op(B) = B**H (Conjugate transpose  =  Tran-
          spose)

ISGN (input)
          Specifies the sign in the equation:
          = +1: solve op(A)*X + X*op(B) = scale*C
          = -1: solve op(A)*X - X*op(B) = scale*C

M (input) The order of the matrix A, and the number of  rows
          in the matrices X and C. M >= 0.

N (input) The order of the  matrix  B,  and  the  number  of
          columns in the matrices X and C. N >= 0.

A (input) The upper  quasi-triangular  matrix  A,  in  Schur
          canonical form.
LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).

B (input) The upper  quasi-triangular  matrix  B,  in  Schur
          canonical form.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

C (input/output)
          On entry, the M-by-N right hand side matrix C.  On
          exit, C is overwritten by the solution matrix X.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M)

SCALE (output)
          The scale factor, scale, set <= 1 to  avoid  over-
          flow in X.

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          = 1: A and B have  common  or  very  close  eigen-
          values;  perturbed  values  were used to solve the
          equation (but the matrices A and B are unchanged).
```

SUBROUTINE TRTI2_64(UPLO, DIAG, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
INTEGER(8) :: N, LDA, INFO
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void strti2(char uplo, char diag, int n, float *a, int  lda,
          int *info);

void strti2_64(char uplo, char diag, long n, float *a,  long
          lda, long *info);
```

PURPOSE

strti2 computes the inverse of a real upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular
= 'L': Lower triangular

DIAG (input)
Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular
= 'U': Unit triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value

          lda, long *info);
```

PURPOSE

strtri computes the inverse of a real upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1. On exit, the (triangular) inverse of the original matrix, in the same storage format.

SUBROUTINE TRTRS_64(UPLO, [TRANSA], DIAG, N, NRHS, A, [LDA], B, [LDB],
       [INFO])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
REAL, DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void strtrs(char uplo, char transa, char diag,  int  n,  int
          nrhs,  float  *a,  int lda, float *b, int ldb, int
          *info);

void strtrs_64(char uplo, char transa, char  diag,  long  n,
          long nrhs, float *a, long lda, float *b, long ldb,
          long *info);
```

PURPOSE

strtrs solves a triangular system of the form where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B  (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input) The triangular matrix A.  If UPLO = 'U', the lead-
          ing  N-by-N  upper  triangular part of the array A
          contains the  upper  triangular  matrix,  and  the
```

strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

```
stzrqf - routine is deprecated and has been replaced by rou-
tine STZRZF
```

SYNOPSIS

```
SUBROUTINE STZRQF(M, N, A, LDA, TAU, INFO)

INTEGER M, N, LDA, INFO
REAL A(LDA,*), TAU(*)

SUBROUTINE STZRQF_64(M, N, A, LDA, TAU, INFO)

INTEGER*8 M, N, LDA, INFO
REAL A(LDA,*), TAU(*)
```

F95 INTERFACE

```
SUBROUTINE TZRQF(M, N, A, [LDA], TAU, [INFO])

INTEGER :: M, N, LDA, INFO
REAL, DIMENSION(:) :: TAU
REAL, DIMENSION(:,:) :: A

SUBROUTINE TZRQF_64(M, N, A, [LDA], TAU, [INFO])

INTEGER(8) :: M, N, LDA, INFO
REAL, DIMENSION(:) :: TAU
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stzrqf(int m, int n, float *a, int lda, float *tau, int
          *info);

void stzrqf_64(long m, long n, float  *a,  long  lda,  float
          *tau, long *info);
```

PURPOSE

stzrqf routine is deprecated and has been replaced by routine STZRZF.

STZRQF reduces the M-by-N (M<=N) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as
   A = (R 0) * Z,

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= M.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

The factorization is obtained by Householder's method. The kth transformation matrix, Z(k), which is used to introduce zeros into the (m - k + 1)th row of A, is given in the form

