vdfftb - compute a periodic sequence from its Fourier  coef-
ficients.  The VRFFT operations are normalized, so a call of
VRFFTF followed by a call of VRFFTB will return the original
sequence.
```

SYNOPSIS

```
SUBROUTINE VDFFTB(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VDFFTB_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT

SUBROUTINE FFTB_64([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER(8) :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdfftb(int m, int n, double *x, double *xt, int  mdimx,
          double *wsave);

void vdfftb_64(long m, long n, double *x, double  *xt,  long
          mdimx, double *wsave);
```

ARGUMENTS

M (input) The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, an array of length N containing the sequence to be transformed. For VRFFTF, a real two-dimensional array X(M,N) whose rows contain the sequences to be transformed.

XT (input)
A real two-dimensional work array with dimensions of (MDIMX x N).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array of dimension (N+15) or greater initialized by VRFFTI.

Contents

NAME

vdfftf - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDFFTF(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VDFFTF_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT

SUBROUTINE FFTF_64([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER(8) :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdfftf(int m, int n, double *x, double *xt, int  mdimx,
          double *wsave);

void vdfftf_64(long m, long n, double *x, double  *xt,  long
          mdimx, double *wsave);
```

ARGUMENTS

M (input)
The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, an array of length N containing the sequence to be transformed. For VRFFTF, a real two- dimensional array X(M,N) whose rows contain the sequences to be transformed.

XT (input)
A real two-dimensional work array with dimensions of (MDIMX x N).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array of dimension (N+15) or greater initialized by VRFFTI.

Contents

NAME

```
vdffti - initialize the array WSAVE, which is used  in  both
VRFFTF and VRFFTB.
```

SYNOPSIS

```
SUBROUTINE VDFFTI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDFFTI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VFFTI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VFFTI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdffti(int n, double *wsave);

void vdffti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input)
On entry, an array of dimension (N + 15) or greater. VRFFTI needs to be called only once to initialize WSAVE before calling VRFFTF and/or VRFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

vdsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDSINQB(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VDSINQB_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```

INTEGER(8) :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdsinqb(int m, int n, double *x, double *xt, int mdimx,
          double *wsave);

void vdsinqb_64(long m, long n, double *x, double *xt,  long
          mdimx, double *wsave);
```

ARGUMENTS

```
M (input)
          The number of sequences to be transformed.   M  >=
          0.

N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input/output)
          On entry,  a  real  two-  dimensional  array  with
          dimensions  of  (MDIMX x N) whose rows contain the
          sequences  to  be  transformed.   On   exit,   the
          quarter-wave sine synthesis of the input.

XT (input)
          A real two-dimensional work array with  dimensions
          of (MDIMX x N).

MDIMX (input)
          Leading dimension of the arrays X and XT as speci-
          fied  in  a dimension or type statement.  MDIMX >=
          M.

WSAVE (input)
          On entry, an array with dimension of at least (2 *
          N  +  15)  for  vector subroutines, initialized by
          VSINQI.
```

Contents

NAME

vdsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VDSINQF(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VDSINQF_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINQF([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT

SUBROUTINE SINQF_64([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER(8) :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void vdsinqf(int m, int n, double *x, double *xt, int mdimx,
          double *wsave);

void vdsinqf_64(long m, long n, double *x, double *xt,  long
          mdimx, double *wsave);
```

ARGUMENTS

M (input)
The number of sequences to be transformed.   M >= 0.

N (input) Length of the sequence to be transformed.   These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. For VSINQF, a real two-dimensional array with dimensions of (MDIMX x N)   whose   rows contain the sequences to be transformed.   On exit, the quarter-wave   sine transform of the input.

XT (input)
A real two-dimensional work array with dimensions of (MDIMX x N).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array with dimension of at least (2 * N + 15), initialized by VSINQI.

Contents

NAME

```
vdsinqi - initialize the array WSAVE, which is used in  both
VSINQF and VSINQB.
```

SYNOPSIS

```
SUBROUTINE VDSINQI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDSINQI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINQI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VSINQI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdsinqi(int n, double *wsave);

void vdsinqi_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array with a dimension of at least (2 * N + 15). The same work array can be used for both VSINQF and VSINQB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to VSINQF or VSINQB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

Contents

NAME

```
vdsint - compute the discrete Fourier sine transform  of  an
odd   sequence.    The  VSINT  transforms  are  unnormalized
inverses of themselves, so  a  call  of  VSINT  followed  by
another  call of VSINT will multiply the input sequence by 2
* (N+1).  The VSINT transforms are normalized, so a call  of
VSINT  followed  by a call of VSINT will return the original
sequence.
```

SYNOPSIS

```
SUBROUTINE VDSINT(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VDSINT_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
DOUBLE PRECISION X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT

SUBROUTINE SINT_64([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER(8) :: M, N, MDIMX
REAL(8), DIMENSION(:) :: WSAVE
REAL(8), DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>

void vdsint(int m, int n, double *x, double *xt, int  mdimx,
          double *wsave);

void vdsint_64(long m, long n, double *x, double  *xt,  long
          mdimx, double *wsave);
```

ARGUMENTS

```
M (input)
          The number of sequences to be transformed.   M  >=
          0.
N (input) Length of the sequence to be  transformed.   These
          subroutines  are most efficient when N+1 is a pro-
          duct of small primes.  N >= 0.

X (input/output)
          On entry, a real two-dimensional array with dimen-
          sions  of  (MDIMX  x (N+1)) whose rows contain the
          sequences to be transformed.  On  exit,  the  sine
          transform of the input.

XT (input/output)
          A real two-dimensional work array with  dimensions
          of (MDIMX x (N+1)).

MDIMX (input)
          Leading dimension of the arrays X and XT as speci-
          fied  in  a dimension or type statement.  MDIMX >=
          M.

WSAVE (input)
          On entry, an array  with  dimension  of  at  least
          int(2.5 * N + 15) initialized by VSINTI.
```

Contents

NAME

```
vdsinti - initialize the array WSAVE, which is used in  sub-
routine VSINT.
```

SYNOPSIS

```
SUBROUTINE VDSINTI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE VDSINTI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINTI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE VSINTI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vdsinti(int n, double *wsave);

void vdsinti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input)
On entry, an array of dimension (2N + N/2 + 15) or greater. VSINTI is called once to initialize WSAVE before calling VSINT and need not be called again between calls to VSINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void vsinqf(int m, int n, float *x, float  *xt,  int  mdimx,
          float *wsave);

void vsinqf_64(long m, long n, float  *x,  float  *xt,  long
          mdimx, float *wsave);
```

ARGUMENTS

M (input)
The number of sequences to be transformed. M >= 0.

N (input)
Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input/output)
On entry, an array of length N containing the sequence to be transformed. For VSINQF, a real two-dimensional array with dimensions of (MDIMX x N) whose rows contain the sequences to be transformed. On exit, the quarter-wave sine transform of the input.

XT (input)
A real two-dimensional work array with dimensions of (MDIMX x N).

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

WSAVE (input)
On entry, an array with dimension of at least (2 * N + 15), initialized by VSINQI.

Contents

NAME

```
vsinqi - initialize the array WSAVE, which is used  in  both
VSINQF and VSINQB.
```

SYNOPSIS

```
SUBROUTINE VSINQI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE VSINQI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINQI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VSINQI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vsinqi(int n, float *wsave);

void vsinqi_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array with a dimension of at least (2 * N + 15). The same work array can be used for both VSINQF and VSINQB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to VSINQF or VSINQB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

NAME

```
vsint - compute the discrete Fourier sine  transform  of  an
odd   sequence.    The  VSINT  transforms  are  unnormalized
inverses of themselves, so  a  call  of  VSINT  followed  by
another  call of VSINT will multiply the input sequence by 2
* (N+1).  The VSINT transforms are normalized, so a call  of
VSINT  followed  by a call of VSINT will return the original
sequence.
```

SYNOPSIS

```
SUBROUTINE VSINT(M, N, X, XT, MDIMX, WSAVE)

INTEGER M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)

SUBROUTINE VSINT_64(M, N, X, XT, MDIMX, WSAVE)

INTEGER*8 M, N, MDIMX
REAL X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE SINT([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,:) :: X, XT

SUBROUTINE SINT_64([M], [N], X, XT, [MDIMX], WSAVE)

INTEGER(8) :: M, N, MDIMX
REAL, DIMENSION(:) :: WSAVE
REAL, DIMENSION(:,:) :: X, XT
```

C INTERFACE

```
#include <sunperf.h>

void vsint(int m, int n, float *x,  float  *xt,  int  mdimx,
          float *wsave);

void vsint_64(long m, long n,  float  *x,  float  *xt,  long
          mdimx, float *wsave);
```

ARGUMENTS

```
M (input)
          The number of sequences to be transformed.   M  >=
          0.
N (input) Length of the sequence to be  transformed.   These
          subroutines  are most efficient when N+1 is a pro-
          duct of small primes.  N >= 0.

X (input/output)
          On entry, a real two-dimensional array with dimen-
          sions  of  (MDIMX  x (N+1)) whose rows contain the
          sequences to be transformed.  On  exit,  the  sine
          transform of the input.

XT (input/output)
          A real two-dimensional work array with  dimensions
          of (MDIMX x (N+1)).

MDIMX (input)
          Leading dimension of the arrays X and XT as speci-
          fied  in  a dimension or type statement.  MDIMX >=
          M.

WSAVE (input)
          On entry, an array  with  dimension  of  at  least
          int(2.5 * N + 15) initialized by VSINTI.
```

Contents

NAME

```
vsinti - initialize the array WSAVE, which is used  in  sub-
routine VSINT.
```

SYNOPSIS

```
SUBROUTINE VSINTI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE VSINTI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE VSINTI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE VSINTI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void vsinti(int n, float *wsave);

void vsinti_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input)
On entry, an array of dimension (2N + N/2 + 15) or greater. VSINTI is called once to initialize WSAVE before calling VSINT and need not be called again between calls to VSINT if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

vzfftb - compute a periodic sequence from its Fourier coefficients. The VZFFT operations are normalized, so a call of VZFFTF followed by a call of VZFFTB will return the original sequence.

SYNOPSIS

```
SUBROUTINE VZFFTB(M, N, X, XT, MDIMX, ROWCOL, WSAVE)

CHARACTER * 1 ROWCOL
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER M, N, MDIMX

SUBROUTINE VZFFTB_64(M, N, X, XT, MDIMX, ROWCOL, WSAVE)

CHARACTER * 1 ROWCOL
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTB([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)

CHARACTER(LEN=1) :: ROWCOL
COMPLEX(8), DIMENSION(:) :: WSAVE
COMPLEX(8), DIMENSION(:,:) :: X, XT
INTEGER :: M, N, MDIMX

SUBROUTINE FFTB_64([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)

CHARACTER(LEN=1) :: ROWCOL
COMPLEX(8), DIMENSION(:) :: WSAVE
COMPLEX(8), DIMENSION(:,:) :: X, XT
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>

void vzfftb(int m, int n,  doublecomplex  *x,  doublecomplex
          *xt,   int   mdimx,   char  rowcol,  doublecomplex
          *wsave);

void vzfftb_64(long m, long n, doublecomplex *x,  doublecom-
          plex  *xt,  long mdimx, char rowcol, doublecomplex
          *wsave);
```

ARGUMENTS

M (input) The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, the rows contain the sequences to be transformed.

XT (input)
A work array.

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

ROWCOL (input)
Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

WSAVE (input/output)
On entry, an array of dimension (K+15) or greater, where K = M if ROWCOL = ('R' or 'r'). Otherwise, K = N. WSAVE is initialized by VZFFTI.

Contents

NAME

```
vzfftf - compute the  Fourier  coefficients  of  a  periodic
sequence.  The VZFFT operations are normalized, so a call of
VZFFTF followed by a call of VZFFTB will return the original
sequence.
```

SYNOPSIS

```
SUBROUTINE VZFFTF(M, N, X, XT, MDIMX, ROWCOL, WSAVE)

CHARACTER * 1 ROWCOL
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER M, N, MDIMX

SUBROUTINE VZFFTF_64(M, N, X, XT, MDIMX, ROWCOL, WSAVE)

CHARACTER * 1 ROWCOL
DOUBLE COMPLEX X(MDIMX,*), XT(MDIMX,*), WSAVE(*)
INTEGER*8 M, N, MDIMX
```

F95 INTERFACE

```
SUBROUTINE FFTF([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)

CHARACTER(LEN=1) :: ROWCOL
COMPLEX(8), DIMENSION(:) :: WSAVE
COMPLEX(8), DIMENSION(:,:) :: X, XT
INTEGER :: M, N, MDIMX

SUBROUTINE FFTF_64([M], [N], X, XT, [MDIMX], ROWCOL, WSAVE)

CHARACTER(LEN=1) :: ROWCOL
COMPLEX(8), DIMENSION(:) :: WSAVE
COMPLEX(8), DIMENSION(:,:) :: X, XT
INTEGER(8) :: M, N, MDIMX
```

C INTERFACE

```
#include <sunperf.h>

void vzfftf(int m, int n,  doublecomplex  *x,  doublecomplex
          *xt,   int   mdimx,   char  rowcol,  doublecomplex
          *wsave);

void vzfftf_64(long m, long n, doublecomplex *x,  doublecom-
          plex  *xt,  long mdimx, char rowcol, doublecomplex
          *wsave);
```

ARGUMENTS

M (input) The number of sequences to be transformed. M >= 0.

N (input) Length of the sequence to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

X (input) On entry, an array X(M,N) whose rows contain the sequences to be transformed.

XT (input)
A work array.

MDIMX (input)
Leading dimension of the arrays X and XT as specified in a dimension or type statement. MDIMX >= M.

ROWCOL (input)
Indicates whether to transform rows ('R' or 'r') or columns ('C' or 'c').

WSAVE (input/output)
On entry, an array of dimension (K+15) or greater, where K = M if ROWCOL = ('R' or 'r'). Otherwise, K = N. WSAVE is initialized by VZFFTI.

Contents

NAME

```
vzffti - initialize the array WSAVE, which is used  in  both
VZFFTF and VZFFTB.
```

SYNOPSIS

```
SUBROUTINE VZFFTI(N, WSAVE)

DOUBLE COMPLEX WSAVE(*)
INTEGER N

SUBROUTINE VZFFTI_64(N, WSAVE)

DOUBLE COMPLEX WSAVE(*)
INTEGER*8 N
```

F95 INTERFACE

```
SUBROUTINE VFFTI(N, WSAVE)

COMPLEX(8), DIMENSION(:) :: WSAVE
INTEGER :: N

SUBROUTINE VFFTI_64(N, WSAVE)

COMPLEX(8), DIMENSION(:) :: WSAVE
INTEGER(8) :: N
```

C INTERFACE

```
#include <sunperf.h>

void vzffti(int n, doublecomplex *wsave);

void vzffti_64(long n, doublecomplex *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input)
On entry, an array of dimension (N + 15) or greater. VZFFTI needs to be called only once to initialize WSAVE before calling VZFFTF and/or VZFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

```
zaxpy - compute y := alpha * x + y
```

SYNOPSIS

```
SUBROUTINE ZAXPY(N, ALPHA, X, INCX, Y, INCY)

DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY

SUBROUTINE ZAXPY_64(N, ALPHA, X, INCX, Y, INCY)

DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE AXPY([N], ALPHA, X, [INCX], Y, [INCY])

COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY

SUBROUTINE AXPY_64([N], ALPHA, X, [INCX], Y, [INCY])

COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zaxpy(int n, doublecomplex  *alpha,  doublecomplex  *x,
          int incx, doublecomplex *y, int incy);

void zaxpy_64(long n,  doublecomplex  *alpha,  doublecomplex
          *x, long incx, doublecomplex *y, long incy);
```

PURPOSE

zaxpy compute y := alpha * x + y where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
array of DIMENSION at least (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
array of DIMENSION at least (1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
zaxpyi - Compute y := alpha * x + y
```

SYNOPSIS

```
 SUBROUTINE ZAXPYI(NZ, A, X, INDX, Y)

 DOUBLE COMPLEX A
 DOUBLE COMPLEX X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE ZAXPYI_64(NZ, A, X, INDX, Y)

 DOUBLE COMPLEX A
 DOUBLE COMPLEX X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE AXPYI([NZ], [A], X, INDX, Y)

 COMPLEX(8) :: A
 COMPLEX(8), DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE AXPYI_64([NZ], [A], X, INDX, Y)

 COMPLEX(8) :: A
 COMPLEX(8), DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
ZAXPYI Compute y := alpha * x + y where alpha is a scalar, x
is a sparse vector, and y is a vector in full storage form

 do i = 1, n
   y(indx(i)) = alpha * x(i) + y(indx(i))
 enddo
```

ARGUMENTS

```
NZ (input) - INTEGER
        Number of elements in the compressed form.
        Unchanged on exit.

A (input)
        On entry, A(LPHA) specifies the scaling value.
        Unchanged on exit.  A is defaulted to (1.0D0,0.0D0)
        for F95 INTERFACE.
X (input)
        Vector containing the values of the compressed form.
        Unchanged on exit.

INDX (input) - INTEGER
        Vector containing the indices of the compressed
        form.  It is assumed that the elements in INDX are
        distinct and greater than zero.  Unchanged on exit.

Y (output)
        Vector on input which contains the vector Y in full
        storage form.  On exit, only the elements
        corresponding to the indices in INDX have been
        modified.

```

```
*   BNNZ, LB, B, [LDB], BETA, C,[LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, MB, N, KB, BNNZ, LB
 INTEGER*8, DIMENSION(:) ::   DESCRA, BINDX, BJNDX
 DOUBLE COMPLEX    ALPHA, BETA
 DOUBLE COMPLEX, DIMENSION(:) :: VAL
 DOUBLE COMPLEX, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
         C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block coordinate format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if the matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
```

```
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

 VAL()         scalar array of length LB*LB*BNNZ consisting of
               the non-zero block entries of A, in any order.
               Each block is stored in standard column-major form.

 BINDX()       integer array of length BNNZ consisting of the
               block row indices of the block entries of A.

 BJNDX()       integer array of length BNNZ consisting of the
               block column indices of the block entries of A.

 BNNZ          number of block entries

 LB            dimension of dense blocks composing A.

 B()           rectangular array with first dimension LDB.
 LDB           leading dimension of B

 BETA          Scalar parameter

 C()           rectangular array with first dimension LDC.

 LDC           leading dimension of C

 WORK()        scratch array of length LWORK. WORK is not
               referenced in the current version.

 LWORK         length of WORK array. LWORK is not referenced
               in the current version.

 VAL()         two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
               consisting of the NBDIAG nonzero block diagonal in
               any order. Each dense block is stored in standard
               column-major form.

 BLDA          leading block dimension of VAL().

 IBDIAG()      integer array of length NBDIAG consisting of the
               corresponding diagonal offsets of the non-zero
               block diagonals of A in VAL.  Lower triangular
               block diagonals have negative offsets, the main
               block diagonal has offset 0, and upper triangular
               block diagonals have positive offset.

 NBDIAG        the number of non-zero block diagonals in A.
 LB            dimension of dense blocks composing A.

 B()           rectangular array with first dimension LDB.

 LDB           leading dimension of B

 BETA          Scalar parameter

 C()           rectangular array with first dimension LDC.

 LDC           leading dimension of C

 WORK()        scratch array of length LWORK. WORK is not
               referenced in the current version.

 LWORK         length of WORK array. LWORK is not referenced
               in the current version.

```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block diagonal format
and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)

DV()          Array of length MB*LB*LB containing the elements of
              the diagonal blocks of the matrix D.  The size of each
              square block is LB-by-LB and each block
              is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))
                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-identity blocks on the main diagonal
                  1 : identity diagonal blocks
                  2 : diagonal blocks are dense matrices
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           Two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
                consisting of the NBDIAG non-zero block diagonal.
                Each dense block is stored in standard column-major form.

BLDA            Leading block dimension of VAL().  Should be greater
                than or equal to MB.

IBDIAG()        integer array of length NBDIAG consisting of the
                corresponding diagonal offsets of the non-zero block
                diagonals of A in VAL.  Lower triangular block diagonals
                have negative offsets, the main block diagonal has offset
                0, and upper triangular block diagonals have positive offset.
                Elements of IBDIAG  MUST be sorted in  increasing order.

NBDIAG          The number of non-zero block diagonals in A.

LB              Dimension of dense blocks composing A.

B()             Rectangular array with first dimension LDB.

LDB             Leading dimension of B.

BETA            Scalar parameter.

C()             Rectangular array with first dimension LDC.

LDC             Leading dimension of C.
```

```
WORK()        scratch array of length LWORK.
              On exit, if LWORK= -1, WORK(1) returns the optimum  size
              of LWORK.

LWORK        length of WORK array. LWORK should be at least
             MB*LB.

             For good performance, LWORK should generally be larger.
             For optimum performance on multiple processors, LWORK
             >=MB*LB*N_CPUS where N_CPUS is the maximum number of
             processors available to the program.

             If LWORK=0, the routine is to allocate workspace needed.

             If LWORK = -1, then a workspace query is assumed; the
             routine only calculates the optimum size of the WORK array,
             returns this value as the first entry of the WORK array,
             and no error message related to LWORK is issued by XERBLA.
```

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BDI representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block

number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

C INTERFACE

```
#include <sunperf.h>

void zbdsqr(char uplo, int n, int ncvt, int  nru,  int  ncc,
          double *d, double *e, doublecomplex *vt, int ldvt,
          doublecomplex *u, int ldu, doublecomplex  *c,  int
          ldc, int *info);
void zbdsqr_64(char uplo, long n, long ncvt, long nru,  long
          ncc, double *d, double *e, doublecomplex *vt, long
          ldvt, doublecomplex *u,  long  ldu,  doublecomplex
          *c, long ldc, long *info);
```

PURPOSE

zbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = Q * S * P' (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes U * Q, P' * VT, or Q' * C, for given complex input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

UPLO (input)
= 'U': B is upper bidiagonal;
= 'L': B is lower bidiagonal.

N (input) The order of the matrix B. N >= 0.

NCVT (input)
The number of columns of the matrix VT. NCVT >= 0.

NRU (input)
The number of rows of the matrix U. NRU >= 0.

NCC (input)
The number of columns of the matrix C. NCC >= 0.

D (input/output)
On entry, the n diagonal elements of the bidiagonal matrix B. On exit, if INFO=0, the singular values of B in decreasing order.

E (input/output)
On entry, the elements of E contain the offdiagonal elements of of the bidiagonal matrix whose SVD is desired. On normal exit (INFO = 0), E is destroyed. If the algorithm does not converge (INFO > 0), D and E will contain the diagonal and superdiagonal elements of a bidiagonal matrix orthogonally equivalent to the one given as input. E(N) is used for workspace.

VT (input/output)
On entry, an N-by-NCVT matrix VT. On exit, VT is overwritten by P' * VT. VT is not referenced if NCVT = 0.

LDVT (input)
The leading dimension of the array VT. LDVT >= max(1,N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U (input/output)
On entry, an NRU-by-N matrix U. On exit, U is overwritten by U * Q. U is not referenced if NRU = 0.

LDU (input)
The leading dimension of the array U. LDU >= max(1,NRU).

C (input/output)
On entry, an N-by-NCC matrix C. On exit, C is overwritten by Q' * C. C is not referenced if NCC = 0.

LDC (input)
The leading dimension of the array C. LDC >= max(1,N) if NCC > 0; LDC >=1 if NCC = 0.

WORK (workspace)
dimension (4*N)

INFO (output)
= 0: successful exit
< 0: If INFO = -i, the i-th argument had an illegal value
> 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block Ellpack format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
```

```
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length LB*LB*BLDA*MAXBNZ containing
                matrix entries, stored column-major within each dense
                block.

 BINDX()        two-dimensional integer BLDA-by-MAXBNZ array such
                BINDX(i,:) consists of the block column indices of the
                nonzero blocks in block row i, padded by the integer
                value i if the number of nonzero blocks is less than
                MAXBNZ.

 BLDA           leading dimension of BINDX(:,:).

 MAXBNZ         max number of nonzeros blocks per row.
 LB             row and column dimension of the dense blocks composing
                VAL.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block Ellpack format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-identity blocks on the main diagonal
                 1 : identity diagonal blocks
                 2 : diagonal blocks are dense matrices
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          scalar array of length LB*LB*BLDA*MAXBNZ containing
               matrix entries, stored column-major within each dense
               block.

BINDX()        two-dimensional integer BLDA-by-MAXBNZ array such
               BINDX(i,:) consists of the block column indices of the
               nonzero blocks in block row i, padded by the integer
               value i if the number of nonzero blocks is less than
               MAXBNZ.  The block column indices MUST be sorted
               in increasing order for each block row.

BLDA           leading dimension of BINDX(:,:).

MAXBNZ         max number of nonzeros blocks per row.

LB             row and column dimension of the dense blocks composing A.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.
               On exit, if LWORK= -1, WORK(1) returns the minimum
```

size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BEL representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
  CALL ZBSCMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

                    0 : C/C++ compatible
                    1 : Fortran compatible
                  DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                    0 : unknown
                    1 : no repeated indices
VAL()             scalar array of length LB*LB*BNNZ consisting of the block
                  entries stored column-major within each dense block.

BINDX()           integer array of length BNNZ consisting of the
                  block row indices of the block entries of A.
                  The block row indices MUST be sorted
                  in increasing order for each block column.

BPNTRB()          integer array of length MB such that
                  BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                  of the first block entry of the J-th block column of A.

BPNTRE()          integer array of length MB such that
                  BPNTRE(J)-BPNTRB(1) points to location in BINDX
                  of the last block entry of the J-th block column of A.

LB                dimension of dense blocks composing A.

B()               rectangular array with first dimension LDB.

LDB               leading dimension of B

BETA              Scalar parameter

C()               rectangular array with first dimension LDC.
```

LDC   leading dimension of C

WORK()   scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum
size of LWORK.

LWORK   length of WORK array. LWORK should be at least
MB*LB.

For good performance, LWORK should generally be larger.
For optimum performance on multiple processors, LWORK
>=MB*LB*N_CPUS where N_CPUS is the maximum number of
processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the
routine only calculates the optimum size of the WORK
array, returns this value as the first entry of the WORK
array, and no error message related to LWORK is issued
by XERBLA.

```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block sparse row format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix A is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
```

```
                 DESCRA(3) main diagonal type
                   0 : non-unit
                   1 : unit
                 DESCRA(4) Array base  (NOT IMPLEMENTED)
                   0 : C/C++ compatible
                   1 : Fortran compatible
                 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                   0 : unknown
                   1 : no repeated indices

   VAL()         scalar array of length LB*LB*BNNZ consisting
                 of the block  entries stored column-major within
                 each dense block.

   BINDX()       integer array of length BNNZ consisting of the
                 block column indices of the block entries of A.

   BPNTRB()      integer array of length MB such that
                 BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                 of the first block entry of the J-th block row of A.
   BPNTRE()      integer array of length MB such that
                 BPNTRE(J)-BPNTRB(1) points to location in BINDX
                 of the last block entry of the J-th block row of A.

   LB            dimension of dense blocks composing A.

   B()           rectangular array with first dimension LDB.

   LDB           leading dimension of B

   BETA          Scalar parameter

   C()           rectangular array with first dimension LDC.

   LDC           leading dimension of C

   WORK()        scratch array of length LWORK. WORK is not
                 referenced in the current version.

   LWORK         length of WORK array. LWORK is not referenced
                 in the current version.
```

NOTES/BUGS

It is known that there exists another representation of the block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse row format the following calling sequence should be used

```
  CALL ZBSRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

 DOUBLE COMPLEX, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block sparse row format
format and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
```

```
               DESCRA(1) matrix structure
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))

               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-identity blocks on the main diagonal
                 1 : identity diagonal blocks
                 2 : diagonal blocks are dense matrices
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          scalar array of length LB*LB*BNNZ consisting of the block
               entries stored column-major within each dense block.

BINDX()        integer array of length BNNZ consisting of the
               block column indices of the block entries of A.
               The block column indices MUST be sorted
               in increasing order for each block row.

BPNTRB()       integer array of length MB such that
               BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
               of the first block entry of the J-th block row of A.

BPNTRE()       integer array of length MB such that
               BPNTRE(J)-BPNTRB(1) points to location in BINDX
               of the last block entry of the J-th block row of A.

LB             dimension of dense blocks composing A.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.
```

LDC leading dimension of C

WORK() scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NIST FORTRAN Sparse Blas User's Guide available at:
http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BSC representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is

used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

6. It is known that there exists another representation of the block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse row format the following calling sequence should be used

```
  CALL ZBSRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

          *work, long lwork);
```

PURPOSE

zcnvcor computes the convolution or correlation of complex vectors.

ARGUMENTS

CNVCOR (input)
'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

FOUR (input)
'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the real and imaginary parts of the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

NX (input)
Length of the filter vector. NX >= 0. ZCNVCOR

will return immediately if NX = 0.

X (input) dimension(*)
Filter vector.

IFX (input)
Index of the first element of X. NX >= IFX >= 1.

INCX (input)
Stride between elements of the filter vector in X. INCX > 0.

NY (input)
Length of the input vectors. NY >= 0. ZCNVCOR will return immediately if NY = 0.

NPRE (input)
The number of implicit zeros prepended to the Y vectors. NPRE >= 0.

M (input)
Number of input vectors. M >= 0. ZCNVCOR will return immediately if M = 0.

Y (input) dimension(*)
Input vectors.

IFY (input)
Index of the first element of Y. NY >= IFY >= 1.

INC1Y (input)
Stride between elements of the input vectors in Y. INC1Y > 0.

INC2Y (input)
Stride between the input vectors in Y. INC2Y > 0.

NZ (input)
Length of the output vectors. NZ >= 0. ZCNVCOR will return immediately if NZ = 0. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

K (input)
Number of Z vectors. K >= 0. If K = 0 then ZCNVCOR will return immediately. If K < M then only the first K input vectors will be processed. If K > M then M input vectors will be processed.

Z (output)
dimension(*)
Result vectors.

IFZ (input)
Index of the first element of Z. NZ >= IFZ >= 1.

INC1Z (input)
Stride between elements of the output vectors in Z. INC1Z > 0.

INC2Z (input)
Stride between the output vectors in Z. INC2Z > 0.

WORK (input/output)
(input/scratch) dimension(LWORK)
Scratch space. Before the first call to ZCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to ZCNVCOR or if ZCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make ZCNVCOR run faster.

LWORK (input)
Length of WORK. LWORK >= 2*MAX(NX,NY,NZ)+8.

          mpre, int npre, doublecomplex *y, int ldy, int mz,
          int nz, doublecomplex *z, int  ldz,  doublecomplex
          *workin, int lwork);

void zcnvcor2_64(char cnvcor, char method, char transx, char
          scratchx,  char  transy,  char  scratchy, long mx,
          long nx, doublecomplex *x, long ldx, long my, long
          ny,  long  mpre, long npre, doublecomplex *y, long
          ldy, long mz, long nz, doublecomplex *z, long ldz,
          doublecomplex *workin, long lwork);
```

PURPOSE

zcnvcor2 computes the convolution or correlation of complex matrices.

ARGUMENTS

CNVCOR (input)
'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

METHOD (input)
'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

TRANSX (input)
'N' or 'n' if X is the filter matrix, 'T' or 't' if transpose(X) is the filter matrix.

SCRATCHX (input)
'N' or 'n' if X must be preserved, 'S' or 's' if X can be used as scratch space. The contents of X are undefined after returning from a call in which X is allowed to be used for scratch.

TRANSY (input)
'N' or 'n' if Y is the input matrix, 'T' or 't' if transpose(Y) is the input matrix.

SCRATCHY (input)
'N' or 'n' if Y must be preserved, 'S' or 's' if Y can be used as scratch space. The contents of Y are undefined after returning from a call in which Y is allowed to be used for scratch.

MX (input)
Number of rows in the filter matrix. MX >= 0.

NX (input)
Number of columns in the filter matrix. NX >= 0.

X (input) dimension(LDX,NX)
On entry, the filter matrix. Unchanged on exit if SCRATCHX is 'N' or 'n', undefined on exit if SCRATCHX is 'S' or 's'.

LDX (input)
Leading dimension of the array that contains the filter matrix.

MY (input)
Number of rows in the input matrix. MY >= 0.

NY (input)
Number of columns in the input matrix. NY >= 0.

MPRE (input)
Number of implicit zeros to prepend to each row of the input matrix. MPRE >= 0.

NPRE (input)
Number of implicit zeros to prepend to each column of the input matrix. NPRE >= 0.

Y (input) dimension(LDY,*)

Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

LDY (input)
Leading dimension of the array that contains the input matrix.

MZ (input)
Number of rows in the output matrix. MZ >= 0. ZCNVCOR2 will return immediately if MZ = 0.

NZ (input)
Number of columns in the output matrix. NZ >= 0. ZCNVCOR2 will return immediately if NZ = 0.

Z (output)
dimension(LDZ,*)
Result matrix.

LDZ (input)
Leading dimension of the array that contains the result matrix. LDZ >= MAX(1,MZ).

WORKIN (input/output)
(input/scratch) dimension(LWORK)
On entry for the first call to ZCNVCOR2, WORKIN(1) must contain CMPLX(0.0,0.0). After the first call, WORKIN(1) must be set to CMPLX(0.0,0.0) iff WORKIN has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

LWORK (input)
Length of the work vector. If the FFT is to be used then for best performance LWORK should be at least 30 words longer than the amount of memory needed to hold the trig tables. If the FFT is not used, the value of LWORK is unimportant.

DESCRIPTION

```
            C <- alpha op(A) B + beta C

      where ALPHA and BETA are scalar, C and B are dense matrices,
      A is a matrix represented in coordinate format and
      op( A )  is one  of
      op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                            ( ' indicates matrix transpose)
```

ARGUMENTS

```
      TRANSA        Indicates how to operate with the sparse matrix
                      0 : operate with matrix
                      1 : operate with transpose matrix
                      2 : operate with the conjugate transpose of matrix.
                          2 is equivalent to 1 if matrix is real.

      M             Number of rows in matrix A

      N             Number of columns in matrix C

      K             Number of columns in matrix A

      ALPHA         Scalar parameter

      DESCRA()      Descriptor argument.  Five element integer array
                    DESCRA(1) matrix structure
                      0 : general
                      1 : symmetric (A=A')
                      2 : Hermitian (A= CONJG(A'))
                      3 : Triangular
                      4 : Skew(Anti)-Symmetric (A=-A')
                      5 : Diagonal
                      6 : Skew-Hermitian (A= -CONJG(A'))
                    DESCRA(2) upper/lower triangular indicator
                      1 : lower
                      2 : upper
```

```
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

 VAL()         scalar array of length NNZ consisting of the
               non-zero entries of A, in any order.

 INDX()        integer array of length NNZ consisting of the
               corresponding row indices of the entries of A.

 JNDX()        integer array of length NNZ consisting of the
               corresponding column indices of the entries of A.

 NNZ           number of non-zero elements in A.
 B()           rectangular array with first dimension LDB.

 LDB           leading dimension of B

 BETA          Scalar parameter

 C()           rectangular array with first dimension LDC.

 LDC           leading dimension of C

 WORK()        scratch array of length LWORK. WORK is not
               referenced in the current version.

 LWORK         length of WORK array. LWORK is not referenced
               in the current version.

NAME

```
zcopy - Copy x to y
```

SYNOPSIS

```
SUBROUTINE ZCOPY(N, X, INCX, Y, INCY)

DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY

SUBROUTINE ZCOPY_64(N, X, INCX, Y, INCY)

DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE COPY([N], X, [INCX], Y, [INCY])

COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY

SUBROUTINE COPY_64([N], X, [INCX], Y, [INCY])

COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>

void zcopy(int n, doublecomplex *x, int incx,  doublecomplex
          *y, int incy);

void zcopy_64(long n, doublecomplex  *x,  long  incx,  doub-
```

```
          lecomplex *y, long incy);
```

PURPOSE

zcopy Copy x to y where x and y are n-vectors.

ARGUMENTS

```
N (input)
          On entry, N specifies the number  of  elements  in
          the  vector.   N must be at least one for the sub-
          routine to have any visible effect.  Unchanged  on
          exit.
X (input)
          of DIMENSION at least ( 1 + ( n - 1 )*abs( INCX  )
          ).   Before  entry,  the  incremented array X must
          contain the vector x.  Unchanged on exit.

INCX (input)
          On entry, INCX specifies  the  increment  for  the
          elements  of X.  INCX must not be zero.  Unchanged
          on exit.

Y (output)
          of DIMENSION at least ( 1 + ( m - 1 )*abs( INCY  )
          ).  On entry, the incremented array Y must contain
          the vector y. On exit, Y  is  overwritten  by  the
          vector x.

INCY (input)
          On entry, INCY specifies  the  increment  for  the
          elements  of Y.  INCY must not be zero.  Unchanged
          on exit.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
  SUBROUTINE SCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,
 *           C, LDC, WORK, LWORK )
```

```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in compressed sparse column format and op(A) is one of
op(A) = inv(A) or op(A) = inv(A') or op(A) =inv(conjg(A'))
(inv denotes matrix inverse, ' indicates matrix transpose)

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic column scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           scalar array of length NNZ consisting of nonzero entries
                of A.

INDX()          integer array of length NNZ consisting of the row indices
                of nonzero entries of A. (Row indices MUST be sorted in
                increasing order for each column).

PNTRB()         integer array of length M such that PNTRB(J)-PNTRB(1)+1
                points to location in VAL of the first nonzero element
                in column J.

PNTRE()         integer array of length M such that PNTRE(J)-PNTRB(1)
                points to location in VAL of the last nonzero element
                in column J.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.

                On exit,  if LWORK = -1, WORK(1) returns the optimum  LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the columns of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the columns have been scaled. UNITD=3 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the column number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the CSC representation

of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the CSC representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

5. It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
  SUBROUTINE SCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,
 *           C, LDC, WORK, LWORK )
```

Contents

NAME

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in compressed sparse row format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
```

```
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length NNZ consisting of nonzero
                entries of A.

 INDX()         integer array of length NNZ consisting of the
                column indices of nonzero entries of A.

 PNTRB()        integer array of length M such that PNTRB(J)-PNTRB(1)+1
                points to location in VAL of the first nonzero element
                in row J.
 PNTRE()        integer array of length M such that PNTRE(J)-PNTRB(1)
                points to location in VAL of the last nonzero element
                in row J.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in compressed sparse row
format and op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of
              the scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, only DESCRA(1)=3 is supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           scalar array of length NNZ consisting of nonzero entries
                of A.

INDX()          integer array of length NNZ consisting of the column
                indices of nonzero entries of A (column indices MUST be
                sorted in increasing order for each row)

PNTRB()         integer array of length M such that PNTRB(J)-PNTRB(1)+1
                points to location in VAL of the first nonzero element
                in row J.

PNTRE()         integer array of length M such that PNTRE(J)-PNTRB(1)
                points to location in VAL of the last nonzero element
                in row J.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.

                On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

                1 : no repeated indices
```

VAL()	two-dimensional LDA-by-NDIAG array such that VAL(:,I) consists of non-zero elements on diagonal IDIAG(I) of A. Diagonals in the lower triangular part of A are padded from the top, and those in the upper triangular part are padded from the bottom.
LDA	leading dimension of VAL, must be .GE. MIN(M,K)
IDIAG()	integer array of length NDIAG consisting of the corresponding diagonal offsets of the non-zero diagonals of A in VAL. Lower triangular diagonals have negative offsets, the main diagonal has offset 0, and upper triangular diagonals have positive offset.
NDIAG	number of non-zero diagonals in A.
B()	rectangular array with first dimension LDB.
LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

NAME

zdiasm - diagonal format triangular solve

SYNOPSIS

```
 SUBROUTINE ZDIASM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*            VAL, LDA, IDIAG, NDIAG,
*            B, LDB, BETA, C, LDC, WORK, LWORK)
 INTEGER     TRANSA, M, N, UNITD, DESCRA(5), LDA, NDIAG,
*            LDB, LDC, LWORK
 INTEGER     IDIAG(NDIAG)
 DOUBLE COMPLEX ALPHA, BETA
 DOUBLE COMPLEX DV(M), VAL(LDA,NDIAG), B(LDB,*), C(LDC,*), WORK(LWORK)

 SUBROUTINE ZDIASM_64( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*            VAL, LDA, IDIAG, NDIAG,
*            B, LDB, BETA, C, LDC, WORK, LWORK)
 INTEGER*8   TRANSA, M, N, UNITD, DESCRA(5), LDA, NDIAG,
*            LDB, LDC, LWORK
 INTEGER*8   IDIAG(NDIAG)
 DOUBLE COMPLEX ALPHA, BETA
 DOUBLE COMPLEX DV(M), VAL(LDA,NDIAG), B(LDB,*), C(LDC,*), WORK(LWORK)
```

F95 INTERFACE

```
  SUBROUTINE DIASM(TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
*   [LDA], IDIAG, NDIAG, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER     TRANSA, M, NDIAG
 INTEGER, DIMENSION(:) ::     DESCRA, IDIAG
 DOUBLE COMPLEX    ALPHA, BETA
 DOUBLE COMPLEX, DIMENSION(:) ::   DV
 DOUBLE COMPLEX, DIMENSION(:, :) ::  VAL, B, C

  SUBROUTINE DIASM_64(TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
```

```
*   [LDA], IDIAG, NDIAG, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, M, NDIAG
 INTEGER*8, DIMENSION(:) ::    DESCRA, IDIAG
 DOUBLE COMPLEX    ALPHA, BETA
 DOUBLE COMPLEX, DIMENSION(:) ::  DV
 DOUBLE COMPLEX, DIMENSION(:, :) ::  VAL, B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in diagonal format and op(A) is one of

```
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, only DESCRA(1)=3 is supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          two-dimensional LDA-by-NDIAG array such that VAL(:,I)
               consists of non-zero elements on diagonal IDIAG(I)
               of A.  Diagonals in the lower triangular part of A
               are padded from the top, and those in the upper
               triangular part are padded from the bottom.

LDA            leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG()        integer array of length NDIAG consisting of the
               corresponding diagonal offsets of the non-zero
               diagonals of A in VAL.  Lower triangular diagonals
               have negative offsets, the main diagonal has offset
               0, and upper triangular diagonals have positive offset.
               Elements of IDIAG of MUST be sorted in  increasing order.

NDIAG          number of non-zero diagonals in A.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.
               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

```
LWORK         length of WORK array.  LWORK should be at least M.

              For good performance, LWORK should generally be larger.
              For optimum performance on multiple processors, LWORK
              >=M*N_CPUS where N_CPUS is the maximum number of
              processors available to the program.

              If LWORK=0, the routine is to allocate workspace needed.

              If LWORK = -1, then a workspace query is assumed; the
              routine only calculates the optimum size of the WORK
              array, returns this value as the first entry of the WORK
              array, and no error message related to LWORK is issued
              by XERBLA.
```

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norm are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the DIA representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the DIA representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

Contents

NAME

```
zdotc - compute the dot product of two vectors conjg(x)  and
y.
```

SYNOPSIS

```
DOUBLE COMPLEX FUNCTION ZDOTC(N, X, INCX, Y, INCY)

DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY

DOUBLE COMPLEX FUNCTION ZDOTC_64(N, X, INCX, Y, INCY)

DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX(8) FUNCTION DOTC([N], X, [INCX], Y, [INCY])

COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY

COMPLEX(8) FUNCTION DOTC_64([N], X, [INCX], Y, [INCY])

COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>

doublecomplex zdotc(int n, doublecomplex *x, int incx, doub-
          lecomplex *y, int incy);
```

```
doublecomplex zdotc_64(long n, doublecomplex *x, long  incx,
          doublecomplex *y, long incy);
```

PURPOSE

zdotc compute the dot product of conjg(x) and y where x and y are n-vectors.

ARGUMENTS

N (input)
: On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

X (input)
: of DIMENSION at least (1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
: On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
: of DIMENSION at least (1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

INCY (input)
: On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
zdotci - Compute the complex conjugated indexed dot product.
```

SYNOPSIS

```
 DOUBLE COMPLEX FUNCTION ZDOTCI(NZ, X, INDX, Y)

 DOUBLE COMPLEX X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 DOUBLE COMPLEX FUNCTION ZDOTCI_64(NZ, X, INDX, Y)

 DOUBLE COMPLEX X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 DOUBLE COMPLEX FUNCTION DOTCI([NZ], X, INDX, Y)

 COMPLEX(8), DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 DOUBLE COMPLEX FUNCTION DOTCI_64([NZ], X, INDX, Y)

 COMPLEX(8), DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
ZDOTCI Compute the complex conjugated indexed dot product of
a complex sparse vector x stored in compressed form with a
```

complex vector y in full storage form.

```
 dot = 0
 do i = 1, n
   dot = dot + conjg(x(i)) * y(indx(i))
 enddo
```

ARGUMENTS

NZ (input)
Number of elements in the compressed form.
Unchanged on exit.

X (input)
Vector in compressed form. Unchanged on exit.

INDX (input)
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)
Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

```
          doublecomplex *y, long incy);
```

PURPOSE

```
zdotu compute the dot product of x and y where x and  y  are
n-vectors.
```

ARGUMENTS

```
N (input)
          On entry, N specifies the number  of  elements  in
          the  vector.   If N is not positive then the func-
          tion returns the value 0.0.  Unchanged on exit.
X (input)
          of DIMENSION at least ( 1 + ( n - 1 )*abs( INCX  )
          ).  On entry, the incremented array X must contain
          the vector x.  Unchanged on exit.

INCX (input)
          On entry, INCX specifies  the  increment  for  the
          elements  of  X. INCX must not be zero.  Unchanged
          on exit.

Y (input)
          of DIMENSION at least ( 1 + ( n - 1 )*abs( INCY  )
          ).  On entry, the incremented array Y must contain
          the vector y.  Unchanged on exit.

INCY (input)
          On entry, INCY specifies  the  increment  for  the
          elements  of  Y. INCY must not be zero.  Unchanged
          on exit.
```

Contents

NAME

```
zdrot - Apply a plane rotation.
```

SYNOPSIS

```
SUBROUTINE ZDROT(N, CX, INCX, CY, INCY, C, S)

DOUBLE PRECISION C, S
DOUBLE COMPLEX CX(*), CY(*)
INTEGER N, INCX, INCY

SUBROUTINE ZDROT_64(N, CX, INCX, CY, INCY, C, S)

DOUBLE PRECISION C, S
DOUBLE COMPLEX CX(*), CY(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE ROT([N], CX, [INCX], CY, [INCY], C, S)

REAL(8) :: C, S
COMPLEX(8), DIMENSION(:) :: CX, CY
INTEGER :: N, INCX, INCY

SUBROUTINE ROT_64([N], CX, [INCX], CY, [INCY], C, S)

REAL(8) :: C, S
COMPLEX(8), DIMENSION(:) :: CX, CY
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zdrot(int n, doublecomplex *cx, int incx, doublecomplex
          *cy, int incy, double c, double s);

void zdrot_64(long n, doublecomplex *cx,  long  incx,  doub-
          lecomplex *cy, long incy, double c, double s);
```

PURPOSE

zdrot Apply a plane rotation, where the cos and sin (c and s) are real and the vectors x and y are complex.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

CX (input)
Before entry, the incremented array CX must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of CX. INCX must not be zero. Unchanged on exit.

CY (output)
On entry, the incremented array CY must contain the vector y. On exit, CY is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of CY. INCY must not be zero. Unchanged on exit.

C (input)
On entry, the cosine. Unchanged on exit.

S (input)
On entry, the sin. Unchanged on exit.

Contents

NAME

```
zdscal - Compute y := alpha * y
```

SYNOPSIS

```
SUBROUTINE ZDSCAL(N, ALPHA, Y, INCY)

DOUBLE COMPLEX Y(*)
INTEGER N, INCY
DOUBLE PRECISION ALPHA

SUBROUTINE ZDSCAL_64(N, ALPHA, Y, INCY)

DOUBLE COMPLEX Y(*)
INTEGER*8 N, INCY
DOUBLE PRECISION ALPHA
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])

COMPLEX(8), DIMENSION(:) :: Y
INTEGER :: N, INCY
REAL(8) :: ALPHA

SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])

COMPLEX(8), DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
REAL(8) :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zdscal(int  n,  double  alpha,  doublecomplex  *y,  int
          incy);

void zdscal_64(long n, double alpha, doublecomplex *y,  long
          incy);
```

PURPOSE

zdscal Compute y := alpha * y where alpha is a scalar and y is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          two-dimensional LDA-by-MAXNZ array such that VAL(I,:)
                consists of non-zero elements in row I of A, padded by
                zero values if the row contains less than MAXNZ.

 INDX()         two-dimensional integer LDA-by-MAXNZ array such
                INDX(I,:) consists of the column indices of the
                nonzero elements in row I, padded by the integer
                value I if the number of nonzeros is less than MAXNZ.

 LDA            leading dimension of VAL and INDX.

 MAXNZ          max number of nonzeros elements per row.

 B()            rectangular array with first dimension LDB.
 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

 INTEGER*8  INDX(LDA,MAXNZ)
 DOUBLE COMPLEX ALPHA, BETA
 DOUBLE COMPLEX DV(M), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

F95 INTERFACE

```
 SUBROUTINE ELLSM( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
*    INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER    TRANSA, M,  MAXNZ
 INTEGER, DIMENSION(:) ::  DESCRA
 INTEGER, DIMENSION(:, :) ::    INDX
 DOUBLE COMPLEX    ALPHA, BETA
 DOUBLE COMPLEX, DIMENSION(:) ::  DV
 DOUBLE COMPLEX, DIMENSION(:, :) ::  VAL, B, C
```

```
 SUBROUTINE ELLSM_64( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
*    INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, M,  MAXNZ
 INTEGER*8, DIMENSION(:) ::  DESCRA
 INTEGER*8, DIMENSION(:, :) ::    INDX
 DOUBLE COMPLEX    ALPHA, BETA
 DOUBLE COMPLEX, DIMENSION(:) ::  DV
 DOUBLE COMPLEX, DIMENSION(:, :) ::  VAL, B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in Ellpack format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, only DESCRA(1)=3 is supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           two-dimensional LDA-by-MAXNZ array such that VAL(I,:)
                consists of non-zero elements in row I of A, padded by
                zero values if the row contains less than MAXNZ.

