Sun Performance Library[tm] Reference Manual

Sun [tm] ONE Studio 8

This reference manual is the Sun Performance Library section 3P man pages, available in HTML and PDF formats. For additional information, see the *Sun Performance Library User's Guide*, available on `docs.sun.com`, or the *LAPACK Users' Guide*, available from the Society for Industrial and Applied Mathematics (SIAM).

---

cbdimm - cbdimm - block diagonal format matrix-matrix multiply

cbdism - cbdism - block diagonal format triangular solve

cbdsqr - cbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

cbelmm - cbelmm - block Ellpack format matrix-matrix multiply

cbelsm - cbelsm - block Ellpack format triangular solve

cbscmm - cbscmm - block sparse column matrix-matrix multiply

cbscsm - cbscsm - block sparse column format triangular solve

cbsrmm - cbsrmm - block sparse row format matrix-matrix multiply

cbsrsm - cbsrsm - block sparse row format triangular solve

ccnvcor - ccnvcor - compute the convolution or correlation of complex vectors

ccnvcor2 - ccnvcor2 - compute the convolution or correlation of complex matrices

ccoomm - ccoomm - coordinate matrix-matrix multiply

ccopy - ccopy - Copy x to y

ccscmm - ccscmm - compressed sparse column format matrix-matrix multiply

ccscsm - ccscsm - compressed sparse column format triangular solve

ccsrmm - ccsrmm - compressed sparse row format matrix-matrix multiply

ccsrsm - ccsrsm - compressed sparse row format triangular solve

cdiamm - cdiamm - diagonal format matrix-matrix multiply

cdiasm - cdiasm - diagonal format triangular solve

cdotc - cdotc - compute the dot product of two vectors conjg(x) and y.

cdotci - cdotci - Compute the complex conjugated indexed dot product.

cdotu - cdotu - compute the dot product of two vectors x and y.

cdotui - cdotci - Compute the complex conjugated indexed dot product.

cellmm - cellmm - Ellpack format matrix-matrix multiply

cellsm - cellsm - Ellpack format triangular solve

cfft2b - cfft2b - compute a periodic sequence from its Fourier coefficients. The xFFT operations are unnormalized, so a call of xFFT2F followed by a call of xFFT2B will multiply the input sequence by M*N.

cfft2f - cfft2f - compute the Fourier coefficients of a periodic sequence. The xFFT operations are unnormalized, so a call of xFFT2F followed by a call of xFFT2B will multiply the input sequence by M*N.

cfft2i - cfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

cfft3b - cfft3b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFT3F followed by a call of CFFT3B will multiply the input sequence by M*N*K.

cfft3f - cfft3f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFT3F followed by a call of CFFT3B will multiply the input sequence by M*N*K.

cfft3i - cfft3i - initialize the array WSAVE, which is used in both CFFT3F and CFFT3B.

cfftb - cfftb - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of CFFTF followed by a call of CFFTB will multiply the input sequence by N.

cfftc - cfftc - initialize the trigonometric weight and factor tables or compute the Fast Fourier transform (forward or inverse) of a complex sequence.

cfftc2 - cfftc2 - initialize the trigonometric weight and factor tables or compute the two-dimensional Fast Fourier Transform (forward or inverse) of a two-dimensional complex array.

cfftc3 - cfftc3 - initialize the trigonometric weight and factor tables or compute the three-dimensional Fast Fourier Transform (forward or inverse) of a three-dimensional complex array.

cfftcm - cfftcm - initialize the trigonometric weight and factor tables or compute the one-dimensional Fast Fourier Transform (forward or inverse) of a set of data sequences stored in a two-dimensional complex array.

cfftf - cfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of CFFTF followed by a call of CFFTB will multiply the input sequence by N.

cffti - cffti - initialize the array WSAVE, which is used in both CFFTF and CFFTB.

cfftopt - cfftopt - compute the length of the closest fast FFT

cffts - cffts - initialize the trigonometric weight and factor tables or compute the inverse Fast Fourier Transform of a complex sequence as follows.

cffts2 - cffts2 - initialize the trigonometric weight and factor tables or compute the two-dimensional inverse Fast Fourier Transform of a two-dimensional complex array.

cffts3 - cffts3 - initialize the trigonometric weight and factor tables or compute the three-dimensional inverse Fast Fourier Transform of a three-dimensional complex array.

cfftsm - cfftsm - initialize the trigonometric weight and factor tables or compute the one-dimensional inverse Fast Fourier Transform of a set of complex data sequences stored in a two-dimensional array.