```
   Z( k ) = ( I     0   ),
            ( 0  T( k ) )
```

where

```
   T( k ) = I - tau*u( k )*u( k )',   u( k ) = (   1    ),
                                               (   0    )
                                               ( z( k ) )
```

tau is a scalar and z(k) is an (n - m) element vector. tau and z(k) are chosen to annihilate the elements of the kth row of X.

The scalar tau is returned in the kth element of TAU and the vector u(k) in the kth row of A, such that the elements of z(k) are in a(k, m + 1), ..., a(k, n). The elements of R are returned in the upper triangular part of A.

Z is given by

```
   Z =  Z( 1 ) * Z( 2 ) * ... * Z( m ).
```

SUBROUTINE STZRZF(M, N, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER M, N, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)

SUBROUTINE STZRZF_64(M, N, A, LDA, TAU, WORK, LWORK, INFO)

INTEGER*8 M, N, LDA, LWORK, INFO
REAL A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE TZRZF([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])

INTEGER :: M, N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A

SUBROUTINE TZRZF_64([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])

INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: TAU, WORK
REAL, DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void stzrzf(int m, int n, float *a, int lda, float *tau, int
          *info);

void stzrzf_64(long m, long n, float  *a,  long  lda,  float
          *tau, long *info);
```

PURPOSE

stzrzf reduces the M-by-N (M<=N) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations.

The upper trapezoidal matrix A is factored as

```
   A = ( R  0 ) * Z,
```

where Z is an N-by-N orthogonal matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the orthogonal matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

Based on contributions by
A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The factorization is obtained by Householder's method. The kth transformation matrix, Z(k), which is used to introduce zeros into the (m - k + 1)th row of A, is given in the form

```
   Z( k ) = ( I     0   ),
            ( 0  T( k ) )
```

where

```
   T( k ) = I - tau*u( k )*u( k )',   u( k ) = (   1    ),
                                               (   0    )
                                               ( z( k ) )
```

tau is a scalar and z(k) is an (n - m) element vector. tau and z(k) are chosen to annihilate the elements of the kth row of X.

The scalar tau is returned in the kth element of TAU and the vector u(k) in the kth row of A, such that the elements of z(k) are in a(k, m + 1), ..., a(k, n). The elements of R are returned in the upper triangular part of A.

Z is given by

```
   Z =  Z( 1 ) * Z( 2 ) * ... * Z( m ).

DESCRIPTION

```
        C <- alpha op(A) B + beta C
where ALPHA and BETA are scalar, C and B are  matrices,
A is a matrix represented in variable block sparse row  format
and op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if the matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
```

```
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
                0 : non-unit
                1 : unit
              DESCRA(4) Array base  (NOT IMPLEMENTED)
                0 : C/C++ compatible
                1 : Fortran compatible
              DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                0 : unknown
                1 : no repeated indices

VAL()         scalar array of length NNZ consisting of the block entries
              of A where each block entry is a dense rectangular matrix
              stored column by column.
              NNZ is the total number of point entries in all nonzero
              block  entries of a matrix A.
INDX()        integer array of length BNNZ+1 where BNNZ is the number of
              block entries of a matrix A such that the I-th element of
              INDX[] points to the location in VAL of the (1,1) element
              of the I-th block entry.

BINDX()       integer array of length BNNZ consisting of the block
              column indices of the block entries of A where BNNZ is
              the number block entries of a matrix A.

RPNTR()       integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1
              is the row index of the first point row in the I-th block
              row.
              RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of
              rows in matrix A.
              Thus, the number of point rows in the I-th block row is
              RPNTR(I+1)-RPNTR(I).

CPNTR()       integer array of length KB+1 such that CPNTR(J)-CPNTR(1)+1
              is the column index of the first point column in the J-th
              block column. CPNTR(KB+1) is set to K+CPNTR(1) where K is
              the number of columns in matrix A.
              Thus, the number of point columns in the J-th block column
              is CPNTR(J+1)-CPNTR(J).

BPNTRB()      integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1
              points to location in BINDX of the first block entry of
              the I-th block row of A.