INDX()          two-dimensional integer LDA-by-MAXNZ array such
                INDX(I,:) consists of the column indices of the
                nonzero elements in row I, padded by the integer
                value I if the number of nonzeros is less than MAXNZ.
                The column indices MUST be sorted in increasing order
                for each row.

LDA             leading dimension of VAL and INDX.

MAXNZ           max number of nonzeros elements per row.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.

                On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the ELL representation of a sparse matrix. They are not used anyway in these cases.

But if UNITD=4, the unit diagonal elements MUST be referenced in the ELL representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

Contents

NAME

```
zfft2b - compute a periodic sequence from its Fourier  coef-
ficients.  The FFT operations are unnormalized, so a call of
ZFFT2F followed by a call of ZFFT2B will multiply the  input
sequence by M*N.
```

SYNOPSIS

```
SUBROUTINE ZFFT2B(M, N, A, LDA, WORK, LWORK)

DOUBLE COMPLEX A(LDA,*)
INTEGER M, N, LDA, LWORK
DOUBLE PRECISION WORK(*)

SUBROUTINE ZFFT2B_64(M, N, A, LDA, WORK, LWORK)

DOUBLE COMPLEX A(LDA,*)
INTEGER*8 M, N, LDA, LWORK
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B([M], [N], A, [LDA], WORK, LWORK)

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, LWORK
REAL(8), DIMENSION(:) :: WORK

SUBROUTINE FFT2B_64([M], [N], A, [LDA], WORK, LWORK)

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LWORK
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void zfft2b(int m, int n, doublecomplex *a, int lda,  double
          *work, int lwork);

void zfft2b_64(long m, long n, doublecomplex *a,  long  lda,
          double *work, long lwork);
```

ARGUMENTS

M (input) Number of rows to be transformed. These subroutines are most efficient when M is a product of small primes. M >= 0.

N (input) Number of columns to be transformed. These subroutines are most efficient when N is a product of small primes. N >= 0.

A (input/output)
On entry, a two-dimensional array A(M,N) that contains the sequences to be transformed.

LDA (input)
Leading dimension of the array containing the data to be transformed. LDA >= M.

WORK (input)
On entry, an array with dimension of at least LWORK. WORK must have been initialized by ZFFT2I.

LWORK (input)
The dimension of the array WORK. LWORK >= (4 * (M + N) + 30)

          *work, int lwork);

void zfft2f_64(long m, long n, doublecomplex *a,  long  lda,
          double *work, long lwork);
```

ARGUMENTS

```
M (input) Number of rows to be transformed.   These  subrou-
          tines  are  most  efficient when M is a product of
          small primes.  M >= 0.
N (input) Number of columns to be transformed.   These  sub-
          routines are most efficient when N is a product of
          small primes.  N >= 0.

A (input/output)
          On entry, a two-dimensional array A(M,N) that con-
          tains the sequences to be transformed.

LDA (input)
          Leading dimension of the array containing the data
          to be transformed.  LDA >= M.

WORK (input)
          On input, workspace WORK must have  been  initial-
          ized by ZFFT2I.

LWORK (input)
          The dimension of the array WORK.  LWORK >= (4 * (M
          + N) + 30)
```

Contents

NAME

```
zfft2i - initialize the array WSAVE, which is used  in  both
the forward and backward transforms.
```

SYNOPSIS

```
SUBROUTINE ZFFT2I(M, N, WORK)

INTEGER M, N
DOUBLE PRECISION WORK(*)

SUBROUTINE ZFFT2I_64(M, N, WORK)

INTEGER*8 M, N
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE ZFFT2I(M, N, WORK)

INTEGER :: M, N
REAL(8), DIMENSION(:) :: WORK

SUBROUTINE ZFFT2I_64(M, N, WORK)

INTEGER(8) :: M, N
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void zfft2i(int m, int n, double *work);

void zfft2i_64(long m, long n, double *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

WORK (input/output)
On entry, an array of dimension (4 * (M + N) + 30) or greater. ZFFT2I needs to be called only once to initialize array WORK before calling ZFFT2F and/or ZFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

SUBROUTINE FFT_64(IOPT, N, [SCALE], X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)
```

```
INTEGER(8), INTENT(IN) :: IOPT, N
INTEGER(8), INTENT(IN), OPTIONAL :: LWORK
REAL(8), INTENT(IN), OPTIONAL :: SCALE
COMPLEX(8), INTENT(IN), DIMENSION(:) :: X
REAL(8), INTENT(OUT), DIMENSION(:) :: Y
REAL(8), INTENT(INOUT), DIMENSION(:) :: TRIGS
INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
REAL(8), INTENT(OUT), DIMENSION(:) :: WORK
INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>

void zfftd_ (int *iopt, int *n, double *scale, doublecomplex
          *x,  double  *y,  double *trigs, int *ifac, double
          *work, int *lwork, int *ierr);

void zfftd_64_ (long *iopt, long *n,  double  *scale,  doub-
          lecomplex  *x,  double  *y,  double  *trigs,  long
          *ifac, double *work, long *lwork, long *ierr);
```

PURPOSE

```
zfftd initializes the trigonometric weight and factor tables
or  computes  the inverse Fast Fourier Transform of a double
complex sequence as follows:

               N-1
Y(k) = scale * SUM  W*X(j)
               j=0

where
k ranges from 0 to N-1
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W = exp(isign*i*j*k*2*pi/N)
In complex-to-real transform of length N, the  (N/2+1)  com-
plex  input  data  points  stored are the positive-frequency
half of the spectrum of the Discrete Fourier Transform.  The
other  half  can be obtained through complex conjugation and
therefore is not stored.  Furthermore, due to symmetries the
imaginary  of the component of X(0) and X(N/2) (if N is even
in the latter) is assumed to be zero and is not referenced.
```

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = 1 computes inverse FFT

N (input)
          Integer specifying length of the input sequence X.
          N  is most efficient when it is a product of small
          primes.  N >= 0.  Unchanged on exit.

SCALE (input)
          Double precision scalar by which transform results
          are   scaled.   Unchanged   on  exit.   SCALE  is
          defaulted to 1.0D0 for F95 INTERFACE.

X (input) On entry, X is a double complex array whose  first
          (N/2+1)  elements  are  the  input  sequence to be
          transformed.
Y (output)
          Double precision array of  dimension  at  least  N
          that  contains the transform results.  X and Y may
          be the same array  starting  at  the  same  memory
          location.   Otherwise, it is assumed that there is
          no overlap between X and Y in memory.

TRIGS (input/output)
          Double precision array of length 2*N that contains
          the  trigonometric  weights.  The weights are com-
          puted when the routine is called with IOPT = 0 and
          they  are  used in subsequent calls when IOPT = 1.
          Unchanged on exit.

IFAC (input/output)
          Integer array of dimension at least 128 that  con-
          tains  the factors of N.  The factors are computed
          when the routine is called with IOPT = 0 and  they
          are  used  in  subsequent  calls  where  IOPT = 1.
          Unchanged on exit.

WORK (workspace)
          Double precision array of dimension  at  least  N.
          The user can also choose to have the routine allo-
          cate its own workspace (see LWORK).

LWORK (input)
          Integer specifying workspace size.  If LWORK =  0,
          the routine will allocate its own workspace.

IERR (output)
```

On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or 1
-2 = N < 0
-3 = (LWORK is not 0) and (LWORK is less than N)
-4 = memory allocation for workspace failed

               *work, long *lwork, long *ierr);
```

PURPOSE

```
     zfftd2  initializes  the  trigonometric  weight  and  factor
     tables  or computes the two-dimensional inverse Fast Fourier
     Transform of a two-dimensional  double  complex  array.   In
     computing  the two-dimensional FFT, one-dimensional FFTs are
     computed along the rows of the input array.  One-dimensional
     FFTs are then computed along the columns of the intermediate
     results.

                        N1-1  N2-1
     Y(k1,k2) = scale * SUM   SUM   W2*W1*X(j1,j2)
                        j1=0  j2=0

     where
     k1 ranges from 0 to N1-1 and k2 ranges from 0 to N2-1
     i = sqrt(-1)
     isign = 1 for inverse transform
     W1 = exp(isign*i*j1*k1*2*pi/N1)
     W2 = exp(isign*i*j2*k2*2*pi/N2)
     In complex-to-real transform of length N1, the (N1/2+1) com-
```

plex input data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = 1 computes inverse FFT

N1 (input)
Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. N2 >= 0. Unchanged on exit.

SCALE (input)
Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N2) that contains input data to be transformed.

LDX (input)
Leading dimension of X. LDX >= (N1/2 + 1) Unchanged on exit.

Y (output)
Y is a double precision array of dimensions (LDY, N2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. If X and Y are the same

array, LDY = 2*LDX Else LDY >= 2*LDX and LDY must be even. Unchanged on exit.

TRIGS (input/output)
: Double precision array of length 2*(N1+N2) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
: Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)
: Double precision array of dimension at least MAX(N1,2*N2) where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
: Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
: On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0, 1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1/2+1)
-5 = LDY not equal 2*LDX when X and Y are same array
-6 = (LDY < 2*LDX or LDY odd) when X and Y are same array
-7 = (LWORK not equal 0) and (LWORK < MAX(N1,2*N2))
-8 = memory allocation failed

SEE ALSO

fft

CAUTIONS

On exit, output subarray Y(1:LDY, 1:N2) is overwritten.

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = +1 computes inverse FFT

N1 (input)
          Integer specifying length of the transform in  the
          first  dimension.  N1 is most efficient when it is
          a product of small primes.  N1 >= 0.  Unchanged on
          exit.

N2 (input)
          Integer specifying length of the transform in  the
          second dimension.  N2 is most efficient when it is
          a product of small primes.  N2 >= 0.  Unchanged on
          exit.

N3 (input)
          Integer specifying length of the transform in  the
          third  dimension.  N3 is most efficient when it is
          a product of small primes.  N3 >= 0.  Unchanged on
          exit.

SCALE (input)
          Double precision scalar by which transform results
          are   scaled.   Unchanged   on  exit.   SCALE  is
          defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of  dimensions  (LDX1,
          LDX2,   N3)   that   contains  input  data  to  be
          transformed.

LDX1 (input)
          first dimension of X.  LDX1 >= N1/2+1 Unchanged on
          exit.

LDX2 (input)
          second dimension of X.  LDX2 >=  N2  Unchanged  on
          exit.

Y (output)
          Y is a double complex array of  dimensions  (LDY1,
```

LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)
first dimension of Y. If X and Y are the same array, LDY1 = 2*LDX1 Else LDY1 >= 2*LDX1 and LDY1 is even Unchanged on exit.

LDY2 (input)
second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)
Double precision array of length 2*(N1+N2+N3) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 3*128 that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)
Double precision array of dimension at least (MAX(N,2*N2,2*N3) + 16*N3) * NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or 1
-2 = N1 < 0
-3 = N2 < 0
-4 = N3 < 0

-5 = (LDX1 < N1/2+1)
-6 = (LDX2 < N2)
-7 = LDY1 not equal 2*LDX1 when X and Y are same array
-8 = (LDY1 < 2*LDX1) or (LDY1 is odd) when X and Y are not same array
-9 = (LDY2 < N2) or (LDY2 not equal LDX2) when X and Y are same array

                      j=0

     where
     k ranges from 0 to N1-1 and l ranges from 0 to N2-1
     i = sqrt(-1)
     isign = 1 for inverse transform
     W = exp(isign*i*j*k*2*pi/N1)
     In complex-to-real transform of length N1, the (N1/2+1) com-
     plex  input  data  points  stored are the positive-frequency
     half of the spectrum of the Discrete Fourier Transform.  The
     other  half  can be obtained through complex conjugation and
     therefore is not stored.  Furthermore, due to symmetries the
```

imaginary of the component of X(0,0:N2-1) and X(N1/2,0:N2-1) (if N1 is even in the latter) is assumed to be zero and is not referenced.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = 1 computes inverse FFT

N1 (input)
Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)
Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns in X(0:N1/2, 0:N2-1).

LDX (input)
Leading dimension of X. LDX >= (N1/2+1) Unchanged on exit.

Y (output)
Y is a double precision array of dimensions (LDY, N2) that contains the transform results of the input sequences in Y(0:N1-1,0:N2-1). X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. If X and Y are the same array, LDY = 2*LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)
double precision array of length 2*N1 that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)
double precision array of dimension at least N1. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or 1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1/2+1)
-5 = (LDY < N1) or (LDY not equal 2*LDX when X and Y are same array)
-6 = (LWORK not equal 0) and (LWORK < N1)
-7 = memory allocation failed

NAME

```
zfftf - compute  the  Fourier  coefficients  of  a  periodic
sequence.  The FFT operations are unnormalized, so a call of
ZFFTF followed by a call of ZFFTB will  multiply  the  input
sequence by N.
```

SYNOPSIS

```
SUBROUTINE ZFFTF(N, X, WSAVE)

DOUBLE COMPLEX X(*)
INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE ZFFTF_64(N, X, WSAVE)

DOUBLE COMPLEX X(*)
INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF([N], X, WSAVE)

COMPLEX(8), DIMENSION(:) :: X
INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE FFTF_64([N], X, WSAVE)

COMPLEX(8), DIMENSION(:) :: X
INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void zfftf(int n, doublecomplex *x, double *wsave);

void zfftf_64(long n, doublecomplex *x, double *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input) On entry, an array  of  length  N  containing  the
          sequence to be transformed.

WSAVE (input)
          On entry, WSAVE must be an array of dimension (4 *
          N  + 15) or greater and must have been initialized
          by ZFFTI.
```

Contents

NAME

```
zffti - initialize the array WSAVE, which is  used  in  both
ZFFTF and ZFFTB.
```

SYNOPSIS

```
SUBROUTINE ZFFTI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE ZFFTI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE ZFFTI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE ZFFTI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void zffti(int n, double *wsave);

void zffti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input/output)
On entry, an array of dimension (4 * N + 15) or greater. ZFFTI needs to be called only once to initialize array WORK before calling ZFFTF and/or ZFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

```
zfftopt - compute the length of the closest fast FFT
```

SYNOPSIS

```
INTEGER FUNCTION ZFFTOPT(LEN)

INTEGER LEN

INTEGER*8 FUNCTION ZFFTOPT_64(LEN)

INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION ZFFTOPT(LEN)

INTEGER :: LEN

INTEGER(8) FUNCTION ZFFTOPT_64(LEN)

INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>

int zfftopt(int len);

long zfftopt_64(long len);
```

PURPOSE

```
zfftopt computes the length of the closest fast  FFT.   Fast
```

Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length 32=2**5 will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

ZFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. ZFFTOPT will return 16 for an input of N=16 and return 18=2*3*3 for an input of N=17.

Note that the length computed here is not guaranteed to be optimal, only to be a
product of small primes. Also, the value returned may change as the underlying
FFTs become capable of handling larger primes. For example, passing in N=51 to day will return 52=2*2*13 rather than 51=3*17 because the FFTs in Performance Li brary do not have fast radix 17 code. In the future, radix 17 code may be added
and then N=51 will return 51.

C INTERFACE

```
#include <sunperf.h>

void zfftz_ (int *iopt, int *n, double *scale, doublecomplex
          *x,  doublecomplex  *y,  double *trigs, int *ifac,
          double *work, int *lwork, int *ierr);

void zfftz_64_ (long *iopt, long *n,  double  *scale,  doub-
          lecomplex  *x,  doublecomplex  *y,  double *trigs,
          long  *ifac,  double  *work,  long  *lwork,   long
          *ierr);
```

PURPOSE

zfftz initializes the trigonometric weight and factor tables or computes the Fast Fourier transform (forward or inverse) of a double complex sequence as follows:

```
               N-1
Y(k) = scale * SUM  W*X(j)
               j=0
```

where
k ranges from 0 to N-1
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W = exp(isign*i*j*k*2*pi/N)

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT
IOPT = +1 computes inverse FFT

N (input)
Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)
Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) On entry, X is a double complex array of dimension at least N that contains the sequence to be transformed.

Y (output)
Double complex array of dimension at least N that contains the transform results. X and Y may be the same array starting at the same memory location. Otherwise, it is assumed that there is no overlap between X and Y in memory.

TRIGS (input/output)
Double precision array of length 2*N that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)
Double precision array of dimension at least 2*N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0, 1 or -1

```
-2 = N < 0
-3 = (LWORK is not 0) and (LWORK is less than 2*N)
-4 = memory allocation for workspace failed
```

C INTERFACE

```
      #include <sunperf.h>
      void zfftz2_ (int *iopt, int *n1, int  *n2,  double  *scale,
                doublecomplex  *x, int *ldx, doublecomplex *y, int
                *ldy, double *trigs, int *ifac, double *work,  int
                *lwork, int *ierr);

      void zfftz2_64_ (long *iopt,  long  *n1,  long  *n2,  double
                *scale, doublecomplex *x, long *ldx, doublecomplex
                *y, long *ldy, double *trigs, long  *ifac,  double
                *work, long *lwork, long *ierr);
```

PURPOSE

zfftz2 initializes the trigonometric weight and factor tables or computes the two-dimensional Fast Fourier Transform (forward or inverse) of a two-dimensional double complex array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the columns of the input array. One-dimensional FFTs are then computed along the rows of the intermediate results.

```
                         N2-1  N1-1
      Y(k1,k2) = scale * SUM   SUM   W2*W1*X(j1,j2)
                         j2=0  j1=0
```

where
k1 ranges from 0 to N1-1 and k2 ranges from 0 to N2-1
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W1 = exp(isign*i*j1*k1*2*pi/N1)
W2 = exp(isign*i*j2*k2*2*pi/N2)

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = -1 computes forward FFT
          IOPT = +1 computes inverse FFT

N1 (input)
          Integer specifying length of the transform in  the
          first  dimension.  N1 is most efficient when it is
          a product of small primes.  N1 >= 0.  Unchanged on
          exit.

N2 (input)
          Integer specifying length of the transform in  the
          second dimension.  N2 is most efficient when it is
          a product of small primes.  N2 >= 0.  Unchanged on
          exit.
SCALE (input)
          Double precision scalar by which transform results
          are   scaled.   Unchanged   on  exit.   SCALE  is
          defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array  of  dimensions  (LDX,
          N2) that contains input data to be transformed.

LDX (input)
          Leading dimension of X.  LDX >=  N1  Unchanged  on
          exit.

Y (output)
          Y is a double complex array  of  dimensions  (LDY,
          N2)  that contains the transform results.  X and Y
          can be the same array starting at the same  memory
          location,   in  which  case  the  input  data  are
          overwritten by their  transform  results.   Other-
          wise,  it  is  assumed  that  there  is no overlap
          between X and Y in memory.

LDY (input)
          Leading dimension of Y.  If X and Y are  the  same
          array, LDY = LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)
          Double precision array of  length  2*(N1+N2)  that
```

contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)
Double precision array of dimension at least 2*MAX(N1,N2)*NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0, 1 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1)
-5 = (LDY < N1) or (LDY not equal LDX when X and Y are same array)
-6 = (LWORK not equal 0) and (LWORK < 2*MAX(N1,N2)*NCPUS)
-7 = memory allocation failed

PURPOSE

zfftz3 initializes the trigonometric weight and factor tables or computes the three-dimensional Fast Fourier Transform (forward or inverse) of a three-dimensional double complex array.

```
                          N3-1  N2-1  N1-1
     Y(k1,k2,k3) = scale * SUM   SUM   SUM   W3*W2*W1*X(j1,j2,j3)
                          j3=0  j2=0  j1=0
```

where
k1 ranges from 0 to N1-1; k2 ranges from 0 to N2-1 and k3 ranges from 0 to N3-1

```
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W1 = exp(isign*i*j1*k1*2*pi/N1)
W2 = exp(isign*i*j2*k2*2*pi/N2)
W3 = exp(isign*i*j3*k3*2*pi/N3)
```

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = -1 computes forward FFT
          IOPT = +1 computes inverse FFT

N1 (input)
          Integer specifying length of the transform in  the
          first  dimension.  N1 is most efficient when it is
          a product of small primes.  N1 >= 0.  Unchanged on
          exit.

N2 (input)
          Integer specifying length of the transform in  the
          second dimension.  N2 is most efficient when it is
          a product of small primes.  N2 >= 0.  Unchanged on
          exit.

N3 (input)
          Integer specifying length of the transform in  the
          third  dimension.  N3 is most efficient when it is
          a product of small primes.  N3 >= 0.  Unchanged on
          exit.

SCALE (input)
          Double precision scalar by which transform results
          are   scaled.   Unchanged   on  exit.   SCALE  is
          defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of  dimensions  (LDX1,
          LDX2,   N3)   that   contains  input  data  to  be
          transformed.

LDX1 (input)
          first dimension of X.  LDX1  >=  N1  Unchanged  on
          exit.

LDX2 (input)
          second dimension of X.  LDX2 >=  N2  Unchanged  on
```

exit.

Y (output)

Y is a double complex array of dimensions (LDY1, LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)

first dimension of Y. If X and Y are the same array, LDY1 = LDX1 Else LDY1 >= N1 Unchanged on exit.

LDY2 (input)

second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)

Double precision array of length 2*(N1+N2+N3) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 3*128 that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least (2*MAX(N,N2,N3) + 32*N3) * NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return

-1 = IOPT is not 0, 1 or -1

-2 = N1 < 0
-3 = N2 < 0
-4 = N3 < 0
-5 = (LDX1 < N1)
-6 = (LDX2 < N2)
-7 = (LDY1 < N1) or (LDY1 not equal LDX1 when X and Y are same array)
-8 = (LDY2 < N2) or (LDY2 not equal LDX2 when X and Y are same array)
-9 = (LWORK not equal 0) and (LWORK < (2*MAX(N,N2,N3) + 16*N3) * NCPUS)
-10 = memory allocation failed

SEE ALSO

fft

CAUTIONS

On exit, output subarray Y(1:LDY1, 1:N2, 1:N3) is overwritten.

               *work, long *lwork, long *ierr);
```

PURPOSE

zfftzm initializes the trigonometric weight and factor tables or computes the one-dimensional Fast Fourier Transform (forward or inverse) of a set of data sequences stored in a two-dimensional double complex array:

```
            N1-1
     Y(k,l) = SUM  W*X(j,l)
            j=0

     where
     k ranges from 0 to N1-1 and l ranges from 0 to N2-1
     i = sqrt(-1)
     isign = 1 for inverse transform or -1 for forward transform
     W = exp(isign*i*j*k*2*pi/N1)
```

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT
IOPT = +1 computes inverse FFT

N1 (input)
Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)
Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns.

LDX (input)
Leading dimension of X. LDX >= N1 Unchanged on exit.

Y (output)
Y is a double complex array of dimensions (LDY, N2) that contains the transform results of the input sequences. X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. If X and Y are the same array, LDY = LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)
Double precision array of length 2*N1 that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Double precision array of dimension at least 2*N1*NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return
-1 = IOPT is not 0, 1 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1)
-5 = (LDY < N1) or (LDY not equal LDX when X and Y are same array)
-6 = (LWORK not equal 0) and (LWORK < 2*N1*NCPUS)
-7 = memory allocation failed

          double *e, doublecomplex *q, long ldq,  doublecom-
          plex  *pt,  long ldpt, doublecomplex *c, long ldc,
          long *info);
```

PURPOSE

zgbbrd reduces a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation: Q' * A * P = B.

The routine computes B, and optionally forms Q or P', or computes Q'*C for a given matrix C.

ARGUMENTS

VECT (input)
Specifies whether or not the matrices Q and P' are to be formed. = 'N': do not form Q or P';
= 'Q': form Q only;
= 'P': form P' only;
= 'B': form both.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NCC (input)

The number of columns of the matrix C. NCC >= 0.

KL (input)
The number of subdiagonals of the matrix A. KL >= 0.

KU (input)
The number of superdiagonals of the matrix A. KU >= 0.

AB (input/output)
On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl). On exit, A is overwritten by values generated during the reduction.

LDAB (input)
The leading dimension of the array A. LDAB >= KL+KU+1.

D (output)
The diagonal elements of the bidiagonal matrix B.

E (output)
The superdiagonal elements of the bidiagonal matrix B.

Q (output)
If VECT = 'Q' or 'B', the m-by-m unitary matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT (output)
If VECT = 'P' or 'B', the n-by-n unitary matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT (input)
The leading dimension of the array PT. LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C (input/output)
On entry, an m-by-ncc matrix C. On exit, C is

```
          overwritten by Q'*C.  C is not referenced if NCC =
          0.

LDC (input)
          The leading dimension of  the  array  C.   LDC  >=
          max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.
WORK (workspace)
          dimension(MAX(M,N))

RWORK (workspace)
          dimension(MAX(M,N))

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.

REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void zgbcon(char norm, int n, int nsub,  int  nsuper,  doub-
          lecomplex  *a, int lda, int *ipivot, double anorm,
          double *rcond, int *info);

void zgbcon_64(char norm, long n, long  nsub,  long  nsuper,
          doublecomplex  *a,  long lda, long *ipivot, double
          anorm, double *rcond, long *info);
```

PURPOSE

zgbcon estimates the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I':   Infinity-norm.

N (input) The order of the matrix A. N >= 0.

NSUB (input)
The number of subdiagonals within the band of A. NSUB >= 0.

NSUPER (input)
The number of superdiagonals within the band of A. NSUPER >= 0.

A (input) Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDA (input)
The leading dimension of the array A. LDA >= 2*NSUB+NSUPER+1.

IPIVOT (input)
The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIVOT(i).

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension (N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

   COMPLEX(8), DIMENSION(:,:) :: A
   INTEGER(8) :: M, N, KL, KU, LDA, INFO
   REAL(8) :: ROWCN, COLCN, AMAX
   REAL(8), DIMENSION(:) :: R, C
```

C INTERFACE

```
#include <sunperf.h>

void zgbequ(int m, int n, int kl, int ku, doublecomplex  *a,
          int lda, double *r, double *c, double *rowcn, dou-
          ble *colcn, double *amax, int *info);
void zgbequ_64(long m, long n, long kl, long ku,  doublecom-
          plex  *a,  long  lda, double *r, double *c, double
          *rowcn, double *colcn, double *amax, long *info);
```

PURPOSE

zgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

A (input) The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

R (output)
If INFO = 0, or INFO > M, R contains the row scale factors for A.

C (output)
If INFO = 0, C contains the column scale factors for A.

ROWCN (output)
If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest R(i) to the largest R(i). If ROWCN >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCN (output)
If INFO = 0, COLCN contains the ratio of the smallest C(i) to the largest C(i). If COLCN >= 0.1, it is not worth scaling by C.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

          doublecomplex *x, int incx,  doublecomplex  *beta,
          doublecomplex *y, int incy);

void zgbmv_64(char transa, long m, long n, long  nsub,  long
          nsuper,  doublecomplex  *alpha,  doublecomplex *a,
          long lda, doublecomplex *x, long incx,  doublecom-
          plex *beta, doublecomplex *y, long incy);
```

PURPOSE

zgbmv performs one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with nsub sub-diagonals and nsuper super-diagonals.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:
TRANSA = 'N' or 'n'   y := alpha*A*x + beta*y.
TRANSA = 'T' or 't'   y := alpha*A'*x + beta*y.
TRANSA = 'C' or 'c'   y := alpha*conjg(A')*x + beta*y.
Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

NSUB (input)
On entry, NSUB specifies the number of sub-diagonals of the matrix A. NSUB must satisfy 0 .le. NSUB. Unchanged on exit.

NSUPER (input)
On entry, NSUPER specifies the number of super-diagonals of the matrix A. NSUPER must satisfy 0 .le. NSUPER. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry, the leading (nsub + nsuper + 1) by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (nsuper + 1) of the array, the first super-diagonal starting at position 2 in row nsuper, the first sub-diagonal starting at position 1 in row (nsuper + 2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left nsuper by nsuper triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
    DO 20, J = 1, N
      K = NSUPER + 1 - J
      DO 10, I = MAX( 1, J - NSUPER ), MIN( M, J +
NSUB )
        A( K + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (nsub + nsuper + 1). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (m - 1)*abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

          *ferr, double *berr, long *info);
```

PURPOSE

zgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)
```

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input)
Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL*KU+1.

IPIVOT (input)
The pivot indices from CGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CGBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
#include <sunperf.h>

void zgbsv(int n, int kl, int ku,  int  nrhs,  doublecomplex
          *a,  int  lda,  int *ipivot, doublecomplex *b, int
          ldb, int *info);

void zgbsv_64(long n, long kl, long  ku,  long  nrhs,  doub-
          lecomplex  *a,  long lda, long *ipivot, doublecom-
          plex *b, long ldb, long *info);
```

PURPOSE

zgbsv computes the solution to a complex system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as A = L * U, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)

On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: A(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL) On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDA (input)
The leading dimension of the array A. LDA >= 2*KL+KU+1.

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

```
On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
```

```
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

          *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

zgbsvx uses the LU factorization to compute the solution to a complex system of linear equations A * X = B, A**T * X = B, or A**H * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are

```
also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X  =
diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X  =
diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X  =
diag(C)*B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(R)*A*diag(C) and B by  diag(R)*B  (if
TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU  decomposition  is  used  to
factor the
   matrix A (after equilibration if FACT = 'E') as
      A = L * U,
   where L is a product of permutation and unit  lower  tri-
angular
   matrices with KL subdiagonals, and U is upper  triangular
with
   KL+KU superdiagonals.

3. If some U(i,i)=0, so that U is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
```

estimates
for it.

6. If equilibration was used, the matrix X is premultiplied by
diag(C) (if TRANS = 'N') or diag(R) (if TRANS = 'T' or 'C') so
that it solves the original system before equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF and IPIVOT contain the factored form of A. If EQUED is not 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF, and IPIVOT are not modified. = 'N': The matrix A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

TRANSA (input)
Specifies the form of the system of equations. = 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the matrix A in band storage, in rows 1

to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A
EQUED = 'C': A := A * diag(C)
EQUED = 'B': A := diag(R) * A * diag(C).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL+KU+1.

IPIVOT (input)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by CGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the equilibrated matrix A.

EQUED (input)

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input/output)

The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input/output)

The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)

On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED

.ne. 'N', and the solution to the equilibrated system is inv(diag(C))*X if TRANSA = 'N' and EQUED = 'C' or 'B', or inv(diag(R))*X if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N) On exit, WORK2(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

NAME

zgbtf2 - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE ZGBTF2(M, N, KL, KU, AB, LDAB, IPIV, INFO)

DOUBLE COMPLEX AB(LDAB,*)
INTEGER M, N, KL, KU, LDAB, INFO
INTEGER IPIV(*)

SUBROUTINE ZGBTF2_64(M, N, KL, KU, AB, LDAB, IPIV, INFO)

DOUBLE COMPLEX AB(LDAB,*)
INTEGER*8 M, N, KL, KU, LDAB, INFO
INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE GBTF2([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])

COMPLEX(8), DIMENSION(:,:) :: AB
INTEGER :: M, N, KL, KU, LDAB, INFO
INTEGER, DIMENSION(:) :: IPIV

SUBROUTINE GBTF2_64([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])

COMPLEX(8), DIMENSION(:,:) :: AB
INTEGER(8) :: M, N, KL, KU, LDAB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>

void zgbtf2(int m, int n, int kl, int ku, doublecomplex *ab,
          int ldab, int *ipiv, int *info);

void zgbtf2_64(long m, long n, long kl, long ku,  doublecom-
          plex *ab, long ldab, long *ipiv, long *info);
```

PURPOSE

zgbtf2 computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

AB (input/output)
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input)
The leading dimension of the array AB. LDAB >=

2*KL+KU+1.

IPIV (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

```
On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U, because of fill-in resulting from the row interchanges.

          plex *ab, long ldab, long *ipivot, long *info);
```

PURPOSE

zgbtrf computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

M (input) Integer
The number of rows of the matrix A. M >= 0.

N (input) Integer
The number of columns of the matrix A. N >= 0.

KL (input) Integer
The number of subdiagonals within the band of A. KL >= 0.

KU (input) Integer
The number of superdiagonals within the band of A. KU >= 0.

AB (input/output) Double complex array of dimension (LDAB,N).
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(KL+KU+1+I-J,J) = A(I,J) for MAX(1,J-KU)<=I<=MIN(M,J+KL)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input) Integer
The leading dimension of the array A. LDA >= 2*KL+KU+1.

IPIVOT (output) Integer array of dimension MIN(M,N)
The pivot indices; for 1 <= I <= min(M,N), row I of the matrix was interchanged with row IPIVOT(I).

INFO (output) Integer
= 0: successful exit
< 0: if INFO = -I, the I-th argument had an illegal value
> 0: if INFO = +I, U(I,I) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

```
On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

             *ipivot, doublecomplex *b, long ldb, long *info);
```

PURPOSE

```
   zgbtrs solves a system of linear equations
      A * X = B,  A**T * X = B,  or  A**H * X = B with  a  gen-
   eral  band  matrix  A using the LU factorization computed by
   CGBTRF.
```

ARGUMENTS

```
   TRANSA (input)
             Specifies the form of the system of equations.   =
             'N':  A * X = B     (No transpose)
             = 'T':  A**T * X = B  (Transpose)
             = 'C':  A**H * X = B  (Conjugate transpose)

             TRANSA is defaulted to 'N' for F95 INTERFACE.

   N (input) The order of the matrix A.  N >= 0.

   NSUB (input)
             The number of subdiagonals within the band  of  A.
             NSUB >= 0.

   NSUPER (input)
             The number of superdiagonals within the band of A.
             NSUPER >= 0.

   NRHS (input)
             The number of right hand sides, i.e.,  the  number
             of columns of the matrix B.  NRHS >= 0.
```

A (input) Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDA (input)
The leading dimension of the array A. LDA >= 2*NSUB+NSUPER+1.

IPIVOT (input)
The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE GEBAK_64(JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
       [INFO])
```

```
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX(8), DIMENSION(:,:) :: V
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void zgebak(char job, char side, int n, int  ilo,  int  ihi,
          double  *scale,  int m, doublecomplex *v, int ldv,
          int *info);

void zgebak_64(char job, char side, long n, long  ilo,  long
          ihi, double *scale, long m, doublecomplex *v, long
          ldv, long *info);
```

PURPOSE

zgebak forms the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL.

ARGUMENTS

JOB (input)
Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to CGEBAL.

SIDE (input)
= 'R': V contains right eigenvectors;
= 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. N >= 0.

ILO (input)
The integer ILO determined by CGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
The integer IHI determined by CGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

SCALE (input)
Details of the permutation and scaling factors, as returned by CGEBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)
On entry, the matrix of right or left eigenvectors to be transformed, as returned by CHSEIN or CTREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)
The leading dimension of the array V. LDV >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

Contents

NAME

```
zgebal - balance a general complex matrix A
```

SYNOPSIS

```
SUBROUTINE ZGEBAL(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)

CHARACTER * 1 JOB
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, ILO, IHI, INFO
DOUBLE PRECISION SCALE(*)

SUBROUTINE ZGEBAL_64(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)

CHARACTER * 1 JOB

DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])

CHARACTER(LEN=1) :: JOB
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, LDA, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: SCALE

SUBROUTINE GEBAL_64(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])

CHARACTER(LEN=1) :: JOB
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, ILO, IHI, INFO
```

```
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void zgebal(char job, int n, doublecomplex *a, int lda,  int
          *ilo, int *ihi, double *scale, int *info);

void zgebal_64(char job, long n, doublecomplex *a, long lda,
          long *ilo, long *ihi, double *scale, long *info);
```

PURPOSE

zgebal balances a general complex matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input)
Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ILO (output)

ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)

ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE (output)

Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The permutations consist of row and column interchanges which put the matrix in the form

```
          ( T1   X   Y  )
  P A P = (  0   B   Z  )
          (  0   0   T2 )
```

where T1 and T2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ILO and IHI mark the starting and ending columns of the submatrix B. Balancing consists of applying a diagonal similarity transformation inv(D) * B * D to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

```
  ( T1     X*D          Y    )
  (  0  inv(D)*B*D  inv(D)*Z ).
  (  0      0           T2   )
```

Information about the permutations P and the diagonal matrix D is returned in the vector SCALE.

This subroutine is based on the EISPACK routine CBAL.

INTEGER*8 M, N, LDA, LWORK, INFO
DOUBLE PRECISION D(*), E(*)
```

F95 INTERFACE

```
SUBROUTINE GEBRD([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK], [LWORK],
       [INFO])

COMPLEX(8), DIMENSION(:) :: TAUQ, TAUP, WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: D, E

SUBROUTINE GEBRD_64([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],
       [LWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: TAUQ, TAUP, WORK
```

```
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>

void zgebrd(int m, int n, doublecomplex *a, int lda,  double
          *d,  double *e, doublecomplex *tauq, doublecomplex
          *taup, int *info);

void zgebrd_64(long m, long n, doublecomplex *a,  long  lda,
          double  *d,  double *e, doublecomplex *tauq, doub-
          lecomplex *taup, long *info);
```

PURPOSE

zgebrd reduces a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation: Q**H * A * P = B.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

ARGUMENTS

M (input) The number of rows in the matrix A. M >= 0.

N (input) The number of columns in the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflec-

tors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

D (output)
The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E (output)
The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP (output)
The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. LWORK >= max(1,M,N). For optimum performance LWORK >= (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrices Q and P are represented as products of elementary reflectors:

If m >= n,

```
   Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

Each H(i) and G(i) has the form:

   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

where tauq and taup are complex scalars, and  v  and  u  are
complex  vectors;  v(1:i-1)  =  0, v(i) = 1, and v(i+1:m) is
stored on exit in A(i+1:m,i); u(1:i) = 0, u(i+1)  =  1,  and
u(i+2:n)  is stored on exit in A(i,i+2:n); tauq is stored in
TAUQ(i) and taup in TAUP(i).
If m < n,

   Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

Each H(i) and G(i) has the form:

   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

where tauq and taup are complex scalars, and  v  and  u  are
complex  vectors;  v(1:i)  =  0, v(i+1) = 1, and v(i+2:m) is
stored on exit in A(i+2:m,i); u(1:i-1) = 0, u(i)  =  1,  and
u(i+1:n)  is stored on exit in A(i,i+1:n); tauq is stored in
TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by  the  following
examples:

m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

  (  d   e   u1  u1  u1 )           (  d   u1   u1   u1   u1
u1 )
  (  v1  d   e   u2  u2 )           (  e   d    u2   u2   u2
u2 )
  (  v1  v2  d   e   u3 )           (  v1  e    d    u3   u3
u3 )
  (  v1  v2  v3  d   e  )           (  v1  v2   e    d    u4
u4 )
  (  v1  v2  v3  v4  d  )           (  v1   v2   v3   e    d
u5 )
  (  v1  v2  v3  v4  v5 )

where d and e denote diagonal and off-diagonal  elements  of
B, vi denotes an element of the vector defining H(i), and ui
an element of the vector defining G(i).
```

    void zgecon(char norm, int n,  doublecomplex  *a,  int  lda,
              double anorm, double *rcond, int *info);

    void zgecon_64(char norm, long  n,  doublecomplex  *a,  long
              lda, double anorm, double *rcond, long *info);
```

PURPOSE

zgecon estimates the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as
   RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

```
    NORM (input)
              Specifies whether the 1-norm condition  number  or
              the infinity-norm condition number is required:
              = '1' or 'O':  1-norm;
              = 'I':         Infinity-norm.

    N (input) The order of the matrix A.  N >= 0.

    A (input) The factors L and U from  the  factorization  A  =
              P*L*U as computed by CGETRF.

    LDA (input)
              The leading dimension of  the  array  A.   LDA  >=
              max(1,N).
```

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

DOUBLE PRECISION R(*), C(*)

SUBROUTINE ZGEEQU_64(M, N, A, LDA, R, C, ROWCN, COLCN, AMAX,
      INFO)

DOUBLE COMPLEX A(LDA,*)
INTEGER*8 M, N, LDA, INFO
DOUBLE PRECISION ROWCN, COLCN, AMAX
DOUBLE PRECISION R(*), C(*)
```

F95 INTERFACE

```
SUBROUTINE GEEQU([M], [N], A, [LDA], R, C, ROWCN, COLCN,
       AMAX, [INFO])

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, INFO
REAL(8) :: ROWCN, COLCN, AMAX
REAL(8), DIMENSION(:) :: R, C

SUBROUTINE GEEQU_64([M], [N], A, [LDA], R, C, ROWCN, COLCN,
       AMAX, [INFO])
```

```
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, INFO
REAL(8) :: ROWCN, COLCN, AMAX
REAL(8), DIMENSION(:) :: R, C
```

C INTERFACE

```
#include <sunperf.h>

void zgeequ(int m, int n, doublecomplex *a, int lda,  double
          *r,  double *c, double *rowcn, double *colcn, dou-
          ble *amax, int *info);

void zgeequ_64(long m, long n, doublecomplex *a,  long  lda,
          double   *r,  double  *c,  double  *rowcn,  double
          *colcn, double *amax, long *info);
```

PURPOSE

zgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input) The M-by-N matrix whose equilibration factors are to be computed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

R (output)
If INFO = 0 or INFO > M, R contains the row scale factors for A.

C (output)
If INFO = 0, C contains the column scale factors for A.

ROWCN (output)
If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest R(i) to the largest R(i). If ROWCN >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCN (output)
If INFO = 0, COLCN contains the ratio of the smallest C(i) to the largest C(i). If COLCN >= 0.1, it is not worth scaling by C.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

C INTERFACE

```
#include <sunperf.h>

void       zgees(char       jobz,        char        sortev,
          int(*select)(doublecomplex),  int n, doublecomplex
          *a, int lda, int *nout,  doublecomplex  *w,  doub-
          lecomplex *z, int ldz, int *info);

void      zgees_64(char       jobz,       char       sortev,
          long(*select)(doublecomplex),  long  n, doublecom-
          plex *a, long lda, long *nout,  doublecomplex  *w,
          doublecomplex *z, long ldz, long *info);
```

PURPOSE

zgees computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z**H).

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

JOBZ (input)

```
          = 'N': Schur vectors are not computed;
          = 'V': Schur vectors are computed.

SORTEV (input)
          Specifies whether or not to order the  eigenvalues
          on  the diagonal of the Schur form.  = 'N': Eigen-
          values are not ordered:
          = 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
          SELECT must be declared EXTERNAL  in  the  calling
          subroutine.   If  SORTEV  = 'S', SELECT is used to
          select eigenvalues to order to the top left of the
          Schur form.  If SORTEV = 'N', SELECT is not refer-
          enced.   The  eigenvalue  W(j)  is   selected   if
          SELECT(W(j)) is true.
N (input) The order of the matrix A. N >= 0.

A (input/output)
          On entry, the N-by-N matrix A.   On  exit,  A  has
          been overwritten by its Schur form T.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

NOUT (output)
          If SORTEV = 'N', NOUT = 0.  If SORTEV = 'S',  NOUT
          = number of eigenvalues for which SELECT is true.

W (output)
          W contains the computed eigenvalues, in  the  same
          order that they appear on the diagonal of the out-
          put Schur form T.

Z (output)
          If JOBZ = 'V', Z contains the unitary matrix Z  of
          Schur  vectors.   If  JOBZ  = 'N', Z is not refer-
          enced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1;
          if JOBZ = 'V', LDZ >= N.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The  dimension  of  the  array  WORK.   LDWORK  >=
```

max(1,2*N).   For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(N)

WORK3 (workspace)
dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is
<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT = .TRUE.. This could also be caused by underflow due to scaling.

```

PURPOSE

zgeesx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z**H).

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

JOBZ (input)
= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

SORTEV (input)
Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue W(j) is selected if SELECT(W(j)) is true.

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for average of selected eigenvalues only;
= 'V': Computed for selected right invariant subspace only;
= 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORTEV must equal 'S'.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the N-by-N matrix A. On exit, A is overwritten by its Schur form T.

LDA (input)

The leading dimension of the array A. LDA >= max(1,N).

NOUT (output)
If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues for which SELECT is true.

W (output)
W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

Z (output)
If JOBZ = 'V', Z contains the unitary matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

RCONE (output)
If SENSE = 'E' or 'B', RCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONV (output)
If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
dimension(LDWORK) On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,2*N). Also, if SENSE = 'E' or 'V' or 'B', LDWORK >= 2*NOUT*(N-NOUT), where NOUT is the number of selected eigenvalues computed by this routine. Note that 2*NOUT*(N-NOUT) <= N*N/2. For good performance, LDWORK must generally be larger.

WORK2 (workspace)
dimension(N)

BWORK3 (workspace)
dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is
<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the transformation which reduces A to its partially converged Schur form.
= N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

C INTERFACE

```
#include <sunperf.h>
void zgeev(char jobvl, char jobvr, int n, doublecomplex  *a,
          int  lda, doublecomplex *w, doublecomplex *vl, int
          ldvl, doublecomplex *vr, int ldvr, int *info);

void zgeev_64(char jobvl, char jobvr, long n,  doublecomplex
          *a, long lda, doublecomplex *w, doublecomplex *vl,
          long ldvl,  doublecomplex  *vr,  long  ldvr,  long
          *info);
```

PURPOSE

```
zgeev computes for an N-by-N complex nonsymmetric matrix  A,
the  eigenvalues  and,  optionally,  the  left  and/or right
eigenvectors.

The right eigenvector v(j) of A satisfies
                 A * v(j) = lambda(j) * v(j)
where lambda(j) is its eigenvalue.
The left eigenvector u(j) of A satisfies
              u(j)**H * A = lambda(j) * u(j)**H
where u(j)**H denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to  have  Euclidean
norm equal to 1 and largest component real.
```

ARGUMENTS

```
JOBVL (input)
          = 'N': left eigenvectors of A are not computed;
          = 'V': left eigenvectors of are computed.

JOBVR (input)
          = 'N': right eigenvectors of A are not computed;
          = 'V': right eigenvectors of A are computed.
```

```
N (input) The order of the matrix A. N >= 0.

A (input/output)
          On entry, the N-by-N matrix A.   On  exit,  A  has
          been overwritten.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

W (output)
          W contains the computed eigenvalues.

VL (output)
          If JOBVL = 'V', the  left  eigenvectors  u(j)  are
          stored  one after another in the columns of VL, in
          the same order as their eigenvalues.  If  JOBVL  =
          'N',  VL  is  not referenced.  u(j) = VL(:,j), the
          j-th column of VL.

LDVL (input)
          The leading dimension of the array VL.  LDVL >= 1;
          if JOBVL = 'V', LDVL >= N.

VR (input)
          If JOBVR = 'V', the right  eigenvectors  v(j)  are
          stored  one after another in the columns of VR, in
          the same order as their eigenvalues.  If  JOBVR  =
          'N',  VR  is  not referenced.  v(j) = VR(:,j), the
          j-th column of VR.

LDVR (input)
          The leading dimension of the array VR.  LDVR >= 1;
          if JOBVR = 'V', LDVR >= N.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The  dimension  of  the  array  WORK.   LDWORK  >=
          max(1,2*N).   For  good  performance,  LDWORK must
          generally be larger.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.
```

WORK2 (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements and i+1:N of W contain eigenvalues which have converged.

          ble*, double*, double*, long*);
```

PURPOSE

zgeevx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right
eigenvectors (RCONDV).

The right eigenvector v(j) of A satisfies

```
                 A * v(j) = lambda(j) * v(j)
```

where lambda(j) is its eigenvalue.
The left eigenvector u(j) of A satisfies

```
               u(j)**H * A = lambda(j) * u(j)**H
```

where u(j)**H denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input)
Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute;
= 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, ie. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)
= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input)
= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

```
SENSE (input)
          Determines which reciprocal condition numbers  are
          computed.  = 'N': None are computed;
          = 'E': Computed for eigenvalues only;
          = 'V': Computed for right eigenvectors only;
          = 'B': Computed for eigenvalues and  right  eigen-
          vectors.

          If SENSE = 'E' or 'B', both left and right  eigen-
          vectors  must  also  be  computed (JOBVL = 'V' and
          JOBVR = 'V').

N (input) The order of the matrix A. N >= 0.

A (input/output)
          On entry, the N-by-N matrix A.   On  exit,  A  has
          been  overwritten.  If JOBVL = 'V' or JOBVR = 'V',
          A contains the Schur form of the balanced  version
          of the matrix A.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

W (output)
          W contains the computed eigenvalues.

VL (output)
          If JOBVL = 'V', the  left  eigenvectors  u(j)  are
          stored  one after another in the columns of VL, in
          the same order as their eigenvalues.  If  JOBVL  =
          'N',  VL  is  not referenced.  u(j) = VL(:,j), the
          j-th column of VL.

LDVL (input)
          The leading dimension of the array VL.  LDVL >= 1;
          if JOBVL = 'V', LDVL >= N.

VR (input)
          If JOBVR = 'V', the right  eigenvectors  v(j)  are
          stored  one after another in the columns of VR, in
          the same order as their eigenvalues.  If  JOBVR  =
          'N',  VR  is  not referenced.  v(j) = VR(:,j), the
          j-th column of VR.

LDVR (input)
          The leading dimension of the array VR.  LDVR >= 1;
          if JOBVR = 'V', LDVR >= N.