cgbbrd - cgbbrd - reduce a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation

cgbcon - cgbcon - estimate the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm,

cgbequ - cgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

cgbmv - cgbmv - perform one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y

cgbrfs - cgbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

cgbsv - cgbsv - compute the solution to a complex system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

cgbsvx - cgbsvx - use the LU factorization to compute the solution to a complex system of linear equations A * X = B, A**T * X = B, or A**H * X = B,

cgbtf2 - cgbtf2 - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

cgbtrf - cgbtrf - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges cgbtrs - cgbtrs - solve a system of linear equations A * X = B, A**T * X = B, or A**H * X = B with a general band matrix A using the LU factorization computed by CGBTRF

cgebak - cgebak - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

cgebal - cgebal - balance a general complex matrix A

cgebrd - cgebrd - reduce a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation

cgecon - cgecon - estimate the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF

cgeequ - cgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

cgees - cgees - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

cgeesx - cgeesx - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

cgeev - cgeev - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

cgeevx - cgeevx - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

cgegs - cgegs - routine is deprecated and has been replaced by routine CGGES

cgegv - cgegv - routine is deprecated and has been replaced by routine CGGEV

cgehrd - cgehrd - reduce a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation

cgelqf - cgelqf - compute an LQ factorization of a complex M-by-N matrix A

cgels - cgels - solve overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A

cgelsd - cgelsd - compute the minimum-norm solution to a real linear least squares problem cgelss - cgelss - compute the minimum norm solution to a complex linear least squares problem

cgelsx - cgelsx - routine is deprecated and has been replaced by routine CGELSY

cgelsy - cgelsy - compute the minimum-norm solution to a complex linear least squares problem

cgemm - cgemm - perform one of the matrix-matrix operations C := alpha*op(A)*op(B) + beta*C

cgemv - cgemv - perform one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y

cgeqlf - cgeqlf - compute a QL factorization of a complex M-by-N matrix A

cgeqp3 - cgeqp3 - compute a QR factorization with column pivoting of a matrix A

cgeqpf - cgeqpf - routine is deprecated and has been replaced by routine CGEQP3

cgeqrf - cgeqrf - compute a QR factorization of a complex M-by-N matrix A

cgerc - cgerc - perform the rank 1 operation A := alpha*x*conjg(y') + A

cgerfs - cgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

cgerqf - cgerqf - compute an RQ factorization of a complex M-by-N matrix A

cgeru - cgeru - perform the rank 1 operation A := alpha*x*y' + A

cgesdd - cgesdd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method

cgesv - cgesv - compute the solution to a complex system of linear equations A * X = B,

cgesvd - cgesvd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors

cgesvx - cgesvx - use the LU factorization to compute the solution to a complex system of linear equations A * X = B,

cgetf2 - cgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges cgetrf - cgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

cgetri - cgetri - compute the inverse of a matrix using the LU factorization computed by CGETRF

cgetrs - cgetrs - solve a system of linear equations A * X = B, A**T * X = B, or A**H * X = B with a general N-by-N matrix A using the LU factorization computed by CGETRF

cggbak - cggbak - form the right or left eigenvectors of a complex generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL

cggbal - cggbal - balance a pair of general complex matrices (A,B)

cgges - cgges - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR)

cggesx - cggesx - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T),

cggev - cggev - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

cggevx - cggevx - compute for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

cggglm - cggglm - solve a general Gauss-Markov linear model (GLM) problem

cgghrd - cgghrd - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

cgglse - cgglse - solve the linear equality-constrained least squares (LSE) problem

cggqrf - cggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

cggrqf - cggrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

cggsvd - cggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B

cggsvp - cggsvp - compute unitary matrices U, V and Q such that N-K-L K L U'*A*Q = K (0 A12 A13) if M-K-L >= 0 cgssco - cgssco - General sparse solver condition number estimate.

cgssda - cgssda - Deallocate working storage for the general sparse solver.

cgssfa - cgssfa - General sparse solver numeric factorization.

cgssfs - cgssfs - General sparse solver one call interface.

cgssin - cgssin - Initialize the general sparse solver.

cgssor - cgssor - General sparse solver ordering and symbolic factorization.

cgssps - cgssps - Print general sparse solver statics.

cgssrp - cgssrp - Return permutation used by the general sparse solver.

cgsssl - cgsssl - Solve routine for the general sparse solver.

cgssuo - cgssuo - User supplied permutation for ordering used in the general sparse solver.

cgtcon - cgtcon - estimate the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF

cgthr - cgthr - Gathers specified elements from y into x.

cgthrz - cgthrz - Gather and zero.