BPNTRE()      integer array of length MB such that BPNTRE(I)-BPNTRB(1)
              points to location in BINDX of the last block entry of
              the I-th block row of A.
```

B()	rectangular array with first dimension LDB.
LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. For a general matrix (*DESCRA*(1)=0), array CPNTR can be different from RPNTR. For all other matrix types, RPNTR must equal CPNTR and a single array can be passed for both arguments.

2. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
  SUBROUTINE SVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *           VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

 INTEGER*8    TRANSA, MB, UNITD
 INTEGER*8, DIMENSION(:) ::  DESCRA, INDX, BINDX
 INTEGER*8, DIMENSION(:) ::  RPNTR, CPNTR, BPNTRB, BPNTRE
 REAL    ALPHA, BETA
 REAL, DIMENSION(:) :: VAL, DV
 REAL, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in variable block sparse row
format and  op( A )  is one  of

 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array containing the block entries of the block
              diagonal matrix D.  The size of the J-th block is
              RPNTR(J+1)-RPNTR(J) and each block contains matrix
              entries stored column-major.  The total length of
              array DV is given by the formula:

              sum over J from 1 to MB:
```

```
                 ((RPNTR(J+1)-RPNTR(J))*(RPNTR(J+1)-RPNTR(J)))

ALPHA           Scalar parameter

DESCRA()        Descriptor argument.  Five element integer array

                DESCRA(1) matrix structure
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))
                Note: For the routine, DESCRA(1)=3 is only supported.
                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-identity blocks on the main diagonal
                  1 : identity diagonal block
                  2 : diagonal blocks are dense matrices
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

VAL()           scalar array of length NNZ consisting of the block entries
                of A where each block entry is a dense rectangular matrix
                stored column by column.
                NNZ is the total number of point entries in all nonzero
                block  entries of a matrix A.

INDX()          integer array of length BNNZ+1 where BNNZ is the number
                block entries of a matrix A such that the I-th element of
                INDX[] points to the location in VAL of the (1,1) element
                of the I-th block entry.

BINDX()         integer array of length BNNZ consisting of the block
                column indices of the block entries of A where BNNZ is
                the number block entries of a matrix A.   Block column
                indices MUST be sorted in increasing order for each block
                row.

RPNTR()         integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1
                is the row index of the first point row in the I-th block
                row.
                RPNTR(MB+1) is set to M+RPNTR(1) where M is the number
```

of rows in square triangular matrix A.
Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR() integer array of length MB+1 such that CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(MB+1) is set to M+CPNTR(1).
Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

BPNTRB() integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A.

BPNTRE() integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least M = RPNTR(MB+1)-RPNTR(1).

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the VBR representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3.

6. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row

format the following calling sequence should be used

```
  SUBROUTINE SVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *            VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
 *            B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

NAME

```
swiener - perform Wiener deconvolution of two signals
```

SYNOPSIS

```
SUBROUTINE SWIENER(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)

INTEGER N_POINTS, ISW, IERR
REAL ACOR(*), XCOR(*), FLTR(*), EROP(*)

SUBROUTINE SWIENER_64(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)

INTEGER*8 N_POINTS, ISW, IERR
REAL ACOR(*), XCOR(*), FLTR(*), EROP(*)
```

F95 INTERFACE

```
SUBROUTINE WIENER(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)

INTEGER :: N_POINTS, ISW, IERR
REAL, DIMENSION(:) :: ACOR, XCOR, FLTR, EROP

SUBROUTINE WIENER_64(N_POINTS, ACOR, XCOR, FLTR, EROP, ISW, IERR)