ILO (output)
```

ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

IHI (output)

ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE (output)

Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)

The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONE (output)

RCONE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONV (output)

RCONV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (output)

The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK >= max(1,2*N), and if SENSE = 'V' or 'B', LDWORK >= N*N+2*N. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of W contain eigenvalues which have converged.

          long ldvsr, long *info);
```

PURPOSE

zgegs routine is deprecated and has been replaced by routine CGGES.

CGEGS computes for a pair of N-by-N complex nonsymmetric matrices A, B: the generalized eigenvalues (alpha, beta), the complex Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver CGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one unitary matrix and both on the right by another unitary matrix, these two unitary matrices being chosen so as to bring the pair of matrices into upper triangular form with the diagonal elements of B being non-negative real numbers (this is also called complex Schur form.)

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the unitary matrices
which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**H A (VSR), (VSL)**H B (VSR))

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) output by CGEGS. The

BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
See the description of ALPHA.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL >= 1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

LDVSR (input)
The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,2*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for CGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the blocksizes for CGEQRF, CUNMQR, and CUNGQR; the optimal LDWORK is N*(NB+1).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from CGGBAL
=N+2: error return from CGEQRF
=N+3: error return from CUNMQR
=N+4: error return from CUNGQR
=N+5: error return from CGGHRD
=N+6: error return from CHGEQZ (other than failed iteration) =N+7: error return from CGGBAK (computing VSL)
=N+8: error return from CGGBAK (computing VSR)
=N+9: error return from CLASCL (various places)

PURPOSE

zgegv routine is deprecated and has been replaced by routine CGGEV.

CGEGV computes for a pair of N-by-N complex nonsymmetric matrices A and B, the generalized eigenvalues (alpha, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that (A - w B) r = 0 . A left generalized eigenvector is a vector l such that l**H * (A - w B) = 0, where l**H is the
conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B. See "Further Details", below.

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHA (output)
On exit, ALPHA(j)/VL(j), j=1,...,N, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/VL(j) may easily over- or underflow, and VL(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and VL always less than and usually comparable with norm(B).

BETA (output)
If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVL = 'N'.

VL (output)
If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVL = 'N'.

LDVL (input)
The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (output)
If JOBVR = 'V', the right generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVR = 'N'.

LDVR (input)
The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,2*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for CGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the blocksizes for CGEQRF, CUNMQR, and

CUNGQR; The optimal LDWORK is MAX(2*N, N*(NB+1)).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(8*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and VL(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from CGGBAL
=N+2: error return from CGEQRF
=N+3: error return from CUNMQR
=N+4: error return from CUNGQR
=N+5: error return from CGGHRD
=N+6: error return from CHGEQZ (other than failed iteration) =N+7: error return from CTGEVC
=N+8: error return from CGGBAK (computing VL)
=N+9: error return from CGGBAK (computing VR)
=N+10: error return from CLASCL (various calls)

FURTHER DETAILS

Balancing

This driver calls CGGBAL to both permute and scale rows and columns of A and B. The permutations PL and PR are chosen so that PL*A*PR and PL*B*R will be upper triangular except for the diagonal blocks A(i:j,i:j) and B(i:j,i:j), with i and j as close together as possible. The diagonal scaling matrices DL and DR are chosen so that the pair DL*PL*A*PR*DR, DL*PL*B*PR*DR have elements close to one (except for the elements that start out zero.)

After the eigenvalues and eigenvectors of the balanced matrices have been computed, CGGBAK transforms the eigenvectors back to what they would have been (in perfect arithmetic) if they had not been balanced.

Contents of A and B on Exit

-------- -- - --- - -- ----

If any eigenvectors are computed (either JOBVL='V' or JOBVR='V' or both), then on exit the arrays A and B will contain the complex Schur form[*] of the "balanced" versions of A and B. If no eigenvectors are computed, then only the diagonal blocks will be correct.

[*] In other words, upper triangular form.

Contents

NAME

```
zgehrd - reduce a complex general matrix A to upper  Hessen-
berg form H by a unitary similarity transformation
```

SYNOPSIS

```
SUBROUTINE ZGEHRD(N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)

DOUBLE COMPLEX A(LDA,*), TAU(*), WORKIN(*)
INTEGER N, ILO, IHI, LDA, LWORKIN, INFO

SUBROUTINE ZGEHRD_64(N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)

DOUBLE COMPLEX A(LDA,*), TAU(*), WORKIN(*)
INTEGER*8 N, ILO, IHI, LDA, LWORKIN, INFO
```

F95 INTERFACE

```
SUBROUTINE GEHRD([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
       [INFO])

COMPLEX(8), DIMENSION(:) :: TAU, WORKIN
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO

SUBROUTINE GEHRD_64([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
       [INFO])

COMPLEX(8), DIMENSION(:) :: TAU, WORKIN
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zgehrd(int n, int ilo, int ihi, doublecomplex  *a,  int
          lda, doublecomplex *tau, int *info);

void zgehrd_64(long n, long ilo, long ihi, doublecomplex *a,
          long lda, doublecomplex *tau, long *info);
```

PURPOSE

zgehrd reduces a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation: Q' * A * Q = H .

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

IHI (input)
See the description of ILO.

A (input/output)
On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)
The length of the array WORKIN. LWORKIN >= max(1,N). For optimum performance LWORKIN >= N*NB, where NB is the optimal blocksize.

If LWORKIN = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of (ihi-ilo) elementary reflectors

```
   Q = H(ilo) H(ilo+1) . . . H(ihi-1).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a complex scalar, and v is a complex vector with v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with n = 7, ilo = 2 and ihi = 6:

```
on entry,                        on exit,

( a   a   a   a   a   a   a )    (  a   a   h    h    h    h
a  )  (      a   a   a   a   a   a )    (      a   h   h   h
h   a ) (     a   a   a   a   a   a )    (       h    h    h
h    h    h  ) (     a   a   a   a   a   a )    (      v2  h
h   h   h   h ) (     a   a   a   a   a   a )     (       v2
v3   h    h    h    h  )  (     a   a   a   a   a   a )    (
v2  v3  v4  h    h   h ) (                          a  )     (
a )
```

where a denotes an element of the original matrix A, h denotes a modified element of the upper Hessenberg matrix H, and vi denotes an element of the vector defining H(i).

          lecomplex *tau, int *info);

void zgelqf_64(long m, long n, doublecomplex *a,  long  lda,
          doublecomplex *tau, long *info);
```

PURPOSE

zgelqf computes an LQ factorization of a complex M-by-N matrix A: A = L * Q.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(k)' . . . H(2)' H(1)', where k = min(m,n).

Each H(i) has the form
   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with v(1:i-1) = 0 and v(i) = 1; conjg(v(i+1:n)) is stored on
exit in A(i,i+1:n), and tau in TAU(i).

COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zgels (char, int, int, int, doublecomplex*, int,  doub-
          lecomplex*, int, int*);

void zgels_64 (char, long, long, long, doublecomplex*, long,
          doublecomplex*, long, long*);
```

PURPOSE

zgels solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and m >= n: find the least squares solution of
   an overdetermined system, i.e., solve the least squares problem
                minimize || B - A*X ||.

2. If TRANS = 'N' and m < n: find the minimum norm solution of
   an underdetermined system A * X = B.

3. If TRANS = 'C' and m >= n: find the minimum norm solution of
   an undetermined system A**H * X = B.

4. If TRANS = 'C' and m < n: find the least squares solution of
   an overdetermined system, i.e., solve the least squares problem
                minimize || B - A**H * X ||.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

```
TRANSA (input)
          = 'N': the linear system involves A;
          = 'C': the linear system involves A**H.

          TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X. NRHS >= 0.
A (input/output)
          On entry, the M-by-N matrix A.  if M >=  N,  A  is
          overwritten  by details of its QR factorization as
          returned by CGEQRF; if M <  N, A is overwritten by
          details  of  its  LQ  factorization as returned by
          CGELQF.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

B (input/output)
          On entry, the matrix B of right hand side vectors,
          stored columnwise; B is M-by-NRHS if TRANSA = 'N',
          or N-by-NRHS if TRANSA  =  'C'.   On  exit,  B  is
          overwritten   by   the  solution  vectors,  stored
          columnwise:  if TRANSA = 'N' and m >= n, rows 1 to
          n of B contain the least squares solution vectors;
          the residual sum of squares for  the  solution  in
          each column is given by the sum of squares of ele-
          ments N+1 to M in that column; if TRANSA = 'N' and
          m  <  n, rows 1 to N of B contain the minimum norm
          solution vectors; if TRANSA = 'C' and m >= n, rows
          1 to M of B contain the minimum norm solution vec-
          tors; if TRANSA = 'C' and m < n, rows 1 to M of  B
          contain  the  least  squares solution vectors; the
          residual sum of squares for the solution  in  each
          column  is given by the sum of squares of elements
          M+1 to N in that column.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          MAX(1,M,N).
```

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (output)
The dimension of the array WORK. LDWORK >= max(1, MN + max(MN, NRHS)). For optimal performance, LDWORK >= max(1, MN + max(MN, NRHS)*NB). where MN = min(M,N) and NB is the optimum block size.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
    #include <sunperf.h>
    void zgelsd(int m, int n, int nrhs,  doublecomplex  *a,  int
              lda,  doublecomplex *b, int ldb, double *s, double
              rcond, int *rank, int *info);

    void zgelsd_64(long m, long n, long nrhs, doublecomplex  *a,
              long  lda,  doublecomplex *b, long ldb, double *s,
              double rcond, long *rank, long *info);
```

PURPOSE

```
    zgelsd computes the minimum-norm solution to a  real  linear
    least squares problem:
        minimize 2-norm(| b - A*x |)
    using the singular value decomposition (SVD) of A. A  is  an
    M-by-N matrix which may be rank-deficient.

    Several right hand side vectors b and solution vectors x can
    be  handled in a single call; they are stored as the columns
    of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
    solution matrix X.

    The problem is solved in three steps:
    (1) Reduce the coefficient matrix A to bidiagonal form with
        Householder tranformations, reducing the original  prob-
    lem
        into a "bidiagonal least squares problem" (BLS)
    (2) Solve the BLS using a divide and conquer approach.
    (3) Apply back all the Householder tranformations to solve
        the original least squares problem.

    The effective rank of A is determined by  treating  as  zero
    those  singular  values  which are less than RCOND times the
    largest singular value.
```

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)
The leading dimension of the array B. LDB >= max(1,M,N).

S (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND (input)
RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK (output)
The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. The exact minimum amount of workspace needed depends on M, N and NRHS. If M >= N, LWORK >= 2*N + N*NRHS. If M < N, LWORK >= 2*M + M*NRHS. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
If M >= N, LRWORK >= 8*N + 2*N*SMLSIZ + 8*N*NLVL + N*NRHS. If M < N, LRWORK >= 8*M + 2*M*SMLSIZ + 8*M*NLVL + M*NRHS. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1

IWORK (workspace)
LIWORK >= 3 * MINMN * NLVL + 11 * MINMN, where MINMN = MIN(M,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

#include <sunperf.h>

void zgelss(int m, int n, int nrhs,  doublecomplex  *a,  int
          lda, doublecomplex *b, int ldb, double *sing, dou-
          ble rcond, int *irank, int *info);
void zgelss_64(long m, long n, long nrhs, doublecomplex  *a,
          long  lda,  doublecomplex  *b,  long  ldb,  double
          *sing, double rcond, long *irank, long *info);
```

PURPOSE

zgelss computes the minimum norm solution to a complex linear least squares problem:

Minimize 2-norm(| b - A*x |).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)

On entry, the M-by-N matrix A. On exit, the first min(m,n) rows of A are overwritten with its right singular vectors, stored rowwise.

LDA (input)

The leading dimension of the array A. LDA >= max(1,M).

B (input/output)

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)

The leading dimension of the array B. LDB >= max(1,M,N).

SING (output)

The singular values of A in decreasing order. The condition number of A in the 2-norm = SING(1)/SING(min(m,n)).

RCOND (input)

RCOND is used to determine the effective rank of A. Singular values SING(i) <= RCOND*SING(1) are treated as zero. If RCOND < 0, machine precision is used instead.

IRANK (output)

The effective rank of A, i.e., the number of singular values which are greater than RCOND*SING(1).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK >= 1, and also: LDWORK >= 2*min(M,N) + max(M,N,NRHS) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(5*min(M,N))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

```

C INTERFACE

```
#include <sunperf.h>
void zgelsx(int m, int n, int nrhs,  doublecomplex  *a,  int
          lda,  doublecomplex *b, int ldb, int *jpivot, dou-
          ble rcond, int *irank, int *info);

void zgelsx_64(long m, long n, long nrhs, doublecomplex  *a,
          long   lda,   doublecomplex  *b,  long  ldb,  long
          *jpivot, double rcond, long *irank, long *info);
```

PURPOSE

zgelsx routine is deprecated and has been replaced by routine CGELSY.

CGELSX computes the minimum-norm solution to a complex linear least squares problem:

```
    minimize || A * X - B ||
```

using a complete orthogonal factorization of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The routine first computes a QR factorization with column pivoting:

```
    A * P = Q * [ R11 R12 ]
                [  0  R22 ]
```

with R11 defined as the largest leading submatrix whose estimated condition number is less than 1/RCOND. The order of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihilated by unitary transformations from the right, arriving at the complete orthogonal factorization:

```
   A * P = Q * [ T11 0 ] * Z
               [  0  0 ]
The minimum-norm solution is then
   X = P * Z' [ inv(T11)*Q1'*B ]
              [        0       ]
where Q1 consists of the first RANK columns of Q.
```

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X. If m >= n and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements N+1:M in that column.

LDB (input)
The leading dimension of the array B. LDB >= max(1,M,N).

JPIVOT (input/output)
On entry, if JPIVOT(i) .ne. 0, the i-th column of A is an initial column, otherwise it is a free column. Before the QR factorization of A, all initial columns are permuted to the leading positions; only the remaining free columns are moved as a result of column pivoting during the factorization. On exit, if JPIVOT(i) = k, then the i-th column of A*P was the k-th column of A.

RCOND (input)

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

IRANK (output)
The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)
(min(M,N) + max(N, 2*min(M,N)+NRHS)),

WORK2 (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>
void zgelsy(int m, int n, int nrhs,  doublecomplex  *a,  int
          lda,  doublecomplex *b, int ldb, int *jpvt, double
          rcond, int *rank, int *info);

void zgelsy_64(long m, long n, long nrhs, doublecomplex  *a,
          long  lda, doublecomplex *b, long ldb, long *jpvt,
          double rcond, long *rank, long *info);
```

PURPOSE

```
zgelsy computes  the  minimum-norm  solution  to  a  complex
linear least squares problem:
    minimize || A * X - B ||
using a complete orthogonal factorization of A.  A is an  M-
by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can
be  handled in a single call; they are stored as the columns
of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
solution matrix X.

The routine first computes a QR  factorization  with  column
pivoting:
    A * P = Q * [ R11 R12 ]
                [  0  R22 ]
with R11 defined as  the  largest  leading  submatrix  whose
estimated  condition number is less than 1/RCOND.  The order
of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihi-
lated by unitary transformations from the right, arriving at
the complete orthogonal factorization:
   A * P = Q * [ T11 0 ] * Z
               [  0  0 ]
```

```
The minimum-norm solution is then
   X = P * Z' [ inv(T11)*Q1'*B ]
              [        0       ]
where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the  original  xGELSX
except three differences:
  o The permutation of matrix B (the  right  hand  side)  is
faster and
    more simple.
  o The call to the subroutine xGEQPF has  been  substituted
by the
    the call to the subroutine xGEQP3. This subroutine is  a
Blas-3
    version of the QR factorization with column pivoting.
  o Matrix B (the right hand side) is updated with Blas-3.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of matrices B and X. NRHS >= 0.

A (input/output)
          On entry, the M-by-N matrix A.   On  exit,  A  has
          been   overwritten  by  details  of  its  complete
          orthogonal factorization.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

B (input/output)
          On entry, the M-by-NRHS right hand side matrix  B.
          On exit, the N-by-NRHS solution matrix X.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,M,N).

JPVT (input/output)
          On entry, if JPVT(i) .ne. 0, the i-th column of  A
          is permuted to the front of AP, otherwise column i
          is a free column.  On exit, if JPVT(i) =  k,  then
```

the i-th column of A*P was the k-th column of A.

RCOND (input)
RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

RANK (output)
The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. The unblocked strategy requires that: LWORK >= MN + MAX(2*MN, N+1, MN+NRHS) where MN = min(M,N). The block algorithm requires that: LWORK >= MN + MAX(2*MN, NB*(N+1), MN+MN*NB, MN+NB*NRHS) where NB is an upper bound on the blocksize returned by ILAENV for the routines CGEQP3, CTZRZF, CTZRQF, CUNMQR, and CUNMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

zgemm - perform one of the matrix-matrix operations C := alpha*op(A)*op(B) + beta*C

SYNOPSIS

```
SUBROUTINE ZGEMM(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
      BETA, C, LDC)

CHARACTER * 1 TRANSA, TRANSB
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER M, N, K, LDA, LDB, LDC

SUBROUTINE ZGEMM_64(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
      BETA, C, LDC)

CHARACTER * 1 TRANSA, TRANSB
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 M, N, K, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE GEMM([TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],
       B, [LDB], BETA, C, [LDC])

CHARACTER(LEN=1) :: TRANSA, TRANSB
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,:) :: A, B, C
INTEGER :: M, N, K, LDA, LDB, LDC

SUBROUTINE GEMM_64([TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],
       B, [LDB], BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: TRANSA, TRANSB
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,:) :: A, B, C
INTEGER(8) :: M, N, K, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>

void zgemm(char transa, char transb, int m, int  n,  int  k,
          doublecomplex  *alpha,  doublecomplex *a, int lda,
          doublecomplex *b, int  ldb,  doublecomplex  *beta,
          doublecomplex *c, int ldc);
void zgemm_64(char transa, char transb, long m, long n, long
          k,  doublecomplex  *alpha,  doublecomplex *a, long
          lda, doublecomplex  *b,  long  ldb,  doublecomplex
          *beta, doublecomplex *c, long ldc);
```

PURPOSE

zgemm performs one of the matrix-matrix operations

C := alpha*op(A)*op(B) + beta*C

where op(X) is one of

op(X) = X   or   op(X) = X'   or   op(X) = conjg(X'), alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', op(A) = A.

TRANSA = 'T' or 't', op(A) = A'.

TRANSA = 'C' or 'c', op(A) = conjg(A').

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

TRANSB (input)

On entry, TRANSB specifies the form of op(B) to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', op(B) = B.

TRANSB = 'T' or 't', op(B) = B'.

TRANSB = 'C' or 'c', op(B) = conjg(B').

Unchanged on exit.

TRANSB is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix op(A) and of the matrix C. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. N >= 0. Unchanged on exit.

K (input)

On entry, K specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). K >= 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka), where ka is K when TRANSA = 'N' or 'n', and is M otherwise. Before entry with TRANSA = 'N' or 'n', the leading M by K part of the array A must contain the matrix A, otherwise the leading K by M part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA >= max(1, M), otherwise LDA >= max(1, K). Unchanged on exit.

B (input)

COMPLEX*16 array of DIMENSION (LDB, kb), where kb is n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then LDB >= max(1, k), otherwise LDB >= max(1, n). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta*C).

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC >= max(1, m). Unchanged on exit.

NAME

zgemv - perform one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y

SYNOPSIS

```
SUBROUTINE ZGEMV(TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y, INCY)

CHARACTER * 1 TRANSA
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)
INTEGER M, N, LDA, INCX, INCY

SUBROUTINE ZGEMV_64(TRANSA, M, N, ALPHA, A, LDA, X, INCX, BETA, Y,
      INCY)

CHARACTER * 1 TRANSA
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), X(*), Y(*)
INTEGER*8 M, N, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE GEMV([TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX], BETA,
       Y, [INCY])

CHARACTER(LEN=1) :: TRANSA
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, INCX, INCY

SUBROUTINE GEMV_64([TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
```

```
          BETA, Y, [INCY])

   CHARACTER(LEN=1) :: TRANSA
   COMPLEX(8) :: ALPHA, BETA
   COMPLEX(8), DIMENSION(:) :: X, Y
   COMPLEX(8), DIMENSION(:,:) :: A
   INTEGER(8) :: M, N, LDA, INCX, INCY
```

C INTERFACE

```
   #include <sunperf.h>

   void zgemv(char transa, int m, int n, doublecomplex  *alpha,
             doublecomplex  *a,  int lda, doublecomplex *x, int
             incx, doublecomplex *beta, doublecomplex  *y,  int
             incy);
   void zgemv_64(char transa, long  m,  long  n,  doublecomplex
             *alpha,  doublecomplex *a, long lda, doublecomplex
             *x, long incx, doublecomplex *beta,  doublecomplex
             *y, long incy);
```

PURPOSE

zgemv performs one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   y := alpha*A*x + beta*y.

TRANSA = 'T' or 't'   y := alpha*A'*x + beta*y.

TRANSA = 'C' or 'c'   y := alpha*conjg(A')*x + beta*y.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)

On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (m - 1)*abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

INTEGER M, N, LDA, LDWORK, INFO

SUBROUTINE ZGEQLF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GEQLF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, LDWORK, INFO

SUBROUTINE GEQLF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeqlf(int m, int n, doublecomplex *a, int  lda,  doub-
          lecomplex *tau, int *info);

void zgeqlf_64(long m, long n, doublecomplex *a,  long  lda,
          doublecomplex *tau, long *info);
```

PURPOSE

zgeqlf computes a QL factorization of a complex M-by-N matrix A: A = Q * L.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N). For optimum performance LDWORK >= N*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(k) . . . H(2) H(1), where k = min(m,n).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a complex scalar, and v is a complex vector with v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in A(1:m-k+i-1,n-k+i), and tau in TAU(i).

    INTEGER(8), DIMENSION(:) :: JPVT
    REAL(8), DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>

void zgeqp3(int m, int n, doublecomplex  *a,  int  lda,  int
          *jpvt, doublecomplex *tau, int *info);

void zgeqp3_64(long m, long n, doublecomplex *a,  long  lda,
          long *jpvt, doublecomplex *tau, long *info);
```

PURPOSE

zgeqp3 computes a QR factorization with column pivoting of a matrix A: A*P = Q*R using Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M,N)-by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of min(M,N) elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

JPVT (input/output)
On entry, if JPVT(J).ne.0, the J-th column of A is permuted to the front of A*P (a leading column); if JPVT(J)=0, the J-th column of A is a free column. On exit, if JPVT(J)=K, then the J-th column of A*P was the the K-th column of A.

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= N+1. For optimal performance LWORK >= (N+1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(1) H(2) . . . H(k), where k = min(m,n).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real/complex scalar, and v is a real/complex vector with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i), and tau in TAU(i).

void zgeqpf_64(long m, long n, doublecomplex *a,  long  lda,
          long *jpivot, doublecomplex *tau, long *info);
```

PURPOSE

zgeqpf routine is deprecated and has been replaced by routine CGEQP3.

CGEQPF computes a QR factorization with column pivoting of a complex M-by-N matrix A: A*P = Q*R.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M,N)-by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

JPIVOT (input/output)
On entry, if JPIVOT(i) .ne. 0, the i-th column of A is permuted to the front of A*P (a leading column); if JPIVOT(i) = 0, the i-th column of A is a free column. On exit, if JPIVOT(i) = k, then

```
          the i-th column of A*P was the k-th column of A.

TAU (output)
          The scalar factors of the elementary reflectors.

WORK (workspace)
          dimension(N)

WORK2 (workspace)
          dimension(2*N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO =  -i,  the  i-th  argument  had  an
          illegal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(n)

Each H(i) has the form

   H = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(1:i-1)  = 0 and v(i) = 1; v(i+1:m) is stored on exit
in A(i+1:m,i).

The matrix P is represented in jpvt as follows: If
   jpvt(j) = i
then the jth column of P is the ith canonical unit vector.

SUBROUTINE GEQRF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgeqrf(int m, int n, doublecomplex *a, int  lda,  doub-
          lecomplex *tau, int *info);

void zgeqrf_64(long m, long n, doublecomplex *a,  long  lda,
          doublecomplex *tau, long *info);
```

PURPOSE

zgeqrf computes a QR factorization of a complex M-by-N matrix A: A = Q * R.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.
N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M,N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N). For optimum performance LDWORK >= N*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form
   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(1:i-1)  = 0 and v(i) = 1; v(i+1:m) is stored on exit
in A(i+1:m,i), and tau in TAU(i).
```

```
zgerc - perform the rank 1 operation   A  :=  alpha*x*conjg(
y' ) + A
```

SYNOPSIS

```
SUBROUTINE ZGERC(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)

DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)
INTEGER M, N, INCX, INCY, LDA

SUBROUTINE ZGERC_64(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)

DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)
INTEGER*8 M, N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE GERC([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: M, N, INCX, INCY, LDA

SUBROUTINE GERC_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>

void zgerc(int m, int n, doublecomplex *alpha, doublecomplex
          *x,  int  incx,  doublecomplex *y, int incy, doub-
          lecomplex *a, int lda);

void zgerc_64(long m, long n,  doublecomplex  *alpha,  doub-
          lecomplex  *x,  long  incx, doublecomplex *y, long
          incy, doublecomplex *a, long lda);
```

PURPOSE

zgerc performs the rank 1 operation A := alpha*x*conjg(y') + A where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

          *x,  long  ldx,  double  *ferr, double *berr, long
          *info);
```

PURPOSE

zgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
```

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The original N-by-N matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CGETRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

```
WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgerqf(int m, int n, doublecomplex *a, int  lda,  doub-
          lecomplex *tau, int *info);

void zgerqf_64(long m, long n, doublecomplex *a,  long  lda,
          doublecomplex *tau, long *info);
```

PURPOSE

zgerqf computes an RQ factorization of a complex M-by-N matrix A: A = R * Q.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK.   LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(1)' H(2)' . . . H(k)', where k = min(m,n).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a complex scalar, and v is a complex vector with v(n-k+i+1:n) = 0 and v(n-k+i) = 1; conjg(v(1:n-k+i-1)) is stored on exit in A(m-k+i,1:n-k+i-1), and tau in TAU(i).

INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>

void zgeru(int m, int n, doublecomplex *alpha, doublecomplex
          *x,  int  incx,  doublecomplex *y, int incy, doub-
          lecomplex *a, int lda);

void zgeru_64(long m, long n,  doublecomplex  *alpha,  doub-
          lecomplex  *x,  long  incx, doublecomplex *y, long
          incy, doublecomplex *a, long lda);
```

PURPOSE

zgeru performs the rank 1 operation A := alpha*x*y' + A where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the

elements of Y. INCY must not be zero. Unchanged on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

```
#include <sunperf.h>

void zgesdd(char jobz, int m, int n, doublecomplex  *a,  int
          lda,  double  *s, doublecomplex *u, int ldu, doub-
          lecomplex *vt, int ldvt, int *info);

void zgesdd_64(char jobz, long m, long n, doublecomplex  *a,
          long  lda,  double *s, doublecomplex *u, long ldu,
          doublecomplex *vt, long ldvt, long *info);
```

PURPOSE

zgesdd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method. The SVD is written
 = U * SIGMA * conjugate-transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V**H, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
Specifies options for computing all or part of the matrix U:
= 'A': all M columns of U and all N rows of V**H are returned in the arrays U and VT; = 'S': the first min(M,N) columns of U and the first min(M,N) rows of V**H are returned in the arrays U and VT; = 'O': If M >= N, the first N columns of U are overwritten on the array A and all rows of V**H are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V**H are overwritten in the array VT; = 'N': no columns of U or rows of V**H are computed.

M (input) The number of rows of the input matrix A. M >= 0.

N (input) The number of columns of the input matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if M >= N; A is overwritten with the first M rows of V**H (the right singular vectors, stored row-wise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

S (output)
The singular values of A, sorted so that S(i) >= S(i+1).

U (output)
UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N; UCOL = min(M,N) if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M unitary matrix U; if JOBZ = 'S', U contains the first min(M,N) columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and M >= N, or

```
          JOBZ = 'N', U is not referenced.

LDU (input)
          The leading dimension of the array U.  LDU  >=  1;
          if  JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU
          >= M.

VT (output)
          If JOBZ = 'A' or JOBZ = 'O' and M >=  N,  VT  con-
          tains  the  N-by-N  unitary matrix V**H; if JOBZ =
          'S', VT contains the first min(M,N) rows  of  V**H
          (the  right  singular vectors, stored rowwise); if
          JOBZ = 'O' and M < N, or JOBZ =  'N',  VT  is  not
          referenced.

LDVT (input)
          The leading dimension of the array VT.  LDVT >= 1;
          if JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N;
          if JOBZ = 'S', LDVT >= min(M,N).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK. LWORK >=  1.   if
          JOBZ = 'N', LWORK >= 2*min(M,N)+max(M,N).  if JOBZ
          =            'O',              LWORK             >=
          2*min(M,N)*min(M,N)+2*min(M,N)+max(M,N).   if JOBZ
          =      'S'      or       'A',       LWORK       >=
          min(M,N)*min(M,N)+2*min(M,N)+max(M,N).   For  good
          performance, LWORK should generally be larger.  If
          LWORK  <  0  but  other input arguments are legal,
          WORK(1) returns optimal LWORK.

RWORK (workspace)
          If JOBZ = 'N', LRWORK >=  7*min(M,N).   Otherwise,
          LRWORK >= 5*min(M,N)*min(M,N) + 5*min(M,N)

IWORK (workspace)
          dimension(8*MIN(M,N))

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  The updating process of SBDSDC did not  con-
          verge.

          *ipivot, doublecomplex *b, int ldb, int *info);

void zgesv_64(long n, long nrhs, doublecomplex *a, long lda,
          long  *ipivot,  doublecomplex  *b,  long ldb, long
          *info);
```

PURPOSE

```
zgesv computes the solution to a complex  system  of  linear
equations
   A * X = B, where A is an N-by-N matrix and X  and  B  are
N-by-NRHS matrices.
The LU decomposition with partial pivoting  and  row  inter-
changes is used to factor A as
   A = P * L * U,
where P is a permutation matrix, L is unit lower triangular,
and  U  is upper triangular.  The factored form of A is then
used to solve the system of equations A * X = B.
```

ARGUMENTS

```
N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the N-by-N  coefficient  matrix  A.   On
          exit, the factors L and U from the factorization A
          = P*L*U; the unit diagonal elements of L  are  not
          stored.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

IPIVOT (output)
          The pivot  indices  that  define  the  permutation
          matrix  P;  row  i  of the matrix was interchanged
          with row IPIVOT(i).

B (input/output)
          On entry, the N-by-NRHS matrix of right hand  side
```

matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

void zgesvd_64(char jobu, char jobvt, long m, long n,  doub-
          lecomplex  *a,  long lda, double *sing, doublecom-
          plex *u, long ldu, doublecomplex *vt,  long  ldvt,
          long *info);
```

PURPOSE

zgesvd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written

= U * SIGMA * conjugate-transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**H, not V.

ARGUMENTS

JOBU (input)
Specifies options for computing all or part of the matrix U:
= 'A': all M columns of U are returned in array U:
= 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of U (the left

singular vectors) are overwritten on the array A;
= 'N': no columns of U (no left singular vectors) are computed.

JOBVT (input)
Specifies options for computing all or part of the matrix V**H:
= 'A': all N rows of V**H are returned in the array VT;
= 'S': the first min(m,n) rows of V**H (the right singular vectors) are returned in the array VT; = 'O': the first min(m,n) rows of V**H (the right singular vectors) are overwritten on the array A;
= 'N': no rows of V**H (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M (input) The number of rows of the input matrix A. M >= 0.

N (input) The number of columns of the input matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if JOBU = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V**H (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

SING (output)
The singular values of A, sorted so that SING(i) >= SING(i+1).

U (input) (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M unitary matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= 1; if JOBU = 'S' or 'A', LDU >= M.

VT (input)
If JOBVT = 'A', VT contains the N-by-N unitary matrix V**H; if JOBVT = 'S', VT contains the first min(m,n) rows of V**H (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT (input)
The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= 1. LDWORK >= 2*MIN(M,N)+MAX(M,N) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
DIMENSION(5*MIN(M,N)). On exit, if INFO > 0, WORK2(1:MIN(M,N)-1) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies A = U * B * VT, so it has the same singular values as A, and singular vectors related by U and VT.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if CBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of WORK2 above for details.

```

PURPOSE

zgesvx uses the LU factorization to compute the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:
      TRANS = 'N': diag(R)*A*diag(C)   *inv(diag(C))*X = diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X = diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X = diag(C)*B
   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').
2. If FACT = 'N' or 'E', the LU decomposition is used to factor the
   matrix A (after equilibration if FACT = 'E') as
      A = P * L * U,
   where P is a permutation matrix, L is a unit lower tri- angular
   matrix, and U is upper triangular.

3. If some U(i,i)=0, so that U is exactly singular, then the routine
   returns with INFO = i. Otherwise, the factored form of A is used
   to estimate the condition number of the matrix A. If the
   reciprocal of the condition number is less than machine precision,
   INFO = N+1 is returned as a warning, but the routine still goes on
   to solve for X and compute error bounds as described below.

4. The system of equations is solved for X using the fac- tored form
   of A.

5. Iterative refinement is applied to improve the computed solution
   matrix and calculate error bounds and backward error estimates
   for it.

6. If equilibration was used, the matrix X is premultiplied by

```
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS  =  'T'  or
'C') so
   that it solves the original system before equilibration.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored form of  the
          matrix A is supplied on entry, and if not, whether
          the matrix A should be equilibrated before  it  is
          factored.  = 'F':  On entry, AF and IPIVOT contain
          the factored form of A.  If EQUED is not 'N',  the
          matrix  A  has been equilibrated with scaling fac-
          tors given by R and C.  A, AF, and IPIVOT are  not
          modified.   = 'N':  The matrix A will be copied to
          AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the N-by-N matrix A.  If FACT = 'F'  and
          EQUED  is  not  'N', then A must have been equili-
          brated by the scaling factors in R and/or C.  A is
          not  modified  if  FACT = 'F' or 'N', or if FACT =
          'E' and EQUED = 'N' on exit.

          On exit, if EQUED .ne. 'N', A is  scaled  as  fol-
          lows:  EQUED = 'R':  A := diag(R) * A
          EQUED = 'C':  A := A * diag(C)
          EQUED = 'B':  A := diag(R) * A * diag(C).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

AF (input/output)
          If FACT = 'F', then AF is an input argument and on
```

entry contains the factors L and U from the factorization A = P*L*U as computed by CGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by CGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED (input/output)

Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input/output)

The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input/output)
The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))*X if TRANSA = 'N' and EQUED = 'C' or 'B', or inv(diag(R))*X if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest ele-

ment in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(2*N) On exit, WORK2(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

SUBROUTINE GETF2([M], [N], A, [LDA], IPIV, [INFO])

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV

SUBROUTINE GETF2_64([M], [N], A, [LDA], IPIV, [INFO])

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgetf2(int m, int n, doublecomplex  *a,  int  lda,  int
          *ipiv, int *info);

void zgetf2_64(long m, long n, doublecomplex *a,  long  lda,
          long *ipiv, long *info);
```

PURPOSE

zgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form
   A = P * L * U
where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

IPIV (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is

exactly singular, and division by zero will occur if it is used to solve a system of equations.

SUBROUTINE GETRF_64([M], [N], A, [LDA], IPIVOT, [INFO])

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zgetrf(int m, int n, doublecomplex  *a,  int  lda,  int
          *ipivot, int *info);

void zgetrf_64(long m, long n, doublecomplex *a,  long  lda,
          long *ipivot, long *info);
```

PURPOSE

zgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form
   A = P * L * U
where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

IPIVOT (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U

is exactly singular, and division by zero will occur if it is used to solve a system of equations.

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE GETRI_64([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void zgetri(int n, doublecomplex *a, int lda,  int  *ipivot,
          int *info);

void zgetri_64(long n,  doublecomplex  *a,  long  lda,  long
          *ipivot, long *info);
```

PURPOSE

zgetri computes the inverse of a matrix using the LU factorization computed by CGETRF.

This method inverts U and then computes inv(A) by solving the system inv(A)*L = inv(U) for inv(A).

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the factors L and U from the factorization A = P*L*U as computed by CGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

WORK (workspace)
On exit, if INFO=0, then WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N). For optimal performance LDWORK >= N*NB, where NB is the optimal blocksize returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

          *a, long lda, long *ipivot, doublecomplex *b, long
          ldb, long *info);
```

PURPOSE

zgetrs solves a system of linear equations
   A * X = B, A**T * X = B, or A**H * X = B with a general N-by-N matrix A using the LU factorization computed by CGETRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B   (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

IPIVOT (input)

The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>

void zggbak(char job, char side, int n, int  ilo,  int  ihi,
          double  *lscale, double *rscale, int m, doublecom-
          plex *v, int ldv, int *info);
void zggbak_64(char job, char side, long n, long  ilo,  long
          ihi, double *lscale, double *rscale, long m, doub-
          lecomplex *v, long ldv, long *info);
```

PURPOSE

zggbak forms the right or left eigenvectors of a complex generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL.

ARGUMENTS

JOB (input)
Specifies the type of backward transformation required:
= 'N': do nothing, return immediately;
= 'P': do backward transformation for permutation only;
= 'S': do backward transformation for scaling only;
= 'B': do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to CGGBAL.

SIDE (input)
= 'R': V contains right eigenvectors;
= 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. N >= 0.

ILO (input)

The integers ILO and IHI determined by CGGBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
The integers ILO and IHI determined by CGGBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

LSCALE (input)
Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by CGGBAL.

RSCALE (input)
Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by CGGBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)
On entry, the matrix of right or left eigenvectors to be transformed, as returned by CTGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)
The leading dimension of the matrix V. LDV >= max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

          double *lscale, double *rscale, long *info);
```

PURPOSE

zggbal balances a pair of general complex matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem A*x = lambda*B*x.

ARGUMENTS

JOB (input)
Specifies the operations to be performed on A and B:
= 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i=1,...,N;
= 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N',

A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

ILO (output)
ILO and IHI are set to integers such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
ILO and IHI are set to integers such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N.

LSCALE (input)
Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then LSCALE(j) = P(j) for J = 1,...,ILO-1 = D(j) for J = ILO,...,IHI = P(j) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (input)
Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then RSCALE(j) = P(j) for J = 1,...,ILO-1 = D(j) for J = ILO,...,IHI = P(j) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK (workspace)
dimension(6*N)

INFO (output)

```
              = 0:  successful exit
              < 0:  if INFO = -i, the i-th argument had an ille-
              gal value.

          lecomplex *beta, doublecomplex *vsl,  long  ldvsl,
          doublecomplex *vsr, long ldvsr, long *info);
```

PURPOSE

zgges computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
        (A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )
```

where (VSR)**H is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver CGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see DELZTG).

DELZTG (input)
DELZTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELZTG is not referenced. If SORT = 'S', DELZTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if DELZTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy DELZTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELZTG is true.

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) output by CGGES. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
See description of ALPHA.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur

```
            vectors.  Not referenced if JOBVSL = 'N'.

LDVSL (input)
            The leading dimension of the matrix VSL. LDVSL  >=
            1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
            If JOBVSR = 'V', VSR will contain the right  Schur
            vectors.  Not referenced if JOBVSR = 'N'.

LDVSR (input)
            The leading dimension of the matrix VSR. LDVSR  >=
            1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)
            On exit, if INFO = 0, WORK(1) returns the  optimal
            LWORK.

LWORK (input)
            The  dimension  of  the  array  WORK.   LWORK   >=
            max(1,2*N).  For good performance, LWORK must gen-
            erally be larger.

            If LWORK = -1, then a workspace query is  assumed;
            the  routine  only  calculates the optimal size of
            the WORK array, returns this value  as  the  first
            entry  of  the  WORK  array,  and no error message
            related to LWORK is issued by XERBLA.

RWORK (workspace)
            dimension(8*N)

BWORK (workspace)
            dimension(N) Not referenced if SORT = 'N'.

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value.
            =1,...,N:  The QZ iteration failed.  (A,B) are not
            in  Schur form, but ALPHA(j) and BETA(j) should be
            correct for j=INFO+1,...,N.   >  N:   =N+1:  other
            than QZ iteration failed in CHGEQZ
            =N+2: after reordering, roundoff changed values of
            some  complex  eigenvalues  so that leading eigen-
            values in the Generalized  Schur  form  no  longer
            satisfy  DELZTG=.TRUE.   This could also be caused
            due  to  scaling.   =N+3:  reordering  falied   in
            CTGSEN.

```

PURPOSE

zggesx computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization A,B) = ((VSL) S (VSR)**H, (VSL) T (VSR)**H)

where (VSR)**H is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if T is upper triangular with non-negative diagonal and S is upper triangular.

ARGUMENTS

JOBVSL (input)
  = 'N': do not compute the left Schur vectors;
  = 'V': compute the left Schur vectors.

JOBVSR (input)
  = 'N': do not compute the right Schur vectors;
  = 'V': compute the right Schur vectors.

SORT (input)
  Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
  = 'S': Eigenvalues are ordered (see DELCTG).

DELCTG (input)
DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. Note that a selected complex eigenvalue may no longer satisfy DELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3 see INFO below).

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N' : None are computed;
= 'E' : Computed for average of selected eigenvalues only;
= 'V' : Computed for selected deflating subspaces only;
= 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true.

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j) and

BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T). BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)

See description of ALPHA.

VSL (input)

If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)

If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE (output)

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV (output)

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition number for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= 2*N. If SENSE = 'E', 'V', or 'B', LWORK >= MAX(2*N, 2*SDIM*(N-SDIM)).

RWORK (workspace)
dimension(8*N) Real workspace.

IWORK (workspace/output)
Not referenced if SENSE = 'N'. On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array WORK. LIWORK >= N+2.

BWORK (workspace)
dimension(N) Not referenced if SORT = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ
=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy DELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in CTGSEN.

PURPOSE

zggev computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right generalized eigenvector v(j) corresponding to the generalized eigenvalue lambda(j) of (A,B) satisfies

A * v(j) = lambda(j) * B * v(j).

The left generalized eigenvector u(j) corresponding to the generalized eigenvalues lambda(j) of (A,B) satisfies

u(j)**H * A = lambda(j) * u(j)**H * B

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

```
     JOBVL (input)
               = 'N':  do not compute the left generalized eigen-
               vectors;
               = 'V':  compute the left generalized eigenvectors.

     JOBVR (input)
               = 'N':   do  not  compute  the  right  generalized
               eigenvectors;
               = 'V':  compute the  right  generalized  eigenvec-
               tors.

     N (input) The order of the matrices A, B, VL, and VR.  N  >=
               0.

     A (input/output)
               On entry, the matrix A  in  the  pair  (A,B).   On
               exit, A has been overwritten.

     LDA (input)
               The leading dimension of A.  LDA >= max(1,N).

     B (input/output)
               On entry, the matrix B  in  the  pair  (A,B).   On
               exit, B has been overwritten.

     LDB (input)
               The leading dimension of B.  LDB >= max(1,N).

     ALPHA (output)
               On exit, ALPHA(j)/BETA(j), j=1,...,N, will be  the
               generalized eigenvalues.

               Note: the quotients  ALPHA(j)/BETA(j)  may  easily
               over-  or underflow, and BETA(j) may even be zero.
               Thus, the user should avoid naively computing  the
               ratio  alpha/beta.   However, ALPHA will be always
               less than and usually comparable with  norm(A)  in
               magnitude,  and  BETA always less than and usually
               comparable with norm(B).

     BETA (output)
               See description of ALPHA.

     VL (output)
               If JOBVL = 'V', the left generalized  eigenvectors
               u(j)  are  stored one after another in the columns
               of VL, in the same  order  as  their  eigenvalues.
```

```
          Each  eigenvector  will  be  scaled so the largest
          component will have  abs(real  part)  +  abs(imag.
          part) = 1.  Not referenced if JOBVL = 'N'.

LDVL (input)
          The leading dimension of the matrix VL. LDVL >= 1,
          and if JOBVL = 'V', LDVL >= N.
VR (output)
          If JOBVR = 'V', the right generalized eigenvectors
          v(j)  are  stored one after another in the columns
          of VR, in the same  order  as  their  eigenvalues.
          Each  eigenvector  will  be  scaled so the largest
          component will have  abs(real  part)  +  abs(imag.
          part) = 1.  Not referenced if JOBVR = 'N'.

LDVR (input)
          The leading dimension of the matrix VR. LDVR >= 1,
          and if JOBVR = 'V', LDVR >= N.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  dimension  of  the  array  WORK.   LWORK   >=
          max(1,2*N).  For good performance, LWORK must gen-
          erally be larger.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

RWORK (workspace)
          dimension(8*N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          =1,...,N:  The QZ iteration failed.  No  eigenvec-
          tors   have  been  calculated,  but  ALPHA(j)  and
          BETA(j) should be correct for  j=INFO+1,...,N.   >
          N:   =N+1:  other  then  QZ  iteration  failed  in
          SHGEQZ,
          =N+2: error return from STGEVC.

```

PURPOSE

```
zggevx computes for a pair of  N-by-N  complex  nonsymmetric
matrices  (A,B) the generalized eigenvalues, and optionally,
the left and/or right generalized eigenvectors.

Optionally, it also computes a balancing  transformation  to
improve the conditioning of the eigenvalues and eigenvectors
(ILO, IHI, LSCALE, RSCALE,  ABNRM,  and  BBNRM),  reciprocal
condition numbers for the eigenvalues (RCONDE), and recipro-
cal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B)  is  a
scalar  lambda or a ratio alpha/beta = lambda, such that A -
lambda*B is singular. It is usually represented as the  pair
(alpha,beta),  as  there  is a reasonable interpretation for
beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to  the  eigenvalue
lambda(j) of (A,B) satisfies
                 A * v(j) = lambda(j) * B * v(j) .
The left eigenvector u(j) corresponding  to  the  eigenvalue
lambda(j) of (A,B) satisfies
                 u(j)**H * A  = lambda(j) * u(j)**H * B.
where u(j)**H is the conjugate-transpose of u(j).
```

ARGUMENTS

```
BALANC (input)
          Specifies the balance option to be performed:
          = 'N':  do not diagonally scale or permute;
          = 'P':  permute only;
          = 'S':  scale only;
          = 'B':  both permute and scale.  Computed recipro-
          cal  condition  numbers  will  be for the matrices
          after permuting and/or balancing.  Permuting  does
          not  change  condition  numbers  (in  exact arith-
          metic), but balancing does.

JOBVL (input)
          = 'N':  do not compute the left generalized eigen-
          vectors;
          = 'V':  compute the left generalized eigenvectors.
```

```
JOBVR (input)
          = 'N':   do  not  compute  the  right  generalized
          eigenvectors;
          = 'V':  compute the  right  generalized  eigenvec-
          tors.

SENSE (input)
          Determines which reciprocal condition numbers  are
          computed.  = 'N': none are computed;
          = 'E': computed for eigenvalues only;
          = 'V': computed for eigenvectors only;
          = 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR.  N  >=
          0.
A (input/output)
          On entry, the matrix A  in  the  pair  (A,B).   On
          exit,  A  has  been  overwritten.  If JOBVL='V' or
          JOBVR='V' or both, then A contains the first  part
          of  the  complex Schur form of the "balanced" ver-
          sions of the input A and B.

LDA (input)
          The leading dimension of A.  LDA >= max(1,N).

B (input/output)
          On entry, the matrix B  in  the  pair  (A,B).   On
          exit,  B  has  been  overwritten.  If JOBVL='V' or
          JOBVR='V' or both, then B contains the second part
          of  the  complex Schur form of the "balanced" ver-
          sions of the input A and B.

LDB (input)
          The leading dimension of B.  LDB >= max(1,N).

ALPHA (output)
          On exit, ALPHA(j)/BETA(j), j=1,...,N, will be  the
          generalized eigenvalues.

          Note: the quotient ALPHA(j)/BETA(j) )  may  easily
          over-  or underflow, and BETA(j) may even be zero.
          Thus, the user should avoid naively computing  the
          ratio  ALPHA/BETA.   However, ALPHA will be always
          less than and usually comparable with  norm(A)  in
          magnitude,  and  BETA always less than and usually
          comparable with norm(B).

BETA (output)
          See description of ALPHA.
```

VL (output)
If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL (input)
The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (output)
If JOBVR = 'V', the right generalized eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR (input)
The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO (output)
ILO is an integer value such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
IHI is an integer value such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

LSCALE (output)
Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1 = DL(j) for j = ILO,...,IHI = PL(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (output)
Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column

j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1 = DR(j) for j = ILO,...,IHI = PR(j) for j = IHI+1,...,N The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)
The one-norm of the balanced matrix A.

BBNRM (output)
The one-norm of the balanced matrix B.

RCONDE (output)
If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If SENSE = 'V', RCONDE is not referenced.

RCONDV (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced. Not referenced if JOB = 'E'.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,2*N). If SENSE = 'N' or 'E', LWORK >= 2*N. If SENSE = 'V' or 'B', LWORK >= 2*N*N+2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(6*N) Real workspace.

IWORK (workspace)
dimension(N+2) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)
dimension(N) If SENSE = 'N', BWORK is not refer-

enced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ.
=N+2: error return from CTGEVC.

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue lambda is
hord(w, lambda) <= EPS * norm(ABNRM, BBNRM) / RCONDE(I)

An approximate error bound for the angle between the i-th computed eigenvector VL(i) or VR(i) is given by
PS * norm(ABNRM, BBNRM) / DIF(i).

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see section 4.11 of LAPACK User's Guide.

          plex *d, doublecomplex *x, doublecomplex *y,  long
          *info);
```

PURPOSE

zggglm solves a general Gauss-Markov linear model (GLM) problem:

```
        minimize || y ||_2   subject to   d = A*x + B*y
            x
```

where A is an N-by-M matrix, B is an N-by-P matrix, and d is a given N-vector. It is assumed that M <= N <= M+P, and

```
           rank(A) = M    and    rank( A B ) = N.
```

Under these assumptions, the constrained equation is always consistent, and there is a unique solution x and a minimal 2-norm solution y, which is obtained using a generalized QR factorization of A and B.