INTEGER(8) :: N_POINTS, ISW, IERR
REAL, DIMENSION(:) :: ACOR, XCOR, FLTR, EROP
```

C INTERFACE

```
#include <sunperf.h>

void swiener(int n_points, float *acor, float  *xcor,  float
          *fltr, float *erop, int *isw, int *ierr);

void swiener_64(long n_points,  float  *acor,  float  *xcor,
```

```
            float *fltr, float *erop, long *isw, long *ierr);
```

PURPOSE

swiener performs Wiener deconvolution of two signals.

ARGUMENTS

N_POINTS (input)
On entry, the number of points in the input correlations. Unchanged on exit.

ACOR (input)
On entry, autocorrelation coefficients. Unchanged on exit.

XCOR (input)
On entry, cross-correlation coefficients. Unchanged on exit.

FLTR (output)
On exit, filter coefficients.

EROP (output)
On exit, the prediction error.

ISW (input)
On entry, if ISW .EQ. 0 then perform spiking deconvolution, otherwise perform general deconvolution. Unchanged on exit.

IERR (output)
On exit, the deconvolution was successful iff IERR .EQ. 0, otherwise there was an error.

Contents

NAME

```
use_threads - set the upper bound on the number  of  threads
that the calling thread wants used
```

SYNOPSIS

```
SUBROUTINE USE_THREADS(NTHREADS)

INTEGER NTHREADS

SUBROUTINE USE_THREADS_64(NTHREADS)

INTEGER*8 NTHREADS
```

F95 INTERFACE

```
SUBROUTINE USE_THREADS(NTHREADS)

INTEGER :: NTHREADS

SUBROUTINE USE_THREADS_64(NTHREADS)

INTEGER(8) :: NTHREADS
```

C INTERFACE

```
#include <sunperf.h>

void use_threads(int nthreads);

void use_threads_64(long nthreads);
```

PURPOSE

use_threads THREADS sets an upper bound on the number of threads that the calling thread wants used. Subsequent calls to this routine result in replacement of the previous Use number for the calling thread. This counts all threads working on the callers behalf, so if it passes 2 for NTHREADS and then calls some subroutine, there will be at most 1 additional thread started to do the computation. There is no restriction that the sum of all NTHREADS from USE_THREADS calls may not exceed the number of CPUs in a system.

Contents

NAME

```
using_threads - returns the current Use number  set  by  the
USE_THREADS subroutine
```

SYNOPSIS

```
INTEGER FUNCTION USING_THREADS()

INTEGER*8 FUNCTION USING_THREADS_64()
```

F95 INTERFACE

```
INTEGER FUNCTION USING_THREADS()

INTEGER(8) FUNCTION USING_THREADS_64()
```

C INTERFACE

```
#include <sunperf.h>

int using_threads();

long using_threads_64();
```

PURPOSE

```
using_threads THREADS will return  the  current  Use  number
from the USE_THREADS subroutine for the calling thread.
```

Contents

NAME

vcfftb - compute a periodic sequence from its Fourier coefficients. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCFFTB(M, N, X, XT, MDIMX, ROWCOL, WSAVE)

CHARACTER * 1 ROWCOL
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER M, N, MDIMX

SUBROUTINE VCFFTB_64(M, N, X, XT, MDIMX, ROWCOL, WSAVE)

CHARACTER * 1 ROWCOL
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTB([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)

CHARACTER(LEN=1) :: ROWCOL
COMPLEX, DIMENSION(:) :: WSAVE
COMPLEX, DIMENSION(:,:) :: X, XT
INTEGER :: M, N, MDIMX

SUBROUTINE FFTB_64([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)

CHARACTER(LEN=1) :: ROWCOL
COMPLEX, DIMENSION(:) :: WSAVE
COMPLEX, DIMENSION(:,:) :: X, XT
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>

void vcfftb(int m, int  n,  complex  *x,  complex  *xt,  int
          mdimx, char rowcol, complex *wsave);

void vcfftb_64(long m, long n, complex *x, complex *xt, long
          mdimx, char rowcol, complex *wsave);
```

ARGUMENTS

M (input) If ROWCOL = 'R' or 'r', M is the number of sequences to be transformed. Otherwise, M is the length of the sequences to be transformed. M >= 0.

N (input) If ROWCOL = 'R' or 'r', N is the length of the sequences to be transformed. Otherwise, N is the number of sequences to be transformed. N >= 0.

X (input) On entry, if ROWCOL = 'R' or 'r' X(MDIMX,N) is an array whose first M rows contain the sequences to be transformed. Otherwise, X(MDIMX,N) contains data sequences of length M stored in N columns of X.