In particular, if matrix B is square nonsingular, then the problem GLM is equivalent to the following weighted linear least squares problem

```
             minimize || inv(B)*(d-A*x) ||_2
                 x
```

where inv(B) denotes the inverse of B.

ARGUMENTS

N (input) The number of rows of the matrices A and B. N >= 0.

M (input) The number of columns of the matrix A. 0 <= M <= N.

```
P (input) The number of columns of the matrix B.  P >= N-M.

A (input/output)
          On entry, the N-by-M matrix A.  On exit, A is des-
          troyed.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,N).

B (input/output)
          On entry, the N-by-P matrix B.  On exit, B is des-
          troyed.
LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

D (input/output)
          On entry, D is the left hand side of the GLM equa-
          tion.  On exit, D is destroyed.

X (output)
          On exit, X and Y are  the  solutions  of  the  GLM
          problem.

Y (output)
          On exit, X and Y are  the  solutions  of  the  GLM
          problem.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The  dimension  of  the  array  WORK.  LDWORK   >=
          max(1,N+M+P).   For optimum performance, LDWORK >=
          M+min(N,P)+max(N,P)*NB, where NB is an upper bound
          for  the  optimal  blocksizes  for CGEQRF, CGERQF,
          CUNMQR and CUNMRQ.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
```

       Q, [LDQ], Z, [LDZ], [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ, COMPZ
COMPLEX(8), DIMENSION(:,:) :: A, B, Q, Z
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zgghrd(char compq, char compz, int n, int ilo, int ihi,
          doublecomplex  *a,  int lda, doublecomplex *b, int
          ldb, doublecomplex *q, int ldq, doublecomplex  *z,
          int ldz, int *info);

void zgghrd_64(char compq, char compz,  long  n,  long  ilo,
          long  ihi,  doublecomplex *a, long lda, doublecom-
          plex *b, long ldb,  doublecomplex  *q,  long  ldq,
          doublecomplex *z, long ldz, long *info);
```

PURPOSE

zgghrd reduces a pair of complex matrices (A,B) to general- ized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular: Q' * A * Z = H and Q' * B * Z = T, where H is upper Hessenberg, T is upper triangular, and Q and Z are unitary, and ' means conjugate transpose.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that
1 * A * Z1' = (Q1*Q) * H * (Z1*Z)'

ARGUMENTS

COMPQ (input)
= 'N': do not compute Q;
= 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the pro- duct Q1*Q is returned.

COMPZ (input)
= 'N': do not compute Q;
= 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the pro- duct Q1*Q is returned.

N (input) The order of the matrices A and B. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See description of ILO.

A (input/output)
On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q' B Z. The elements below the diagonal are set to zero.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

Q (input/output)
If COMPQ='N': Q is not referenced.
If COMPQ='I': on entry, Q need not be set, and on exit it contains the unitary matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain a unitary matrix Q1, and on exit this is overwritten by Q1*Q.

LDQ (input)
The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z (input/output)
If COMPZ='N': Z is not referenced.
If COMPZ='I': on entry, Z need not be set, and on exit it contains the unitary matrix Z, which is

the product of the Givens transformations which are applied to A and B on the right. If COMPZ='V': on entry, Z must contain a unitary matrix Z1, and on exit this is overwritten by Z1*Z.

LDZ (input)
The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in _Matrix_Computations_, by Golub and van Loan (Johns Hopkins Press).

SUBROUTINE ZGGLSE_64(M, N, P, A, LDA, B, LDB, C, D, X, WORK, LDWORK,
      INFO)

DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(*), D(*), X(*), WORK(*)
INTEGER*8 M, N, P, LDA, LDB, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GGLSE([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],
       [LDWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: C, D, X, WORK
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER :: M, N, P, LDA, LDB, LDWORK, INFO

SUBROUTINE GGLSE_64([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],
       [LDWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: C, D, X, WORK
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zgglse(int m, int n, int p, doublecomplex *a, int  lda,
          doublecomplex *b, int ldb, doublecomplex *c, doub-
          lecomplex *d, doublecomplex *x, int *info);

void zgglse_64(long m, long n,  long  p,  doublecomplex  *a,
          long  lda,  doublecomplex *b, long ldb, doublecom-
          plex *c, doublecomplex *d, doublecomplex *x,  long
          *info);
```

PURPOSE

zgglse solves the linear equality-constrained least squares (LSE) problem:

```
        minimize || c - A*x ||_2   subject to   B*x = d
```

where A is an M-by-N matrix, B is a P-by-N matrix, c is a given M-vector, and d is a given P-vector. It is assumed that
P <= N <= M+P, and

```
         rank(B) = P and  rank( ( A ) ) = N.
                              ( ( B ) )
```

These conditions ensure that the LSE problem has a unique solution, which is obtained using a GRQ factorization of the matrices B and A.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. 0 <= P <= N <= M+P.

A (input/output)
On entry, the M-by-N matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. LDA >=

max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

C (input/output)
On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D (input/output)
On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X (output)
On exit, X is the solution of the LSE problem.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M+N+P). For optimum performance LDWORK >= P+min(M,N)+max(M,N)*NB, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

       [WORK], [LWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: TAUA, TAUB, WORK
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: N, M, P, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zggqrf(int n, int m, int p, doublecomplex *a, int  lda,
          doublecomplex  *taua,  doublecomplex  *b, int ldb,
          doublecomplex *taub, int *info);

void zggqrf_64(long n, long m,  long  p,  doublecomplex  *a,
          long  lda,  doublecomplex *taua, doublecomplex *b,
          long ldb, doublecomplex *taub, long *info);
```

PURPOSE

```
zggqrf computes a generalized QR factorization of an  N-by-M
matrix A and an N-by-P matrix B:
            A = Q*R,        B = Q*T*Z,

where Q is an N-by-N unitary matrix, Z is a  P-by-P  unitary
matrix, and R and T assume one of the forms:

if N >= M,  R = ( R11 ) M  ,   or if N < M,  R = ( R11   R12
) N,
                (  0  ) N-M                         N   M-N
                   M

where R11 is upper triangular, and

if N <= P,  T = ( 0  T12 ) N,   or if N > P,  T =  (  T11  )
N-P,
                 P-N  N                           ( T21 ) P
                                                     P

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR  fac-
torization  of A and B implicitly gives the QR factorization
of inv(B)*A:

             inv(B)*A = Z'*(inv(T)*R)

where inv(B) denotes the inverse of the  matrix  B,  and  Z'
denotes the conjugate transpose of matrix Z.
```

ARGUMENTS

N (input) The number of rows of the matrices A and B. N >=

0.

M (input) The number of columns of the matrix A. M >= 0.

P (input) The number of columns of the matrix B. P >= 0.

A (input/output)
On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N,M)-by-M upper trapezoidal matrix R (R is upper triangular if N >= M); the elements below the diagonal, with the array TAUA, represent the unitary matrix Q as a product of min(N,M) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAUA (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B (input/output)
On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

TAUB (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >=

max(1,N,M,P). For optimum performance LWORK >= max(N,M,P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of CUNMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(1) H(2) . . . H(k), where k = min(n,m).
```

Each H(i) has the form

```
   H(i) = I - taua * v * v'
```

where taua is a complex scalar, and v is a complex vector with v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is stored on exit in A(i+1:n,i), and taua in TAUA(i).
To form Q explicitly, use LAPACK subroutine CUNGQR.
To use Q to update another matrix, use LAPACK subroutine CUNMQR.

The matrix Z is represented as a product of elementary reflectors

```
   Z = H(1) H(2) . . . H(k), where k = min(n,p).
```

Each H(i) has the form

```
   H(i) = I - taub * v * v'
```

where taub is a complex scalar, and v is a complex vector with v(p-k+i+1:p) = 0 and v(p-k+i) = 1; v(1:p-k+i-1) is stored on exit in B(n-k+i,1:p-k+i-1), and taub in TAUB(i).
To form Z explicitly, use LAPACK subroutine CUNGRQ.
To use Z to update another matrix, use LAPACK subroutine CUNMRQ.

```
#include <sunperf.h>

void zggrqf(int m, int p, int n, doublecomplex *a, int  lda,
          doublecomplex  *taua,  doublecomplex  *b, int ldb,
          doublecomplex *taub, int *info);

void zggrqf_64(long m, long p,  long  n,  doublecomplex  *a,
          long  lda,  doublecomplex *taua, doublecomplex *b,
          long ldb, doublecomplex *taub, long *info);
```

PURPOSE

```
zggrqf computes a generalized RQ factorization of an  M-by-N
matrix A and a P-by-N matrix B:
            A = R*Q,        B = Z*T*Q,

where Q is an N-by-N unitary matrix, Z is a  P-by-P  unitary
matrix, and R and T assume one of the forms:

if M <= N,  R = ( 0  R12 ) M,   or if M > N,  R =  (  R11  )
M-N,
                 N-M  M                           ( R21 ) N
                                                     N

where R12 or R21 is upper triangular, and

if P >= N,  T = ( T11 ) N  ,   or if P < N,  T = ( T11   T12
) P,
                (  0  ) P-N                        P   N-P
                   N

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ  fac-
torization  of A and B implicitly gives the RQ factorization
of A*inv(B):

             A*inv(B) = (R*inv(T))*Z'

where inv(B) denotes the inverse of the  matrix  B,  and  Z'
denotes the conjugate transpose of the matrix Z.
```

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if M <= N, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if M > N, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAUA (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B (input/output)
On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P,N)-by-N upper trapezoidal matrix T (T is upper triangular if P >= N); the elements below the diagonal, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

TAUB (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,N,M,P). For optimum performance LWORK >=

```
          max(N,M,P)*max(NB1,NB2,NB3),  where  NB1  is   the
          optimal  blocksize  for the RQ factorization of an
          M-by-N matrix, NB2 is the  optimal  blocksize  for
          the  QR  factorization of a P-by-N matrix, and NB3
          is the optimal blocksize for a call of CUNMRQ.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.
INFO (output)
          = 0:  successful exit
          < 0:  if INFO=-i, the i-th argument had an illegal
          value.
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form

   H(i) = I - taua * v * v'

where taua is a complex scalar, and v is  a  complex  vector
with  v(n-k+i+1:n)  =  0  and  v(n-k+i) = 1; v(1:n-k+i-1) is
stored on exit in A(m-k+i,1:n-k+i-1), and taua in TAUA(i).
To form Q explicitly, use LAPACK subroutine CUNGRQ.
To use Q to update another  matrix,  use  LAPACK  subroutine
CUNMRQ.

The matrix Z is  represented  as  a  product  of  elementary
reflectors

   Z = H(1) H(2) . . . H(k), where k = min(p,n).

Each H(i) has the form

   H(i) = I - taub * v * v'

where taub is a complex scalar, and v is  a  complex  vector
with  v(1:i-1)  = 0 and v(i) = 1; v(i+1:p) is stored on exit
in B(i+1:p,i), and taub in TAUB(i).
To form Z explicitly, use LAPACK subroutine CUNGQR.
To use Z to update another  matrix,  use  LAPACK  subroutine
CUNMQR.

```
#include <sunperf.h>

void zggsvd(char jobu, char jobv, char jobq, int m,  int  n,
          int  p, int *k, int *l, doublecomplex *a, int lda,
          doublecomplex *b, int ldb, double  *alpha,  double
          *beta,  doublecomplex  *u,  int ldu, doublecomplex
          *v,  int  ldv,  doublecomplex  *q,  int  ldq,  int
          *iwork3, int *info);

void zggsvd_64(char jobu, char jobv, char jobq, long m, long
          n,  long  p,  long  *k, long *l, doublecomplex *a,
          long  lda,  doublecomplex  *b,  long  ldb,  double
          *alpha,  double *beta, doublecomplex *u, long ldu,
          doublecomplex *v, long ldv, doublecomplex *q, long
          ldq, long *iwork3, long *info);
```

PURPOSE

zggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B:

```
      U'*A*Q = D1*( 0 R ),    V'*B*Q = D2*( 0 R )
```

where U, V and Q are unitary matrices, and Z' means the conjugate transpose of Z. Let K+L = the effective numerical rank of the matrix (A',B')', then R is a (K+L)-by-(K+L) nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

```
                   K  L
       D1 =     K ( I  0 )
                L ( 0  C )
            M-K-L ( 0  0 )

                 K  L
       D2 =   L ( 0  S )
            P-L ( 0  0 )

                N-K-L  K    L
  ( 0 R ) = K (  0   R11  R12 )
            L (  0    0   R22 )
```

where

```
  C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
  S = diag( BETA(K+1),  ... , BETA(K+L) ),
  C**2 + S**2 = I.
  R is stored in A(1:K+L,N-K-L+1:N) on exit.
```

If M-K-L < 0,

```
                 K M-K K+L-M
       D1 =   K ( I  0    0   )
            M-K ( 0  C    0   )

                   K M-K K+L-M
       D2 =   M-K ( 0  S    0  )
            K+L-M ( 0  0    I  )
              P-L ( 0  0    0  )

                  N-K-L  K   M-K  K+L-M
  ( 0 R ) =     K ( 0    R11  R12  R13  )
              M-K ( 0     0   R22  R23  )
            K+L-M ( 0     0    0   R33  )
```

where

```
  C = diag( ALPHA(K+1), ... , ALPHA(M) ),
  S = diag( BETA(K+1),  ... , BETA(M) ),
  C**2 + S**2 = I.

  (R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33  is
stored
  ( 0  R22 R23 )
  in B(M-K+1:L,N+M-K-L+1:N) on exit.
```

The routine computes C, S, R, and optionally the unitary transformation matrices U, V and Q.

In particular, if B is an N-by-N nonsingular matrix, then the GSVD of A and B implicitly gives the SVD of A*inv(B):

```
                     A*inv(B) = U*(D1*inv(D2))*V'.
```

If (A',B')' has orthnormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

```
                     A'*A x = lambda* B'*B x.
```

In some literature, the GSVD of A and B is presented in the form

```
                 U'*A*X = ( 0 D1 ),   V'*B*X = ( 0 D2 )
```

where U and V are orthogonal and X is nonsingular, and D1 and D2 are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

```
                      X = Q*(  I   0    )
                            (  0 inv(R) )
```

ARGUMENTS

JOBU (input)
= 'U': Unitary matrix U is computed;
= 'N': U is not computed.

JOBV (input)
= 'V': Unitary matrix V is computed;
= 'N': V is not computed.

JOBQ (input)
= 'Q': Unitary matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. P >= 0.

K (output)
On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of (A',B')'.

L (output)
On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of (A',B')'.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains part of the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

ALPHA (output)
On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1,
ALPHA(1:K) = 1,
BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = C,
BETA(K+1:K+L) = S, or if M-K-L < 0, ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0
BETA(K+1:M) = S, BETA(M+1:K+L) = 1 and
ALPHA(K+L+1:N) = 0
BETA(K+L+1:N) = 0

BETA (output)
See description of ALPHA.

U (output)
If JOBU = 'U', U contains the M-by-M unitary matrix U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (output)
If JOBV = 'V', V contains the P-by-P unitary matrix V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (output)
If JOBQ = 'Q', Q contains the N-by-N unitary matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)
dimension(MAX(3*N,M,P)+N)

WORK2 (workspace)
dimension(2*N)

IWORK3 (output)
dimension(N) On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK3(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine CTGSJA.

```

PURPOSE

```
zggsvp computes unitary matrices U, V and Q such that
              L ( 0     0   A23 )
          M-K-L ( 0     0    0  )

                   N-K-L  K    L
        =     K ( 0    A12  A13 )  if M-K-L < 0;
            M-K ( 0     0   A23 )
```

```
                N-K-L  K    L
 V'*B*Q =   L ( 0     0   B13 )
          P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix (A',B')'. Z' denotes the conjugate transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine CGGSVD.

ARGUMENTS

JOBU (input)
= 'U': Unitary matrix U is computed;
= 'N': U is not computed.

JOBV (input)
= 'V': Unitary matrix V is computed;
= 'N': V is not computed.

JOBQ (input)
= 'Q': Unitary matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

TOLA (input)
TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a sub-block of A. Generally, they are set to TOLA = MAX(M,N)*norm(A)*MACHEPS, TOLB = MAX(P,N)*norm(B)*MACHEPS. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
See description of TOLA.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in Purpose section. K + L = effective numerical rank of (A',B')'.

L (output)
See the description of K.

U (input) If JOBU = 'U', U contains the unitary matrix U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) If JOBV = 'V', V contains the unitary matrix V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) If JOBQ = 'Q', Q contains the unitary matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

IWORK (workspace)
dimension(N)

RWORK (workspace)

dimension(2*N)

TAU (workspace)
dimension(N)

WORK (workspace)
dimension(MAX(3*N,M,P))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine CGEQPF for the QR factorization with column pivoting to detect the effective numerical rank of the a matrix. It may be replaced by a better rank determination strategy.

Contents

NAME

zgssco - General sparse solver condition number estimate.

SYNOPSIS

```
SUBROUTINE ZGSSCO ( COND, HANDLE, IER )

INTEGER             IER
DOUBLE PRECISION    COND
DOUBLE PRECISION    HANDLE(150)
```

PURPOSE

ZGSSCO - Condition number estimate.

PARAMETERS

```
COND       - DOUBLE PRECISION
        On exit, an estimate of the condition number of the
        factored matrix.  Must be called after the numerical
        factorization subroutine, ZGSSFA().

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER        - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -700 : Invalid calling sequence - need to call ZGSSFA first.
```

```
-710 : Condition number estimate not available (not implemented
       for this HANDLE's matix type).
```

Contents

NAME

```
zgssda - Deallocate working storage for the general sparse
solver.
```

SYNOPSIS

```
 SUBROUTINE ZGSSDA ( HANDLE, IER )

 INTEGER            IER
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

ZGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

```
HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER        - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         none
```

Contents

NAME

```
zgssfa - General sparse solver numeric factorization.
```

SYNOPSIS

```
 SUBROUTINE ZGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )

 INTEGER            NEQNS, COLSTR(*), ROWIND(*), IER
 DOUBLE COMPLEX     VALUES(*)
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

ZGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

```
NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        coefficient matrix.  Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.

ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

VALUES(*) - DOUBLE COMPLEX array
        On entry, VALUES(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the numeric values of
```

```
        the sparse matrix to be factored.  Unchanged on
        exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -300 : Invalid calling sequence - need to call ZGSSOR first.
         -301 : Failure to dynamically allocate memory.
         -666 : Internal error.
```

NAME

```
zgssfs - General sparse solver one call interface.
```

SYNOPSIS

```
 SUBROUTINE ZGSSFS ( MTXTYP, PIVOT , NEQNS, COLSTR, ROWIND,
                     VALUES, NRHS  , RHS   , LDRHS , ORDMTHD,
                     OUTUNT, MSGLVL, HANDLE, IER )

 CHARACTER*2        MTXTYP
 CHARACTER*1        PIVOT
 INTEGER            NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,
                    OUTUNT, MSGLVL, IER
 CHARACTER*3        ORDMTHD
 DOUBLE COMPLEX     VALUES(*), RHS(*)
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

ZGSSFS - General sparse solver one call interface.

PARAMETERS

```
MTXTYP    - CHARACTER*2
        On entry, MTXTYP specifies the coefficient matrix
        type.  Specifically, the valid options are:

         'sp' or 'SP' - symmetric structure, Hermitian positive definite
values
         'ss' or 'SS' - symmetric structure, symmetric values
         'su' or 'SU' - symmetric structure, unsymmetric values
         'uu' or 'UU' - unsymmetric structure, unsymmetric values

        Unchanged on exit.
```

```
PIVOT     - CHARACTER*1
        On entry, pivot specifies whether or not pivoting is
        used in the course of the numeric factorization.
        The valid options are:

         'n' or 'N' - no pivoting is used
         (Pivoting is not supported for this release).

        Unchanged on exit.

NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        the coefficient matrix.  NEQNS must be at least one.
        Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.
ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

VALUES(*) - DOUBLE COMPLEX array
        On entry, VALUES(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the non-zero numeric
        values of the sparse matrix to be factored.
        Unchanged on exit.

NRHS      - INTEGER
        On entry, NRHS specifies the number of right hand
        sides to solve for.  Unchanged on exit.

RHS(*)    - DOUBLE COMPLEX array
        On entry, RHS(LDRHS,NRHS) contains the NRHS right
        hand sides.  On exit, it contains the solutions.

LDRHS     - INTEGER
        On entry, LDRHS specifies the leading dimension of
        the RHS array. Unchanged on exit.

ORDMTHD   - CHARACTER*3
        On entry, ORDMTHD specifies the fill-reducing
        ordering to be used by the sparse solver.
        Specifically, the valid options are:

         'nat' or 'NAT' - natural ordering (no ordering)
         'mmd' or 'MMD' - multiple minimum degree
```

```
          'gnd' or 'GND' - general nested dissection
          'uso' or 'USO' - user specified ordering (see ZGSSUO)

         Unchanged on exit.

 OUTUNT    - INTEGER
         Output unit.  Unchanged on exit.

 MSGLVL    - INTEGER
         Message level.

          0 - no output from solver.
          (No messages supported for this release.)

         Unchanged on exit.

 HANDLE(150)  - DOUBLE PRECISION array
         On entry, HANDLE(*) is an array of containing
         information needed by the solver, and must be passed
         unchanged to each sparse solver subroutine.
         Modified on exit.
 IER       - INTEGER
         Error number.  If no error encountered, unchanged on
         exit.  If error encountered, it is set to a non-zero
         integer.  Error numbers set by this subroutine:

          -101 : Failure to dynamically allocate memory.
          -102 : Invalid matrix type.
          -103 : Invalid pivot option.
          -104 : Number of nonzeros is less than NEQNS.
          -105 : NEQNS < 1
          -201 : Failure to dynamically allocate memory.
          -301 : Failure to dynamically allocate memory.
          -401 : Failure to dynamically allocate memory.
          -402 : NRHS < 1
          -403 : NEQNS > LDRHS
          -666 : Internal error.
```

Contents

NAME

```
zgssin - Initialize the general sparse solver.
```

SYNOPSIS

```
SUBROUTINE ZGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,
                    MSGLVL, HANDLE, IER )

CHARACTER*2       MTXTYP
CHARACTER*1       PIVOT
INTEGER           NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGLVL, IER
DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

ZGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

```
MTXTYP    - CHARACTER*2
        On entry, MTXTYP specifies the coefficient matrix
        type.  Specifically, the valid options are:

         'sp' or 'SP' - symmetric structure, Hermitian positive definite
values
         'ss' or 'SS' - symmetric structure, symmetric values
         'su' or 'SU' - symmetric structure, unsymmetric values
         'uu' or 'UU' - unsymmetric structure, unsymmetric values

        Unchanged on exit.

PIVOT     - CHARACTER*1
        On entry, PIVOT specifies whether or not pivoting is
```

```
        used in the course of the numeric factorization.
        The valid options are:

         'n' or 'N' - no pivoting is used
         (Pivoting is not supported for this release).

        Unchanged on exit.

NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        the coefficient matrix.  NEQNS must be at least one.
        Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.

ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

OUTUNT    - INTEGER
        Output unit.  Unchanged on exit.

MSGLVL    - INTEGER
        Message level.

         0 - no output from solver.
         (No messages supported for this release.)

        Unchanged on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -101 : Failure to dynamically allocate memory.
         -102 : Invalid matrix type.
         -103 : Invalid pivot option.
         -104 : Number of nonzeros less than NEQNS.
         -105 : NEQNS < 1
```

Contents

NAME

```
zgssor - General sparse solver ordering and symbolic
factorization.
```

SYNOPSIS

```
 SUBROUTINE ZGSSOR ( ORDMTHD, HANDLE, IER )

 CHARACTER*3       ORDMTHD
 INTEGER           IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

ZGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

```
ORDMTHD   - CHARACTER*3
        On entry, ORDMTHD specifies the fill-reducing
        ordering to be used by the sparse solver.
        Specifically, the valid options are:

         'nat' or 'NAT' - natural ordering (no ordering)
         'mmd' or 'MMD' - multiple minimum degree
         'gnd' or 'GND' - general nested dissection
         'uso' or 'USO' - user specified ordering (see ZGSSUO)

        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
```

Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-200 : Invalid calling sequence - need to call ZGSSIN first.
-201 : Failure to dynamically allocate memory.
-666 : Internal error.

Contents

NAME

```
zgssps - Print general sparse solver statics.
```

SYNOPSIS

```
 SUBROUTINE ZGSSPS ( HANDLE, IER )

 INTEGER            IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

ZGSSPS - Print solver statistics.

PARAMETERS

```
HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -800 : Invalid calling sequence - need to call ZGSSSL first.
         -899 : Printed solver statistics not supported this release.
```

Contents

NAME

zgssrp - Return permutation used by the general sparse solver.

SYNOPSIS

```
 SUBROUTINE ZGSSRP ( PERM, HANDLE, IER )

 INTEGER           PERM(*), IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

ZGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

```
PERM(NEQNS)  - INTEGER array
        Undefined on entry.  PERM(NEQNS) is the permutation
        array used by the sparse solver for the fill-
        reducing ordering.  Modified on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER      - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:
```

-600 : Invalid calling sequence - need to call ZGSSOR first.

Contents

NAME

zgsssl - Solve routine for the general sparse solver.

SYNOPSIS

```
 SUBROUTINE ZGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )

 INTEGER            NRHS, LDRHS, IER
 DOUBLE COMPLEX     RHS(LDRHS,NRHS)
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

ZGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

```
NRHS      - INTEGER
        On entry, NRHS specifies the number of right hand
        sides to solve for.  Unchanged on exit.

RHS(LDRHS,*) - DOUBLE COMPLEX array
        On entry, RHS(LDRHS,NRHS) contains the NRHS right
        hand sides.  On exit, it contains the solutions.

LDRHS     - INTEGER
        On entry, LDRHS specifies the leading dimension of
        the RHS array. Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.
```

```
IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -400 : Invalid calling sequence - need to call ZGSSFA first.
         -401 : Failure to dynamically allocate memory.
         -402 : NRHS < 1
         -403 : NEQNS > LDRHS
```

Contents

NAME

```
zgssuo - User supplied permutation for ordering used in the
general sparse solver.
```

SYNOPSIS

```
 SUBROUTINE ZGSSUO ( PERM, HANDLE, IER )

 INTEGER           PERM(*), IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

ZGSSUO - User supplied permutation for ordering. Must be called after *ZGSSIN*() (sparse solver initialization) and before *ZGSSOR*() (sparse solver ordering).

PARAMETERS

```
PERM(NEQNS)  - INTEGER array
        On entry, PERM(NEQNS) is a permutation array
        supplied by the user for the fill-reducing ordering.
        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:
```

-500 : Invalid calling sequence - need to call ZGSSIN first.

SUBROUTINE ZGTCON_64(NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
      RCOND, WORK, INFO)

CHARACTER * 1 NORM
DOUBLE COMPLEX LOW(*), DIAG(*), UP1(*), UP2(*), WORK(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE GTCON(NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
       RCOND, [WORK], [INFO])

CHARACTER(LEN=1) :: NORM
COMPLEX(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
REAL(8) :: ANORM, RCOND

SUBROUTINE GTCON_64(NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
       RCOND, [WORK], [INFO])

CHARACTER(LEN=1) :: NORM
COMPLEX(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
void zgtcon(char norm, int n, doublecomplex *low, doublecom-
          plex   *diag,  doublecomplex  *up1,  doublecomplex
          *up2, int *ipivot, double  anorm,  double  *rcond,
          int *info);

void zgtcon_64(char norm, long n, doublecomplex *low,  doub-
          lecomplex *diag, doublecomplex *up1, doublecomplex
          *up2, long *ipivot, double anorm,  double  *rcond,
          long *info);
```

PURPOSE

zgtcon estimates the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I':   Infinity-norm.

N (input) The order of the matrix A. N >= 0.

LOW (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

DIAG (input)
The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input)
The (n-1) elements of the first superdiagonal of U.

UP2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

```
zgthr - Gathers specified elements from y into x.
```

SYNOPSIS

```
 SUBROUTINE ZGTHR(NZ, Y, X, INDX)

 DOUBLE COMPLEX Y(*), X(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE ZGTHR_64(NZ, Y, X, INDX)

 DOUBLE COMPLEX Y(*), X(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE GTHR([NZ], Y, X, INDX)

 COMPLEX(8), DIMENSION(:) :: Y, X
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE GTHR_64([NZ], Y, X, INDX)

 COMPLEX(8), DIMENSION(:) :: Y, X
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
ZGTHR - Gathers the specified elements from a vector y in
full storage form into a vector x in compressed form.  Only
```

the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form. Unchanged on exit.

Y (input)
Vector in full storage form. Unchanged on exit.

X (output)
Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Contents

NAME

```
zgthrz - Gather and zero.
```

SYNOPSIS

```
 SUBROUTINE ZGTHRZ(NZ, Y, X, INDX)

 DOUBLE COMPLEX Y(*), X(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE ZGTHRZ_64(NZ, Y, X, INDX)

 DOUBLE COMPLEX Y(*), X(*)

 SUBROUTINE GTHRZ_64([NZ], Y, X, INDX)

 COMPLEX(8), DIMENSION(:) :: Y, X
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
ZGTHRZ - Gathers the specified elements from a vector y in
full storage form into a vector x in compressed form.  The
```

gathered elements of y are set to zero. Only the elements of y whose indices are listed in indx are referenced.

```
 do i = 1, n
   x(i) = y(indx(i))
   y(indx(i)) = 0
 enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form. Unchanged on exit.

Y (input/output)
Vector in full storage form. Gathered elements are set to zero.

X (output)
Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

          *ipivot, doublecomplex *b, long ldb, doublecomplex
          *x,  long  ldx,  double  *ferr, double *berr, long
          *info);
```

PURPOSE

zgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input)
The (n-1) subdiagonal elements of A.

DIAG (input)
The diagonal elements of A.

UP (input)
The (n-1) superdiagonal elements of A.

LOWF (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

DIAGF (input)
The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input)
The (n-1) elements of the first superdiagonal of U.

UPF2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CGTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          lecomplex  *diag, doublecomplex *up, doublecomplex
          *b, long ldb, long *info);
```

PURPOSE

zgtsv solves the equation

where A is an N-by-N tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation A'*X = B may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input/output)
On entry, LOW must contain the (n-1) subdiagonal elements of A. On exit, LOW is overwritten by the (n-2) elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A. On exit, DIAG is overwritten by the n diagonal elements of U.

UP (input/output)
On entry, UP must contain the (n-1) superdiagonal elements of A. On exit, UP is overwritten by the (n-1) elements of the first superdiagonal of U.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

```

PURPOSE

zgtsvx uses the LU factorization to compute the solution to a complex system of linear equations A * X = B, A**T * X = B, or A**H * X = B, where A is a tridiagonal matrix of order

N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A
   as A = L * U, where L is a product of permutation and unit lower
   bidiagonal matrices and U is upper triangular with nonzeros in
   only the main diagonal and first two superdiagonals.

2. If some U(i,i)=0, so that U is exactly singular, then the routine
   returns with INFO = i. Otherwise, the factored form of A is used
   to estimate the condition number of the matrix A. If the
   reciprocal of the condition number is less than machine precision,
   INFO = N+1 is returned as a warning, but the routine still goes on
   to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form
   of A.

4. Iterative refinement is applied to improve the computed solution
   matrix and calculate error bounds and backward error estimates
   for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': LOWF, DIAGF, UPF1, UPF2, and IPIVOT contain the factored form of A; LOW, DIAG, UP, LOWF, DIAGF, UPF1, UPF2 and IPIVOT will not be modified. = 'N': The matrix will be copied to LOWF, DIAGF, and UPF1 and factored.

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

LOW (input)
          The (n-1) subdiagonal elements of A.
DIAG (input)
          The n diagonal elements of A.

UP (input/output)
          The (n-1) superdiagonal elements of A.

LOWF (input/output)
          If FACT = 'F', then LOWF is an input argument  and
          on  entry  contains  the  (n-1)  multipliers  that
          define the matrix L from the LU factorization of A
          as computed by CGTTRF.

          If FACT = 'N', then LOWF is an output argument and
          on exit contains the (n-1) multipliers that define
          the matrix L from the LU factorization of A.

DIAGF (input/output)
          If FACT = 'F', then DIAGF is an input argument and
          on  entry  contains the n diagonal elements of the
          upper triangular matrix U from the  LU  factoriza-
          tion of A.

          If FACT = 'N', then DIAGF is  an  output  argument
          and  on  exit  contains the n diagonal elements of
          the upper triangular matrix U from the LU factori-
          zation of A.

UPF1 (input/output)
          If FACT = 'F', then UPF1 is an input argument  and
          on  entry contains the (n-1) elements of the first
          superdiagonal of U.

          If FACT = 'N', then UPF1 is an output argument and
          on  exit  contains the (n-1) elements of the first
```

superdiagonal of U.

UPF2 (input/output)
If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIVOT (input/output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated

upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

          *ipivot, int *info);

void zgttrf_64(long  n,  doublecomplex  *low,  doublecomplex
          *diag,  doublecomplex  *up1,  doublecomplex  *up2,
          long *ipivot, long *info);
```

PURPOSE

zgttrf computes an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.
The factorization has the form
   A = L * U
where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)
On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)
On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

             lecomplex  *a,  long lda, double *w, doublecomplex
             *z, long ldz, long *info);
```

PURPOSE

zhbev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  A,  stored in the first KD+1
          rows of the array.  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
          UPLO = 'U', A(kd+1+i-j,j) =  A(i,j)  for  max(1,j-
          kd)<=i<=j;  if  UPLO = 'L', A(1+i-j,j)    = A(i,j)
```

```
          for j<=i<=min(n,j+kd).

          On exit, A is overwritten by values generated dur-
          ing  the reduction to tridiagonal form.  If UPLO =
          'U', the first superdiagonal and the  diagonal  of
          the  tridiagonal  matrix T are returned in rows KD
          and KD+1 of A, and if UPLO = 'L', the diagonal and
          first  subdiagonal  of T are returned in the first
          two rows of A.

LDA (input)
          The leading dimension of the array A.  LDA >= KD +
          1.
W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          orthonormal eigenvectors of the matrix A, with the
          i-th column of Z holding the  eigenvector  associ-
          ated  with  W(i).   If  JOBZ  = 'N', then Z is not
          referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          dimension(N)

WORK2 (workspace)
          dimension(max(1,3*N-2))

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  if INFO = i, the algorithm  failed  to  con-
          verge;  i off-diagonal elements of an intermediate
          tridiagonal form did not converge to zero.

COMPLEX(8), DIMENSION(:,:) :: AB, Z
INTEGER(8) :: N, KD, LDAB, LDZ, LWORK, LRWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: W, RWORK
```

C INTERFACE

```
#include <sunperf.h>
void zhbevd(char jobz, char uplo, int n, int kd,  doublecom-
          plex  *ab,  int ldab, double *w, doublecomplex *z,
          int ldz, int *info);

void zhbevd_64(char jobz, char uplo, long n, long kd,  doub-
          lecomplex *ab, long ldab, double *w, doublecomplex
          *z, long ldz, long *info);
```

PURPOSE

zhbevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).
On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD + 1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N**2.

If LWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N .

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

          lecomplex *z, long ldz, long *ifail, long *info);
```

PURPOSE

zhbevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;

= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found;
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, A is overwritten by values generated during the reduction to tridiagonal form.

LDA (input)
The leading dimension of the array A. LDA >= KD + 1.

Q (output)
If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tri- diagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)

The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)

The first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(N)

WORK2 (workspace)
dimension(7*N)

IWORK3 (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

```
#include <sunperf.h>

void zhbgst(char vect, char uplo, int n,  int  ka,  int  kb,
          doublecomplex  *ab,  int  ldab, doublecomplex *bb,
          int ldbb, doublecomplex *x, int ldx, int *info);
void zhbgst_64(char vect, char uplo, long n, long  ka,  long
          kb,  doublecomplex  *ab,  long ldab, doublecomplex
          *bb, long ldbb, doublecomplex *x, long  ldx,  long
          *info);
```

PURPOSE

zhbgst reduces a complex Hermitian-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y, such that C has the same bandwidth as A.

B must have been previously factorized as S**H*S by CPBSTF, using a split Cholesky factorization. A is overwritten by C = X**H*A*X, where X = S**(-1)*Q and Q is a unitary matrix chosen to preserve the bandwidth of A.

ARGUMENTS

```
VECT (input)
          = 'N':  do not form the transformation matrix X;
          = 'V':  form X.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrices A and B.  N >= 0.

KA (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KA >= 0.
```

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).
On exit, the transformed matrix X**H*A*X, stored in the same format as A.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input)
The banded factor S from the split Cholesky factorization of B, as returned by CPBSTF, stored in the first kb+1 rows of the array.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

X (output)
If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N) if VECT = 'V'; LDX >= 1 otherwise.

WORK (workspace)
dimension(N)

RWORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

          *bb, long ldbb, double *w, doublecomplex *z,  long
          ldz, long *info);
```

PURPOSE

zhbgv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

```
KB (input)
          The number of superdiagonals of the  matrix  B  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'. KB >= 0.

AB (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  A,  stored in the first ka+1
          rows of the array.  The j-th column of A is stored
          in the j-th column of the array AB as follows:  if
          UPLO = 'U', AB(ka+1+i-j,j) = A(i,j)  for  max(1,j-
          ka)<=i<=j;  if UPLO = 'L', AB(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+ka).
          On exit, the contents of AB are destroyed.

LDAB (input)
          The leading dimension of the array  AB.   LDAB  >=
          KA+1.

BB (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  B,  stored in the first kb+1
          rows of the array.  The j-th column of B is stored
          in the j-th column of the array BB as follows:  if
          UPLO = 'U', BB(kb+1+i-j,j) = B(i,j)  for  max(1,j-
          kb)<=i<=j;  if UPLO = 'L', BB(1+i-j,j)    = B(i,j)
          for j<=i<=min(n,j+kb).

          On exit, the factor S from the split Cholesky fac-
          torization B = S**H*S, as returned by CPBSTF.

LDBB (input)
          The leading dimension of the array  BB.   LDBB  >=
          KB+1.

W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          matrix  Z of eigenvectors, with the i-th column of
          Z holding the eigenvector  associated  with  W(i).
          The eigenvectors are normalized so that Z**H*B*Z =
          I.  If JOBZ = 'N', then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= N.

WORK (workspace)
          dimension(N)
```

RWORK (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value
> 0: if INFO = i, and i is:
<= N: the algorithm failed to converge: i off-
diagonal elements of an intermediate tridiagonal
form did not converge to zero; > N: if INFO = N
+ i, for 1 <= i <= N, then CPBSTF
returned INFO = i: B is not positive definite.
The factorization of B could not be completed and
no eigenvalues or eigenvectors were computed.

INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: W, RWORK
```

C INTERFACE

```
#include <sunperf.h>

void zhbgvd(char jobz, char uplo, int n,  int  ka,  int  kb,
          doublecomplex  *ab,  int  ldab, doublecomplex *bb,
          int ldbb, double *w, doublecomplex  *z,  int  ldz,
          int *info);

void zhbgvd_64(char jobz, char uplo, long n, long  ka,  long
          kb,  doublecomplex  *ab,  long ldab, doublecomplex
          *bb, long ldbb, double *w, doublecomplex *z,  long
          ldz, long *info);
```

PURPOSE

zhbgvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S**H*S, as returned by CPBSTF.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z**H*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK (workspace)
On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N. If JOBZ = 'V' and N > 1, LWORK >= 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
On exit, if INFO=0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO=0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:
<= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then CPBSTF
returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

PURPOSE

zhbgvx computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found;
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangles of A and B are stored;
= 'L': Lower triangles of A and B are stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)
On entry, the upper or lower triangle of the Her-

mitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S**H*S, as returned by CPBSTF.

LDBB (input)

The leading dimension of the array BB. LDBB >= KB+1.

Q (output)

If JOBZ = 'V', the n-by-n matrix used in the reduction of A*x = (lambda)*B*x to standard form, i.e. C*x = (lambda)*x, and consequently C to tri-diagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1,N).

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)

If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)

The absolute error tolerance for the eigenvalues.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tridiagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z**H*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK (workspace)
dimension(N)

RWORK (workspace)
dimension(7*N)

IWORK (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is

not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:
<= N: then i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then CPBSTF returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

   COMPLEX(8), DIMENSION(:,:) :: A
   INTEGER(8) :: N, K, LDA, INCX, INCY
```

C INTERFACE

```
   #include <sunperf.h>

   void zhbmv(char uplo, int n, int  k,  doublecomplex  *alpha,
             doublecomplex  *a,  int lda, doublecomplex *x, int
             incx, doublecomplex *beta, doublecomplex  *y,  int
             incy);
   void zhbmv_64(char  uplo,  long  n,  long  k,  doublecomplex
             *alpha,  doublecomplex *a, long lda, doublecomplex
             *x, long incx, doublecomplex *beta,  doublecomplex
             *y, long incy);
```

PURPOSE

zhbmv performs the matrix-vector operation y := alpha*A*x + beta*y where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian band matrix, with k super-diagonals.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is being supplied.

UPLO = 'L' or 'l'   The lower triangular part of A is being supplied.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)

On entry, K specifies the number of super-diagonals of the matrix A. K must satisfy 0 .le. K. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
    DO 20, J = 1, N
      M = K + 1 - J
      DO 10, I = MAX( 1, J - K ), J
        A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

REAL(8), DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>

void zhbtrd(char vect, char uplo, int n, int kd,  doublecom-
          plex  *ab,  int  ldab, double *d, double *e, doub-
          lecomplex *q, int ldq, int *info);
void zhbtrd_64(char vect, char uplo, long n, long kd,  doub-
          lecomplex  *ab,  long  ldab, double *d, double *e,
          doublecomplex *q, long ldq, long *info);
```

PURPOSE

zhbtrd reduces a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: Q**H * A * Q = T.

ARGUMENTS

VECT (input)
- = 'N': do not form Q;
- = 'V': form Q;
- = 'U': update a matrix X, by forming X*Q.

UPLO (input)
- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1

rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if KD > 0, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

D (output)
The diagonal elements of the tridiagonal matrix T.

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = T(i,i+1) if UPLO = 'U'; E(i) = T(i+1,i) if UPLO = 'L'.

Q (input/output)
On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N unitary matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

C INTERFACE

```
#include <sunperf.h>
void zhecon(char uplo, int n, doublecomplex *a, int lda, int
          *ipivot, double anorm, double *rcond, int *info);

void zhecon_64(char uplo, long  n,  doublecomplex  *a,  long
          lda,  long  *ipivot,  double anorm, double *rcond,
          long *info);
```

PURPOSE

zhecon estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDA (input)
The leading dimension of the array A. LDA >=

max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHETRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: W, WORK2
```

C INTERFACE

```
#include <sunperf.h>

void zheev(char jobz, char uplo, int  n,  doublecomplex  *a,
          int lda, double *w, int *info);

void zheev_64(char jobz, char uplo,  long  n,  doublecomplex
          *a, long lda, double *w, long *info);
```

PURPOSE

zheev computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)

The leading dimension of the array A. LDA >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,2*N-1). For optimal efficiency, LDWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(max(1,3*N-2))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

C INTERFACE

```
#include <sunperf.h>
void zheevd(char jobz, char uplo, int n,  doublecomplex  *a,
          int lda, double *w, int *info);

void zheevd_64(char jobz, char uplo, long  n,  doublecomplex
          *a, long lda, double *w, long *info);
```

PURPOSE

zheevd computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
- = 'N': Compute eigenvalues only;
- = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N + 1. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of the array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message

```
          related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LIWORK.

LIWORK (input)
          The dimension of the array  IWORK.   If  N  <=  1,
          LIWORK must be at least 1.  If JOBZ  = 'N' and N >
          1, LIWORK must be at least 1.  If JOBZ  = 'V'  and
          N > 1, LIWORK must be at least 3 + 5*N.

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, the algorithm  failed  to  con-
          verge;  i off-diagonal elements of an intermediate
          tridiagonal form did not converge to zero.

```

PURPOSE

zheevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, CHEEVR calls CSTEGR to compute the eigenspectrum using Relatively Robust Representations.

CSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,

(a) Compute T - sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T is a relatively robust representation,

(b) Compute the eigenvalues, lambda_j, of L_i D_i L_i^T to high relative accuracy by the dqds algorithm,

(c) If there is a cluster of close eigenvalues, "choose" sigma_i close to the cluster, and go to step (a),

(d) Given the approximate eigenvalue lambda_j of L_i D_i L_i^T, compute the corresponding eigenvector by forming a rank-revealing twisted factorization.

The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : CHEEVR calls CSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. CHEEVR calls SSTEBZ and CSTEIN on non-ieee machines and
when partial spectrum requests are made.

Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval

```
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the  matrix  A.   On  exit, the lower triangle (if
          UPLO='L') or the upper triangle (if  UPLO='U')  of
          A, including the diagonal, is destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

VU (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

IL (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.

IU (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.

ABSTOL (input)
          The absolute error tolerance for the  eigenvalues.
          An approximate eigenvalue is accepted as converged
```

when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

If high relative accuracy is important, set ABSTOL to SLAMCH('Safe minimum'). Doing so will guarantee that eigenvalues are computed to high relative accuracy when possible in future releases. The current code does not make any guarantees about high relative accuracy, but furutre releases will. See J. Barlow and J. Demmel, "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7, for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)

The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)

The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)

The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

```
ISUPPZ (output)
          The support of the eigenvectors in  Z,  i.e.,  the
          indices  indicating the nonzero elements in Z. The
          i-th  eigenvector  is  nonzero  only  in  elements
          ISUPPZ( 2*i-1 ) through ISUPPZ( 2*i ).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  length  of  the   array   WORK.    LWORK   >=
          max(1,2*N).   For  optimal  efficiency,  LWORK  >=
          (NB+1)*N, where NB is the max of the blocksize for
          CHETRD and for CUNMTR as returned by ILAENV.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

RWORK (workspace)
          On exit, if INFO = 0, RWORK(1) returns the optimal
          (and minimal) LRWORK.

LRWORK (input)
          The  length  of  the  array  RWORK.    LRWORK   >=
          max(1,24*N).

          If LRWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the RWORK array, returns this value as  the  first
          entry  of  the  RWORK  array, and no error message
          related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          (and minimal) LIWORK.

LIWORK (input)
          The dimension  of  the  array  IWORK.   LIWORK  >=
          max(1,10*N).

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.
```

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  Internal error

```

C INTERFACE

```
#include <sunperf.h>

void zheevx(char jobz, char range, char uplo, int  n,  doub-
          lecomplex  *a,  int lda, double vl, double vu, int
          il, int iu, double abtol, int *nfound, double  *w,
          doublecomplex *z, int ldz, int *ifail, int *info);

void zheevx_64(char jobz, char range,  char  uplo,  long  n,
          doublecomplex  *a, long lda, double vl, double vu,
          long il, long iu, double abtol, long *nfound, dou-
          ble  *w,  doublecomplex *z, long ldz, long *ifail,
          long *info);
```

PURPOSE

zheevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,2*N). For optimal efficiency, LDWORK >= (NB+1)*N, where NB is the max of the blocksize for CHETRD and for CUNMTR as returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(7*N)

IWORK3 (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

void zhegs2(int itype, char uplo, int n,  doublecomplex  *a,
          int lda, doublecomplex *b, int ldb, int *info);

void zhegs2_64(long itype, char uplo, long n,  doublecomplex
          *a,  long  lda,  doublecomplex  *b, long ldb, long
          *info);
```

PURPOSE

zhegs2 reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U')*A*inv(U) or inv(L)*A*inv(L')
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U` or L'*A*L.

B must have been previously factorized as U'*U or L*L' by CPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U')*A*inv(U) or inv(L)*A*inv(L');
= 2 or 3: compute U*A*U' or L'*A*L.

UPLO (input)
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored, and how B has been factorized. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

          *info);
```

PURPOSE

zhegst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U**H)*A*inv(U) or inv(L)*A*inv(L**H)

If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U**H or L**H*A*L.

B must have been previously factorized as U**H*U or L*L**H by CPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U**H)*A*inv(U) or inv(L)*A*inv(L**H);
= 2 or 3: compute U*A*U**H or L**H*A*L.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as U**H*U; = 'L': Lower triangle of A is stored and B is factored as L*L**H.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          doublecomplex *a, long lda, doublecomplex *b, long
          ldb, double *w, long *info);
```

PURPOSE

zhegv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also
positive definite.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.
```

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U**H*U or B = L*L**H.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,2*N-1). For optimal efficiency, LDWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(max(1,3*N-2))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or CHEEV returned an error code:
<= N: if INFO = i, CHEEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

void zhegvd(int itype, char jobz, char uplo,  int  n,  doub-
          lecomplex  *a, int lda, doublecomplex *b, int ldb,
          double *w, int *info);

void zhegvd_64(long itype, char jobz,  char  uplo,  long  n,
          doublecomplex *a, long lda, doublecomplex *b, long
          ldb, double *w, long *info);
```

PURPOSE

zhegvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

```
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.
A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the matrix A.

          On exit, if JOBZ = 'V', then if INFO = 0,  A  con-
          tains the matrix Z of eigenvectors.  The eigenvec-
          tors are normalized as follows:  if ITYPE =  1  or
          2,  Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I.
          If JOBZ = 'N', then on exit the upper triangle (if
          UPLO='U')  or  the lower triangle (if UPLO='L') of
          A, including the diagonal, is destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input/output)
          On entry, the Hermitian matrix B.  If UPLO =  'U',
          the leading N-by-N upper triangular part of B con-
          tains the upper triangular part of the  matrix  B.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of B contains the lower  triangular  part  of
          the matrix B.

          On exit, if INFO <= N, the part  of  B  containing
          the matrix is overwritten by the triangular factor
          U or L from the Cholesky factorization B =  U**H*U
          or B = L*L**H.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).
```

```
W (output)
          If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  length  of  the  array  WORK.   If  N  <=  1,
          LWORK  >= 1.  If JOBZ  = 'N' and N > 1, LWORK >= N
          + 1.  If JOBZ  = 'V' and N > 1,  LWORK  >=  2*N  +
          N**2.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

RWORK (workspace)
          On exit, if INFO = 0, RWORK(1) returns the optimal
          LRWORK.

LRWORK (input)
          The dimension of the array  RWORK.   If  N  <=  1,
          LRWORK  >= 1.  If JOBZ  = 'N' and N > 1, LRWORK >=
          N.  If JOBZ  = 'V' and N > 1, LRWORK >= 1 + 5*N  +
          2*N**2.

          If LRWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the RWORK array, returns this value as  the  first
          entry  of  the  RWORK  array, and no error message
          related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LIWORK.

LIWORK (input)
          The dimension of the array  IWORK.   If  N  <=  1,
          LIWORK  >= 1.  If JOBZ  = 'N' and N > 1, LIWORK >=
          1.  If JOBZ  = 'V' and N > 1, LIWORK >= 3 + 5*N.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  CPOTRF or CHEEVD returned an error code:
```

```
<= N:  if INFO = i, CHEEVD failed to  converge;  i
off-diagonal elements of an intermediate tridiago-
nal form did not converge to zero; > N:   if  INFO
=  N  + i, for 1 <= i <= N, then the leading minor
of order i of B is  not  positive  definite.   The
factorization  of  B could not be completed and no
eigenvalues or eigenvectors were computed.

          plex *z, long ldz, long *ifail, long *info);
```

PURPOSE

zhegvx computes selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the matrix A.

          On exit,  the lower triangle (if UPLO='L') or  the
          upper  triangle  (if UPLO='U') of A, including the
          diagonal, is destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input/output)
          On entry, the Hermitian matrix B.  If UPLO =  'U',
          the leading N-by-N upper triangular part of B con-
          tains the upper triangular part of the  matrix  B.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of B contains the lower  triangular  part  of
          the matrix B.
```

```
            On exit, if INFO <= N, the part  of  B  containing
            the matrix is overwritten by the triangular factor
            U or L from the Cholesky factorization B =  U**H*U
            or B = L*L**H.

LDB (input)
            The leading dimension of  the  array  B.   LDB  >=
            max(1,N).

VL (input)
            If RANGE='V', the lower and upper  bounds  of  the
            interval  to be searched for eigenvalues. VL < VU.
            Not referenced if RANGE = 'A' or 'I'.
VU (input)
            If RANGE='V', the lower and upper  bounds  of  the
            interval  to be searched for eigenvalues. VL < VU.
            Not referenced if RANGE = 'A' or 'I'.

IL (input)
            If RANGE='I', the indices (in ascending order)  of
            the   smallest   and  largest  eigenvalues  to  be
            returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
            and  IU  =  0 if N = 0.  Not referenced if RANGE =
            'A' or 'V'.

IU (input)
            If RANGE='I', the indices (in ascending order)  of
            the   smallest   and  largest  eigenvalues  to  be
            returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
            and  IU  =  0 if N = 0.  Not referenced if RANGE =
            'A' or 'V'.

ABSTOL (input)
            The absolute error tolerance for the  eigenvalues.
            An approximate eigenvalue is accepted as converged
            when it is determined to lie in an interval  [a,b]
            of width less than or equal to

            ABSTOL + EPS *   max( |a|,|b| ) ,

            where EPS is the machine precision.  If ABSTOL  is
            less than or equal to zero, then  EPS*|T|  will be
            used in its place, where |T| is the 1-norm of  the
            tridiagonal  matrix obtained by reducing A to tri-
            diagonal form.

            Eigenvalues will be computed most accurately  when
            ABSTOL  is  set  to  twice the underflow threshold
            2*SLAMCH('S'), not zero.  If this routine  returns
            with INFO>0, indicating that some eigenvectors did
```

not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (output)
If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace/output)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. LWORK >= max(1,2*N-1). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(7*N)

IWORK (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or CHEEVX returned an error code:
<= N: if INFO = i, CHEEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

C INTERFACE

```
#include <sunperf.h>

void zhemm(char side, char uplo, int m, int n, doublecomplex
          *alpha,  doublecomplex  *a, int lda, doublecomplex
          *b, int ldb,  doublecomplex  *beta,  doublecomplex
          *c, int ldc);
void zhemm_64(char side, char uplo, long m,  long  n,  doub-
          lecomplex  *alpha,  doublecomplex  *a,  long  lda,
          doublecomplex *b, long ldb,  doublecomplex  *beta,
          doublecomplex *c, long ldc);
```

PURPOSE

zhemm performs one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C where alpha and beta are scalars, A is an hermitian matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether the hermitian matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of the hermitian matrix is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of the hermitian matrix is to be referenced.

Unchanged on exit.

M (input)
On entry, M specifies the number of rows of the matrix C. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix C. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX*16 array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1, m), other- wise LDA >= max(1, n). Unchanged on exit.

B (input)
COMPLEX*16 array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)
COMPLEX*16 array of DIMENSION (LDC, n).

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry.

On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m). Unchanged on exit.

          incx, doublecomplex *beta, doublecomplex *y,  long
          incy);
```

PURPOSE

zhemv performs the matrix-vector operation y := alpha*A*x + beta*y where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

X (input)

(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

void zher_64(char uplo, long n, double alpha,  doublecomplex
          *x, long incx, doublecomplex *a, long lda);
```

PURPOSE

zher performs the hermitian rank 1 operation A := alpha*x*conjg(x') + A where alpha is a real scalar, x is an n element vector and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

A (input/output)
Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

NAME

zher2 - perform the hermitian rank 2 operation A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A

SYNOPSIS

```
SUBROUTINE ZHER2(UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)

CHARACTER * 1 UPLO
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)
INTEGER N, INCX, INCY, LDA

SUBROUTINE ZHER2_64(UPLO, N, ALPHA, X, INCX, Y, INCY, A, LDA)

CHARACTER * 1 UPLO
DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX X(*), Y(*), A(LDA,*)
INTEGER*8 N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE HER2(UPLO, [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, INCX, INCY, LDA

SUBROUTINE HER2_64(UPLO, [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA
```

```
COMPLEX(8), DIMENSION(:) :: X, Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>

void zher2(char uplo, int  n,  doublecomplex  *alpha,  doub-
          lecomplex  *x,  int  incx,  doublecomplex  *y, int
          incy, doublecomplex *a, int lda);

void zher2_64(char uplo, long n, doublecomplex *alpha, doub-
          lecomplex  *x,  long  incx, doublecomplex *y, long
          incy, doublecomplex *a, long lda);
```

PURPOSE

zher2 performs the hermitian rank 2 operation A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A where alpha is a scalar, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the

incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

Y (input)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

A (input/output)
Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>
void zher2k(char uplo, char transa, int n, int k, doublecom-
          plex *alpha, doublecomplex *a, int lda, doublecom-
          plex *b, int ldb, double beta,  doublecomplex  *c,
          int ldc);

void zher2k_64(char uplo, char transa, long n, long k, doub-
          lecomplex  *alpha,  doublecomplex  *a,  long  lda,
          doublecomplex *b, long  ldb,  double  beta,  doub-
          lecomplex *c, long ldc);
```

PURPOSE

zher2k performs one of the Hermitian rank 2k operations C := alpha*A*conjg(B') + conjg(alpha)*B*conjg(A') + beta*C or C := alpha*conjg(A')*B + conjg(alpha)*conjg(B')*A + beta*C where alpha and beta are scalars with beta real, C is an n by n Hermitian matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)
On entry,   UPLO specifies whether the   upper or   lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u'   Only the   upper triangular part of C is to be referenced.

UPLO = 'L' or 'l'   Only the   lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' C := alpha*A*conjg(B') + conjg(alpha)*B*conjg(A') + beta*C.

TRANSA = 'C' or 'c' C := alpha*conjg(A')*B + conjg(alpha)*conjg(B')*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)
On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX*16 array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

B (input)
COMPLEX*16 array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is

n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)
COMPLEX*16 array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

              *x,  long  ldx,  double  *ferr, double *berr, long
              *info);
```

PURPOSE

zherfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
    UPLO (input)
              = 'U':  Upper triangle of A is stored;
              = 'L':  Lower triangle of A is stored.

    N (input) The order of the matrix A.  N >= 0.

    NRHS (input)
              The number of right hand sides, i.e.,  the  number
              of columns of the matrices B and X.  NRHS >= 0.
```

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHETRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHETRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CHETRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as

reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

REAL(8) :: ALPHA, BETA

SUBROUTINE HERK_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
       C, [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX(8), DIMENSION(:,:) :: A, C
INTEGER(8) :: N, K, LDA, LDC
REAL(8) :: ALPHA, BETA
```

C INTERFACE

```
#include <sunperf.h>

void zherk(char uplo, char transa,  int  n,  int  k,  double
          alpha,  doublecomplex  *a,  int  lda, double beta,
          doublecomplex *c, int ldc);

void zherk_64(char uplo, char transa, long n, long k, double
          alpha,  doublecomplex  *a,  long lda, double beta,
          doublecomplex *c, long ldc);
```

PURPOSE

zherk performs one of the Hermitian rank k operations C := alpha*A*conjg(A') + beta*C or C := alpha*conjg(A')*A + beta*C where alpha and beta are real scalars, C is an n by n Hermitian matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   C := alpha*A*conjg(A') + beta*C.

TRANSA = 'C' or 'c'   C := alpha*conjg(A')*A +

beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)
On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX*16 array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)
COMPLEX*16 array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated

matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

C INTERFACE

```
   #include <sunperf.h>

   void zhesv(char uplo, int n, int nrhs, doublecomplex *a, int
             lda,  int  *ipivot, doublecomplex *b, int ldb, int
             *info);
   void zhesv_64(char uplo, long n,  long  nrhs,  doublecomplex
             *a, long lda, long *ipivot, doublecomplex *b, long
             ldb, long *info);
```

PURPOSE

zhesv computes the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
   A = U * D * U**H, if UPLO = 'U', or
   A = L * D * L**H, if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
  = 'U': Upper triangle of A is stored;
  = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
  The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHETRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
Details of the interchanges and the block structure of D, as determined by CHETRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >= 1, and for best performance LDWORK >= N*NB, where NB is the optimal blocksize for CHETRF.

If LDWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

#include <sunperf.h>

void zhesvx(char fact, char uplo, int  n,  int  nrhs,  doub-
          lecomplex  *a,  int  lda,  doublecomplex  *af, int
          ldaf, int  *ipivot,  doublecomplex  *b,  int  ldb,
          doublecomplex  *x,  int ldx, double *rcond, double
          *ferr, double *berr, int *info);

void zhesvx_64(char fact, char  uplo,  long  n,  long  nrhs,
          doublecomplex  *a,  long  lda,  doublecomplex *af,
          long ldaf, long *ipivot,  doublecomplex  *b,  long
          ldb,  doublecomplex  *x,  long ldx, double *rcond,
          double *ferr, double *berr, long *info);
```

PURPOSE

zhesvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to

```
factor A.
   The form of the factorization is
      A = U * D * U**H,  if UPLO = 'U', or
      A = L * D * L**H,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper
(lower)
   triangular matrices, and D is Hermitian and block  diago-
nal with
   1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

3. The system of equations is solved for X  using  the  fac-
tored form
   of A.

4. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored  form  of  A
          has  been supplied on entry.  = 'F':  On entry, AF
          and IPIVOT contain the factored form of A.  A,  AF
          and  IPIVOT  will  not  be  modified.  = 'N':  The
          matrix A will be copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.
```

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHETRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHETRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by

CHETRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >= 2*N, and for best performance LDWORK >= N*NB, where NB is the optimal blocksize for CHETRF.

If LDWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

COMPLEX(8), DIMENSION(:,:) :: A
```

```
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>

void zhetf2(char uplo, int n, doublecomplex *a, int lda, int
          *ipiv, int *info);

void zhetf2_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, long *ipiv, long *info);
```

PURPOSE

zhetf2 computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

   A = U*D*U' or A = L*D*L'

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)
Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

```
1-96 - Based on modifications by
  J. Lewis, Boeing Computer Services Company
  A. Petitet, Computer Science Dept., Univ. of Tenn., Knox-
ville, USA

If UPLO = 'U', then A = U*D*U', where
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where  k  decreases
from  n  to  1 in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation  matrix  as defined by IPIV(k), and U(k) is a
unit upper triangular matrix,  such  that  if  the  diagonal
block D(k) is of order s (s = 1 or 2), then

           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where

```
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
```

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

C INTERFACE

```
   #include <sunperf.h>

   void zhetrd(char uplo, int n,  doublecomplex  *a,  int  lda,
             double  *d,  double  *e,  doublecomplex  *tau, int
             *info);
   void zhetrd_64(char uplo, long  n,  doublecomplex  *a,  long
             lda,  double  *d,  double  *e, doublecomplex *tau,
             long *info);
```

PURPOSE

zhetrd reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: Q**H * A * Q = T.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tri- diagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

D (output)
The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille- gal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

Q = H(n-1) . . . H(2) H(1).

Each H(i) has the form

```
   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(i+1:n)  = 0 and v(i) = 1; v(1:i-1) is stored on exit
in
A(1:i-1,i+1), and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(1) H(2) . . . H(n-1).
Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(1:i)  = 0 and v(i+1) = 1; v(i+2:n) is stored on exit
in A(i+2:n,i), and tau in TAU(i).

The contents of A on exit are illustrated by  the  following
examples with n = 5:

if UPLO = 'U':                       if UPLO = 'L':

  (    d     e     v2    v3    v4   )                (     d
)
  (       d    e    v3    v4   )                (    e     d
)
  (           d    e    v4  )               (   v1   e     d
)
  (              d   e  )               (   v1   v2   e    d
)
  (                  d  )              (  v1  v2  v3  e    d
)

where d and e denote diagonal and off-diagonal  elements  of
T, and vi denotes an element of the vector defining H(i).

          *ipivot, int *info);

void zhetrf_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, long *ipivot, long *info);
```

PURPOSE

zhetrf computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

A = U*D*U**H or A = L*D*L**H

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >=1. For best performance LDWORK >= N*NB, where NB is the block size returned by ILAENV.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If UPLO = 'U', then A = U*D*U', where
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal

block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

void zhetri_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, long *ipivot, long *info);
```

PURPOSE

zhetri computes the inverse of a complex Hermitian indefinite matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHETRF.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

          doublecomplex *b, long ldb, doublecomplex  *alpha,
          doublecomplex  *beta,  doublecomplex *q, long ldq,
          doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhgeqz implements a single-shift version of the QZ method for finding the generalized eigenvalues w(i)=ALPHA(i)/BETA(i) of the equation A are then ALPHA(1),...,ALPHA(N), and of B are BETA(1),...,BETA(N).

If JOB='S' and COMPQ and COMPZ are 'V' or 'I', then the unitary transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:
(in) A(in) Z(in)* = Q(out) A(out) Z(out)*

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrixigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

JOB (input)
= 'E': compute only ALPHA and BETA. A and B will not necessarily be put into generalized Schur form. = 'S': put A and B into generalized Schur form, as well as computing ALPHA and BETA.

COMPQ (input)
= 'N': do not modify Q.
= 'V': multiply the array Q on the right by the conjugate transpose of the unitary tranformation that is applied to the left side of A and B to reduce them to Schur form. = 'I': like COMPQ='V', except that Q will be initialized to the identity first.

COMPZ (input)
= 'N': do not modify Z.
= 'V': multiply the array Z on the right by the unitary tranformation that is applied to the right side of A and B to reduce them to Schur form. = 'I': like COMPZ='V', except that Z will be initialized to the identity first.

N (input) The order of the matrices A, B, Q, and Z. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A (input) On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to upper triangular form. If JOB='E', then on exit A will have been destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1, N).

B (input) On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. If

JOB='S', then on exit A and B will have been simultaneously reduced to upper triangular form. If JOB='E', then on exit B will have been destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

ALPHA (output)
The diagonal elements of A when the pair (A,B) has been reduced to Schur form. ALPHA(i)/BETA(i) i=1,...,N are the generalized eigenvalues.

BETA (output)
The diagonal elements of B when the pair (A,B) has been reduced to Schur form. ALPHA(i)/BETA(i) i=1,...,N are the generalized eigenvalues. A and B are normalized so that BETA(1),...,BETA(N) are non-negative real numbers.

Q (input/output)
If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the conjugate transpose of the unitary transformations which are applied to A and B on the left will be applied to the array Q on the right.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1. If COMPQ='V' or 'I', then LDQ >= N.

Z (input/output)
If COMPZ='N', then Z will not be referenced. If COMPZ='V' or 'I', then the unitary transformations which are applied to A and B on the right will be applied to the array Z on the right.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If COMPZ='V' or 'I', then LDZ >= N.

WORK (workspace)
On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1,...,N: the QZ iteration did not converge. (A,B) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (A,B) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO-N+1,...,N should be correct. > 2*N: various "impossible" errors.

FURTHER DETAILS

We assume that complex ABS works as long as its value is less than overflow.

void zhpcon_64(char uplo, long  n,  doublecomplex  *a,  long
          *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

zhpcon estimates the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHPTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          double *w, doublecomplex *z, int ldz, int *info);

void zhpev_64(char jobz, char uplo,  long  n,  doublecomplex
          *a,  double  *w,  doublecomplex *z, long ldz, long
          *info);
```

PURPOSE

zhpev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding

```
          elements of A.

W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          orthonormal eigenvectors of the matrix A, with the
          i-th column of Z holding the  eigenvector  associ-
          ated  with  W(i).   If  JOBZ  = 'N', then Z is not
          referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).
WORK (workspace)
          dimension(MAX(1,2*N-1))

WORK2 (workspace)
          dimension(max(1,3*N-2))

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  if INFO = i, the algorithm  failed  to  con-
          verge;  i off-diagonal elements of an intermediate
          tridiagonal form did not converge to zero.
```

          *ap,  double  *w, doublecomplex *z, long ldz, long
          *info);
```

PURPOSE

zhpevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

```
AP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  AP  as  follows:  if UPLO = 'U', AP(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L',  AP(i
          + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

          On exit, AP is  overwritten  by  values  generated
          during the reduction to tridiagonal form.  If UPLO
          = 'U', the diagonal and first superdiagonal of the
          tridiagonal  matrix  T overwrite the corresponding
          elements of A, and if UPLO = 'L', the diagonal and
          first subdiagonal of T overwrite the corresponding
          elements of A.

W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          orthonormal eigenvectors of the matrix A, with the
          i-th column of Z holding the  eigenvector  associ-
          ated  with  W(i).   If  JOBZ  = 'N', then Z is not
          referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  dimension  of  array  WORK.   If  N   <=   1,
          LWORK  must  be at least 1.  If JOBZ = 'N' and N >
          1, LWORK must be at least N.  If JOBZ = 'V' and  N
          > 1, LWORK must be at least 2*N.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

RWORK (workspace)
          dimension (LRWORK) On exit, if INFO = 0,  RWORK(1)
          returns the optimal LRWORK.
```

LRWORK (input)

The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)

On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)

The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```
#include <sunperf.h>

void zhpevx(char jobz, char range, char uplo, int  n,  doub-
          lecomplex  *a,  double  vl, double vu, int il, int
          iu, double abtol, int *nfound,  double  *w,  doub-
          lecomplex *z, int ldz, int *ifail, int *info);

void zhpevx_64(char jobz, char range,  char  uplo,  long  n,
          doublecomplex  *a,  double vl, double vu, long il,
          long iu, double abtol, long  *nfound,  double  *w,
          doublecomplex  *z,  long  ldz,  long  *ifail, long
          *info);
```

PURPOSE

zhpevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found;
          = 'V': all eigenvalues in the  half-open  interval
```

(VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.
On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)
The absolute error tolerance for the eigenvalues.

An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
If INFO = 0, the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)
dimension(7*N)

IWORK3 (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void zhpgst(int itype, char uplo, int n, doublecomplex  *ap,
          doublecomplex *bp, int *info);

void zhpgst_64(long itype, char uplo, long n,  doublecomplex
          *ap, doublecomplex *bp, long *info);
```

PURPOSE

zhpgst reduces a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U**H)*A*inv(U) or inv(L)*A*inv(L**H)
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U**H or L**H*A*L.

B must have been previously factorized as U**H*U or L*L**H by CPPTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U**H)*A*inv(U) or inv(L)*A*inv(L**H);
= 2 or 3: compute U*A*U**H or L**H*A*L.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as U**H*U; = 'L': Lower triangle of A is stored and B is factored as L*L**H.

N (input) The order of the matrices A and B. N >= 0.

AP (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP (input)
The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by CPPTRF.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          doublecomplex  *a,  doublecomplex  *b,  double *w,
          doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhpgv computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.
```

A (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, the contents of A are destroyed.

B (input/output)
On entry, the upper or lower triangle of the Hermitian matrix B, packed columnwise in a linear array. The j-th column of B is stored in the array B as follows: if UPLO = 'U', B(i + (j-1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', B(i + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

On exit, the triangular factor U or L from the Cholesky factorization B = U**H*U or B = L*L**H, in the same storage format as B.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(MAX(1,2*N-1))

WORK2 (workspace)
dimension(MAX(1,3*N-2))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPPTRF or CHPEV returned an error code:
<= N: if INFO = i, CHPEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO =

N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

          doublecomplex *z, long ldz, long *info);
```

PURPOSE

zhpgvd computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.
If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

```
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.
AP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  AP  as  follows:  if UPLO = 'U', AP(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L',  AP(i
          + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

          On exit, the contents of AP are destroyed.

BP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  B,  packed  columnwise in a linear
          array.  The j-th column of  B  is  stored  in  the
          array  BP  as  follows:  if UPLO = 'U', BP(i + (j-
          1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L',  BP(i
          + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

          On exit, the triangular factor U  or  L  from  the
          Cholesky  factorization  B = U**H*U or B = L*L**H,
          in the same storage format as B.

W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          matrix  Z  of  eigenvectors.  The eigenvectors are
          normalized  as  follows:   if  ITYPE  =  1  or  2,
          Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I.  If
          JOBZ = 'N', then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
```

```
            On exit, if INFO = 0, WORK(1) returns the  optimal
            LWORK.

LWORK (input)
            The  dimension  of  array  WORK.   If  N   <=   1,
            LWORK  >= 1.  If JOBZ = 'N' and N > 1, LWORK >= N.
            If JOBZ = 'V' and N > 1, LWORK >= 2*N.

            If LWORK = -1, then a workspace query is  assumed;
            the  routine  only  calculates the optimal size of
            the WORK array, returns this value  as  the  first
            entry  of  the  WORK  array,  and no error message
            related to LWORK is issued by XERBLA.

RWORK (workspace)
            On exit, if INFO = 0, RWORK(1) returns the optimal
            LRWORK.

LRWORK (input)
            The  dimension  of  array  RWORK.   If  N  <=   1,
            LRWORK  >=  1.  If JOBZ = 'N' and N > 1, LRWORK >=
            N.  If JOBZ = 'V' and N > 1, LRWORK >= 1 +  5*N  +
            2*N**2.

            If LRWORK = -1, then a workspace query is assumed;
            the  routine  only  calculates the optimal size of
            the RWORK array, returns this value as  the  first
            entry  of  the  RWORK  array, and no error message
            related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
            On exit, if INFO = 0, IWORK(1) returns the optimal
            LIWORK.

LIWORK (input)
            The dimension of array IWORK.  If JOBZ  = 'N' or N
            <=  1,  LIWORK  >=  1.   If JOBZ  = 'V' and N > 1,
            LIWORK >= 3 + 5*N.

            If LIWORK = -1, then a workspace query is assumed;
            the  routine  only  calculates the optimal size of
            the IWORK array, returns this value as  the  first
            entry  of  the  IWORK  array, and no error message
            related to LIWORK is issued by XERBLA.

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  CPPTRF or CHPEVD returned an error code:
```

<= N: if INFO = i, CHPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

#include <sunperf.h>

void zhpgvx(int itype, char jobz, char range, char uplo, int
          n,  doublecomplex  *ap,  doublecomplex *bp, double
          vl, double vu, int il, int iu, double abstol,  int
          *m,  double  *w,  doublecomplex  *z,  int ldz, int
          *ifail, int *info);

void zhpgvx_64(long itype, char jobz, char range, char uplo,
          long n, doublecomplex *ap, doublecomplex *bp, dou-
          ble vl,  double  vu,  long  il,  long  iu,  double
          abstol, long *m, double *w, doublecomplex *z, long
          ldz, long *ifail, long *info);
```

PURPOSE

zhpgvx computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found;
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be  found; = 'I': the IL-th through
          IU-th eigenvalues will be found.
UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

AP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  AP  as  follows:  if UPLO = 'U', AP(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L',  AP(i
          + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

          On exit, the contents of AP are destroyed.

BP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  B,  packed  columnwise in a linear
          array.  The j-th column of  B  is  stored  in  the
          array  BP  as  follows:  if UPLO = 'U', BP(i + (j-
          1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L',  BP(i
          + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

          On exit, the triangular factor U  or  L  from  the
          Cholesky  factorization  B = U**H*U or B = L*L**H,
          in the same storage format as B.

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.
```

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tri-diagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix

A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(2*N)

RWORK (workspace)
dimension(7*N)

IWORK (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPPTRF or CHPEVX returned an error code:
<= N: if INFO = i, CHPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

INTEGER :: N, INCX, INCY

SUBROUTINE HPMV_64(UPLO, [N], ALPHA, A, X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: A, X, Y
```

```
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>

void zhpmv(char uplo, int  n,  doublecomplex  *alpha,  doub-
          lecomplex  *a,  doublecomplex  *x, int incx, doub-
          lecomplex *beta, doublecomplex *y, int incy);

void zhpmv_64(char uplo, long n, doublecomplex *alpha, doub-
          lecomplex  *a,  doublecomplex *x, long incx, doub-
          lecomplex *beta, doublecomplex *y, long incy);
```

PURPOSE

zhpmv performs the matrix-vector operation y := alpha*A*x + beta*y where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l'   The lower triangular part of A is supplied in A.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed

sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

X (input)

(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

          int ldb, doublecomplex *x, int ldx, double  *ferr,
          double *berr, int *info);

void zhprfs_64(char uplo, long n, long  nrhs,  doublecomplex
          *a, doublecomplex *af, long *ipivot, doublecomplex
          *b, long ldb, doublecomplex *x, long  ldx,  double
          *ferr, double *berr, long *info);
```

PURPOSE

zhprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The upper  or  lower  triangle  of  the  Hermitian
          matrix  A,  packed  columnwise  in a linear array.
```

The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AF (input)
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHPTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CHPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)

```
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO =  -i,  the  i-th  argument  had  an
          illegal value
```

          *ipivot, doublecomplex *b, int ldb, int *info);

void zhpsv_64(char uplo, long n,  long  nrhs,  doublecomplex
          *a, long *ipivot, doublecomplex *b, long ldb, long
          *info);
```

PURPOSE

```
zhpsv computes the solution to a complex  system  of  linear
equations
   A * X = B, where A is an N-by-N Hermitian  matrix  stored
in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
   A = U * D * U**H,  if UPLO = 'U', or
   A = L * D * L**H,  if UPLO = 'L',
where U (or L) is a product of permutation  and  unit  upper
(lower) triangular matrices, D is Hermitian and block diago-
nal with 1-by-1 and 2-by-2 diagonal  blocks.   The  factored
form  of A is then used to solve the system of equations A *
X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
```

array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (output)
Details of the interchanges and the block structure of D, as determined by CHPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44

Packed storage of the upper triangle of A:

A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

```
#include <sunperf.h>

void zhpsvx(char fact, char uplo, int  n,  int  nrhs,  doub-
          lecomplex  *a,  doublecomplex  *af,  int  *ipivot,
          doublecomplex *b, int ldb, doublecomplex  *x,  int
          ldx,  double  *rcond,  double *ferr, double *berr,
          int *info);

void zhpsvx_64(char fact, char  uplo,  long  n,  long  nrhs,
          doublecomplex *a, doublecomplex *af, long *ipivot,
          doublecomplex *b, long ldb, doublecomplex *x, long
          ldx,  double  *rcond,  double *ferr, double *berr,
          long *info);
```

PURPOSE

zhpsvx uses the diagonal pivoting factorization A = U*D*U**H or A = L*D*L**H to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to

```
factor A as
      A = U * D * U**H,  if UPLO = 'U', or
      A = L * D * L**H,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper
(lower)
   triangular matrices and D is Hermitian and block diagonal
with
   1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

3. The system of equations is solved for X  using  the  fac-
tored form
   of A.

4. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored  form  of  A
          has  been supplied on entry.  = 'F':  On entry, AF
          and IPIVOT contain the factored form of A.  AF and
          IPIVOT will not be modified.  = 'N':  The matrix A
          will be copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
```

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AF (input/output)

If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHPTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine

precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':
Two-dimensional storage of the Hermitian matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

          double *e, doublecomplex *tau, int *info);

void zhptrd_64(char uplo, long n, doublecomplex *ap,  double
          *d, double *e, doublecomplex *tau, long *info);
```

PURPOSE

zhptrd reduces a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation: Q**H * A * Q = T.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

```
D (output)
          The diagonal elements of the tridiagonal matrix T:
          D(i) = A(i,i).

E (output)
          The  off-diagonal  elements  of  the   tridiagonal
          matrix  T:   E(i) = A(i,i+1) if UPLO = 'U', E(i) =
          A(i+1,i) if UPLO = 'L'.

TAU (output)
          The scalar factors of  the  elementary  reflectors
          (see Further Details).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
If UPLO = 'U', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(n-1) . . . H(2) H(1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(i+1:n)  = 0 and v(i) = 1; v(1:i-1) is stored on exit
in AP,  overwriting  A(1:i-1,i+1),  and  tau  is  stored  in
TAU(i).

If UPLO = 'L', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(1:i)  = 0 and v(i+1) = 1; v(i+2:n) is stored on exit
in AP, overwriting A(i+2:n,i), and tau is stored in TAU(i).

```

C INTERFACE

```
#include <sunperf.h>

void zhptrf(char uplo, int n, doublecomplex *a, int *ipivot,
          int *info);

void zhptrf_64(char uplo, long  n,  doublecomplex  *a,  long
          *ipivot, long *info);
```

PURPOSE

zhptrf computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)

Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

```
5-96 - Based on modifications by J. Lewis,  Boeing  Computer
Services
       Company

If UPLO = 'U', then A = U*D*U', where
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where  k  decreases
from  n  to  1 in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation matrix as defined by IPIVOT(k), and U(k) is a
unit upper triangular matrix,  such  that  if  the  diagonal
block D(k) is of order s (s = 1 or 2), then

           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k

If s = 1, D(k) overwrites A(k,k), and  v  overwrites  A(1:k-
1,k).   If s = 2, the upper triangle of D(k) overwrites A(k-
1,k-1), A(k-1,k), and A(k,k), and  v  overwrites  A(1:k-2,k-
1:k).

If UPLO = 'L', then A = L*D*L', where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where  k  increases
```

from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

          int *info);

void zhptri_64(char uplo, long  n,  doublecomplex  *a,  long
          *ipivot, long *info);
```

PURPOSE

zhptri computes the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHPTRF.

WORK (workspace)
dimension(N)

```
INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          > 0: if INFO = i, D(i,i) = 0; the matrix is singu-
          lar and its inverse could not be computed.

          *info);
```

PURPOSE

zhptrs solves a system of linear equations A*X = B with a complex Hermitian matrix A stored in packed format using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHPTRF.

B (input/output)

On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          *select, long n, doublecomplex *h, long ldh, doub-
          lecomplex *w, doublecomplex *vl, long ldvl,  doub-
          lecomplex  *vr,  long ldvr, long mm, long *m, long
          *ifaill, long *ifailr, long *info);
```

PURPOSE

zhsein uses inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

```
H * x = w * x,     y**h * H = w * y**h
```

where y**h denotes the conjugate transpose of the vector y.

ARGUMENTS

```
SIDE (input)
          = 'R': compute right eigenvectors only;
          = 'L': compute left eigenvectors only;
          = 'B': compute both right and left eigenvectors.

EIGSRC (input)
          Specifies the source of eigenvalues supplied in W:
          = 'Q': the eigenvalues were  found  using  CHSEQR;
          thus,  if  H has zero subdiagonal elements, and so
          is block-triangular, then the j-th eigenvalue  can
          be  assumed  to be an eigenvalue of the block con-
          taining the j-th row/column.  This property allows
          CHSEIN  to  perform  inverse iteration on just one
          diagonal block.  = 'N': no assumptions are made on
          the  correspondence between eigenvalues and diago-
          nal blocks.  In  this  case,  CHSEIN  must  always
          perform  inverse  iteration using the whole matrix
          H.

INITV (input)
          = 'N': no initial vectors are supplied;
          = 'U': user-supplied initial vectors are stored in
          the arrays VL and/or VR.

SELECT (input)
          Specifies the  eigenvectors  to  be  computed.  To
          select the eigenvector corresponding to the eigen-
          value W(j), SELECT(j) must be set to .TRUE..

N (input) The order of the matrix H.  N >= 0.

H (input) The upper Hessenberg matrix H.

LDH (input)
          The leading dimension of  the  array  H.   LDH  >=
          max(1,N).

W (input/output)
          On entry, the eigenvalues of H.  On exit, the real
          parts  of  W  may  have  been  altered since close
          eigenvalues are perturbed  slightly  in  searching
          for independent eigenvectors.

VL (input/output)
          On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL
          must  contain  starting  vectors  for  the inverse
          iteration for the left eigenvectors; the  starting
```

vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR required to store the eigenvectors (= the number of .TRUE. elements in SELECT).

WORK (workspace)
dimension(N*N)

RWORK (workspace)
dimension(N)

IFAILL (output)
If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'R', IFAILL is

not referenced.

IFAILR (output)
If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'L', IFAILR is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

FURTHER DETAILS

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x|+|y|.

```

C INTERFACE

```
   #include <sunperf.h>

   void zhseqr (char, char, int, int, int, doublecomplex*, int,
             doublecomplex*, doublecomplex*, int, int*);

   void zhseqr_64 (char, char,  long,  long,  long,  doublecom-
             plex*, long, doublecomplex*, doublecomplex*, long,
             long*);
```

PURPOSE

zhseqr computes the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition H = Z T Z**H, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input unitary matrix Q, so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the unitary matrix Q: A = Q*H*Q**H = (QZ)*T*(QZ)**H.

ARGUMENTS

JOB (input)
= 'E': compute eigenvalues only;
= 'S': compute eigenvalues and the Schur form T.

COMPZ (input)
= 'N': no Schur vectors are computed;
= 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an unitary matrix Q on entry, and the product Q*Z is returned.

N (input) The order of the matrix H. N >= 0.

ILO (input)

```
            It is assumed that H is already  upper  triangular
            in  rows  and columns 1:ILO-1 and IHI+1:N. ILO and
            IHI are normally set by a previous call to CGEBAL,
            and  then  passed to CGEHRD when the matrix output
            by CGEBAL is reduced to Hessenberg form. Otherwise
            ILO and IHI should be set to 1 and N respectively.
            1 <= ILO <= IHI <= N, if N > 0; ILO=1  and  IHI=0,
            if N=0.

IHI (input)
            See the description of ILO.

H (input/output)
            On entry, the upper Hessenberg matrix H.  On exit,
            if  JOB  =  'S',  H  contains the upper triangular
            matrix T from the Schur decomposition  (the  Schur
            form).  If  JOB  =  'E',  the  contents  of  H are
            unspecified on exit.

LDH (input)
            The leading dimension  of  the  array  H.  LDH  >=
            max(1,N).

W (output)
            The computed eigenvalues. If JOB = 'S', the eigen-
            values  are  stored  in  the  same order as on the
            diagonal of the Schur form  returned  in  H,  with
            W(i) = H(i,i).

Z (input)   If COMPZ = 'N': Z is not referenced.
            If COMPZ = 'I': on entry, Z need not be  set,  and
            on  exit,  Z  contains the unitary matrix Z of the
            Schur vectors of H.  If COMPZ = 'V':  on  entry  Z
            must  contain an N-by-N matrix Q, which is assumed
            to be equal to the unit matrix except for the sub-
            matrix Z(ILO:IHI,ILO:IHI); on exit Z contains Q*Z.
            Normally Q is  the  unitary  matrix  generated  by
            CUNGHR  after  the call to CGEHRD which formed the
            Hessenberg matrix H.

LDZ (input)
            The leading dimension of  the  array  Z.   LDZ  >=
            max(1,N)  if  COMPZ  = 'I' or 'V'; LDZ >= 1 other-
            wise.

WORK (workspace)
            On exit, if INFO = 0, WORK(1) returns the  optimal
            LWORK.

LWORK (output)
```

The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, CHSEQR failed to compute all the eigenvalues in a total of 30*(IHI-ILO+1) iterations; elements 1:ilo-1 and i+1:n of W contain those eigenvalues which have been successfully computed.

                     3 : Triangular
                     4 : Skew(Anti)-Symmetric (A=-A')
                     5 : Diagonal
                     6 : Skew-Hermitian (A= -CONJG(A'))
                   DESCRA(2) upper/lower triangular indicator
                     1 : lower
```

```
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

VAL()          array of length NNZ consisting of entries of A.
               VAL can be viewed as a column major ordering of a
               row permutation of the Ellpack representation of A,
               where the Ellpack representation is permuted so that
               the rows are non-increasing in the number of nonzero
               entries.  Values added for padding in Ellpack are
               not included in the Jagged-Diagonal format.

INDX()         array of length NNZ consisting of the column indices
               of the corresponding entries in VAL.
PNTR()         array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
               points to the location in VAL of the first element
               in the row-permuted Ellpack represenation of A.

MAXNZ          max number of nonzeros elements per row.

IPERM()        integer array of length M such that I = IPERM(I'),
               where row I in the original Ellpack representation
               corresponds to row I' in the permuted representation.
               If IPERM(1) = 0, it is assumed by convention that
               IPERM(I) = I. IPERM is used to determine the order
               in which rows of C are updated.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK. WORK is not
               referenced in the current version.

LWORK          length of WORK array. LWORK is not referenced
               in the current version.

NAME

zjadrp - right permutation of a jagged diagonal matrix

SYNOPSIS

```
 SUBROUTINE ZJADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                      IPERM,WORK,LWORK)
 INTEGER    TRANSP, M, K, MAXNZ, LWORK
 INTEGER    INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
 DOUBLE COMPLEX VAL(*)

 SUBROUTINE ZJADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                      IPERM,WORK,LWORK)
 INTEGER*8  TRANSP, M, K, MAXNZ, LWORK
 INTEGER*8  INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
 DOUBLE COMPLEX VAL(*)
```

F95 INTERFACE

```
 SUBROUTINE JADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
 INTEGER TRANSP, M, K,  MAXNZ
 INTEGER, DIMENSION(:) :: INDX, PNTR, IPERM
 DOUBLE COMPLEX, DIMENSION(:) :: VAL

 SUBROUTINE JADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
 INTEGER*8 TRANSP, M, K,  MAXNZ
 INTEGER*8, DIMENSION(:) :: INDX, PNTR, IPERM
 DOUBLE COMPLEX, DIMENSION(:) :: VAL
```

DESCRIPTION

```
A <- A P
A <- A P'
                                   ( ' indicates matrix transpose)
```

where permutation P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symetrically permuted jagged diagonal matrix P A P', one can explicitly permute the columns P A by calling

```
   SJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP — Indicates how to operate with the permutation matrix
  0 : operate with matrix
  1 : operate with transpose matrix

M — Number of rows in matrix A

K — Number of columns in matrix A

VAL() — array of length PNTR(MAXNZ+1)-PNTR(1) consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format.

INDX() — array of length PNTR(MAXNZ+1)-PNTR(1) consisting of the column indices of the corresponding entries in VAL.

PNTR() — array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack represenation of A.

MAXNZ — max number of nonzeros elements per row.

IPERM() — integer array of length K such that I = IPERM(I').

```
                Array IPERM represents a permutation P, such that
                IPERM(I) is equal to the position of the only nonzero
                element in row I of permutation matrix P.
                For example, if
                               | 0 0 1 |
                           P  =| 1 0 0 |
                               | 0 1 0 |
                then IPERM = (3, 1, 2).

WORK()          scratch array of length LWORK.  LWORK should be at
                least K.

LWORK           length of WORK array

                If LWORK = -1, then a workspace query is assumed;
                the routine only calculates the optimal size of the
                WORK array, returns this value as the first entry of
                the WORK array, and no error message related to LWORK
                is issued by XERBLA.
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in jagged-diagonal format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))
                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           array of length NNZ consisting of entries of A.
                VAL can be viewed as a column major ordering of a
                row permutation of the Ellpack representation of A,
                where the Ellpack representation is permuted so that
                the rows are non-increasing in the number of nonzero
                entries.  Values added for padding in Ellpack are
                not included in the Jagged-Diagonal format.

INDX()          array of length NNZ consisting of the column indices
                of the corresponding entries in VAL.

PNTR()          array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
                points to the location in VAL of the first element
                in the row-permuted Ellpack represenation of A.

MAXNZ           max number of nonzeros elements per row.

IPERM()         integer array of length M such that I = IPERM(I'),
                where row I in the original Ellpack representation
                corresponds to row I' in the permuted representation.
                If IPERM(1)=0,   it's assumed by convention that
                IPERM(I)=I. IPERM is used to determine the order
                in which rows of C are updated.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter
```

```
C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.
               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK          length of WORK array.  LWORK should be at least 2*M.

               For good performance, LWORK should generally be larger.
               For optimum performance on multiple processors, LWORK
               >=2*M*N_CPUS where N_CPUS is the maximum number of
               processors available to the program.

               If LWORK=0, the routine is to allocate workspace needed.

               If LWORK = -1, then a workspace query is assumed; the
               routine only calculates the optimum size of the WORK
               array, returns this value as the first entry of the WORK
               array, and no error message related to LWORK is issued
               by XERBLA.
```

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the JAD representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the JAD representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

SUBROUTINE LARZ(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])

CHARACTER(LEN=1) :: SIDE
COMPLEX(8) :: TAU
COMPLEX(8), DIMENSION(:) :: V, WORK
COMPLEX(8), DIMENSION(:,:) :: C
INTEGER :: M, N, L, INCV, LDC

SUBROUTINE LARZ_64(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])

CHARACTER(LEN=1) :: SIDE
```

```
COMPLEX(8) :: TAU
COMPLEX(8), DIMENSION(:) :: V, WORK
COMPLEX(8), DIMENSION(:,:) :: C
INTEGER(8) :: M, N, L, INCV, LDC
```

C INTERFACE

```
#include <sunperf.h>

void zlarz(char side, int m, int n, int l, doublecomplex *v,
          int  incv,  doublecomplex  *tau, doublecomplex *c,
          int ldc);

void zlarz_64(char side, long m, long n, long l,  doublecom-
          plex *v, long incv, doublecomplex *tau, doublecom-
          plex *c, long ldc);
```

PURPOSE

zlarz applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

H = I - tau * v * v'

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H' (the conjugate transpose of H), supply conjg(tau) instead tau.

H is a product of k elementary reflectors as returned by CTZRZF.

ARGUMENTS

SIDE (input)
= 'L': form H * C
= 'R': form C * H

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

L (input) The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L

>= 0.

V (input) The vector v in the representation of H as returned by CTZRZF. V is not used if TAU = 0.

INCV (input)
The increment between elements of v. INCV <> 0.

TAU (input)
The value tau in the representation of H.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
(N) if SIDE = 'L' or (M) if SIDE = 'R'

          int ldc, int ldwork);

void zlarzb_64(char side,  char  trans,  char  direct,  char
          storev, long m, long n, long k, long l, doublecom-
          plex *v, long ldv,  doublecomplex  *t,  long  ldt,
          doublecomplex *c, long ldc, long ldwork);
```

PURPOSE

zlarzb applies a complex block reflector H or its transpose H**H to a complex distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

```
SIDE (input)
          = 'L': apply H or H' from the Left
          = 'R': apply H or H' from the Right

TRANS (input)
          = 'N': apply H (No transpose)
          = 'C': apply H' (Conjugate transpose)

DIRECT (input)
          Indicates how H is formed from a product  of  ele-
          mentary reflectors = 'F': H = H(1) H(2) . . . H(k)
          (Forward, not supported yet)
          = 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV (input)
          Indicates how the vectors which define the elemen-
          tary reflectors are stored:
          = 'C': Columnwise                        (not sup-
          ported yet)
          = 'R': Rowwise
```

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

K (input) The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L (input) The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V (input) If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV (input)
The leading dimension of the array V. If STOREV = 'C', LDV >= L; if STOREV = 'R', LDV >= K.

T (input) The triangular K-by-K matrix T in the representation of the block reflector.

LDT (input)
The leading dimension of the array T. LDT >= K.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by H*C or H'*C or C*H or C*H'.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
dimension(MAX(M,N),K)

LDWORK (input)
The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1,N); if SIDE = 'R', LDWORK >= max(1,M).

NAME

```
zlarzt - form the triangular factor T  of  a  complex  block
reflector H of order > n, which is defined as a product of k
elementary reflectors
```

SYNOPSIS

```
SUBROUTINE ZLARZT(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)

CHARACTER * 1 DIRECT, STOREV
DOUBLE COMPLEX V(LDV,*), TAU(*), T(LDT,*)
INTEGER N, K, LDV, LDT

SUBROUTINE ZLARZT_64(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)

CHARACTER * 1 DIRECT, STOREV
DOUBLE COMPLEX V(LDV,*), TAU(*), T(LDT,*)
INTEGER*8 N, K, LDV, LDT
```

F95 INTERFACE

```
SUBROUTINE LARZT(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])

CHARACTER(LEN=1) :: DIRECT, STOREV
COMPLEX(8), DIMENSION(:) :: TAU
COMPLEX(8), DIMENSION(:,:) :: V, T
INTEGER :: N, K, LDV, LDT

SUBROUTINE LARZT_64(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])

CHARACTER(LEN=1) :: DIRECT, STOREV
COMPLEX(8), DIMENSION(:) :: TAU
COMPLEX(8), DIMENSION(:,:) :: V, T
```

```
INTEGER(8) :: N, K, LDV, LDT
```

C INTERFACE

```
#include <sunperf.h>

void zlarzt(char direct, char storev, int n,  int  k,  doub-
          lecomplex  *v,  int ldv, doublecomplex *tau, doub-
          lecomplex *t, int ldt);

void zlarzt_64(char direct, char storev,  long  n,  long  k,
          doublecomplex  *v,  long  ldv, doublecomplex *tau,
          doublecomplex *t, long ldt);
```

PURPOSE

zlarzt forms the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

   H = I - V * T * V'

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

   H = I - V' * T * V

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

DIRECT (input)
Specifies the order in which the elementary reflectors are multiplied to form the block reflector:
= 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet)
= 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV (input)
Specifies how the vectors which define the elementary reflectors are stored (see also Further Details):
= 'R': rowwise

N (input) The order of the block reflector H. N >= 0.

K (input) The order of the triangular factor T (= the number of elementary reflectors). K >= 1.

V (input) (LDV,K) if STOREV = 'C' (LDV,N) if STOREV = 'R'
The matrix V. See further details.

LDV (input)
The leading dimension of the array V. If STOREV = 'C', LDV >= max(1,N); if STOREV = 'R', LDV >= K.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i).

T (input) The k by k triangular factor T of the block reflector. If DIRECT = 'F', T is upper triangular; if DIRECT = 'B', T is lower triangular. The rest of the array is not used.

LDT (input)
The leading dimension of the array T. LDT >= K.

FURTHER DETAILS

Based on contributions by
A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The shape of the matrix V and the storage of the vectors which define the H(i) is best illustrated by the following example with n = 5 and k = 3. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV = 'C': DIRECT = 'F' and STOREV = 'R':

```
                                                  ______V_____
       (    v1    v2    v3    )                              /
( v1 v2 v3 )                      ( v1 v1 v1 v1 v1 . . . . 1
)
   V = ( v1 v2 v3 )                      ( v2 v2 v2 v2 v2  .
```

```
. . 1   )
       ( v1 v2 v3 )                      ( v3 v3 v3 v3 v3  .
. 1     )
       ( v1 v2 v3 )
          .  .  .
          1  .  .
             1  .
                1

DIRECT = 'B' and STOREV =  'C':          DIRECT  =  'B'  and
STOREV = 'R':

                                                     ______V_____

INTEGER(8) :: M, N, INCV, LDC
```

C INTERFACE

```
#include <sunperf.h>

void zlatzm(char side, int m, int n, doublecomplex  *v,  int
          incv, doublecomplex *tau, doublecomplex *c1, doub-
          lecomplex *c2, int ldc);

void zlatzm_64(char side, long m, long n, doublecomplex  *v,
          long  incv, doublecomplex *tau, doublecomplex *c1,
          doublecomplex *c2, long ldc);
```

PURPOSE

zlatzm routine is deprecated and has been replaced by routine CUNMRZ.