XT (input)
A work array. The size of this workspace depends on the number of threads that are used to execute this routine. There are various functions that can be used to determine the number of threads available (get_env, available_threads, etc). The appropriate amount, which is (number of threads * length of data sequences), can then be dynamically allocated for XT from the driver routine. If XT can only be allocated statically, then the size of XT should be (length of data sequences * number of sequences).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

ROWCOL (input)
Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

WSAVE (input/output)

On entry, an array of dimension (L2+15) or greater, where L2 = 2*M if ROWCOL = ('R' or 'r'). Otherwise, L2 = 2*N. WSAVE is initialized by VCFFTI.

Contents

NAME

```
vcfftf - compute the  Fourier  coefficients  of  a  periodic
sequence.  The VCFFT operations are normalized, so a call of
VCFFTF followed by a call of VCFFTB will return the original
sequence.
```

SYNOPSIS

```
SUBROUTINE VCFFTF(M, N, X, XT, MDIMX, ROWCOL, WSAVE)

CHARACTER * 1 ROWCOL
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER M, N, MDIMX

SUBROUTINE VCFFTF_64(M, N, X, XT, MDIMX, ROWCOL, WSAVE)

CHARACTER * 1 ROWCOL
COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTF([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)

CHARACTER(LEN=1) :: ROWCOL
COMPLEX, DIMENSION(:) :: WSAVE
COMPLEX, DIMENSION(:,:) :: X, XT
INTEGER :: M, N, MDIMX

SUBROUTINE FFTF_64([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)

CHARACTER(LEN=1) :: ROWCOL
COMPLEX, DIMENSION(:) :: WSAVE
COMPLEX, DIMENSION(:,:) :: X, XT
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>

void vcfftf(int m, int  n,  complex  *x,  complex  *xt,  int
          mdimx, char rowcol, complex *wsave);

void vcfftf_64(long m, long n, complex *x, complex *xt, long
          mdimx, char rowcol, complex *wsave);
```

ARGUMENTS

M (input) If ROWCOL = 'R' or 'r', M is the number of sequences to be transformed. Otherwise, M is the length of the sequences to be transformed. M >= 0.

N (input) If ROWCOL = 'R' or 'r', N is the length of the sequences to be transformed. Otherwise, N is the number of sequences to be transformed. N >= 0.

X (input) On entry, if ROWCOL = 'R' or 'r' X(MDIMX,N) is an array whose first M rows contain the sequences to be transformed. Otherwise, X(MDIMX,N) contains data sequences of length M stored in N columns of X.

XT (input)
A work array. The size of this workspace depends on the number of threads that are used to execute this routine. There are various functions that can be used to determine the number of threads available (get_env, available_threads, etc). The appropriate amount, which is (number of threads * length of data sequences), can then be dynamically allocated for XT from the driver routine. If XT can only be allocated statically, then the size of XT should be (length of data sequences * number of sequences).

MDIMX (input)
Leading dimension of the arrays X. MDIMX >= M.

ROWCOL (input)
Indicates whether data sequences in X are stored row-wise ('R' or 'r') or column-wise ('C' or 'c').

WSAVE (input/output)
On entry, an array of dimension (L2+15) or

greater, where L2 = 2*M if ROWCOL = ('R' or 'r'). Otherwise, L2 = 2*N. WSAVE is initialized by VCFFTI.

Contents

NAME

```
vcffti - initialize the array WSAVE, which is used  in  both
VCFFTF and VCFFTB.
```

SYNOPSIS

```
SUBROUTINE VCFFTI(N, WSAVE)

COMPLEX WSAVE(*)
INTEGER N

SUBROUTINE VCFFTI_64(N, WSAVE)

COMPLEX WSAVE(*)
INTEGER*8 N
```

F95 INTERFACE

```
SUBROUTINE VFFTI(N, WSAVE)

COMPLEX, DIMENSION(:) :: WSAVE
INTEGER :: N

SUBROUTINE VFFTI_64(N, WSAVE)

COMPLEX, DIMENSION(:) :: WSAVE
INTEGER(8) :: N
```