CLATZM applies a Householder matrix generated by CTZRQF to a matrix.

```
Let P = I - tau*u*u',   u = ( 1 ),
                            ( v )
where v is an (m-1) vector if SIDE = 'L', or a (n-1)  vector
if SIDE = 'R'.

If SIDE equals 'L', let
       C = [ C1 ] 1
           [ C2 ] m-1
             n
Then C is overwritten by P*C.

If SIDE equals 'R', let
       C = [ C1, C2 ] m
              1  n-1
Then C is overwritten by C*P.
```

ARGUMENTS

SIDE (input)
= 'L': form P * C
= 'R': form C * P

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

V (input) (1 + (M-1)*abs(INCV)) if SIDE = 'L' (1 + (N-1)*abs(INCV)) if SIDE = 'R' The vector v in the representation of P. V is not used if TAU = 0.

INCV (input)
The increment between elements of v. INCV <> 0

TAU (input)
The value tau in the representation of P.

C1 (input/output)
(LDC,N) if SIDE = 'L' (M,1) if SIDE = 'R' On entry, the n-vector C1 if SIDE = 'L', or the m-vector C1 if SIDE = 'R'.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

C2 (input/output)
(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

LDC (input)
The leading dimension of the arrays C1 and C2. LDC >= max(1,M).

WORK (workspace)
(N) if SIDE = 'L' (M) if SIDE = 'R'

INTEGER(8) :: N, KD, LDA, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void zpbcon(char uplo, int n, int kd, doublecomplex *a,  int
          lda, double anorm, double *rcond, int *info);

void zpbcon_64(char uplo, long n, long kd, doublecomplex *a,
          long   lda,  double  anorm,  double  *rcond,  long
          *info);
```

PURPOSE

zpbcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangular factor stored in A;
= 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO ='U', A(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', A(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

ANORM (input)
The 1-norm (or infinity-norm) of the Hermitian band matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

zpbequ - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE ZPBEQU(UPLO, N, KD, A, LDA, SCALE, SCOND, AMAX, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER N, KD, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)

SUBROUTINE ZPBEQU_64(UPLO, N, KD, A, LDA, SCALE, SCOND, AMAX,
      INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, KD, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PBEQU(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,
       [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, KD, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

```
SUBROUTINE PBEQU_64(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,
       [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, KD, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void zpbequ(char uplo, int n, int kd, doublecomplex *a,  int
          lda,  double  *scale, double *scond, double *amax,
          int *info);

void zpbequ_64(char uplo, long n, long kd, doublecomplex *a,
          long  lda,  double  *scale,  double *scond, double
          *amax, long *info);
```

PURPOSE

zpbequ computes row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
= 'U': Upper triangular of A is stored;
= 'L': Lower triangular of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input) The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          *x,  long  ldx,  double  *ferr, double *berr, long
          *info);
```

PURPOSE

zpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS (input)
The number of right hand sides, i.e., the number

of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A as computed by CPBTRF, in the same storage format as A (see A).

LDAF (input)
The leading dimension of the array AF. LDAF >= KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CPBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each

solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

SUBROUTINE PBSTF_64(UPLO, [N], KD, AB, [LDAB], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: AB
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zpbstf(char uplo, int n, int kd, doublecomplex *ab, int
          ldab, int *info);

void zpbstf_64(char uplo, long  n,  long  kd,  doublecomplex
          *ab, long ldab, long *info);
```

PURPOSE

zpbstf computes a split Cholesky factorization of a complex Hermitian positive definite band matrix A.

This routine is designed to be used in conjunction with CHBGST.
The factorization has the form A = S**H*S where S is a band matrix of the same bandwidth as A and the following structure:

```
  S = ( U    )
      ( M  L )
```

where U is upper triangular of order m = (n+kd)/2, and L is lower triangular of order n-m.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the factor S from the split Cholesky factorization A = S**H*S. See Further Details.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 7, KD = 2:

```
S = ( s11  s12  s13                     )
    (      s22  s23  s24                )
    (           s33  s34                )
    (                s44                )
    (           s53  s54  s55           )
    (                s64  s65  s66      )
    (                     s75  s76  s77 )
```

If UPLO = 'U', the array AB holds:

on entry: on exit:

```
 *    *   a13  a24  a35  a46  a57   *    *   s13  s24   s53'
s64' s75'
 *   a12  a23  a34  a45  a56  a67   *   s12  s23  s34   s54'
s65'  s76'  a11  a22  a33  a44  a55  a66  a77  s11  s22  s33
s44  s55  s66  s77
```

If UPLO = 'L', the array AB holds:

on entry: on exit:

```
a11  a22  a33  a44  a55  a66  a77  s11  s22  s33   s44   s55
s66   s77  a21  a32  a43  a54  a65  a76   *   s12' s23' s34'
s54  s65  s76   * a31  a42  a53  a64  a64    *     *    s13'
s24' s53  s64  s75   *    *
```

Array elements marked * are not used by the routine; s12' denotes conjg(s12); the diagonal elements of S are real.

NAME

```
zpbsv - compute the solution to a complex system  of  linear
equations  A * X = B,
```

SYNOPSIS

```
SUBROUTINE ZPBSV(UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER N, NDIAG, NRHS, LDA, LDB, INFO

SUBROUTINE ZPBSV_64(UPLO, N, NDIAG, NRHS, A, LDA, B, LDB, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*), B(LDB,*)
INTEGER*8 N, NDIAG, NRHS, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE PBSV(UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER :: N, NDIAG, NRHS, LDA, LDB, INFO

SUBROUTINE PBSV_64(UPLO, [N], NDIAG, [NRHS], A, [LDA], B, [LDB],
       [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zpbsv(char uplo, int n, int ndiag, int nrhs, doublecom-
          plex  *a,  int lda, doublecomplex *b, int ldb, int
          *info);

void zpbsv_64(char uplo, long  n,  long  ndiag,  long  nrhs,
          doublecomplex *a, long lda, doublecomplex *b, long
          ldb, long *info);
```

PURPOSE

```
zpbsv computes the solution to a complex  system  of  linear
equations
   A * X = B,  where  A  is  an  N-by-N  Hermitian  positive
definite band matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as
   A = U**H * U,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower
triangular  band matrix, with the same number of superdiago-
nals or subdiagonals as A.  The factored form of A  is  then
used to solve the system of equations A * X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NDIAG (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  NDIAG >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band matrix A, stored in the first NDIAG+1
```

rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(NDIAG+1+i-j,j) = A(i,j) for max(1,j-NDIAG)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(N,j+NDIAG). See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, in the same storage format as A.

LDA (input)
The leading dimension of the array A. LDA >= NDIAG+1.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, NDIAG = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:
```

```
   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

Array elements marked * are not used by the routine.

          lecomplex  *b,  long  ldb,  doublecomplex *x, long
          ldx, double *rcond, double  *ferr,  double  *berr,
          long *info);
```

PURPOSE

zpbsvx uses the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

```
1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is  used
to
   factor the matrix A (after equilibration if FACT  =  'E')
as
      A = U**H * U,  if UPLO = 'U', or
      A = L * L**H,  if UPLO = 'L',
   where U is an upper triangular band matrix, and  L  is  a
lower
   triangular band matrix.

3. If the leading i-by-i principal  minor  is  not  positive
definite,
   then the routine returns with INFO =  i.  Otherwise,  the
factored
   form of A is used to estimate the condition number of the
matrix
   A.  If the reciprocal of the  condition  number  is  less
than machine
   precision, INFO = N+1 is returned as a warning,  but  the
routine
   still goes on to solve for X and compute error bounds as
   described below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.

6. If equilibration was used, the matrix X is  premultiplied
by
   diag(S) so that it solves the original system before
   equilibration.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored form of  the
          matrix A is supplied on entry, and if not, whether
          the matrix A should be equilibrated before  it  is
          factored.   = 'F':  On entry, AF contains the fac-
          tored form of A.  If EQUED = 'Y', the matrix A has
          been equilibrated with scaling factors given by S.
          A and AF will not be modified.  = 'N':  The matrix
          A will be copied to AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NDIAG (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  NDIAG >= 0.

NRHS (input)
          The number of right-hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band matrix A, stored in the first NDIAG+1
          rows of the array, except if FACT = 'F' and  EQUED
          = 'Y', then A must contain the equilibrated matrix
          diag(S)*A*diag(S).  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
          UPLO  =  'U',  A(NDIAG+1+i-j,j)   =   A(i,j)   for
          max(1,j-NDIAG)<=i<=j;  if  UPLO  = 'L', A(1+i-j,j)
          = A(i,j) for j<=i<=min(N,j+NDIAG).  See below  for
          further details.

          On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
          overwritten by diag(S)*A*diag(S).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          NDIAG+1.

AF (input/output)
```

If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, in the same storage format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= NDIAG+1.

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations.

Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to work-

ing precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, NDIAG = 2, and UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```
   a11  a12  a13
        a22  a23  a24
             a33  a34  a35
                  a44  a45  a46
                       a55  a56
   (aij=conjg(aji))         a66
```

Band storage of the upper triangle of A:

```
    *    *   a13  a24  a35  a46
    *   a12  a23  a34  a45  a56
   a11  a22  a33  a44  a55  a66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
   a11  a22  a33  a44  a55  a66
   a21  a32  a43  a54  a65   *
   a31  a42  a53  a64   *    *
```

Array elements marked * are not used by the routine.

Contents

NAME

zpbtf2 - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

SYNOPSIS

```
SUBROUTINE ZPBTF2(UPLO, N, KD, AB, LDAB, INFO)

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: AB
INTEGER :: N, KD, LDAB, INFO

SUBROUTINE PBTF2_64(UPLO, [N], KD, AB, [LDAB], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: AB
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zpbtf2(char uplo, int n, int kd, doublecomplex *ab, int
          ldab, int *info);

void zpbtf2_64(char uplo, long  n,  long  kd,  doublecomplex
          *ab, long ldab, long *info);
```

PURPOSE

zpbtf2 computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form
```
   A = U' * U ,  if UPLO = 'U', or
   A = L  * L',  if UPLO = 'L',
```
where U is an upper triangular matrix, U' is the conjugate transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L

from the Cholesky factorization A = U'*U or A = L*L' of the band matrix A, in the same storage format as A.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

          lda, int *info);

void zpbtrf_64(char uplo, long n, long kd, doublecomplex *a,
          long lda, long *info);
```

PURPOSE

```
zpbtrf computes the Cholesky factorization of a complex Her-
mitian positive definite band matrix A.

The factorization has the form
   A = U**H * U,  if UPLO = 'U', or
   A = L  * L**H,  if UPLO = 'L',
where U is an upper triangular matrix and L  is  lower  tri-
angular.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  A,  stored in the first KD+1
          rows of the array.  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
          UPLO = 'U', A(kd+1+i-j,j) =  A(i,j)  for  max(1,j-
          kd)<=i<=j;  if  UPLO = 'L', A(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+kd).

          On exit, if INFO = 0, the triangular factor U or L
          from  the Cholesky factorization A = U**H*U or A =
          L*L**H of the band matrix A, in the  same  storage
          format as A.

LDA (input)
```

The leading dimension of the array A. LDA >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

```

PURPOSE

zpbtrs solves a system of linear equations A*X = B with a Hermitian positive definite band matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPBTRF.

ARGUMENTS

UPLO (input)
= 'U': Upper triangular factor stored in A;
= 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO ='U', A(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', A(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

```
B (input/output)
          On entry, the right hand side matrix B.  On  exit,
          the solution matrix X.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

void zpocon_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, double anorm, double *rcond, long *info);
```

PURPOSE

zpocon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, as computed by CPOTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ANORM (input)
The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)

NAME

zpoequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

SYNOPSIS

```
SUBROUTINE ZPOEQU(N, A, LDA, SCALE, SCOND, AMAX, INFO)

DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)

SUBROUTINE ZPOEQU_64(N, A, LDA, SCALE, SCOND, AMAX, INFO)

DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION SCOND, AMAX
DOUBLE PRECISION SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE POEQU([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, LDA, INFO
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE

SUBROUTINE POEQU_64([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
```

```
REAL(8) :: SCOND, AMAX
REAL(8), DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void zpoequ(int n, doublecomplex *a, int lda, double *scale,
          double *scond, double *amax, int *info);

void zpoequ_64(long n, doublecomplex *a,  long  lda,  double
          *scale, double *scond, double *amax, long *info);
```

PURPOSE

zpoequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

A (input) The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          *a,  long lda, doublecomplex *af, long ldaf, doub-
          lecomplex *b, long  ldb,  doublecomplex  *x,  long
          ldx, double *ferr, double *berr, long *info);
```

PURPOSE

zporfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, as computed by CPOTRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CPOTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

```
WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO =  -i,  the  i-th  argument  had  an
          illegal value
```

          *a,  long  lda,  doublecomplex  *b, long ldb, long
          *info);
```

PURPOSE

```
zposv computes the solution to a complex  system  of  linear
equations
   A * X = B, where A is an N-by-N Hermitian positive defin-
ite matrix and X and B are N-by-NRHS matrices.
The Cholesky decomposition is used to factor A as
   A = U**H* U,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular matrix and  L is a lower tri-
angular  matrix.   The  factored  form  of A is then used to
solve the system of equations A * X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A,
          and the strictly lower triangular part of A is not
          referenced.  If UPLO =  'L',  the  leading  N-by-N
          lower triangular part of A contains the lower tri-
          angular part of the matrix  A,  and  the  strictly
          upper triangular part of A is not referenced.

          On exit, if INFO = 0, the factor U or L  from  the
          Cholesky factorization A = U**H*U or A = L*L**H.
```

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

C INTERFACE

```
#include <sunperf.h>

void zposvx(char fact, char uplo, int  n,  int  nrhs,  doub-
          lecomplex  *a,  int  lda,  doublecomplex  *af, int
          ldaf, char equed, double *s, doublecomplex *b, int
          ldb,  doublecomplex  *x,  int  ldx, double *rcond,
          double *ferr, double *berr, int *info);

void zposvx_64(char fact, char  uplo,  long  n,  long  nrhs,
          doublecomplex  *a,  long  lda,  doublecomplex *af,
          long ldaf, char equed,  double  *s,  doublecomplex
          *b,  long  ldb, doublecomplex *x, long ldx, double
          *rcond, double *ferr, double *berr, long *info);
```

PURPOSE

```
zposvx uses the Cholesky factorization A =  U**H*U  or  A  =
L*L**H to compute the solution to a complex system of linear
equations
   A * X = B, where A is an N-by-N Hermitian positive defin-
ite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
```

the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
factor the matrix A (after equilibration if FACT = 'E') as
```
A = U**H* U,  if UPLO = 'U', or
A = L * L**H,  if UPLO = 'L',
```
where U is an upper triangular matrix and L is a lower triangular
matrix.

3. If the leading i-by-i principal minor is not positive definite,
then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.

4. The system of equations is solved for X using the factored form
of A.

5. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

6. If equilibration was used, the matrix X is premultiplied by
diag(S) so that it solves the original system before
equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the
matrix A is supplied on entry, and if not, whether

the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the Hermitian matrix A, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (output)
If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, in the same storage format as A. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix diag(S)*A*diag(S).

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >= max(1,N).

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)

The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N-by-NRHS righthand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)

The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

NAME

zpotf2 - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

SYNOPSIS

```
SUBROUTINE ZPOTF2(UPLO, N, A, LDA, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER N, LDA, INFO

SUBROUTINE ZPOTF2_64(UPLO, N, A, LDA, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE POTF2(UPLO, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, LDA, INFO

SUBROUTINE POTF2_64(UPLO, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zpotf2(char uplo, int n, doublecomplex *a, int lda, int
          *info);

void zpotf2_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, long *info);
```

PURPOSE

```
zpotf2 computes the Cholesky factorization of a complex Her-
mitian positive definite matrix A.

The factorization has the form
   A = U' * U ,  if UPLO = 'U', or
   A = L  * L',  if UPLO = 'L',
where U is an upper triangular matrix and L  is  lower  tri-
angular.

This is the unblocked  version  of  the  algorithm,  calling
Level 2 BLAS.
```

ARGUMENTS

```
UPLO (input)
          Specifies whether the upper  or  lower  triangular
          part  of the Hermitian matrix A is stored.  = 'U':
          Upper triangular
          = 'L':  Lower triangular

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading n by n upper triangular part of A con-
          tains the upper triangular part of the  matrix  A,
          and the strictly lower triangular part of A is not
          referenced.  If UPLO = 'L', the  leading  n  by  n
          lower triangular part of A contains the lower tri-
          angular part of the matrix  A,  and  the  strictly
          upper triangular part of A is not referenced.

          On exit, if INFO = 0, the factor U or L  from  the
          Cholesky factorization A = U'*U  or A = L*L'.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).
```

```
INFO (output)
          = 0: successful exit
          < 0: if INFO = -k, the k-th argument had an  ille-
          gal value
          > 0: if INFO = k, the leading minor of order k  is
          not positive definite, and the factorization could
          not be completed.

          lda, long *info);
```

PURPOSE

zpotri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, as computed by CPOTRF. On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

INTEGER :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

```
SUBROUTINE PPCON_64(UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void zppcon(char  uplo,  int  n,  doublecomplex  *a,  double
          anorm, double *rcond, int *info);
void zppcon_64(char uplo, long n, doublecomplex  *a,  double
          anorm, double *rcond, long *info);
```

PURPOSE

zppcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input) The triangular factor U or  L  from  the  Cholesky
          factorization  A  =  U**H*U  or A = L*L**H, packed
          columnwise in a linear array.  The j-th column  of
          U  or  L  is stored in the array A as follows:  if
          UPLO = 'U', A(i + (j-1)*j/2) = U(i,j) for 1<=i<=j;
          if  UPLO = 'L', A(i + (j-1)*(2n-j)/2) = L(i,j) for
          j<=i<=n.

ANORM (input)
          The 1-norm (or  infinity-norm)  of  the  Hermitian
          matrix A.
```

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>

void zppequ(char  uplo,  int  n,  doublecomplex  *a,  double
          *scale, double *scond, double *amax, int *info);
void zppequ_64(char uplo, long n, doublecomplex  *a,  double
          *scale, double *scond, double *amax, long *info);
```

PURPOSE

zppequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i)=1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j)=S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

```
SCOND (output)
          If INFO = 0, SCALE contains the ratio of the smal-
          lest  SCALE(i)  to the largest SCALE(i).  If SCOND
          >= 0.1 and AMAX  is  neither  too  large  nor  too
          small, it is not worth scaling by SCALE.

AMAX (output)
          Absolute value of largest matrix element.  If AMAX
          is  very close to overflow or very close to under-
          flow, the matrix should be scaled.
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, the i-th  diagonal  element  is
          nonpositive.

          *berr, long *info);
```

PURPOSE

zpprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The upper  or  lower  triangle  of  the  Hermitian
          matrix  A,  packed  columnwise  in a linear array.
          The j-th column of A is stored in the array  A  as
          follows:  if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j)
          for 1<=i<=j; if UPLO = 'L', A(i +  (j-1)*(2n-j)/2)
```

= A(i,j) for j<=i<=n.

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, as computed by SPPTRF/CPPTRF, packed columnwise in a linear array in the same format as A (see A).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CPPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

void zppsv(char uplo, int n,  int  nrhs,  doublecomplex  *a,
          doublecomplex *b, int ldb, int *info);

void zppsv_64(char uplo, long n,  long  nrhs,  doublecomplex
          *a, doublecomplex *b, long ldb, long *info);
```

PURPOSE

```
zppsv computes the solution to a complex  system  of  linear
equations
   A * X = B, where A is an N-by-N Hermitian positive defin-
ite matrix stored in packed format and X and B are N-by-NRHS
matrices.

The Cholesky decomposition is used to factor A as
   A = U**H* U,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower  tri-
angular  matrix.   The  factored  form  of A is then used to
solve the system of equations A * X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  A  as  follows:   if  UPLO = 'U', A(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i +
          (j-1)*(2n-j)/2)  =  A(i,j) for j<=i<=n.  See below
          for further details.
```

```
          On exit, if INFO = 0, the factor U or L  from  the
          Cholesky  factorization  A = U**H*U or A = L*L**H,
          in the same storage format as A.

B (input/output)
          On entry, the N-by-NRHS right hand side matrix  B.
          On  exit,  if  INFO  =  0,  the N-by-NRHS solution
          matrix X.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, the leading minor of order i of
          A  is  not positive definite, so the factorization
          could not be completed, and the solution  has  not
          been computed.
```

FURTHER DETAILS

```
The packed storage scheme is illustrated  by  the  following
example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44

Packed storage of the upper triangle of A:

A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

void zppsvx(char fact, char uplo, int  n,  int  nrhs,  doub-
          lecomplex  *a, doublecomplex *af, char equed, dou-
          ble *s, doublecomplex *b, int  ldb,  doublecomplex
          *x,  int  ldx, double *rcond, double *ferr, double
          *berr, int *info);

void zppsvx_64(char fact, char  uplo,  long  n,  long  nrhs,
          doublecomplex  *a,  doublecomplex *af, char equed,
          double *s, doublecomplex *b, long ldb,  doublecom-
          plex  *x,  long  ldx, double *rcond, double *ferr,
          double *berr, long *info);
```

PURPOSE

```
zppsvx uses the Cholesky factorization A =  U**H*U  or  A  =
L*L**H to compute the solution to a complex system of linear
equations
   A * X = B, where A is an N-by-N Hermitian positive defin-
ite matrix stored in packed format and X and B are N-by-NRHS
matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
```

is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
   factor the matrix A (after equilibration if FACT = 'E') as
      A = U'* U , if UPLO = 'U', or
      A = L * L', if UPLO = 'L',
   where U is an upper triangular matrix, L is a lower triangular
   matrix, and ' indicates conjugate transpose.

3. If the leading i-by-i principal minor is not positive definite,
   then the routine returns with INFO = i. Otherwise, the factored
   form of A is used to estimate the condition number of the matrix
   A. If the reciprocal of the condition number is less than machine
   precision, INFO = N+1 is returned as a warning, but the routine
   still goes on to solve for X and compute error bounds as
   described below.

4. The system of equations is solved for X using the factored form
   of A.

5. Iterative refinement is applied to improve the computed solution
   matrix and calculate error bounds and backward error estimates
   for it.

6. If equilibration was used, the matrix X is premultiplied by
   diag(S) so that it solves the original system before
   equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the fac-

```
            tored form of A.  If EQUED = 'Y', the matrix A has
            been equilibrated with scaling factors given by S.
            A and AF will not be modified.  = 'N':  The matrix
            A will be copied to AF and factored.
            = 'E':  The  matrix  A  will  be  equilibrated  if
            necessary, then copied to AF and factored.

UPLO (input)
            = 'U':  Upper triangle of A is stored;
            = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
            the matrix A.  N >= 0.

NRHS (input)
            The number of right hand sides, i.e.,  the  number
            of columns of the matrices B and X.  NRHS >= 0.
A (input/output)
            On entry, the upper or lower triangle of the  Her-
            mitian  matrix  A,  packed  columnwise in a linear
            array, except if FACT = 'F' and EQUED = 'Y',  then
            A    must    contain    the    equilibrated    matrix
            diag(S)*A*diag(S).  The j-th column of A is stored
            in  the  array A as follows:  if UPLO = 'U', A(i +
            (j-1)*j/2) = A(i,j) for 1<=i<=j; if  UPLO  =  'L',
            A(i  +  (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.  See
            below for further details.  A is not  modified  if
            FACT  =  'F'  or 'N', or if FACT = 'E' and EQUED =
            'N' on exit.

            On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
            overwritten by diag(S)*A*diag(S).

AF (input/output)
            If FACT = 'F', then AF is an input argument and on
            entry  contains  the triangular factor U or L from
            the Cholesky factorization  A  =  U**H*U  or  A  =
            L*L**H, in the same storage format as A.  If EQUED
            .ne. 'N', then AF is  the  factored  form  of  the
            equilibrated matrix A.

            If FACT = 'N', then AF is an output  argument  and
            on  exit returns the triangular factor U or L from
            the Cholesky factorization  A  =  U**H*U  or  A  =
            L*L**H of the original matrix A.

            If FACT = 'E', then AF is an output  argument  and
            on  exit returns the triangular factor U or L from
            the Cholesky factorization  A  =  U**H*U  or  A  =
            L*L**H  of  the  equilibrated  matrix  A  (see the
```

description of A for the form of the equilibrated matrix).

EQUED (input)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)

The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)

The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

          *info);
```

PURPOSE

zpptrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format.

The factorization has the form

```
   A = U**H * U,  if UPLO = 'U', or
   A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)
  = 'U': Upper triangle of A is stored;
  = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
  On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

  On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, in the same storage format as A.

INFO (output)
  = 0: successful exit
  < 0: if INFO = -i, the i-th argument had an illegal value
  > 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

```
The packed storage scheme is illustrated  by  the  following
example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44

Packed storage of the upper triangle of A:

A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

          *a, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zpptrs solves a system of linear equations A*X = B with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B.   LDB >= max(1,N).

INFO (output)

```
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an ille-
gal value

void zptcon(int n, double *diag, doublecomplex *offd, double
          anorm, double *rcond, int *info);

void zptcon_64(long n, double  *diag,  doublecomplex  *offd,
          double anorm, double *rcond, long *info);
```

PURPOSE

zptcon computes the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization A = L*D*L**H or A = U**H*D*U computed by CPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as
RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

DIAG (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by CPTTRF.

OFFD (input)
The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by CPTTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The method used is described in Nicholas J. Higham, "Efficient Algorithms for Computing the Condition Number of a Tridiagonal Matrix", SIAM J. Sci. Stat. Comput., Vol. 7, No. 1, January 1986.

COMPLEX(8), DIMENSION(:,:) :: Z
INTEGER :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK

SUBROUTINE PTEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:,:) :: Z
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>

void zpteqr(char compz, int n, double *d, double  *e,  doub-
          lecomplex *z, int ldz, int *info);

void zpteqr_64(char compz, long n,  double  *d,  double  *e,
          doublecomplex *z, long ldz, long *info);
```

PURPOSE

zpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band positive definite Hermitian matrix can also be found if CHETRD, CHPTRD, or CHBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvectors of original Hermitian matrix also. Array Z contains the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix. On normal exit, D contains the eigenvalues, in descending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', the unitary matrix used in the reduction to tridiagonal form. On exit, if COMPZ = 'V', the orthonormal eigenvectors of the original Hermitian matrix; if COMPZ = 'I', the orthonormal eigenvectors of the tridiagonal matrix. If INFO > 0 on exit, Z contains the eigenvectors associated with only the stored eigenvalues. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK (workspace)
dimension(4*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is: <= N the Cholesky factorization of the matrix could not be performed because the i-th principal minor was not positive definite. > N the SVD algorithm failed to converge; if INFO = N+i, i off-diagonal elements of the bidiagonal factor did not converge to zero.

          *x,  long  ldx,  double  *ferr, double *berr, long
          *info);
```

PURPOSE

zptrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization:
= 'U': OFFD is the superdiagonal of A, and A = U**H*DIAG*U;
= 'L': OFFD is the subdiagonal of A, and A = L*DIAG*L**H. (The two forms are equivalent if A is real.)

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input)
The n real diagonal elements of the tridiagonal matrix A.

OFFD (input)
The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

DIAGF (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization computed by CPTTRF.

OFFDF (input)
The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by CPTTRF (see UPLO).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CPTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

```

          *sub, doublecomplex *b, long ldb, long *info);
```

PURPOSE

zptsv computes the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as A = L*D*L**H, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the factorization A = L*DIAG*L**H.

SUB (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**H factorization of A. SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U**H*DIAG*U factorization of A.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution

```
            matrix X.

LDB (input)
            The leading dimension of  the  array  B.   LDB  >=
            max(1,N).

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  if INFO = i, the leading minor of order i is
            not  positive  definite,  and the solution has not
            been computed.  The  factorization  has  not  been
            completed unless i = N.
```

          *x,  long ldx, double *rcond, double *ferr, double
          *berr, long *info);
```

PURPOSE

zptsvx uses the factorization A = L*D*L**H to compute the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the matrix A is factored as A = L*D*L**H, where L
   is a unit lower bidiagonal matrix and D is diagonal. The factorization can also be regarded as having the form
   A = U**H*D*U.

2. If the leading i-by-i principal minor is not positive

definite,
then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.

3. The system of equations is solved for X using the factored form
of A.

4. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry. = 'F': On entry, DIAGF and SUBF contain the factored form of A. DIAG, SUB, DIAGF, and SUBF will not be modified. = 'N': The matrix A will be copied to DIAGF and SUBF and factored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

DIAG (input)
The n diagonal elements of the tridiagonal matrix A.

SUB (input)
The (n-1) subdiagonal elements of the tridiagonal matrix A.

DIAGF (input/output)
If FACT = 'F', then DIAGF is an input argument and

on entry contains the n diagonal elements of the diagonal matrix DIAG from the L*DIAG*L**H factorization of A. If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the diagonal matrix DIAG from the L*DIAG*L**H factorization of A.

SUBF (input/output)
If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**H factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**H factorization of A.

B (input) On entry, the N-by-NRHS right hand side matrix B. Unchanged on exit.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each

solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

          *info);

void zpttrf_64(long n, double  *diag,  doublecomplex  *offd,
          long *info);
```

PURPOSE

zpttrf computes the L*D*L' factorization of a complex Hermitian positive definite tridiagonal matrix A. The factorization may also be regarded as having the form A = U'*D*U.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

DIAG (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the L*DIAG*L' factorization of A.

OFFD (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L' factorization of A. OFFD can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U'*DIAG*U factorization of A.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite; if k < N, the factorization could not be completed, while if k = N, the factorization was completed, but DIAG(N) = 0.

#include <sunperf.h>

void zpttrs(char uplo, int n, int nrhs, double *diag,  doub-
          lecomplex  *offd,  doublecomplex  *b, int ldb, int
          *info);

void zpttrs_64(char uplo, long n, long nrhs,  double  *diag,
          doublecomplex  *offd,  doublecomplex *b, long ldb,
          long *info);
```

PURPOSE

zpttrs solves a tridiagonal system of the form
A * X = B using the factorization A = U'*D*U or A = L*D*L' computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

UPLO (input)
Specifies the form of the factorization and whether the vector OFFD is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 'U': A = U'*DIAG*U, OFFD is the superdiagonal of U
= 'L': A = L*DIAG*L', OFFD is the subdiagonal of L

N (input) The order of the tridiagonal matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization A = U'*DIAG*U or A = L*DIAG*L'.

OFFD (input/output)

If UPLO = 'U', the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization A = U'*DIAG*U. If UPLO = 'L', the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization A = L*DIAG*L'.

B (input/output)

On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

COMPLEX(8), DIMENSION(:,:) :: B
INTEGER(8) :: IUPLO, N, NRHS, LDB
REAL(8), DIMENSION(:) :: D
```

C INTERFACE

```
#include <sunperf.h>

void zptts2(int iuplo, int n, int  nrhs,  double  *d,  doub-
          lecomplex *e, doublecomplex *b, int ldb);

void zptts2_64(long iuplo, long n,  long  nrhs,  double  *d,
          doublecomplex *e, doublecomplex *b, long ldb);
```

PURPOSE

zptts2 solves a tridiagonal system of the form
   A * X = B using the factorization A = U'*D*U or A =
L*D*L' computed by CPTTRF. D is a diagonal matrix specified
in the vector D, U (or L) is a unit bidiagonal matrix whose
superdiagonal (subdiagonal) is specified in the vector E,
and X and B are N by NRHS matrices.

ARGUMENTS

IUPLO (input)
Specifies the form of the factorization   and
whether the vector E is the superdiagonal of the
upper bidiagonal factor U or the subdiagonal of
the lower bidiagonal factor L. = 1: A = U'*D*U,
E is the superdiagonal of U
= 0: A = L*D*L', E is the subdiagonal of L

N (input) The order of the tridiagonal matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number
of columns of the matrix B. NRHS >= 0.

D (input) The n diagonal elements of the diagonal matrix D
from the factorization A = U'*D*U or A = L*D*L'.

E (input) If IUPLO = 1, the (n-1) superdiagonal elements of
the unit bidiagonal factor U from the factoriza-
tion A = U'*D*U. If IUPLO = 0, the (n-1) subdiag-
onal elements of the unit bidiagonal factor L from
the factorization A = L*D*L'.

B (input/output)
On entry, the right hand side vectors B for the
system of linear equations. On exit, the solution

vectors, X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

NAME

zrot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex

SYNOPSIS

```
SUBROUTINE ZROT(N, X, INCX, Y, INCY, C, S)

DOUBLE COMPLEX S
DOUBLE COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY
DOUBLE PRECISION C

SUBROUTINE ZROT_64(N, X, INCX, Y, INCY, C, S)

DOUBLE COMPLEX S
DOUBLE COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
DOUBLE PRECISION C
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)

COMPLEX(8) :: S
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY
REAL(8) :: C

SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)

COMPLEX(8) :: S
COMPLEX(8), DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

```
REAL(8) :: C
```

C INTERFACE

```
#include <sunperf.h>

void zrot(int n, doublecomplex *x, int  incx,  doublecomplex
          *y, int incy, double c, doublecomplex *s);

void zrot_64(long n, doublecomplex *x, long incx, doublecom-
          plex *y, long incy, double c, doublecomplex *s);
```

PURPOSE

zrot applies a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex.

ARGUMENTS

N (input)
The number of elements in the vectors X and Y.

X (input/output)
On input, the vector X. On output, X is overwritten with C*X + S*Y.

INCX (input)
The increment between successive values of Y. INCX <> 0.

Y (input/output)
On input, the vector Y. On output, Y is overwritten with -CONJG(S)*X + C*Y.

INCY (input)
The increment between successive values of Y. INCY <> 0.

C (input)

S (input)

```
C and S define a rotation
[  C          S  ]
[ -conjg(S)   C  ]

where C*C + S*CONJG(S) = 1.0.
```

Contents

NAME

```
zrotg - Construct a Given's plane rotation
```

SYNOPSIS

```
SUBROUTINE ZROTG(A, B, C, S)

DOUBLE COMPLEX A, B, S
DOUBLE PRECISION C

SUBROUTINE ZROTG_64(A, B, C, S)

DOUBLE COMPLEX A, B, S
DOUBLE PRECISION C
```

F95 INTERFACE

```
SUBROUTINE ROTG(A, B, C, S)

COMPLEX(8) :: A, B, S
REAL(8) :: C

SUBROUTINE ROTG_64(A, B, C, S)

COMPLEX(8) :: A, B, S
REAL(8) :: C
```

C INTERFACE

```
#include <sunperf.h>

void zrotg(doublecomplex *a, doublecomplex  *b,  double  *c,
          doublecomplex *s);

void zrotg_64(doublecomplex *a, doublecomplex *b, double *c,
```

```
              doublecomplex *s);
```

PURPOSE

zrotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

A (input/output)
On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

B (input)
On entry, B contains the entry to be annihilated in the second vector. Unchanged on exit.

C (output)
On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

S (output)
On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

NAME

```
zscal - Compute y := alpha * y
```

SYNOPSIS

```
SUBROUTINE ZSCAL(N, ALPHA, Y, INCY)

DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX Y(*)
INTEGER N, INCY

SUBROUTINE ZSCAL_64(N, ALPHA, Y, INCY)

DOUBLE COMPLEX ALPHA
DOUBLE COMPLEX Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])

COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: Y
INTEGER :: N, INCY

SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])

COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zscal(int n, doublecomplex  *alpha,  doublecomplex  *y,
          int incy);

void zscal_64(long n,  doublecomplex  *alpha,  doublecomplex
          *y, long incy);
```

PURPOSE

zscal Compute y := alpha * y where alpha is a scalar and y is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
zsctr - Scatters elements from x into y.
```

SYNOPSIS

```
 SUBROUTINE ZSCTR(NZ, X, INDX, Y)

 DOUBLE COMPLEX X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE ZSCTR_64(NZ, X, INDX, Y)

 DOUBLE COMPLEX X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE SCTR([NZ], X, INDX, Y)

 COMPLEX(8), DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE SCTR_64([NZ], X, INDX, Y)

 COMPLEX(8), DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
ZSCTR - Scatters the components of a sparse vector x stored
in compressed form into specified components of a vector y
```

in full storage form.

```
 do i = 1, n
   y(indx(i)) = x(i)
 enddo
```

ARGUMENTS

```
NZ (input) - INTEGER
        Number of elements in the compressed form.
        Unchanged on exit.

X (input)
        Vector containing the values to be scattered from
        compressed form into full storage form.  Unchanged
        on exit.

INDX (input) - INTEGER
        Vector containing the indices of the compressed
        form.  It is assumed that the elements in INDX are
        distinct and greater than zero.  Unchanged on exit.

Y (output)
        Vector whose elements specified by indx have been
        set to the corresponding entries of x.  Only the
        elements corresponding to the indices in indx have
        been modified.

 DOUBLE COMPLEX    ALPHA, BETA
 DOUBLE COMPLEX, DIMENSION(:) ::  VAL
 DOUBLE COMPLEX, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in skyline format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                    ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general (NOT SUPPORTED)
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
```

```
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          array contain the nonzeros of A in skyline profile form.
                Row-oriented if DESCRA(2) = 1 (lower triangular),
                column oriented if DESCRA(2) = 2 (upper triangular).

 PNTR()         integer array of length M+1 (lower triangular) or
                K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
                points to the location in VAL of the first element of
                the skyline profile in row (column) I.

 B()            rectangular array with first dimension LDB.
 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

 SUBROUTINE SKYSM_64( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA,
*    VAL, PNTR,  B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, M, UNITD
 INTEGER*8, DIMENSION(:) ::  DESCRA,  PNTR
 DOUBLE COMPLEX    ALPHA, BETA
 DOUBLE COMPLEX, DIMENSION(:) ::  VAL, DV
 DOUBLE COMPLEX, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in skyline format and
op( A )  is one  of

 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' )).
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row or column scaling (see section
                    NOTES for further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter
```

```
DESCRA()        Descriptor argument.  Five element integer array
                DESCRA(1) matrix structure
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.
                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

VAL()           array contain the nonzeros of A in skyline profile form.
                Row-oriented if DESCRA(2) = 1 (lower triangular),
                column oriented if DESCRA(2) = 2 (upper triangular).

PNTR()          integer array of length M+1 (lower triangular) or
                K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
                points to the location in VAL of the first element of
                the skyline profile in row (column) I.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.
                On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK           length of WORK array.  LWORK should be at least M.

                For good performance, LWORK should generally be larger.
```

For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. Also not supported:
   a. lower triangular matrix A of size m by n where m > n
   b. upper triangular matrix A of size m by n where m < n

2. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

3. If UNITD =4, the routine scales the rows of A if *DESCRA*(2)=1 and the columns of A if *DESCRA*(2)=2 such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in this particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows (columns) have been scaled. UNITD=2 if *DESCRA*(2)=1 and UNITD=3 if *DESCRA*(2)=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row (column) number which 2-norm is exactly zero.

4. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements

might or might not be referenced in the SKY representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the SKY representation.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

NAME

zspcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by ZSPTRF

SYNOPSIS

```
SUBROUTINE ZSPCON(UPLO, N, AP, IPIVOT, ANORM, RCOND, WORK, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX AP(*), WORK(*)
INTEGER N, INFO
INTEGER IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND

SUBROUTINE ZSPCON_64(UPLO, N, AP, IPIVOT, ANORM, RCOND, WORK, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX AP(*), WORK(*)
INTEGER*8 N, INFO
INTEGER*8 IPIVOT(*)
DOUBLE PRECISION ANORM, RCOND
```

F95 INTERFACE

```
SUBROUTINE SPCON(UPLO, N, AP, IPIVOT, ANORM, RCOND, [WORK], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: AP, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
```

```
SUBROUTINE SPCON_64(UPLO, N, AP, IPIVOT, ANORM, RCOND, [WORK], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: AP, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>

void  zspcon(char  uplo,  int  n,  doublecomplex  *ap,   int
          *ipivot, double anorm, double *rcond, int *info);
void zspcon_64(char uplo, long n,  doublecomplex  *ap,  long
          *ipivot, double anorm, double *rcond, long *info);
```

PURPOSE

zspcon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by ZSPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

AP (input)
Double complex array, dimension (N*(N+1)/2) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by ZSPTRF.

```
ANORM (input)
          The 1-norm of the original matrix A.

RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix  A, computed as RCOND = 1/(ANORM * AINVNM),
          where AINVNM is  an  estimate  of  the  1-norm  of
          inv(A) computed in this routine.

WORK (workspace)
          Double complex array, dimension(2*N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

C INTERFACE

```
#include <sunperf.h>

void zsprfs(char uplo, int n, int  nrhs,  doublecomplex  *a,
          doublecomplex  *af, int *ipivot, doublecomplex *b,
          int ldb, doublecomplex *x, int ldx, double  *ferr,
          double *berr, int *info);

void zsprfs_64(char uplo, long n, long  nrhs,  doublecomplex
          *a, doublecomplex *af, long *ipivot, doublecomplex
          *b, long ldb, doublecomplex *x, long  ldx,  double
          *ferr, double *berr, long *info);
```

PURPOSE

zsprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) Double complex array,  dimension  (N*(N+1)/2)  The
          upper or lower triangle of the symmetric matrix A,
```

packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AF (input)
Double complex array, dimension (N*(N+1)/2) The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by CSPTRF.

B (input) Double complex array, dimension (LDB,NRHS) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
Double complex array, dimension (LDX,NRHS) On entry, the solution matrix X, as computed by CSPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
Double precision array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Double precision array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative

change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
Double precision array, dimension(2*N)

WORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

CHARACTER(LEN=1) :: UPLO
```

```
COMPLEX(8), DIMENSION(:) :: AP
COMPLEX(8), DIMENSION(:,:) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void zspsv(char uplo, int n, int  nrhs,  doublecomplex  *ap,
          int   *ipivot,  doublecomplex  *b,  int  ldb,  int
          *info);

void zspsv_64(char uplo, long n,  long  nrhs,  doublecomplex
          *ap,  long  *ipivot,  doublecomplex  *b, long ldb,
          long *info);
```

PURPOSE

```
zspsv computes the solution to a complex  system  of  linear
equations
   A * X = B, where A is an N-by-N symmetric  matrix  stored
in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
   A = U * D * U**T,  if UPLO = 'U', or
   A = L * D * L**T,  if UPLO = 'L',
where U (or L) is a product of permutation  and  unit  upper
(lower) triangular matrices, D is symmetric and block diago-
nal with 1-by-1 and 2-by-2 diagonal  blocks.   The  factored
form  of A is then used to solve the system of equations A *
X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

AP (input/output)
          Double complex  array,  dimension  (N*(N+1)/2)  On
```

entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (output)
Integer array, dimension (N) Details of the interchanges and the block structure of D, as determined by CSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
Double complex array, dimension (LDB,NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following

```
example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44

Packed storage of the upper triangle of A:

AP = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

PURPOSE

zspsvx uses the diagonal pivoting factorization A = U*D*U**T or A = L*D*L**T to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to

```
factor A as
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper
(lower)
   triangular matrices and D is symmetric and block diagonal
with
   1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

3. The system of equations is solved for X  using  the  fac-
tored form
   of A.

4. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored  form  of  A
          has  been supplied on entry.  = 'F':  On entry, AF
          and IPIVOT contain the factored form of A.  A,  AF
          and  IPIVOT  will  not  be  modified.  = 'N':  The
          matrix A will be copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
```

The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) Double complex array, dimension (N*(N+1)/2) The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AF (input/output)

Double complex array, dimension (N*(N+1)/2) If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)

Integer array, dimension (N) If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CSPTRF.

B (input) Double complex array, dimension (LDB,NRHS) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
Double complex array, dimension (LDX,NRHS) If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
Double complex array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Double complex array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
Double complex array, dimension(2*N)

WORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

SUBROUTINE SPTRF_64(UPLO, N, AP, IPIVOT, [INFO])

CHARACTER(LEN=1) :: UPLO
```

```
COMPLEX(8), DIMENSION(:) :: AP
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void  zsptrf(char  uplo,  int  n,  doublecomplex  *ap,   int
          *ipivot, int *info);

void zsptrf_64(char uplo, long n,  doublecomplex  *ap,  long
          *ipivot, long *info);
```

PURPOSE

zsptrf computes the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

A = U*D*U**T or A = L*D*L**T

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Double complex array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)
Integer array, dimension (N) Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then A = U*D*U', where
U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where
L = P(1)*L(1)* ... *P(k)*L(k)* ...,

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

#include <sunperf.h>

void  zsptri(char  uplo,  int  n,  doublecomplex  *ap,   int
          *ipivot, int *info);

void zsptri_64(char uplo, long n,  doublecomplex  *ap,  long
          *ipivot, long *info);
```

PURPOSE

zsptri computes the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization A = U*D*U**T or A = L*D*L**T computed by ZSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Double complex array, dimension (N*(N+1)/2) On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by ZSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by ZSPTRF.

WORK (workspace)
Double complex array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

SUBROUTINE STEDC_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [LWORK],
       [RWORK], [LRWORK], [IWORK], [LIWORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:,:) :: Z
INTEGER(8) :: N, LDZ, LWORK, LRWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL(8), DIMENSION(:) :: D, E, RWORK
```

C INTERFACE

```
#include <sunperf.h>
void zstedc(char compz, int n, double *d, double  *e,  doub-
          lecomplex *z, int ldz, int *info);

void zstedc_64(char compz, long n,  double  *d,  double  *e,
          doublecomplex *z, long ldz, long *info);
```

PURPOSE

zstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'I': Compute eigenvectors of tridiagonal matrix also.
= 'V': Compute eigenvectors of original Hermitian matrix also. On entry, Z contains the unitary

matrix used to reduce the original matrix to tri-
diagonal form.

N (input) The dimension of the symmetric tridiagonal matrix.
N >= 0.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If COMPZ = 'N' or 'I', or N <= 1, LWORK must be at least 1. If COMPZ = 'V' and N > 1, LWORK must be at least N*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of the array RWORK. If COMPZ = 'N' or N <= 1, LRWORK must be at least 1. If COMPZ =

'V' and N > 1, LRWORK must be at least 1 + 3*N + 2*N*lg N + 3*N**2 , where lg(N) = smallest integer k such that 2**k >= N. If COMPZ = 'I' and N > 1, LRWORK must be at least 1 + 4*N + 2*N**2 .

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If COMPZ = 'N' or N <= 1, LIWORK must be at least 1. If COMPZ = 'V' or N > 1, LIWORK must be at least 6 + 6*N + 5*N*lg N. If COMPZ = 'I' or N > 1, LIWORK must be at least 3 + 5*N .

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

#include <sunperf.h>

void zstegr(char jobz, char range, int n, double *d,  double
          *e,  double  vl, double vu, int il, int iu, double
          abstol, int *m, double *w, doublecomplex  *z,  int
          ldz, int *isuppz, int *info);

void zstegr_64(char jobz, char range,  long  n,  double  *d,
          double *e, double vl, double vu, long il, long iu,
          double abstol, long *m, double  *w,  doublecomplex
          *z, long ldz, long *isuppz, long *info);
```

PURPOSE

```
zstegr b) Compute the  eigenvalues,  lambda_j,  of  L_i  D_i
L_i^T to high
       relative accuracy by the dqds algorithm,
   (c) If there is a cluster of close eigenvalues,  "choose"
sigma_i
       close to the cluster, and go to step (a),
   (d) Given the approximate eigenvalue lambda_j of L_i  D_i
L_i^T,
       compute the corresponding eigenvector by forming a
       rank-revealing twisted factorization.
The desired accuracy of the output can be specified  by  the
input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for  the  sym-
metric   tridiagonal   eigenvalue/eigenvector  problem",  by
Inderjit Dhillon, Computer Science Division Technical Report
No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently CSTEGR is only set up to find ALL  the  n
eigenvalues and eigenvectors of T in O(n^2) time
```

Note 2 : Currently the routine CSTEIN is called when an appropriate sigma_i cannot be chosen in step (c) above. CSTEIN invokes modified Gram-Schmidt when eigenvalues are close.
Note 3 : CSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the n diagonal elements of the tridiagonal matrix T. On exit, D is overwritten.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix T in elements 1 to N-1 of E; E(N) need not be set. On exit, E is overwritten.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
The absolute error tolerance for the eigenvalues/eigenvectors. IF JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than N*EPS*|T|, then N*EPS*|T| will be used in its place, where EPS is the machine precision and |T| is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of EPS*|T| irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)
The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal (and minimal) LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,18*N)

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= max(1,10*N)

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = 1, internal error in SLARRE, if INFO = 2, internal error in CLARRV.

```

```
        [WORK], [IWORK], IFAIL, [INFO])

   COMPLEX(8), DIMENSION(:,:) :: Z
   INTEGER(8) :: N, M, LDZ, INFO
   INTEGER(8), DIMENSION(:) :: IBLOCK, ISPLIT, IWORK, IFAIL
   REAL(8), DIMENSION(:) :: D, E, W, WORK
```

C INTERFACE

```
   #include <sunperf.h>

   void zstein(int n, double *d, double *e, int m,  double  *w,
             int  *iblock,  int  *isplit, doublecomplex *z, int
             ldz, int *ifail, int *info);
   void zstein_64(long n, double *d, double *e, long m,  double
             *w,  long *iblock, long *isplit, doublecomplex *z,
             long ldz, long *ifail, long *info);
```

PURPOSE

zstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Although the eigenvectors are real, they are stored in a complex array, which may be passed to CUNMTR or CUPMTR for back
transformation to the eigenvectors of a complex Hermitian matrix which was reduced to tridiagonal form.

ARGUMENTS

N (input) The order of the matrix. N >= 0.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix T, stored in elements 1 to N-1; E(N) need not be set.

M (input) The number of eigenvectors to be found. 0 <= M <= N.

```
W (input) The first M elements of W contain the  eigenvalues
          for  which  eigenvectors  are to be computed.  The
          eigenvalues should be grouped by  split-off  block
          and  ordered  from  smallest to largest within the
          block.  ( The output  array  W  from  SSTEBZ  with
          ORDER = 'B' is expected here. )

IBLOCK (input)
          The  submatrix   indices   associated   with   the
          corresponding  eigenvalues  in  W;  IBLOCK(i)=1 if
          eigenvalue W(i) belongs  to  the  first  submatrix
          from  the  top,  =2  if W(i) belongs to the second
          submatrix, etc.  ( The output  array  IBLOCK  from
          SSTEBZ is expected here. )

ISPLIT (input)
          The splitting points, at which T  breaks  up  into
          submatrices.   The  first  submatrix  consists  of
          rows/columns 1 to  ISPLIT(  1  ),  the  second  of
          rows/columns  ISPLIT(  1  )+1 through ISPLIT( 2 ),
          etc.  ( The output array  ISPLIT  from  SSTEBZ  is
          expected here. )

Z (output)
          The computed eigenvectors.  The eigenvector  asso-
          ciated  with  the eigenvalue W(i) is stored in the
          i-th column of Z.  Any vector which fails to  con-
          verge  is  set to its current iterate after MAXITS
          iterations.  The imaginary parts of the  eigenvec-
          tors are set to zero.

LDZ (input)
          The leading dimension of  the  array  Z.   LDZ  >=
          max(1,N).

WORK (workspace)
          dimension(5*N)

IWORK (workspace)
          dimension(N)

IFAIL (output)
          On normal exit, all elements of  IFAIL  are  zero.
          If one or more eigenvectors fail to converge after
          MAXITS iterations, then their indices  are  stored
          in array IFAIL.

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
```

gal value
> 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

NAME

zsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

SYNOPSIS

```
SUBROUTINE ZSTEQR(COMPZ, N, D, E, Z, LDZ, WORK, INFO)

CHARACTER * 1 COMPZ
DOUBLE COMPLEX Z(LDZ,*)
INTEGER N, LDZ, INFO
DOUBLE PRECISION D(*), E(*), WORK(*)

SUBROUTINE ZSTEQR_64(COMPZ, N, D, E, Z, LDZ, WORK, INFO)

CHARACTER * 1 COMPZ
DOUBLE COMPLEX Z(LDZ,*)
INTEGER*8 N, LDZ, INFO
DOUBLE PRECISION D(*), E(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE STEQR(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:,:) :: Z
INTEGER :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK

SUBROUTINE STEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
COMPLEX(8), DIMENSION(:,:) :: Z
```

```
INTEGER(8) :: N, LDZ, INFO
REAL(8), DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>

void zsteqr(char compz, int n, double *d, double  *e,  doub-
          lecomplex *z, int ldz, int *info);

void zsteqr_64(char compz, long n,  double  *d,  double  *e,
          doublecomplex *z, long ldz, long *info);
```

PURPOSE

zsteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors of the original Hermitian matrix. On entry, Z must contain the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ =

'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
dimension(max(1,2*N-2)) If COMPZ = 'N', then WORK is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: the algorithm has failed to find all the eigenvalues in a total of 30*N iterations; if INFO = i, then i elements of E have not converged to zero; on exit, D and E contain the elements of a symmetric tridiagonal matrix which is unitarily similar to the original matrix.

          *d,  doublecomplex  *subl,  doublecomplex  *b, int
          ldb, int *ipiv, int *info);

void zstsv_64(long n, long  nrhs,  doublecomplex  *l,  doub-
          lecomplex  *d,  doublecomplex *subl, doublecomplex
          *b, long ldb, long *ipiv, long *info);
```

PURPOSE

zstsv computes the solution to a complex system of linear equations A * X = B where A is a Hermitian tridiagonal matrix.

ARGUMENTS

N (input)
The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides in B.

L (input/output)
COMPLEX array, dimension (N)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
COMPLEX array, dimension (N)
On exit, part of the factorization of A.

B (input/output)
The columns of B contain the right hand sides.

LDB (input)
The leading dimension of B as specified in a type

```
          or DIMENSION statement.

IPIV (output)
           INTEGER array, dimension (N)
          On exit, the pivot indices of the factorization.

INFO (output)
           INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, D(k,k) is  exactly  zero.   The
          factorization  has  been  completed, but the block
          diagonal matrix D is exactly singular and division
          by zero will occur if it is used to solve a system
          of equations.

```

PURPOSE

zsttrs computes the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

```
N (input)  INTEGER
          The order of the matrix A.  N >= 0.

NRHS (input)
           INTEGER
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B. NRHS >= 0.

L (input)  COMPLEX array, dimension (N-1)
          On entry, the subdiagonal elements of LL and DD.

D (input)  COMPLEX array, dimension (N)
          On entry, the diagonal elements of DD.

SUBL (input)
           COMPLEX array, dimension (N-2)
          On entry, the second subdiagonal elements of LL.

B (input/output)
           COMPLEX array, dimension (LDB, NRHS)
          On entry, the N-by-NRHS right hand side matrix  B.
          On  exit,  if  INFO  =  0,  the N-by-NRHS solution
          matrix X.

LDB (input)
           INTEGER
          The leading dimension of  the  array  B.   LDB  >=
          max(1, N)
```

```
IPIV (output)
           INTEGER array, dimension (N)
          Details of the interchanges and block  pivot.   If
          IPIV(K)  > 0, 1 by 1 pivot, and if IPIV(K) = K + 1
          an interchange done;  If  IPIV(K)  <  0,  2  by  2
          pivot, no interchange required.

INFO (output)
           INTEGER
          = 0:  successful exit
          < 0:  if INFO = -k, the k-th argument had an ille-
          gal value
```

#include <sunperf.h>

void zswap(int n, doublecomplex *x, int incx,  doublecomplex
          *y, int incy);

void zswap_64(long n, doublecomplex  *x,  long  incx,  doub-
```

```
          lecomplex *y, long incy);
```

PURPOSE

zswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

```
N (input)
          On entry, N specifies the number  of  elements  in
          the  vector.   N must be at least one for the sub-
          routine to have any visible effect.  Unchanged  on
          exit.
X (input/output)
          ( 1 + ( n - 1 )*abs( INCX  )  ).   On  entry,  the
          incremented array X must contain the vector x.  On
          exit, the y vector.

INCX (input)
          On entry, INCX specifies  the  increment  for  the
          elements  of  X. INCX must not be zero.  Unchanged
          on exit.

Y (input/output)
          ( 1 + ( n - 1 )*abs( INCY  )  ).   On  entry,  the
          incremented array Y must contain the vector y.  On
          exit, the x vector.

INCY (input)
          On entry, INCY specifies  the  increment  for  the
          elements  of  Y. INCY must not be zero.  Unchanged
          on exit.
```

SUBROUTINE SYCON_64(UPLO, [N], A, [LDA], IPIVOT, ANORM, RCOND, [WORK],
       [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8) :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
void zsycon(char uplo, int n, doublecomplex *a, int lda, int
          *ipivot, double anorm, double *rcond, int *info);

void zsycon_64(char uplo, long  n,  doublecomplex  *a,  long
          lda,  long  *ipivot,  double anorm, double *rcond,
          long *info);
```

PURPOSE

zsycon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDA (input)
The leading dimension of the array A.   LDA >=

max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CSYTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

INTEGER M, N, LDA, LDB, LDC

SUBROUTINE ZSYMM_64(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
      LDC)

CHARACTER * 1 SIDE, UPLO
DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 M, N, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE SYMM(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])

CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,:) :: A, B, C
INTEGER :: M, N, LDA, LDB, LDC

SUBROUTINE SYMM_64(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,:) :: A, B, C
INTEGER(8) :: M, N, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>

void zsymm(char side, char uplo, int m, int n, doublecomplex
          *alpha,  doublecomplex  *a, int lda, doublecomplex
          *b, int ldb,  doublecomplex  *beta,  doublecomplex
          *c, int ldc);
void zsymm_64(char side, char uplo, long m,  long  n,  doub-
          lecomplex  *alpha,  doublecomplex  *a,  long  lda,
          doublecomplex *b, long ldb,  doublecomplex  *beta,
          doublecomplex *c, long ldc);
```

PURPOSE

zsymm performs one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of the matrix C. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix C. N >= 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1, m), otherwise LDA >= max(1, n). Unchanged on exit.

B (input)

COMPLEX*16 array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB >= max(1, m). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC >= max(1, m). Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>

void zsyr2k(char uplo, char transa, int n, int k, doublecom-
          plex *alpha, doublecomplex *a, int lda, doublecom-
          plex *b, int ldb, doublecomplex *beta,  doublecom-
          plex *c, int ldc);
void zsyr2k_64(char uplo, char transa, long n, long k, doub-
          lecomplex  *alpha,  doublecomplex  *a,  long  lda,
          doublecomplex *b, long ldb,  doublecomplex  *beta,
          doublecomplex *c, long ldc);
```

PURPOSE

zsyr2k performs one of the symmetric rank 2k operations C := alpha*A*B' + alpha*B*A' + beta*C or C := alpha*A'*B + alpha*B'*A + beta*C where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   C := alpha*A*B' + alpha*B*A' + beta*C.

TRANSA = 'T' or 't'   C := alpha*A'*B + alpha*B'*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)
On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX*16 array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

B (input)
COMPLEX*16 array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

COMPLEX*16 array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

          *x,  long  ldx,  double  *ferr, double *berr, long
          *info);
```

PURPOSE

zsyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
```

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSYTRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CSYTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CSYTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as

reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

```

```
COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:,:) :: A, C
INTEGER(8) :: N, K, LDA, LDC
```

C INTERFACE

```
#include <sunperf.h>

void zsyrk(char uplo, char transa, int n, int k,  doublecom-
          plex *alpha, doublecomplex *a, int lda, doublecom-
          plex *beta, doublecomplex *c, int ldc);

void zsyrk_64(char uplo, char transa, long n, long k,  doub-
          lecomplex  *alpha,  doublecomplex  *a,  long  lda,
          doublecomplex *beta, doublecomplex *c, long ldc);
```

PURPOSE

zsyrk performs one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' C := alpha*A*A' + beta*C.

TRANSA = 'T' or 't' C := alpha*A'*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)
On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX*16 array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)
COMPLEX*16 array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>

void zsysv(char uplo, int n, int nrhs, doublecomplex *a, int
          lda,  int  *ipivot, doublecomplex *b, int ldb, int
          *info);
void zsysv_64(char uplo, long n,  long  nrhs,  doublecomplex
          *a, long lda, long *ipivot, doublecomplex *b, long
          ldb, long *info);
```

PURPOSE

zsysv computes the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
   A = U * D * U**T, if UPLO = 'U', or
   A = L * D * L**T, if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
          = 'U': Upper triangle of A is stored;
          = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
          The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSYTRF.

LDA (input)

The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)

Details of the interchanges and the block structure of D, as determined by CSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The length of WORK. LWORK >= 1, and for best performance LWORK >= N*NB, where NB is the optimal blocksize for CSYTRF.

If LWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

          *ferr, double *berr, int *info);

void zsysvx_64(char fact, char  uplo,  long  n,  long  nrhs,
          doublecomplex  *a,  long  lda,  doublecomplex *af,
          long ldaf, long *ipivot,  doublecomplex  *b,  long
          ldb,  doublecomplex  *x,  long ldx, double *rcond,
          double *ferr, double *berr, long *info);
```

PURPOSE

zsysvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to

```
factor A.
   The form of the factorization is
      A = U * D * U**T,  if UPLO = 'U', or
      A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper
(lower)
   triangular matrices, and D is symmetric and block  diago-
nal with
   1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

3. The system of equations is solved for X  using  the  fac-
tored form
   of A.

4. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored  form  of  A
          has  been supplied on entry.  = 'F':  On entry, AF
          and IPIVOT contain the factored form of A.  A,  AF
          and  IPIVOT  will  not  be  modified.  = 'N':  The
          matrix A will be copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.
```

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSYTRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSYTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by

```
          CSYTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (output)
          If INFO = 0 or INFO = N+1, the N-by-NRHS  solution
          matrix X.
LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

RCOND (output)
          The estimate of the reciprocal condition number of
          the  matrix  A.  If RCOND is less than the machine
          precision (in  particular,  if  RCOND  =  0),  the
          matrix  is  singular  to  working precision.  This
          condition is indicated by a return code of INFO  >
          0.

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The length of WORK.  LDWORK >= 2*N, and  for  best
          performance  LDWORK  >=  N*NB,  where  NB  is  the
          optimal blocksize for CSYTRF.

          If LDWORK = -1, then a workspace query is assumed;
```

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>

void zsytf2(char uplo, int n, doublecomplex *a, int lda, int
          *ipiv, int *info);

void zsytf2_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, long *ipiv, long *info);
```

PURPOSE

zsytf2 computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

```
   A = U*D*U'  or  A = L*D*L'
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)
Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then A = U*D*U', where
U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-

1,k).   If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where

```
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
```

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

          *ipivot, int *info);

void zsytrf_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, long *ipivot, long *info);
```

PURPOSE

zsytrf computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

A = U*D*U**T or A = L*D*L**T

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >=1. For best performance LDWORK >= N*NB, where NB is the block size returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If UPLO = 'U', then A = U*D*U', where

```
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where  k  decreases
from  n  to  1 in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation matrix as defined by IPIVOT(k), and U(k) is a
unit upper triangular matrix,  such  that  if  the  diagonal
block D(k) is of order s (s = 1 or 2), then

           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k

If s = 1, D(k) overwrites A(k,k), and  v  overwrites  A(1:k-
1,k).   If s = 2, the upper triangle of D(k) overwrites A(k-
1,k-1), A(k-1,k), and A(k,k), and  v  overwrites  A(1:k-2,k-
1:k).

If UPLO = 'L', then A = L*D*L', where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where  k  increases
from  1  to  n in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation matrix as defined by IPIVOT(k), and L(k) is a
unit lower triangular matrix,  such  that  if  the  diagonal
block D(k) is of order s (s = 1 or 2), then

           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1

If  s  =  1,  D(k)  overwrites  A(k,k),  and  v   overwrites
A(k+1:n,k).  If s = 2, the lower triangle of D(k) overwrites
A(k,k),  A(k+1,k),  and   A(k+1,k+1),   and   v   overwrites
A(k+2:n,k:k+1).

void zsytri_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, long *ipivot, long *info);
```

PURPOSE

zsytri computes the inverse of a complex symmetric indefinite matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CSYTRF.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

C INTERFACE

```
#include <sunperf.h>
void ztbcon(char norm, char uplo, char diag, int n, int  kd,
          doublecomplex  *a,  int  lda,  double  *rcond, int
          *info);

void ztbcon_64(char norm, char uplo, char diag, long n, long
          kd,  doublecomplex  *a,  long  lda, double *rcond,
          long *info);
```

PURPOSE

ztbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
```

= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

A (input) The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

NAME

ztbmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

SYNOPSIS

```
SUBROUTINE ZTBMV(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER N, K, LDA, INCY

SUBROUTINE ZTBMV_64(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, K, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBMV(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, K, LDA, INCY

SUBROUTINE TBMV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, K, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ztbmv(char uplo, char transa, char diag, int n, int  k,
          doublecomplex  *a,  int lda, doublecomplex *y, int
          incy);

void ztbmv_64(char uplo, char transa,  char  diag,  long  n,
          long  k, doublecomplex *a, long lda, doublecomplex
          *y, long incy);
```

PURPOSE

ztbmv performs one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := conjg(A')*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the transformed vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

Contents

C INTERFACE

```
#include <sunperf.h>

void ztbrfs(char uplo, char transa, char diag,  int  n,  int
          kd,  int  nrhs,  doublecomplex  *a, int lda, doub-
          lecomplex *b, int ldb, doublecomplex *x, int  ldx,
          double *ferr, double *berr, int *info);

void ztbrfs_64(char uplo, char transa, char  diag,  long  n,
          long  kd,  long  nrhs, doublecomplex *a, long lda,
          doublecomplex *b, long ldb, doublecomplex *x, long
          ldx, double *ferr, double *berr, long *info);
```

PURPOSE

ztbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by CTBTRS or some other means before entering this routine. CTBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.
```

```
DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals  or  subdiagonals  of
          the triangular band matrix A.  KD >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
A (input) The upper  or  lower  triangular  band  matrix  A,
          stored  in  the  first kd+1 rows of the array. The
          j-th column of A is stored in the j-th  column  of
          the  array A as follows:  if UPLO = 'U', A(kd+1+i-
          j,j) = A(i,j) for  max(1,j-kd)<=i<=j;  if  UPLO  =
          'L', A(1+i-j,j)    = A(i,j) for j<=i<=min(n,j+kd).
          If DIAG = 'U', the diagonal elements of A are  not
          referenced and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          KD+1.

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
```

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

Contents

DOUBLE COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, K, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBSV(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, K, LDA, INCY

SUBROUTINE TBSV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, K, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ztbsv(char uplo, char transa, char diag, int n, int  k,
          doublecomplex  *a,  int lda, doublecomplex *y, int
          incy);

void ztbsv_64(char uplo, char transa,  char  diag,  long  n,
          long  k, doublecomplex *a, long lda, doublecomplex
          *y, long incy);
```

PURPOSE

ztbsv solves one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   conjg(A')*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the

leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10  CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

#include <sunperf.h>

void ztbtrs(char uplo, char transa, char diag,  int  n,  int
          kd,  int  nrhs,  doublecomplex  *a, int lda, doub-
          lecomplex *b, int ldb, int *info);

void ztbtrs_64(char uplo, char transa, char  diag,  long  n,
          long  kd,  long  nrhs, doublecomplex *a, long lda,
          doublecomplex *b, long ldb, long *info);
```

PURPOSE

ztbtrs solves a triangular system of the form

where A is a triangular band matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals  or  subdiagonals  of
          the triangular band matrix A.  KD >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.
```

A (input) The upper or lower triangular band matrix A, stored in the first kd+1 rows of A. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

          ldb, doublecomplex *vl, long  ldvl,  doublecomplex
          *vr, long ldvr, long mm, long *m, long *info);
```

PURPOSE

ztgevc computes some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

```
        (A - wB) * x = 0  and  y**H * (A - wB) = 0
```

where y**H denotes the conjugate tranpose of y.

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products Z*X and/or Q*Y, where Z and Q are input unitary matrices. If (A,B) was obtained from the gen-

eralized Schur factorization of an original pair of matrices
   (A0,B0) = (Q*A*Z**H,Q*B*Z**H),
then Z*X and Q*Y are the matrices of right or left eigenvectors of A.

ARGUMENTS

SIDE (input)
= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)
= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input)
If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrices A and B. N >= 0.

A (input) The upper triangular matrix A.

LDA (input)
The leading dimension of array A. LDA >= max(1,N).

B (input) The upper triangular matrix B. B must have real diagonal elements.

LDB (input)
The leading dimension of array B. LDB >= max(1,N).

VL (input/output)
On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of left Schur vectors returned by CHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left

eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Z of right Schur vectors returned by CHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK (workspace)
dimension(2*N)

RWORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

Contents

NAME

ztgexc - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation (A, B) := Q * (A, B) * Z', so that the diagonal block of (A, B) with row index IFST is moved to row ILST

SYNOPSIS

F95 INTERFACE

```
SUBROUTINE TGEXC(WANTQ, WANTZ, [N], A, [LDA], B, [LDB], Q, [LDQ], Z,
       [LDZ], IFST, ILST, [INFO])

COMPLEX(8), DIMENSION(:,:) :: A, B, Q, Z
INTEGER :: N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL :: WANTQ, WANTZ

SUBROUTINE TGEXC_64(WANTQ, WANTZ, [N], A, [LDA], B, [LDB], Q, [LDQ],
       Z, [LDZ], IFST, ILST, [INFO])
```

```
COMPLEX(8), DIMENSION(:,:) :: A, B, Q, Z
INTEGER(8) :: N, LDA, LDB, LDQ, LDZ, IFST, ILST, INFO
LOGICAL(8) :: WANTQ, WANTZ
```

C INTERFACE

```
#include <sunperf.h>

void ztgexc(int wantq, int wantz, int n,  doublecomplex  *a,
          int  lda, doublecomplex *b, int ldb, doublecomplex
          *q, int ldq, doublecomplex *z, int ldz, int *ifst,
          int *ilst, int *info);

void ztgexc_64(long wantq, long wantz, long n, doublecomplex
          *a,  long  lda,  doublecomplex *b, long ldb, doub-
          lecomplex *q, long  ldq,  doublecomplex  *z,  long
          ldz, long *ifst, long *ilst, long *info);
```

PURPOSE

ztgexc reorders the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation (A, B) := Q * (A, B) * Z', so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)' = Q(out) * A(out) * Z(out)'
Q(in) * B(in) * Z(in)' = Q(out) * B(out) * Z(out)'
```

ARGUMENTS

WANTQ (input)

WANTZ (input)

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the upper triangular matrix A in the pair (A, B). On exit, the updated matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the upper triangular matrix B in the pair (A, B). On exit, the updated matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

Q (input/output)
On entry, if WANTQ = .TRUE., the unitary matrix Q. On exit, the updated matrix Q. If WANTQ = .FALSE., Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1; If WANTQ = .TRUE., LDQ >= N.

Z (input/output)
On entry, if WANTZ = .TRUE., the unitary matrix Z. On exit, the updated matrix Z. If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1; If WANTZ = .TRUE., LDZ >= N.

IFST (input/output)
Specify the reordering of the diagonal blocks of (A, B). The block with row index IFST is moved to row ILST, by a sequence of swapping between adjacent blocks.

ILST (input/output)
See the description of IFST.

INFO (output)
=0: Successful exit.
<0: if INFO = -i, the i-th argument had an illegal value.
=1: The transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is ill- conditioned. (A, B) may have been partially reordered, and ILST points to the first row of the current position of the block being moved.

          double *pr, double *dif, long *info);
```

PURPOSE

ztgsen reorders the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence trans- formation Q' * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diag- onal blocks of the pair (A,B). The leading columns of Q and Z form unitary bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in gen- eralized Schur canonical form, that is, A and B are both upper triangular.

ZTGSEN also computes the generalized eigenvalues

w(j)= ALPHA(j) / BETA(j)

of the reordered matrix pair (A, B).

Optionally, the routine computes estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

IJOB (input)

Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):
=0: Only reorder w.r.t. SELECT. No extras.
=1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate
(DIF(1:2)).
=3: Estimate of Difu and Difl. 1-norm-based esti- mate
(DIF(1:2)). About 5 times as expensive as IJOB = 2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Com- pute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ (input)

```
WANTZ (input)

SELECT (input)
          SELECT specifies the eigenvalues in  the  selected
          cluster.  To  select an eigenvalue w(j), SELECT(j)
          must be set to

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
          On entry, the upper triangular matrix A,  in  gen-
          eralized  Schur  canonical  form.   On  exit, A is
          overwritten by the reordered matrix A.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,N).

B (input/output)
          On entry, the upper triangular matrix B,  in  gen-
          eralized  Schur  canonical  form.   On  exit, B is
          overwritten by the reordered matrix B.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

ALPHA (output)
          The diagonal elements of A  and  B,  respectively,
          when  the  pair (A,B) has been reduced to general-
          ized Schur form.  ALPHA(i)/BETA(i)  i=1,...,N  are
          the generalized eigenvalues.

BETA (output)
          See the description of ALPHA.

Q (input/output)
          On entry, if  WANTQ  =  .TRUE.,  Q  is  an  N-by-N
          matrix.  On exit, Q has been postmultiplied by the
          left unitary transformation matrix  which  reorder
          (A,  B); The leading M columns of Q form orthonor-
          mal bases for the specified pair  of  left  eigen-
          spaces (deflating subspaces).  If WANTQ = .FALSE.,
          Q is not referenced.

LDQ (input)
          The leading dimension of the array Q.  LDQ  >=  1.
          If WANTQ = .TRUE., LDQ >= N.

Z (input/output)
```

On entry, if WANTZ = .TRUE., Z is an N-by-N matrix. On exit, Z has been postmultiplied by the left unitary transformation matrix which reorder (A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

M (output)
The dimension of the specified pair of left and right eigenspaces, (deflating subspaces) 0 <= M <= N.

PL (output)
IF IJOB = 1, 4, or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspace with respect to the selected cluster.
0 < PL, PR <= 1. If M = 0 or M = N, PL = PR = 1.
If IJOB = 0, 2, or 3 PL, PR are not referenced.

PR (output)
See the description of PL.

DIF (output)
If IJOB >= 2, DIF(1:2) store the estimates of Difu and Difl.
If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on
Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl, computed using reversed communication with CLACON. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK (workspace)
If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1 If IJOB = 1, 2 or 4, LWORK >= 2*M*(N-M) If IJOB = 3 or 5, LWORK >= 4*M*(N-M)

If LWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+2; If IJOB = 3 or 5, LIWORK >= MAX(N+2, 2*M*(N-M));

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
=0: Successful exit.
<0: If INFO = -i, the i-th argument had an illegal value.
=1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

FURTHER DETAILS

ZTGSEN first collects the selected eigenvalues by computing unitary U and W that move them to the top left corner of (A, B). In other words, the selected eigenvalues are the eigenvalues of (A11, B11) in

```
U'*(A, B)*W = (A11 A12) (B11 B12) n1
              ( 0  A22),( 0  B22) n2
                n1  n2    n1  n2
```

where N = n1+n2 and U' means the conjugate transpose of U. The first n1 columns of U and W span the specified pair of left and right eigenspaces (deflating subspaces) of (A, B).

If (A, B) has been obtained from the generalized real Schur decomposition of a matrix pair (C, D) = Q*(A, B)*Z', then the reordered generalized Schur form of (C, D) is given by

```
(C, D) = (Q*U)*(U'*(A, B)*W)*(Z*W)',
```

and the first n1 columns of Q*U and Z*W span the corresponding deflating subspaces of (C, D) (Q and Z store Q*U and Z*W, resp.).
Note that if the selected eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

The reciprocal condition numbers of the left and right eigenspaces spanned by the first n1 columns of U and W (or Q*U and Z*W) may be returned in DIF(1:2), corresponding to Difu and Difl, resp.

The Difu and Difl are defined as:
ifu[(A11, B11), (A22, B22)] = sigma-min(Zu)
and

where sigma-min(Zu) is the smallest singular value of the (2*n1*n2)-by-(2*n1*n2) matrix

```
u = [ kron(In2, A11)  -kron(A22', In1) ]
          [ kron(In2, B11)  -kron(B22', In1) ].
```

Here, Inx is the identity matrix of size nx and A22' is the transpose of A22. kron(X, Y) is the Kronecker product between the matrices X and Y.

When DIF(2) is small, small changes in (A, B) can cause large changes in the deflating subspace. An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is PS * norm((A, B)) / DIF(2),

where EPS is the machine precision.

The reciprocal norm of the projectors on the left and right eigenspaces associated with (A11, B11) may be returned in PL and PR. They are computed as follows. First we compute L and R so that P*(A, B)*Q is block diagonal, where

```
 = ( I -L ) n1           Q = ( I R ) n1
         ( 0  I ) n2    and        ( 0 I ) n2
           n1 n2                    n1 n2
```

and (L, R) is the solution to the generalized Sylvester equation 11*R - L*A22 = -A12

Then PL = (F-norm(L)**2+1)**(-1/2) and PR = (F-norm(R)**2+1)**(-1/2). An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is
EPS * norm((A, B)) / PL.

There are also global error bounds which valid for perturbations up to a certain restriction: A lower bound (x) on the smallest F-norm(E,F) for which an eigenvalue of (A11, B11) may move and coalesce with an eigenvalue of (A22, B22) under perturbation (E,F), (i.e. (A + E, B + F), is

x = min(Difu,Difl)/((1/(PL*PL)+1/(PR*PR))**(1/2)+2*max(1/PL,1/PR)).

An approximate bound on x can be computed from DIF(1:2), PL and PR.

If y = (F-norm(E,F) / x) <= 1, the angles between the perturbed (L', R') and unperturbed (L, R) left and right deflating subspaces associated with the selected cluster in the (1,1)-blocks can be bounded as

```
 max-angle(L, L') <= arctan( y * PL / (1 - y *  (1  -  PL  *
PL)**(1/2))
 max-angle(R, R') <= arctan( y * PR / (1 - y *  (1  -  PR  *
PR)**(1/2))
```

See LAPACK User's Guide section 4.11 or the following references for more information.

Note that if the default method for computing the Frobenius-norm- based estimate DIF is not wanted (see CLATDF), then the parameter IDIFJB (see below) should be changed from 3 to 4 (routine CLATDF (IJOB = 2 will be used)). See CTGSYL for more details.

```

PURPOSE

ztgsja computes the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine CGGSVP from a general M-by-N matrix A and P-by-N matrix B:

```
             N-K-L  K    L
   A =    K ( 0    A12  A13 ) if M-K-L >= 0;
          L ( 0     0   A23 )
      M-K-L ( 0     0    0  )

           N-K-L  K    L
   A =  K ( 0    A12  A13 ) if M-K-L < 0;
      M-K ( 0     0   A23 )

           N-K-L  K    L
   B =  L ( 0     0   B13 )
      P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are non-
singular upper triangular; A23 is L-by-L upper triangular if
M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.
On exit,

```
       U'*A*Q = D1*( 0 R ),    V'*B*Q = D2*( 0 R ),
```

where U, V and Q are unitary matrices, Z' denotes the conju-
gate transpose of Z, R is a nonsingular upper triangular
matrix, and D1 and D2 are ``diagonal'' matrices, which are
of the following structures:

If M-K-L >= 0,

```
                    K  L
       D1 =     K ( I  0 )
                L ( 0  C )
            M-K-L ( 0  0 )

                   K  L
       D2 = L   ( 0  S )
            P-L ( 0  0 )

               N-K-L  K    L
  ( 0 R ) = K (  0   R11  R12 ) K
            L (  0    0   R22 ) L
```

where

```
  C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
  S = diag( BETA(K+1),  ... , BETA(K+L) ),
  C**2 + S**2 = I.
```

R is stored in A(1:K+L,N-K-L+1:N) on exit.

```
If M-K-L < 0,

               K M-K K+L-M
    D1 =   K ( I  0    0   )
         M-K ( 0  C    0   )

                 K M-K K+L-M
    D2 =   M-K ( 0  S    0   )
         K+L-M ( 0  0    I   )
           P-L ( 0  0    0   )

               N-K-L  K   M-K  K+L-M

          M-K ( 0     0   R22  R23  )
        K+L-M ( 0     0    0   R33  )

where
C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1),  ... , BETA(M) ),
C**2 + S**2 = I.
R = ( R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N)  and  R33
is stored
    (  0  R22 R23 )
in B(M-K+1:L,N+M-K-L+1:N) on exit.
```

The computation of the unitary transformation matrices U, V or Q is optional. These matrices may either be formed explicitly, or they may be postmultiplied into input matrices U1, V1, or Q1.

CTGSJA essentially uses a variant of Kogbetliantz algorithm to reduce min(L,M-K)-by-L triangular (or trapezoidal) matrix A23 and L-by-L matrix B13 to the form:

```
   U1'*A13*Q1 = C1*R1; V1'*B13*Q1 = S1*R1,
```

where U1, V1 and Q1 are unitary matrix, and Z' is the conjugate transpose of Z. C1 and S1 are diagonal matrices satisfying

```
   C1**2 + S1**2 = I,
```

and R1 is an L-by-L nonsingular upper triangular matrix.

ARGUMENTS

JOBU (input)
= 'U': U must contain a unitary matrix U1 on entry, and the product U1*U is returned; = 'I': U is initialized to the unit matrix, and the unitary matrix U is returned; = 'N': U is not computed.

JOBV (input)

= 'V': V must contain a unitary matrix V1 on entry, and the product V1*V is returned; = 'I': V is initialized to the unit matrix, and the unitary matrix V is returned; = 'N': V is not computed.

JOBQ (input)
= 'Q': Q must contain a unitary matrix Q1 on entry, and the product Q1*Q is returned; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

K (input) K and L specify the subblocks in the input matrices A and B:
A23 = A(K+1:MIN(K+L,M),N-L+1:N) and B13 = B(1:L,,N-L+1:N) of A and B, whose GSVD is going to be computed by CTGSJA. See the Further Details section below.

L (input) See the description of K.

A (input/output)
On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L,M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

TOLA (input)
TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say TOLA = MAX(M,N)*norm(A)*MACHEPS, TOLB = MAX(P,N)*norm(B)*MACHEPS.

```
TOLB (input)
          See the description of TOLA.

ALPHA (output)
          On exit, ALPHA and BETA  contain  the  generalized
          singular value pairs of A and B; ALPHA(1:K) = 1,
          BETA(1:K)  = 0, and if M-K-L >= 0,  ALPHA(K+1:K+L)
          = diag(C),
          BETA(K+1:K+L)   =  diag(S),  or  if  M-K-L  <   0,
          ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0
          BETA(K+1:M) = S, BETA(M+1:K+L) = 1.   Furthermore,
          if K+L < N, ALPHA(K+L+1:N) = 0
          BETA(K+L+1:N)  = 0.

BETA (output)
          See the description of ALPHA.

U (input) On entry, if JOBU = 'U', U must contain  a  matrix
          U1   (usually   the  unitary  matrix  returned  by
          CGGSVP).  On exit, if JOBU = 'I', U  contains  the
          unitary  matrix  U;  if JOBU = 'U', U contains the
          product U1*U.  If JOBU = 'N', U is not referenced.

LDU (input)
          The leading dimension  of  the  array  U.  LDU  >=
          max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) On entry, if JOBV = 'V', V must contain  a  matrix
          V1   (usually   the  unitary  matrix  returned  by
          CGGSVP).  On exit, if JOBV = 'I', V  contains  the
          unitary  matrix  V;  if JOBV = 'V', V contains the
          product V1*V.  If JOBV = 'N', V is not referenced.

LDV (input)
          The leading dimension  of  the  array  V.  LDV  >=
          max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) On entry, if JOBQ = 'Q', Q must contain  a  matrix
          Q1   (usually   the  unitary  matrix  returned  by
          CGGSVP).  On exit, if JOBQ = 'I', Q  contains  the
          unitary  matrix  Q;  if JOBQ = 'Q', Q contains the
          product Q1*Q.  If JOBQ = 'N', Q is not referenced.

LDQ (input)
          The leading dimension  of  the  array  Q.  LDQ  >=
          max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)
          dimension(2*N)
```

NCYCLE (output)
The number of cycles required for convergence.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1: the procedure does not converge after MAXIT cycles.

          *vr,  long  ldvr, double *s, double *dif, long mm,
          long *m, long *info);
```

PURPOSE

ztgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B).

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ARGUMENTS

JOB (input)

Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (DIF):
= 'E': for eigenvalues only (S);
= 'V': for eigenvectors only (DIF);
= 'B': for both eigenvalues and eigenvectors (S and DIF).

HOWMNT (input)
= 'A': compute condition numbers for all eigenpairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the corresponding j-th eigenvalue and/or eigenvector, SELECT(j) must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

N (input) The order of the square matrix pair (A, B). N >= 0.

A (input) The upper triangular matrix A in the pair (A,B).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The upper triangular matrix B in the pair (A, B).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

VL (input)
If JOB = 'E' or 'B', VL must contain left eigenvectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CTGEVC. If JOB = 'V', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= 1; and If JOB = 'E' or 'B', LDVL >= N.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigen-

vectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CTGEVC. If JOB = 'V', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= 1; If JOB = 'E' or 'B', LDVR >= N.

S (output)
If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If JOB = 'V', S is not referenced.

DIF (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of Difl. If JOB = 'E', DIF is not referenced.

MM (input)
The number of elements in the arrays S and DIF. MM >= M.

M (output)
The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected eigenvalue one element is used. If HOWMNT = 'A', M is set to N.

WORK (workspace)
If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. If JOB = 'V' or 'B', LWORK >= 2*N*N.

IWORK (workspace)
dimension(N+2) If JOB = 'E', IWORK is not referenced.

INFO (output)

```
= 0: Successful exit
< 0: If INFO = -i, the i-th argument had an  ille-
gal value
```

FURTHER DETAILS

```
The reciprocal of the condition number of the i-th  general-
ized eigenvalue w = (a, b) is defined as

        S(I)   =   (|v'Au|**2    +    |v'Bu|**2)**(1/2)    /
(norm(u)*norm(v))

where u and v are the right and left eigenvectors of (A,  B)
corresponding  to  w;  |z| denotes the absolute value of the
complex number, and norm(u) denotes the 2-norm of the vector
u.  The  pair (a, b) corresponds to an eigenvalue w = a/b (=
v'Au/v'Bu) of the matrix pair (A, B). If both a and b  equal
zero, then (A,B) is singular and S(I) = -1 is returned.

An approximate error bound on the chordal  distance  between
the   i-th   computed   generalized  eigenvalue  w  and  the
corresponding exact eigenvalue lambda is

        chord(w, lambda) <=   EPS * norm(A, B) / S(I),

where EPS is the machine precision.

The reciprocal of the condition number of the  right  eigen-
vector  u  and  left eigenvector v corresponding to the gen-
eralized eigenvalue w is defined as follows. Suppose

               (A, B) = ( a   *  ) ( b  *  )  1
                        ( 0  A22 ),( 0 B22 )  n-1
                          1  n-1     1 n-1

Then the reciprocal condition number DIF(I) is

        Difl[(a, b), (A22, B22)]  = sigma-min( Zl )

where sigma-min(Zl) denotes the smallest singular value of

       Zl = [ kron(a, In-1) -kron(1, A22) ]
            [ kron(b, In-1) -kron(1, B22) ].

Here In-1 is the identity matrix of size n-1 and X'  is  the
conjugate  transpose  of X. kron(X, Y) is the Kronecker pro-
duct between the matrices X and Y.

We approximate the smallest singular value  of  Zl  with  an
```

upper bound. This is done by CLATDF.

An approximate error bound for a computed eigenvector VL(i) or VR(i) is given by

EPS * norm(A, B) / DIF(i).

```

PURPOSE

ztgsyl solves the generalized Sylvester equation:

```
            A * R - L * B = scale * C            (1)
            D * R - L * E = scale * F
```

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with complex entries. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

```
The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1
is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve Zx =  scale*b,
where Z is defined as

       Z = [ kron(In, A)  -kron(B', Im) ]         (2)
           [ kron(In, D)  -kron(E', Im) ],

Here Ix is the identity matrix of size x and X' is the  con-
jugate  transpose  of X. Kron(X, Y) is the Kronecker product
between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system Z'*y  =
scale*b  is  solved  for, which is equivalent to solve for R
and L in

            A' * R + D' * L = scale * C           (3)
            R * B' + L * E' = scale * -F
This case (TRANS = 'C') is used to compute an one-norm-based
estimate  of  Dif[(A,D),  (B,E)], the separation between the
matrix pairs (A,D) and (B,E), using CLACON.

If IJOB >= 1, CTGSYL computes a Frobenius  norm-based  esti-
mate of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower
bound on the reciprocal of the smallest singular value of Z.

This is a level-3 BLAS algorithm.
```

ARGUMENTS

```
TRANS (input)
          = 'N': solve the  generalized  sylvester  equation
          (1).
          = 'C': solve  the  "conjugate  transposed"  system
          (3).

IJOB (input)
          Specifies what kind of functionality  to  be  per-
          formed.  =0: solve (1) only.
          =1: The functionality of 0 and 3.
          =2: The functionality of 0 and 4.
          =3: Only an estimate of Dif[(A,D), (B,E)] is  com-
          puted.   (look  ahead strategy is used).  =4: Only
          an estimate  of  Dif[(A,D),  (B,E)]  is  computed.
          (CGECON  on  sub-systems is used).  Not referenced
          if TRANS = 'C'.
```

M (input) The order of the matrices A and D, and the row dimension of the matrices C, F, R and L.

N (input) The order of the matrices B and E, and the column dimension of the matrices C, F, R and L.

A (input) The upper triangular matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1, M).

B (input) The upper triangular matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

C (input/output)
On entry, C contains the right-hand-side of the first matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, C has been overwritten by the solution R. If IJOB = 3 or 4 and TRANS = 'N', C holds R, the solution achieved during the computation of the Dif-estimate.

LDC (input)
The leading dimension of the array C. LDC >= max(1, M).

D (input) The upper triangular matrix D.

LDD (input)
The leading dimension of the array D. LDD >= max(1, M).

E (input) The upper triangular matrix E.

LDE (input)
The leading dimension of the array E. LDE >= max(1, N).

F (input/output)
On entry, F contains the right-hand-side of the second matrix equation in (1) or (3). On exit, if IJOB = 0, 1 or 2, F has been overwritten by the solution L. If IJOB = 3 or 4 and TRANS = 'N', F holds L, the solution achieved during the computation of the Dif-estimate.

LDF (input)
The leading dimension of the array F. LDF >= max(1, M).

SCALE (output)
On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of Dif[(A,D), (B,E)] = sigma-min(Z), where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

DIF (output)
On exit SCALE is the reciprocal of a lower bound of the reciprocal of the Dif-function, i.e. SCALE is an upper bound of Dif[(A,D), (B,E)] = sigma-min(Z), where Z as in (2). If IJOB = 0 or TRANS = 'C', SCALE is not referenced.

WORK (workspace)
If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO=0 then WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK > = 1. If IJOB = 1 or 2 and TRANS = 'N', LWORK >= 2*M*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
If IJOB = 0, IWORK is not referenced.

INFO (output)
=0: successful exit
<0: If INFO = -i, the i-th argument had an illegal value.
>0: (A, D) and (B, E) have common or very close eigenvalues.

C INTERFACE

```
#include <sunperf.h>

void ztpcon(char norm, char uplo, char diag,  int  n,  doub-
          lecomplex *a, double *rcond, int *info);
void ztpcon_64(char norm, char  uplo,  char  diag,  long  n,
          doublecomplex *a, double *rcond, long *info);
```

PURPOSE

ztpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
   RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.
```

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE ZTPMV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(*), Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPMV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: A, Y
INTEGER :: N, INCY

SUBROUTINE TPMV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: A, Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztpmv(char uplo, char transa, char diag, int  n,  doub-
          lecomplex *a, doublecomplex *y, int incy);

void ztpmv_64(char uplo, char transa,  char  diag,  long  n,
          doublecomplex *a, doublecomplex *y, long incy);
```

PURPOSE

ztpmv performs one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := conjg(A')*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit tri-

```
          angular.

          DIAG = 'N' or 'n'   A is not assumed  to  be  unit
          triangular.

          Unchanged on exit.

N (input)
          On entry, N specifies the order of the  matrix  A.
          N >= 0.  Unchanged on exit.

A (input)
          ( ( n*( n + 1 ) )/2 ).  Before entry with  UPLO  =
          'U'  or  'u',  the  array A must contain the upper
          triangular matrix packed sequentially,  column  by
          column,  so that A( 1 ) contains a( 1, 1 ), A( 2 )
          and A( 3 ) contain a( 1, 2 ) and a( 2, 2 ) respec-
          tively,  and  so on.  Before entry with UPLO = 'L'
          or 'l', the array A must contain  the  lower  tri-
          angular  matrix  packed  sequentially,  column  by
          column, so that A( 1 ) contains a( 1, 1 ), A( 2  )
          and A( 3 ) contain a( 2, 1 ) and a( 3, 1 ) respec-
          tively, and so on.  Note that when  DIAG = 'U'  or
          'u',  the  diagonal  elements  of A are not refer-
          enced, but are assumed to be unity.  Unchanged  on
          exit.

Y (input/output)
          ( 1 + ( n - 1 )*abs( INCY ) ).  Before entry,  the
          incremented  array  Y  must  contain the n element
          vector x. On exit, Y is overwritten with the tran-
          formed vector x.

INCY (input)
          On entry, INCY specifies  the  increment  for  the
          elements of Y. INCY <> 0.  Unchanged on exit.

void ztprfs(char uplo, char transa, char diag,  int  n,  int
          nrhs, doublecomplex *a, doublecomplex *b, int ldb,
          doublecomplex *x, int ldx,  double  *ferr,  double
          *berr, int *info);

void ztprfs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs,  doublecomplex  *a,  doublecomplex *b,
          long  ldb,  doublecomplex  *x,  long  ldx,  double
          *ferr, double *berr, long *info);
```

PURPOSE

ztprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by CTPTRS or some other means before entering this routine. CTPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.
```

```
DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The upper or lower  triangular  matrix  A,  packed
          columnwise  in a linear array.  The j-th column of
          A is stored in the array A as follows:  if UPLO  =
          'U',  A(i  +  (j-1)*j/2)  = A(i,j) for 1<=i<=j; if
          UPLO = 'L', A(i +  (j-1)*(2n-j)/2)  =  A(i,j)  for
          j<=i<=n.   If DIAG = 'U', the diagonal elements of
          A are not referenced and are assumed to be 1.

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(2*N)
```

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

Contents

NAME

```
ztpsv - solve one of the systems of equations   A*x = b,  or
A'*x = b, or conjg( A' )*x = b
```

SYNOPSIS

```
SUBROUTINE ZTPSV(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(*), Y(*)
INTEGER N, INCY

SUBROUTINE ZTPSV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
DOUBLE COMPLEX A(*), Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPSV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: A, Y
INTEGER :: N, INCY

SUBROUTINE TPSV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: A, Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztpsv(char uplo, char transa, char diag, int  n,  doub-
          lecomplex *a, doublecomplex *y, int incy);

void ztpsv_64(char uplo, char transa,  char  diag,  long  n,
          doublecomplex *a, doublecomplex *y, long incy);
```

PURPOSE

ztpsv solves one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   conjg(A')*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

Contents

NAME

ztptri - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

SYNOPSIS

```
SUBROUTINE ZTPTRI(UPLO, DIAG, N, A, INFO)

CHARACTER * 1 UPLO, DIAG
DOUBLE COMPLEX A(*)
INTEGER N, INFO

SUBROUTINE ZTPTRI_64(UPLO, DIAG, N, A, INFO)

DOUBLE COMPLEX A(*)
INTEGER*8 N, INFO
```

F95 INTERFACE

```
SUBROUTINE TPTRI(UPLO, DIAG, N, A, [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: A
INTEGER :: N, INFO

SUBROUTINE TPTRI_64(UPLO, DIAG, N, A, [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: A
INTEGER(8) :: N, INFO
```

C INTERFACE

```
#include <sunperf.h>

void ztptri(char uplo, char diag, int n,  doublecomplex  *a,
          int *info);

void ztptri_64(char uplo, char diag, long  n,  doublecomplex
          *a, long *info);
```

PURPOSE

ztptri computes the inverse of a complex upper or lower triangular matrix A stored in packed format.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the upper or lower triangular matrix  A,
          stored  columnwise  in  a  linear array.  The j-th
          column of A is stored in the array A  as  follows:
          if  UPLO  =  'U',  A(i  +  (j-1)*j/2) = A(i,j) for
          1<=i<=j; if UPLO = 'L', A(i + (j-1)*((2*n-j)/2)  =
          A(i,j)   for   j<=i<=n.   See  below  for  further
          details.  On exit, the (triangular) inverse of the
          original  matrix,  in the same packed storage for-
          mat.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, A(i,i) is  exactly  zero.   The
          triangular  matrix is singular and its inverse can
          not be computed.
```

FURTHER DETAILS

A triangular matrix A can be transferred to packed storage using one of the following program segments:

UPLO = 'U':

```
      JC = 1
      DO 2 J = 1, N
         DO 1 I = 1, J
            A(JC+I-1) = A(I,J)
    1    CONTINUE
         JC = JC + J
    2 CONTINUE
```

UPLO = 'L':

```
      JC = 1
      DO 2 J = 1, N
         DO 1 I = J, N
            A(JC+I-J) = A(I,J)
    1    CONTINUE
         JC = JC + N - J + 1
    2 CONTINUE
```

```

C INTERFACE

```
#include <sunperf.h>

void ztptrs(char uplo, char transa, char diag,  int  n,  int
          nrhs, doublecomplex *a, doublecomplex *b, int ldb,
          int *info);

void ztptrs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs,  doublecomplex  *a,  doublecomplex *b,
          long ldb, long *info);
```

PURPOSE

ztptrs solves a triangular system of the form where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input) The upper or lower  triangular  matrix  A,  packed
          columnwise  in a linear array.  The j-th column of
          A is stored in the array A as follows:  if UPLO  =
          'U',  A(i  +  (j-1)*j/2)  = A(i,j) for 1<=i<=j; if
          UPLO = 'L', A(i + (j-1)*(2*n-j)/2)  =  A(i,j)  for
          j<=i<=n.
```

```
B (input/output)
          On entry, the right hand side matrix B.  On  exit,
          if INFO = 0, the solution matrix X.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, the i-th diagonal element of  A
          is  zero,  indicating  that the matrix is singular
          and the solutions X have not been computed.
```

DOUBLE COMPLEX SCALE
DOUBLE COMPLEX SOURCE(*), DEST(*)
INTEGER*8 M, N
```

F95 INTERFACE

```
SUBROUTINE TRANS([PLACE], SCALE, SOURCE, M, N, [DEST])

CHARACTER(LEN=1) :: PLACE
COMPLEX(8) :: SCALE
COMPLEX(8), DIMENSION(:) :: SOURCE, DEST
INTEGER :: M, N

SUBROUTINE TRANS_64([PLACE], SCALE, SOURCE, M, N, [DEST])

CHARACTER(LEN=1) :: PLACE
COMPLEX(8) :: SCALE
COMPLEX(8), DIMENSION(:) :: SOURCE, DEST
INTEGER(8) :: M, N
```

C INTERFACE

```
#include <sunperf.h>

void ztrans(char place, doublecomplex *scale,  doublecomplex
          *source, int m, int n, doublecomplex *dest);

void ztrans_64(char place, doublecomplex *scale,  doublecom-
          plex   *source,  long  m,  long  n,  doublecomplex
          *dest);
```

PURPOSE

ztrans scales and transposes the source matrix. The N2 x N1 result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE'

PLACE = 'O' or 'o': DEST = SCALE * SOURCE'

ARGUMENTS

PLACE (input)
Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place. 'I' is default.

SCALE (input)
Scale factor on the SOURCE matrix.

SOURCE (input/output)
on input. Array of (N, M) on output if in-place transpose.

M (input)
Number of rows in the SOURCE matrix on input.

N (input)
Number of columns in the SOURCE matrix on input.

DEST (output)
Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

      INFO)

CHARACTER * 1 NORM, UPLO, DIAG
DOUBLE COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
DOUBLE PRECISION RCOND
DOUBLE PRECISION WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON(NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK], [WORK2],
       [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, LDA, INFO
```

```
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK2

SUBROUTINE TRCON_64(NORM, UPLO, DIAG, N, A, [LDA], RCOND, [WORK],
       [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
REAL(8) :: RCOND
REAL(8), DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
void ztrcon(char norm, char uplo, char diag,  int  n,  doub-
          lecomplex *a, int lda, double *rcond, int *info);

void ztrcon_64(char norm, char  uplo,  char  diag,  long  n,
          doublecomplex  *a,  long  lda, double *rcond, long
          *info);
```

PURPOSE

ztrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

UPLO (input)
= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)
= 'N': A is non-unit triangular;

```
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

A (input) The triangular matrix A.  If UPLO = 'U', the lead-
          ing  N-by-N  upper  triangular part of the array A
          contains the  upper  triangular  matrix,  and  the
          strictly  lower triangular part of A is not refer-
          enced.  If UPLO = 'L', the  leading  N-by-N  lower
          triangular  part of the array A contains the lower
          triangular matrix, and the strictly upper triangu-
          lar  part  of A is not referenced.  If DIAG = 'U',
          the diagonal elements of A are also not referenced
          and are assumed to be 1.
LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix   A,  computed  as  RCOND  =  1/(norm(A)  *
          norm(inv(A))).

WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

       VR, [LDVR], MM, M, [WORK], [RWORK], [INFO])

CHARACTER(LEN=1) :: SIDE, HOWMNY
COMPLEX(8), DIMENSION(:) :: WORK
COMPLEX(8), DIMENSION(:,:) :: T, VL, VR
INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL(8), DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
void ztrevc(char side, char  howmny,  int  *select,  int  n,
          doublecomplex  *t, int ldt, doublecomplex *vl, int
          ldvl, doublecomplex *vr, int ldvr, int mm, int *m,
          int *info);

void ztrevc_64(char side, char howmny, long *select, long n,
          doublecomplex  *t,  long  ldt,  doublecomplex *vl,
          long ldvl, doublecomplex *vr, long ldvr, long  mm,
          long *m, long *info);
```

PURPOSE

ztrevc computes some or all of the right and/or left eigenvectors of a complex upper triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

T*x = w*x,   y'*T = w*y'

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input unitary
matrix. If T was obtained from the Schur factorization of an original matrix A = Q*T*Q', then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

ARGUMENTS

SIDE (input)
= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)
= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input/output)
If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrix T. N >= 0.