C INTERFACE

```
#include <sunperf.h>

void vcffti(int n, complex *wsave);

void vcffti_64(long n, complex *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input)
On entry, an array of dimension (2*N + 15) or greater. VCFFTI needs to be called only once to initialize WSAVE before calling VCFFTF and/or VCFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

```
vcosqb - synthesize a Fourier sequence from its  representa-
tion in terms of a cosine series with odd wave numbers.  The
VCOSQ operations are normalized, so a call  of  VCOSQF  fol-
lowed by a call of VCOSQB will return the original sequence.
```

SYNOPSIS

```
SUBROUTINE VCOSQB(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VCOSQB_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,:) :: X, XT

SUBROUTINE COSQB_64([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER(8) :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcosqb(int m, int n, float *x, float  *xt,  int  mdimx,
          float *wsave);

void vcosqb_64(long m, long n, float  *x,  float  *xt,  long
          mdimx, float *wsave);
```

ARGUMENTS

M (input) The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input/output)
On entry, the rows contain the sequences to be transformed. On exit, the quarter-wave cosine synthesis of the input.

XT (input)
A work array.

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array of dimension (2 * N + 15) or greater initialized by VCOSQI.

Contents

NAME

vcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VCOSQF(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VCOSQF_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQF([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,:) :: X, XT

SUBROUTINE COSQF_64([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER(8) :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcosqf(int m, int n, float *x, float  *xt,  int  mdimx,
          float *wsave);

void vcosqf_64(long m, long n, float  *x,  float  *xt,  long
          mdimx, float *wsave);
```

ARGUMENTS

M (input)
The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. For VCOSQF, a real two-dimensional array with dimensions of (MDIMX x N) whose rows contain the sequences to be transformed. On exit, the quarter-wave cosine transform of the input.

XT (input)
A real two-dimensional work array with dimensions of (MDIMX x N).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array of dimension (2 * N + 15) or greater initialized by VCOSTI.

Contents

NAME

```
vcosqi - initialize the array WSAVE, which is used  in  both
VCOSQF and VCOSQB.
```

SYNOPSIS

```
SUBROUTINE VCOSQI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE VCOSQI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VCOSQI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VCOSQI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vcosqi(int n, float *wsave);

void vcosqi_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array of dimension (2 * N + 15) or greater. VCOSQI needs to be called only once to initialize WSAVE before calling VCOSQF and/or VCOSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

```
vcost - compute the discrete Fourier cosine transform of  an
even sequence.  The VCOST transform is normalized, so a call
of VCOST followed by a call of VCOST will return the  origi-
nal sequence.
```

SYNOPSIS

```
SUBROUTINE VCOST(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VCOST_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```

INTEGER :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,:) :: X, XT

SUBROUTINE COST_64([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER(8) :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vcost(int m, int n, float *x,  float  *xt,  int  mdimx,
          float *wsave);

void vcost_64(long m, long n,  float  *x,  float  *xt,  long
          mdimx, float *wsave);
```

ARGUMENTS

M (input)
The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N - 1 is a product of small primes. N >= 2.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. For VCOST, a real two- dimensional array with dimensions of (MDIMX x (N+1)) whose rows contain the sequences to be transformed. On exit, the cosine transform of the input.

XT (input)
A real two-dimensional work array with dimensions of (MDIMX x (N-1)).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array of dimension (2 * N + 15) or greater initialized by VCOSTI.

Contents

NAME

```
vcosti - initialize the array WSAVE, which is used in VCOST.
```

SYNOPSIS

```
SUBROUTINE VCOSTI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE VCOSTI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VCOSTI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VCOSTI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vcosti(int n, float *wsave);

void vcosti_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N - 1 is a product of small primes. N >= 2.

WSAVE (input)
On entry, an array of dimension (2 * N + 15) or greater. VCOSTI is called once to initialize WSAVE before calling VCOST and need not be called again between calls to VCOST if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.