T (input/output)
The upper triangular matrix T. T is modified, but restored on exit.

LDT (input)
The leading dimension of the array T. LDT >= max(1,N).

VL (input/output)
On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL is lower triangular. The i-th column VL(i) of VL is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR is upper triangular. The i-th column VR(i) of VR is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK (workspace)
dimension(2*N)

RWORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The algorithm used in this program is basically backward (forward) substitution, with scaling to make the the code robust against possible overflow.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|.

SUBROUTINE ZTREXC_64(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)

CHARACTER * 1 COMPQ
DOUBLE COMPLEX T(LDT,*), Q(LDQ,*)
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
```

F95 INTERFACE

```
SUBROUTINE TREXC(COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])

CHARACTER(LEN=1) :: COMPQ
COMPLEX(8), DIMENSION(:,:) :: T, Q
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO

SUBROUTINE TREXC_64(COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])

CHARACTER(LEN=1) :: COMPQ
COMPLEX(8), DIMENSION(:,:) :: T, Q
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
```

C INTERFACE

```
#include <sunperf.h>

void ztrexc(char compq, int n, doublecomplex  *t,  int  ldt,
          doublecomplex *q, int ldq, int ifst, int ilst, int
          *info);

void ztrexc_64(char compq, long n,  doublecomplex  *t,  long
          ldt,  doublecomplex  *q, long ldq, long ifst, long
          ilst, long *info);
```

PURPOSE

ztrexc reorders the Schur factorization of a complex matrix A = Q*T*Q**H, so that the diagonal element of T with row index IFST is moved to row ILST.
The Schur form T is reordered by a unitary similarity transformation Z**H*T*Z, and optionally the matrix Q of Schur vectors is updated by postmultplying it with Z.

ARGUMENTS

COMPQ (input)
= 'V': update the matrix Q of Schur vectors;
= 'N': do not update Q.

N (input) The order of the matrix T. N >= 0.

T (input/output)
On entry, the upper triangular matrix T. On exit, the reordered upper triangular matrix.

LDT (input)
The leading dimension of the array T. LDT >= max(1,N).

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N).

IFST (input)
Specify the reordering of the diagonal elements of

T: The element with row index IFST is moved to row ILST by a sequence of transpositions between adjacent elements. 1 <= IFST <= N; 1 <= ILST <= N.

ILST (input)
See the description of IFST.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
SUBROUTINE TRMM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
       [LDA], B, [LDB])

CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>

void ztrmm(char side, char uplo, char transa, char diag, int
          m,  int n, doublecomplex *alpha, doublecomplex *a,
          int lda, doublecomplex *b, int ldb);
void ztrmm_64(char side, char uplo, char transa, char  diag,
          long  m,  long n, doublecomplex *alpha, doublecom-
          plex *a, long lda, doublecomplex *b, long ldb);
```

PURPOSE

ztrmm performs one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A) where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of op(A) = A or op(A) = A' or op(A) = conjg(A')

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether op(A) multiplies B from the left or right as follows:

SIDE = 'L' or 'l'   B := alpha*op(A)*B.

SIDE = 'R' or 'r'   B := alpha*B*op(A).

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular

```
            matrix.

            Unchanged on exit.

  TRANSA (input)
            On entry, TRANSA specifies the form of op( A )  to
            be used in the matrix multiplication as follows:

            TRANSA = 'N' or 'n'   op( A ) = A.

            TRANSA = 'T' or 't'   op( A ) = A'.

            TRANSA = 'C' or 'c'   op( A ) = conjg( A' ).

            Unchanged on exit.

            TRANSA is defaulted to 'N' for F95 INTERFACE.
  DIAG (input)
            On entry, DIAG specifies whether or not A is  unit
            triangular as follows:

            DIAG = 'U' or 'u'   A is assumed to be  unit  tri-
            angular.

            DIAG = 'N' or 'n'   A is not assumed  to  be  unit
            triangular.

            Unchanged on exit.

  M (input)
            On entry, M specifies the number of rows of  B.  M
            >= 0.  Unchanged on exit.

  N (input)
            On entry, N specifies the number of columns of  B.
            N >= 0.  Unchanged on exit.

  ALPHA (input)
            On entry,  ALPHA specifies the scalar  alpha. When
            alpha  is  zero  then   A is not referenced and  B
            need not be set before entry.  Unchanged on exit.

  A (input)
            COMPLEX*16 array of DIMENSION ( LDA, k ), where  k
            is  m  when   SIDE  =  'L' or 'l'  and is  n  when
            SIDE = 'R' or 'r'.

            Before entry  with  UPLO = 'U' or 'u',  the  lead-
            ing   k by k upper triangular part of the array  A
            must contain the upper triangular matrix  and  the
```

strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1,M), when SIDE = 'R' or 'r' then LDA >= max(1,N). Unchanged on exit.

B (input/output)

COMPLEX*16 array of DIMENSION (LDB, n). Before entry, the leading M by N part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB must be at least max(1,M). Unchanged on exit.

SUBROUTINE TRMV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX(8), DIMENSION(:) :: Y
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ztrmv(char uplo, char transa, char diag, int  n,  doub-
          lecomplex  *a,  int  lda,  doublecomplex  *y,  int
          incy);

void ztrmv_64(char uplo, char transa,  char  diag,  long  n,
          doublecomplex *a, long lda, doublecomplex *y, long
          incy);
```

PURPOSE

ztrmv performs one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := conjg(A')*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tranformed vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>

void ztrrfs(char uplo, char transa, char diag,  int  n,  int
          nrhs, doublecomplex *a, int lda, doublecomplex *b,
          int ldb, doublecomplex *x, int ldx, double  *ferr,
          double *berr, int *info);

void ztrrfs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs, doublecomplex *a, long lda, doublecom-
          plex *b, long ldb,  doublecomplex  *x,  long  ldx,
          double *ferr, double *berr, long *info);
```

PURPOSE

ztrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by CTRTRS or some other means before entering this routine. CTRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.
```

```
DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The triangular matrix A.  If UPLO = 'U', the lead-
          ing  N-by-N  upper  triangular part of the array A
          contains the  upper  triangular  matrix,  and  the
          strictly   lower  triangular  part  of  A  is  not
          referenced.  If UPLO =  'L',  the  leading  N-by-N
          lower  triangular part of the array A contains the
          lower triangular matrix, and  the  strictly  upper
          triangular part of A is not referenced.  If DIAG =
          'U', the diagonal  elements  of  A  are  also  not
          referenced and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
```

solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

REAL(8) :: S, SEP
```

C INTERFACE

```
#include <sunperf.h>

void ztrsen(char job, char compq, int *select, int n,  doub-
          lecomplex  *t, int ldt, doublecomplex *q, int ldq,
          doublecomplex *w, int *m, double *s, double  *sep,
          int *info);

void ztrsen_64(char job, char compq, long *select,  long  n,
          doublecomplex *t, long ldt, doublecomplex *q, long
          ldq, doublecomplex *w, long *m, double *s,  double
          *sep, long *info);
```

PURPOSE

ztrsen reorders the Schur factorization of a complex matrix A = Q*T*Q**H, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invari-

```
          ant subspace (SEP):
          = 'N': none;
          = 'E': for eigenvalues only (S);
          = 'V': for invariant subspace only (SEP);
          = 'B': for both eigenvalues and invariant subspace
          (S and SEP).

COMPQ (input)
          = 'V': update the matrix Q of Schur vectors;
          = 'N': do not update Q.

SELECT (input)
          SELECT specifies the eigenvalues in  the  selected
          cluster.  To select the j-th eigenvalue, SELECT(j)
          must be set to .TRUE..

N (input) The order of the matrix T. N >= 0.
T (input/output)
          On entry, the upper triangular matrix T.  On exit,
          T  is  overwritten by the reordered matrix T, with
          the selected eigenvalues as the  leading  diagonal
          elements.

LDT (input)
          The leading dimension  of  the  array  T.  LDT  >=
          max(1,N).

Q (input) On entry, if COMPQ = 'V', the matrix  Q  of  Schur
          vectors.   On  exit,  if  COMPQ  = 'V', Q has been
          postmultiplied  by  the   unitary   transformation
          matrix  which reorders T; the leading M columns of
          Q form an  orthonormal  basis  for  the  specified
          invariant  subspace.   If  COMPQ  =  'N', Q is not
          referenced.

LDQ (input)
          The leading dimension of the array Q.  LDQ  >=  1;
          and if COMPQ = 'V', LDQ >= N.

W (output)
          The reordered eigenvalues of T, in the same  order
          as they appear on the diagonal of T.

M (output)
          The dimension of the specified invariant subspace.
          0 <= M <= N.

S (output)
          If JOB = 'E' or 'B', S is a  lower  bound  on  the
          reciprocal condition number for the selected clus-
```

```
          ter of eigenvalues.  S  cannot  underestimate  the
          true  reciprocal  condition  number by more than a
          factor of sqrt(N). If M = 0 or N, S = 1.  If JOB =
          'N' or 'V', S is not referenced.

SEP (output)
          If JOB = 'V' or 'B', SEP is the estimated recipro-
          cal  condition  number  of the specified invariant
          subspace. If M = 0 or N, SEP = norm(T).  If JOB  =
          'N' or 'E', SEP is not referenced.
WORK (workspace)
          If JOB = 'N', WORK is not referenced.   Otherwise,
          on  exit, if INFO = 0, WORK(1) returns the optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If  JOB  =  'N',
          LWORK  >= 1; if JOB = 'E', LWORK = M*(N-M); if JOB
          = 'V' or 'B', LWORK >= 2*M*(N-M).

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
CTRSEN first collects the selected eigenvalues by  computing
a  unitary  transformation  Z  to  move them to the top left
corner of T. In other words, the  selected  eigenvalues  are
the eigenvalues of T11 in:

              Z'*T*Z = ( T11 T12 ) n1
                       (  0  T22 ) n2
                          n1  n2

where N = n1+n2 and Z' means the conjugate transpose  of  Z.
The  first n1 columns of Z span the specified invariant sub-
space of T.

If T has been obtained from the  Schur  factorization  of  a
matrix A = Q*T*Q', then the reordered Schur factorization of
A is given by A = (Q*Z)*(Z'*T*Z)*(Q*Z)', and  the  first  n1
columns  of Q*Z span the corresponding invariant subspace of
```

A.

The reciprocal condition number of the average of the eigenvalues of T11 may be returned in S. S lies between 0 (very badly conditioned) and 1 (very well conditioned). It is computed as follows. First we compute R so that

```
P = ( I  R ) n1
    ( 0  0 ) n2
      n1 n2
```

is the projector on the invariant subspace associated with T11. R is the solution of the Sylvester equation:

```
T11*R - R*T22 = T12.
```

Let F-norm(M) denote the Frobenius-norm of M and 2-norm(M) denote the two-norm of M. Then S is computed as the lower bound

```
(1 + F-norm(R)**2)**(-1/2)
```

on the reciprocal of 2-norm(P), the true reciprocal condition number. S cannot underestimate 1 / 2-norm(P) by more than a factor of sqrt(N).

An approximate error bound for the computed average of the eigenvalues of T11 is

```
EPS * norm(T) / S
```

where EPS is the machine precision.

The reciprocal condition number of the right invariant subspace spanned by the first n1 columns of Z (or of Q*Z) is returned in SEP. SEP is defined as the separation of T11 and T22:

```
sep( T11, T22 ) = sigma-min( C )
```

where sigma-min(C) is the smallest singular value of the n1*n2-by-n1*n2 matrix

```
C  = kprod( I(n2), T11 ) - kprod( transpose(T22), I(n1) )
```

I(m) is an m by m identity matrix, and kprod denotes the Kronecker product. We estimate sigma-min(C) by the reciprocal of an estimate of the 1-norm of inverse(C). The true reciprocal 1-norm of inverse(C) cannot differ from sigma-min(C) by more than a factor of sqrt(n1*n2).

When SEP is small, small changes in T can cause large changes in the invariant subspace. An approximate bound on the maximum angular error in the computed right invariant subspace is

```
EPS * norm(T) / SEP
```

SUBROUTINE TRSM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
       [LDA], B, [LDB])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX(8) :: ALPHA
COMPLEX(8), DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>

void ztrsm(char side, char uplo, char transa, char diag, int
          m,  int n, doublecomplex *alpha, doublecomplex *a,
          int lda, doublecomplex *b, int ldb);

void ztrsm_64(char side, char uplo, char transa, char  diag,
          long    m,    long    n,   doublecomplex   *alpha,
          doublecomplex *a, long lda, doublecomplex *b, long
          ldb);
```

PURPOSE

ztrsm solves one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

op(A) = A or op(A) = A' or op(A) = conjg(A').

The matrix X is overwritten on B.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l'   op(A)*X = alpha*B.

SIDE = 'R' or 'r'   X*op(A) = alpha*B.

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular

matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = conjg(A').
Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)

On entry, M specifies the number of rows of B. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of B. N >= 0. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)

COMPLEX*16 array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1,M), when SIDE = 'R' or 'r' then LDA >= max(1,N). Unchanged on exit.

B (input/output)

COMPLEX*16 array of DIMENSION (LDB, n). Before entry, the leading M by N part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB >= max(1,M). Unchanged on exit.

          *s,  double  *sep,  long mm, long *m, long ldwork,
          long *info);
```

PURPOSE

ztrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix Q*T*Q**H with Q unitary).

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):
= 'E': for eigenvalues only (S);
= 'V': for eigenvectors only (SEP);
= 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY (input)
= 'A': compute condition numbers for all eigen-

```
          pairs;
          = 'S':  compute  condition  numbers  for  selected
          eigenpairs specified by the array SELECT.

SELECT (input)
          If HOWMNY = 'S', SELECT specifies  the  eigenpairs
          for  which  condition  numbers  are  required.  To
          select condition numbers for the  j-th  eigenpair,
          SELECT(j) must be set to .TRUE..  If HOWMNY = 'A',
          SELECT is not referenced.

N (input) The order of the matrix T. N >= 0.

T (input) The upper triangular matrix T.
LDT (input)
          The leading dimension  of  the  array  T.  LDT  >=
          max(1,N).

VL (input)
          If JOB = 'E' or 'B', VL must contain  left  eigen-
          vectors  of T (or of any Q*T*Q**H with Q unitary),
          corresponding  to  the  eigenpairs  specified   by
          HOWMNY and SELECT. The eigenvectors must be stored
          in consecutive  columns  of  VL,  as  returned  by
          CHSEIN  or CTREVC.  If JOB = 'V', VL is not refer-
          enced.

LDVL (input)
          The leading dimension of the array VL.  LDVL >= 1;
          and if JOB = 'E' or 'B', LDVL >= N.

VR (input)
          If JOB = 'E' or 'B', VR must contain right  eigen-
          vectors  of T (or of any Q*T*Q**H with Q unitary),
          corresponding  to  the  eigenpairs  specified   by
          HOWMNY and SELECT. The eigenvectors must be stored
          in consecutive  columns  of  VR,  as  returned  by
          CHSEIN  or CTREVC.  If JOB = 'V', VR is not refer-
          enced.

LDVR (input)
          The leading dimension of the array VR.  LDVR >= 1;
          and if JOB = 'E' or 'B', LDVR >= N.

S (output)
          If JOB = 'E'  or  'B',  the  reciprocal  condition
          numbers  of  the  selected  eigenvalues, stored in
          consecutive elements  of  the  array.  Thus  S(j),
          SEP(j),  and  the  j-th  columns  of VL and VR all
          correspond to the same eigenpair (but not in  gen-
```

eral the j-th eigenpair, unless all eigenpairs are selected). If JOB = 'V', S is not referenced.

SEP (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If JOB = 'E', SEP is not referenced.

MM (input)
The number of elements in the arrays S (if JOB = 'E' or 'B') and/or SEP (if JOB = 'V' or 'B'). MM >= M.

M (output)
The number of elements of the arrays S and/or SEP actually used to store the estimated condition numbers. If HOWMNY = 'A', M is set to N.

WORK (workspace)
dimension(LDWORK,N+1) If JOB = 'E', WORK is not referenced.

LDWORK (input)
The leading dimension of the array WORK. LDWORK >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

WORK1 (workspace)
dimension(N) If JOB = 'E', WORK1 is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of an eigenvalue lambda is defined as

S(lambda) = |v'*u| / (norm(u)*norm(v))

where u and v are the right and left eigenvectors of T corresponding to lambda; v' denotes the conjugate transpose of v, and norm(u) denotes the Euclidean norm. These reciprocal condition numbers always lie between zero (very badly conditioned) and one (very well conditioned). If n = 1, S(lambda) is defined to be 1.

An approximate error bound for a computed eigenvalue W(i) is given by

```
EPS * norm(T) / S(i)
```

where EPS is the machine precision.
The reciprocal of the condition number of the right eigenvector u corresponding to lambda is defined as follows. Suppose

```
T = ( lambda  c  )
    (   0    T22 )
```

Then the reciprocal condition number is

```
SEP( lambda, T22 ) = sigma-min( T22 - lambda*I )
```

where sigma-min denotes the smallest singular value. We approximate the smallest singular value by the reciprocal of an estimate of the one-norm of the inverse of T22 - lambda*I. If n = 1, SEP(1) is defined to be abs(T(1,1)).

An approximate error bound for a computed right eigenvector VR(i) is given by

```
EPS * norm(T) / SEP(i)
```

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ztrsv(char uplo, char transa, char diag, int  n,  doub-
          lecomplex  *a,  int  lda,  doublecomplex  *y,  int
          incy);

void ztrsv_64(char uplo, char transa,  char  diag,  long  n,
          doublecomplex *a, long lda, doublecomplex *y, long
          incy);
```

PURPOSE

ztrsv solves one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   conjg(A')*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

SUBROUTINE TRSYL(TRANA, TRANB, ISGN, [M], [N], A, [LDA], B, [LDB], C,
       [LDC], SCALE, [INFO])

CHARACTER(LEN=1) :: TRANA, TRANB
COMPLEX(8), DIMENSION(:,:) :: A, B, C
INTEGER :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL(8) :: SCALE

SUBROUTINE TRSYL_64(TRANA, TRANB, ISGN, [M], [N], A, [LDA], B, [LDB],
       C, [LDC], SCALE, [INFO])
```

```
CHARACTER(LEN=1) :: TRANA, TRANB
COMPLEX(8), DIMENSION(:,:) :: A, B, C
INTEGER(8) :: ISGN, M, N, LDA, LDB, LDC, INFO
REAL(8) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void ztrsyl(char trana, char tranb, int isgn, int m, int  n,
          doublecomplex  *a,  int lda, doublecomplex *b, int
          ldb, doublecomplex *c, int ldc, double *scale, int
          *info);

void ztrsyl_64(char trana, char tranb, long  isgn,  long  m,
          long  n, doublecomplex *a, long lda, doublecomplex
          *b, long ldb, doublecomplex *c, long  ldc,  double
          *scale, long *info);
```

PURPOSE

ztrsyl solves the complex Sylvester matrix equation:

```
   op(A)*X + X*op(B) = scale*C or
   op(A)*X - X*op(B) = scale*C,
```

where op(A) = A or A**H, and A and B are both upper triangular. A is M-by-M and B is N-by-N; the right hand side C and the solution X are M-by-N; and scale is an output scale factor, set <= 1 to avoid overflow in X.

ARGUMENTS

```
TRANA (input)
          Specifies the option op(A):
          = 'N': op(A) = A    (No transpose)
          = 'C': op(A) = A**H (Conjugate transpose)

TRANB (input)
          Specifies the option op(B):
          = 'N': op(B) = B    (No transpose)
          = 'C': op(B) = B**H (Conjugate transpose)

ISGN (input)
          Specifies the sign in the equation:
          = +1: solve op(A)*X + X*op(B) = scale*C
          = -1: solve op(A)*X - X*op(B) = scale*C
```

M (input) The order of the matrix A, and the number of rows in the matrices X and C. M >= 0.

N (input) The order of the matrix B, and the number of columns in the matrices X and C. N >= 0.

A (input) The upper triangular matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input) The upper triangular matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

C (input/output)
On entry, the M-by-N right hand side matrix C. On exit, C is overwritten by the solution matrix X.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M)

SCALE (output)
The scale factor, scale, set <= 1 to avoid overflow in X.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1: A and B have common or very close eigenvalues; perturbed values were used to solve the equation (but the matrices A and B are unchanged).

INTEGER :: N, LDA, INFO

SUBROUTINE TRTI2_64(UPLO, DIAG, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztrti2(char uplo, char diag, int n,  doublecomplex  *a,
          int lda, int *info);

void ztrti2_64(char uplo, char diag, long  n,  doublecomplex
          *a, long lda, long *info);
```

PURPOSE

ztrti2 computes the inverse of a complex upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

```
UPLO (input)
          Specifies whether the matrix A is upper  or  lower
          triangular.  = 'U':  Upper triangular
          = 'L':  Lower triangular

DIAG (input)
          Specifies whether or not the matrix A is unit tri-
          angular.  = 'N':  Non-unit triangular
          = 'U':  Unit triangular

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the triangular matrix A.  If UPLO = 'U',
          the  leading  n  by n upper triangular part of the
          array A contains the upper triangular matrix,  and
          the  strictly  lower  triangular  part of A is not
          referenced.  If UPLO = 'L', the  leading  n  by  n
          lower  triangular part of the array A contains the
          lower triangular matrix, and  the  strictly  upper
          triangular part of A is not referenced.  If DIAG =
          'U', the diagonal  elements  of  A  are  also  not
          referenced and are assumed to be 1.

          On exit, the (triangular) inverse of the  original
          matrix, in the same storage format.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).
```

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an ille-
gal value

```

C INTERFACE

```
#include <sunperf.h>

void ztrtrs(char uplo, char transa, char diag,  int  n,  int
          nrhs, doublecomplex *a, int lda, doublecomplex *b,
          int ldb, int *info);

void ztrtrs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs, doublecomplex *a, long lda, doublecom-
          plex *b, long ldb, long *info);
```

PURPOSE

ztrtrs solves a triangular system of the form where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

UPLO (input)
= 'U': A is upper triangular;
= 'L': A is lower triangular.

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztzrqf(int m, int n, doublecomplex *a, int  lda,  doub-
          lecomplex *tau, int *info);

void ztzrqf_64(long m, long n, doublecomplex *a,  long  lda,
          doublecomplex *tau, long *info);
```

PURPOSE

ztzrqf routine is deprecated and has been replaced by routine CTZRZF.

CTZRQF reduces the M-by-N (M<=N) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as
   A = (R 0) * Z,

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= M.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

```
The  factorization is obtained by Householder's method.  The
kth transformation matrix, Z( k ), whose conjugate transpose
is used to introduce zeros into the (m - k + 1)th row of  A,
is given in the form

   Z( k ) = ( I     0   ),
            ( 0  T( k ) )

where

   T( k ) = I - tau*u( k )*u( k )',   u( k ) = (   1    ),
                                               (   0    )
                                               ( z( k ) )

tau is a scalar and z( k ) is an ( n - m )  element  vector.
tau  and z( k ) are chosen to annihilate the elements of the
kth row of X.

The scalar tau is returned in the kth element of TAU and the
vector u( k ) in the kth row of A, such that the elements of
z( k ) are in  a( k, m + 1 ), ..., a( k, n ).  The  elements
of R are returned in the upper triangular part of A.

Z is given by

   Z =  Z( 1 ) * Z( 2 ) * ... * Z( m ).
```

COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ztzrzf(int m, int n, doublecomplex *a, int  lda,  doub-
          lecomplex *tau, int *info);

void ztzrzf_64(long m, long n, doublecomplex *a,  long  lda,
          doublecomplex *tau, long *info);
```

PURPOSE

ztzrzf reduces the M-by-N (M<=N) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

   A = (R 0) * Z,

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

Based on contributions by
A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The factorization is obtained by Householder's method. The kth transformation matrix, Z(k), which is used to introduce zeros into the (m - k + 1)th row of A, is given in the form

```
   Z( k ) = ( I     0   ),
            ( 0  T( k ) )
```

where

```
   T( k ) = I - tau*u( k )*u( k )',   u( k ) = (   1    ),
                                               (   0    )
                                               ( z( k ) )
```

tau is a scalar and z(k) is an (n - m) element vector. tau and z(k) are chosen to annihilate the elements of the kth row of X.

The scalar tau is returned in the kth element of TAU and the vector u(k) in the kth row of A, such that the elements of z(k) are in a(k, m + 1), ..., a(k, n). The elements of R are returned in the upper triangular part of A.

Z is given by

```
   Z =  Z( 1 ) * Z( 2 ) * ... * Z( m ).
```

void zung2l_64(long m, long n,  long  k,  doublecomplex  *a,
          long lda, doublecomplex *tau, long *info);
```

PURPOSE

zung2l L generates an m by n complex matrix Q with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m

Q = H(k) . . . H(2) H(1)

as returned by CGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)
On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQLF in the last k columns of its array argument A. On exit, the m-by-n matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

WORK (workspace)

void zung2r_64(long m, long n,  long  k,  doublecomplex  *a,
          long lda, doublecomplex *tau, long *info);
```

PURPOSE

zung2r R generates an m by n complex matrix Q with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

      Q = H(1) H(2) . . . H(k)

as returned by CGEQRF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)
On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQRF in the first k columns of its array argument A. On exit, the m by n matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

WORK (workspace)
dimension(N)

CHARACTER * 1 VECT
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, K, LDA, LWORK, INFO

SUBROUTINE ZUNGBR_64(VECT, M, N, K, A, LDA, TAU, WORK, LWORK, INFO)

CHARACTER * 1 VECT
DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGBR(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: VECT
COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: M, N, K, LDA, LWORK, INFO

SUBROUTINE UNGBR_64(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: VECT
COMPLEX(8), DIMENSION(:) :: TAU, WORK
```

```
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zungbr(char vect, int m, int n,  int  k,  doublecomplex
          *a, int lda, doublecomplex *tau, int *info);

void zungbr_64(char vect, long m, long n, long k, doublecom-
          plex   *a,  long  lda,  doublecomplex  *tau,  long
          *info);
```

PURPOSE

zungbr generates one of the complex unitary matrices Q or P**H determined by CGEBRD when reducing a complex matrix A to bidiagonal form: A = Q * B * P**H. Q and P**H are defined as products of elementary reflectors H(i) or G(i) respectively.

If VECT = 'Q', A is assumed to have been an M-by-K matrix, and Q is of order M:
if m >= k, Q = H(1) H(2) . . . H(k) and CUNGBR returns the first n columns of Q, where m >= n >= k;
if m < k, Q = H(1) H(2) . . . H(m-1) and CUNGBR returns Q as an M-by-M matrix.

If VECT = 'P', A is assumed to have been a K-by-N matrix, and P**H is of order N:
if k < n, P**H = G(k) . . . G(2) G(1) and CUNGBR returns the first m rows of P**H, where n >= m >= k;
if k >= n, P**H = G(n-1) . . . G(2) G(1) and CUNGBR returns P**H as an N-by-N matrix.

ARGUMENTS

VECT (input)
Specifies whether the matrix Q or the matrix P**H is required, as defined in the transformation applied by CGEBRD:
= 'Q': generate Q;
= 'P': generate P**H.

M (input) The number of rows of the matrix Q or P**H to be returned. M >= 0.

N (input) The number of columns of the matrix Q or P**H to be returned. N >= 0. If VECT = 'Q', M >= N >= min(M,K); if VECT = 'P', N >= M >= min(N,K).

K (input) If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by CGEBRD. K >= 0.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by CGEBRD. On exit, the M-by-N matrix Q or P**H.

LDA (input)
The leading dimension of the array A. LDA >= M.

TAU (input)
(min(M,K)) if VECT = 'Q' (min(N,K)) if VECT = 'P' TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P**H, as returned by CGEBRD in its array argument TAUQ or TAUP.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,min(M,N)). For optimum performance LWORK >= min(M,N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

zunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

SYNOPSIS

```
SUBROUTINE ZUNGHR(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)

DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER N, ILO, IHI, LDA, LWORK, INFO

SUBROUTINE ZUNGHR_64(N, ILO, IHI, A, LDA, TAU, WORK, LWORK, INFO)

DOUBLE COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 N, ILO, IHI, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGHR([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK], [INFO])

COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER :: N, ILO, IHI, LDA, LWORK, INFO

SUBROUTINE UNGHR_64([N], ILO, IHI, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

COMPLEX(8), DIMENSION(:) :: TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: A
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zunghr(int n, int ilo, int ihi, doublecomplex  *a,  int
          lda, doublecomplex *tau, int *info);

void zunghr_64(long n, long ilo, long ihi, doublecomplex *a,
          long lda, doublecomplex *tau, long *info);
```

PURPOSE

zunghr generates a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

ARGUMENTS

N (input) The order of the matrix Q. N >= 0.

ILO (input)
ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description of IHI.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by CGEHRD. On exit, the N-by-N unitary matrix Q.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= IHI-ILO. For optimum performance LWORK >= (IHI-ILO)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

          doublecomplex *tau, int *info);

void zungl2_64(long m, long n,  long  k,  doublecomplex  *a,
          long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungl2 generates an m-by-n complex matrix Q with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

```
      Q  =  H(k)' . . . H(2)' H(1)'
```

as returned by CGELQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)
On entry, the i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGELQF in the first k rows of its array argument A. On exit, the m by n matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

WORK (workspace)
dimension(M)

          doublecomplex *tau, int *info);

void zungql_64(long m, long n,  long  k,  doublecomplex  *a,
          long lda, doublecomplex *tau, long *info);
```

PURPOSE

zungql generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

      Q = H(k) . . . H(2) H(1)

as returned by CGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)
On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >=

```
            max(1,N).   For optimum performance LWORK >= N*NB,
            where NB is the optimal blocksize.

            If LWORK = -1, then a workspace query is  assumed;
            the  routine  only  calculates the optimal size of
            the WORK array, returns this value  as  the  first
            entry  of  the  WORK  array,  and no error message
            related to LWORK is issued by XERBLA.

```

PURPOSE

zungqr generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

```
      Q  =  H(1) H(2) . . . H(k)
```

as returned by CGEQRF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)
On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

WORKIN (workspace)
On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)
The dimension of the array WORKIN. LWORKIN >=

max(1,N). For optimum performance LWORKIN >= N*NB, where NB is the optimal blocksize.

If LWORKIN = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

```
#include <sunperf.h>

void zungtr(char uplo, int n,  doublecomplex  *a,  int  lda,
          doublecomplex *tau, int *info);

void zungtr_64(char uplo, long  n,  doublecomplex  *a,  long
          lda, doublecomplex *tau, long *info);
```

PURPOSE

zungtr generates a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD:
if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

N (input) The order of the matrix Q. N >= 0.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by CHETRD. On exit, the N-by-N unitary matrix Q.

LDA (input)
The leading dimension of the array A. LDA >= N.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= N-1. For optimum performance LWORK >= (N-1)*NB, where

NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void zunmbr(char vect, char side, char trans, int m, int  n,
          int  k,  doublecomplex  *a, int lda, doublecomplex
          *tau, doublecomplex *c, int ldc, int *info);

void zunmbr_64(char vect, char side,  char  trans,  long  m,
          long  n, long k, doublecomplex *a, long lda, doub-
          lecomplex *tau, doublecomplex *c, long  ldc,  long
          *info);
```

PURPOSE

```
zunmbr VECT = 'Q', CUNMBR overwrites the general complex  M-
by-N matrix C with
                SIDE = 'L'      SIDE  =  'R'  TRANS  =  'N':
Q  *  C           C * Q TRANS = 'C':      Q**H * C       C *
Q**H

If VECT = 'P', CUNMBR overwrites the general complex  M-by-N
matrix C with
                SIDE = 'L'     SIDE = 'R'
TRANS = 'N':      P * C          C * P
TRANS = 'C':      P**H * C       C * P**H

Here Q and P**H  are  the  unitary  matrices  determined  by
CGEBRD  when reducing a complex matrix A to bidiagonal form:
A = Q * B * P**H. Q and P**H are defined as products of ele-
mentary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'.  Thus  nq
is  the  order  of  the  unitary  matrix  Q  or P**H that is
applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K  matrix:
if nq >= k, Q = H(1) H(2) . . . H(k);
if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a  K-by-NQ  matrix:
if k < nq, P = G(1) G(2) . . . G(k);
if k >= nq, P = G(1) G(2) . . . G(nq-1).
```

ARGUMENTS

VECT (input)
= 'Q': apply Q or Q**H;
= 'P': apply P or P**H.

SIDE (input)
= 'L': apply Q, Q**H, P or P**H from the Left;
= 'R': apply Q, Q**H, P or P**H from the Right.

TRANS (input)
= 'N': No transpose, apply Q or P;
= 'C': Conjugate transpose, apply Q**H or P**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.
N (input) The number of columns of the matrix C. N >= 0.

K (input) If VECT = 'Q', the number of columns in the original matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original matrix reduced by CGEBRD. K >= 0.

A (input) (LDA,min(nq,K)) if VECT = 'Q' (LDA,nq) if VECT = 'P' The vectors which define the elementary reflectors H(i) and G(i), whose products determine the matrices Q and P, as returned by CGEBRD.

LDA (input)
The leading dimension of the array A. If VECT = 'Q', LDA >= max(1,nq); if VECT = 'P', LDA >= max(1,min(nq,K)).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i) which determines Q or P, as returned by CGEBRD in the array argument TAUQ or TAUP.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q or P*C or P**H*C or C*P or C*P**H.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

          *tau, doublecomplex *c, int ldc, int *info);

void zunmhr_64(char side, char trans, long m, long  n,  long
          ilo,  long  ihi, doublecomplex *a, long lda, doub-
          lecomplex *tau, doublecomplex *c, long  ldc,  long
          *info);
```

PURPOSE

zunmhr overwrites the general complex M-by-N matrix C with
TRANS = 'C':   Q**H * C   C * Q**H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by CGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**H from the Left;
= 'R': apply Q or Q**H from the Right.

TRANS (input)
= 'N': apply Q (No transpose)
= 'C': apply Q**H (Conjugate transpose)

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

ILO (input)
ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit

matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). If SIDE = 'L', then 1 <= ILO <= IHI <= M, if M > 0, and ILO = 1 and IHI = 0, if M = 0; if SIDE = 'R', then 1 <= ILO <= IHI <= N, if N > 0, and ILO = 1 and IHI = 0, if N = 0.

IHI (input)
See the description of ILO.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CGEHRD.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M) if SIDE = 'L'; LDA >= max(1,N) if SIDE = 'R'.

TAU (input)
(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit

< 0: if INFO = -i, the i-th argument had an ille-
gal value

          k, doublecomplex *a, long lda, doublecomplex *tau,
          doublecomplex *c, long ldc, long *info);
```

PURPOSE

zunml2 overwrites the general complex m-by-n matrix C with

where Q is a complex unitary matrix defined as the product of k elementary reflectors

Q = H(k)' . . . H(2)' H(1)'

as returned by CGELQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q' from the Left
= 'R': apply Q or Q' from the Right

TRANS (input)
= 'N': apply Q (No transpose)
= 'C': apply Q' (Conjugate transpose)

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

```
A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE =  'R'  The
          i-th row must contain the vector which defines the
          elementary reflector H(i), for i =  1,2,...,k,  as
          returned  by  CGELQF  in  the  first k rows of its
          array argument A.  A is modified  by  the  routine
          but restored on exit.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,K).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by CGELQF.

C (input/output)
          On entry, the m-by-n matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q'*C or C*Q' or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

PURPOSE

zunmql overwrites the general complex M-by-N matrix C with
TRANS = 'C':   Q**H * C   C * Q**H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

      Q = H(k) . . . H(2) H(1)

as returned by CGEQLF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
  = 'L': apply Q or Q**H from the Left;
  = 'R': apply Q or Q**H from the Right.

TRANS (input)
  = 'N': No transpose, apply Q;
  = 'C': Transpose, apply Q**H.

  TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

```
A (input) The i-th column  must  contain  the  vector  which
          defines  the  elementary  reflector  H(i), for i =
          1,2,...,k, as returned by CGEQLF  in  the  last  k
          columns of its array argument A.  A is modified by
          the routine but restored on exit.

LDA (input)
          The leading dimension of the array A.  If  SIDE  =
          'L',  LDA  >=  max(1,M);  if  SIDE  =  'R', LDA >=
          max(1,N).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by CGEQLF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

PURPOSE

zunmrz overwrites the general complex M-by-N matrix C with TRANS = 'C': Q**H * C C * Q**H

where Q is a complex unitary matrix defined as the product of k elementary reflectors

Q = H(1) H(2) . . . H(k)

as returned by CTZRZF. Q is of order M if SIDE = 'L' and of order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**H from the Left;
= 'R': apply Q or Q**H from the Right.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q**H.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

```
L (input) The number of columns of the matrix  A  containing
          the meaningful part of the Householder reflectors.
          If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >=  L
          >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE =  'R'  The
          i-th row must contain the vector which defines the
          elementary reflector H(i), for i =  1,2,...,k,  as
          returned by CTZRZF in the last k rows of its array
          argument A.  A is  modified  by  the  routine  but
          restored on exit.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,K).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by CTZRZF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

```

PURPOSE

zunmtr overwrites the general complex M-by-N matrix C with
TRANS = 'C':   Q**H * C   C * Q**H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by CHETRD:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**H from the Left;
= 'R': apply Q or Q**H from the Right.

UPLO (input)
= 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHETRD.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M) if SIDE = 'L'; LDA >= max(1,N) if SIDE = 'R'.

TAU (input)
(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >=M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

Contents

NAME

zupgtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

SYNOPSIS

```
SUBROUTINE ZUPGTR(UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX AP(*), TAU(*), Q(LDQ,*), WORK(*)
INTEGER N, LDQ, INFO

SUBROUTINE ZUPGTR_64(UPLO, N, AP, TAU, Q, LDQ, WORK, INFO)

CHARACTER * 1 UPLO
DOUBLE COMPLEX AP(*), TAU(*), Q(LDQ,*), WORK(*)
INTEGER*8 N, LDQ, INFO
```

F95 INTERFACE

```
SUBROUTINE UPGTR(UPLO, [N], AP, TAU, Q, [LDQ], [WORK], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX(8), DIMENSION(:) :: AP, TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: Q
INTEGER :: N, LDQ, INFO

SUBROUTINE UPGTR_64(UPLO, [N], AP, TAU, Q, [LDQ], [WORK], [INFO])

INTEGER(8) :: N, LDQ, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zupgtr(char uplo, int n, doublecomplex *ap,  doublecom-
          plex *tau, doublecomplex *q, int ldq, int *info);

void zupgtr_64(char uplo, long n, doublecomplex  *ap,  doub-
          lecomplex  *tau,  doublecomplex *q, long ldq, long
          *info);
```

PURPOSE

zupgtr generates a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage:

if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

ARGUMENTS

UPLO (input)
= 'U': Upper triangular packed storage used in previous call to CHPTRD; = 'L': Lower triangular packed storage used in previous call to CHPTRD.

N (input) The order of the matrix Q. N >= 0.

AP (input)
The vectors which define the elementary reflectors, as returned by CHPTRD.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHPTRD.

Q (output)
The N-by-N unitary matrix Q.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N).

WORK (workspace)
dimension(N-1)

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

       [WORK], [INFO])

CHARACTER(LEN=1) :: SIDE, UPLO, TRANS
```

```
COMPLEX(8), DIMENSION(:) :: AP, TAU, WORK
COMPLEX(8), DIMENSION(:,:) :: C
INTEGER(8) :: M, N, LDC, INFO
```

C INTERFACE

```
#include <sunperf.h>

void zupmtr(char side, char uplo, char trans, int m, int  n,
          doublecomplex  *ap, doublecomplex *tau, doublecom-
          plex *c, int ldc, int *info);

void zupmtr_64(char side, char uplo,  char  trans,  long  m,
          long  n,  doublecomplex  *ap,  doublecomplex *tau,
          doublecomplex *c, long ldc, long *info);
```

PURPOSE

zupmtr overwrites the general complex M-by-N matrix C with
TRANS = 'C':   Q**H * C   C * Q**H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by CHPTRD using packed storage:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**H from the Left;
= 'R': apply Q or Q**H from the Right.

UPLO (input)
= 'U': Upper triangular packed storage used in previous call to CHPTRD; = 'L': Lower triangular packed storage used in previous call to CHPTRD.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

AP (input)
(M*(M+1)/2) if SIDE = 'L' (N*(N+1)/2) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHPTRD. AP is modified by the routine but restored on exit.

TAU (input)
or (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHPTRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
(N) if SIDE = 'L' (M) if SIDE = 'R'

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

DESCRIPTION

```
        C <- alpha op(A) B + beta C
where ALPHA and BETA are scalar, C and B are  matrices,
A is a matrix represented in variable block sparse row  format
and op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if the matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
```

DESCRA(2) upper/lower triangular indicator
  1 : lower
  2 : upper
DESCRA(3) main diagonal type
  0 : non-unit
  1 : unit
DESCRA(4) Array base (NOT IMPLEMENTED)
  0 : C/C++ compatible
  1 : Fortran compatible
DESCRA(5) repeated indices? (NOT IMPLEMENTED)
  0 : unknown
  1 : no repeated indices

VAL() scalar array of length NNZ consisting of the block entries of A where each block entry is a dense rectangular matrix stored column by column.
NNZ is the total number of point entries in all nonzero block entries of a matrix A.

INDX() integer array of length BNNZ+1 where BNNZ is the number of block entries of a matrix A such that the I-th element of INDX[] points to the location in VAL of the (1,1) element of the I-th block entry.

BINDX() integer array of length BNNZ consisting of the block column indices of the block entries of A where BNNZ is the number block entries of a matrix A.

RPNTR() integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1 is the row index of the first point row in the I-th block row.
RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of rows in matrix A.
Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I).

CPNTR() integer array of length KB+1 such that CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(KB+1) is set to K+CPNTR(1) where K is the number of columns in matrix A.
Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J).

BPNTRB() integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A.

BPNTRE() integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A.

B()   rectangular array with first dimension LDB.

LDB   leading dimension of B

BETA   Scalar parameter

C()   rectangular array with first dimension LDC.

LDC   leading dimension of C

WORK()   scratch array of length LWORK. WORK is not referenced in the current version.

LWORK   length of WORK array. LWORK is not referenced in the current version.

NOTES/BUGS

1. For a general matrix (*DESCRA*(1)=0), array CPNTR can be different from RPNTR. For all other matrix types, RPNTR must equal CPNTR and a single array can be passed for both arguments.

2.It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
  SUBROUTINE ZVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *            VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
 *            B, LDB, BETA, C, LDC, WORK, LWORK )
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in variable block sparse row
format and  op( A )  is one  of

 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array containing the block entries of the block
              diagonal matrix D.  The size of the J-th block is
              RPNTR(J+1)-RPNTR(J) and each block contains matrix
              entries stored column-major.  The total length of
              array DV is given by the formula:

              sum over J from 1 to MB:
```

```
                ((RPNTR(J+1)-RPNTR(J))*(RPNTR(J+1)-RPNTR(J)))

ALPHA          Scalar parameter

DESCRA()       Descriptor argument.  Five element integer array
               DESCRA(1) matrix structure
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, DESCRA(1)=3 is only supported.
               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-identity  blocks on the main diagonal
                 1 : identity diagonal blocks
                 2 : diagonal blocks are dense matrices
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

VAL()          scalar array of length NNZ consisting of the block entries
               of A where each block entry is a dense rectangular matrix
               stored column by column.
               NNZ is the total number of point entries in all nonzero
               block  entries of a matrix A.

INDX()         integer array of length BNNZ+1 where BNNZ is the number
               block entries of a matrix A such that the I-th element of
               INDX[] points to the location in VAL of the (1,1) element
               of the I-th block entry.

BINDX()        integer array of length BNNZ consisting of the block
               column indices of the block entries of A where BNNZ is
               the number block entries of a matrix A.   Block column
               indices MUST be sorted in increasing order for each block
               row.

RPNTR()        integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1
               is the row index of the first point row in the I-th block
               row.
               RPNTR(MB+1) is set to M+RPNTR(1) where M is the number
               of rows  in square triangular matrix A.
```

Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR()	integer array of length MB+1 such that CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(MB+1) is set to M+CPNTR(1). Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J). NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments
BPNTRB()	integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A.
BPNTRE()	integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A.
B()	rectangular array with first dimension LDB.
LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.
LWORK	length of WORK array. LWORK should be at least M = RPNTR(MB+1)-RPNTR(1). For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program. If LWORK=0, the routine is to allocate workspace needed. If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued

by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the VBR representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3.

6. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
      SUBROUTINE ZVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
     *           VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
     *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

NAME

```
zvmul - compute the scaled product of complex vectors
```

SYNOPSIS

```
SUBROUTINE ZVMUL(N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)

DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX X(*), Y(*), Z(*)
INTEGER N, INCX, INCY, INCZ

SUBROUTINE ZVMUL_64(N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)

DOUBLE COMPLEX ALPHA, BETA
DOUBLE COMPLEX X(*), Y(*), Z(*)
INTEGER*8 N, INCX, INCY, INCZ
```

F95 INTERFACE

```
SUBROUTINE VMUL([N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])

COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y, Z
INTEGER :: N, INCX, INCY, INCZ

SUBROUTINE VMUL_64([N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])

COMPLEX(8) :: ALPHA, BETA
COMPLEX(8), DIMENSION(:) :: X, Y, Z
INTEGER(8) :: N, INCX, INCY, INCZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void zvmul(int n, doublecomplex  *alpha,  doublecomplex  *x,
          int  incx,  doublecomplex *y, int incy, doublecom-
          plex *beta, doublecomplex *z, int incz);

void zvmul_64(long n,  doublecomplex  *alpha,  doublecomplex
          *x,  long incx, doublecomplex *y, long incy, doub-
          lecomplex *beta, doublecomplex *z, long incz);
```

PURPOSE

```
zvmul computes the scaled product of complex vectors:
  z(i) = ALPHA * x(i) * y(i) + BETA * z(i)
for 1 <= i <= N.
```

ARGUMENTS

```
N (input)
          Length of the vectors.  N >= 0.  ZVMUL will return
          immediately if N = 0.

ALPHA (input)
          Scale factor on the multiplicand vectors.

X (input)  dimension(*)
          Multiplicand vector.

INCX (input)
          Stride between elements of the multiplicand vector
          X.  INCX > 0.

Y (input)  dimension(*)
          Multiplicand vector.

INCY (input)
          Stride between elements of the multiplicand vector
          Y.  INCY > 0.

BETA (input)
          Scale factor on the product vector.

Z (input/output)
           dimension(*)
          Product vector.  On exit, z(i) = ALPHA  *  x(i)  *
          y(i) + BETA * z(i).

INCZ (input)
          Stride between elements of Z.  INCZ > 0.
```