cgtrfs - cgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

cgtsv - cgtsv - solve the equation A*X = B,

cgtsvx - cgtsvx - use the LU factorization to compute the solution to a complex system of linear equations A * X = B, A**T * X = B, or A**H * X = B,

cgttrf - cgttrf - compute an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges

cgttrs - cgttrs - solve one of the systems of equations A * X = B, A**T * X = B, or A**H * X = B,

chbev - chbev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A chbevd - chbevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

chbevx - chbevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

chbgst - chbgst - reduce a complex Hermitian-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y,

chbgv - chbgv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x

chbgvd - chbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x

chbgvx - chbgvx - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x

chbmv - chbmv - perform the matrix-vector operation y := alpha*A*x + beta*y

chbtrd - chbtrd - reduce a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

checon - checon - estimate the reciprocal of the condition number of a complex Hermitian matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF

cheev - cheev - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

cheevd - cheevd - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

cheevr - cheevr - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T

cheevx - cheevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

chegs2 - chegs2 - reduce a complex Hermitian-definite generalized eigenproblem to standard form

chegst - chegst - reduce a complex Hermitian-definite generalized eigenproblem to standard form

chegv - chegv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

chegvd - chegvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized

Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

chegvx - chegvx - compute selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

chemm - chemm - perform one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C

chemv - chemv - perform the matrix-vector operation y := alpha*A*x + beta*y

cher - cher - perform the hermitian rank 1 operation A := alpha*x*conjg(x') + A

cher2 - cher2 - perform the hermitian rank 2 operation A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A

cher2k - cher2k - perform one of the Hermitian rank 2k operations C := alpha*A*conjg(B') + conjg(alpha) *B*conjg(A') + beta*C or C := alpha*conjg(A')*B + conjg(alpha)*conjg(B')*A + beta*C

cherfs - cherfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution

cherk - cherk - perform one of the Hermitian rank k operations C := alpha*A*conjg(A') + beta*C or C := alpha*conjg(A')*A + beta*C

chesv - chesv - compute the solution to a complex system of linear equations A * X = B,

chesvx - chesvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B,

chetf2 - chetf2 - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

chetrd - chetrd - reduce a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

chetrf - chetrf - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

chetri - chetri - compute the inverse of a complex Hermitian indefinite matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF

chetrs - chetrs - solve a system of linear equations A*X = B with a complex Hermitian matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF chgeqz - chgeqz - implement a single-shift version of the QZ method for finding the generalized eigenvalues w(i) =ALPHA(i)/BETA(i) of the equation det(A-w(i) B) = 0 If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary tranformation (usually called Q) on the left and another (usually called Z) on the right

chpcon - chpcon - estimate the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF

chpev - chpev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage

chpevd - chpevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

chpevx - chpevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

chpgst - chpgst - reduce a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage

chpgv - chpgv - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

chpgvd - chpgvd - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

chpgvx - chpgvx - compute selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

chpmv - chpmv - perform the matrix-vector operation y := alpha*A*x + beta*y

chpr - chpr - perform the hermitian rank 1 operation A := alpha*x*conjg(x') + A

chpr2 - chpr2 - perform the Hermitian rank 2 operation A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A

chprfs - chprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution

chpsv - chpsv - compute the solution to a complex system of linear equations A * X = B,

chpsvx - chpsvx - use the diagonal pivoting factorization A = U*D*U**H or A = L*D*L**H to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices chptrd - chptrd - reduce a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation

chptrf - chptrf - compute the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method

chptri - chptri - compute the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF

chptrs - chptrs - solve a system of linear equations A*X = B with a complex Hermitian matrix A stored in packed format using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF

chsein - chsein - use inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H

chseqr - chseqr - compute the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition H = Z T Z**H, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors

cjadmm - cjadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

cjadrp - cjadrp - right permutation of a jagged diagonal matrix

cjadsm - cjadsm - Jagged-diagonal format triangular solve

clarz - clarz - applie a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right

clarzb - clarzb - applie a complex block reflector H or its transpose H**H to a complex distributed M-by-N C from the left or the right

clarzt - clarzt - form the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors

clatzm - clatzm - routine is deprecated and has been replaced by routine CUNMRZ

cosqb - cosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by 4 * N.

cosqf - cosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by 4 * N.

cosqi - cosqi - initialize the array WSAVE, which is used in both COSQF and COSQB.

cost - cost - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by 2 * (N-1).

costi - costi - initialize the array WSAVE, which is used in COST.

cpbcon - cpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPBTRF

cpbequ - cpbequ - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

cpbrfs - cpbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution

cpbstf - cpbstf - compute a split Cholesky factorization of a complex Hermitian positive definite band matrix A

cpbsv - cpbsv - compute the solution to a complex system of linear equations A * X = B,

cpbsvx - cpbsvx - use the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations A * X = B,

cpbtf2 - cpbtf2 - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

cpbtrf - cpbtrf - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

cpbtrs - cpbtrs - solve a system of linear equations A*X = B with a Hermitian positive definite band matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPBTRF

cpocon - cpocon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF

cpoequ - cpoequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

cporfs - cporfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite,

cposv - cposv - compute the solution to a complex system of linear equations A * X = B, cposvx - cposvx - use the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations A * X = B,

cpotf2 - cpotf2 - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

cpotrf - cpotrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

cpotri - cpotri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF

cpotrs - cpotrs - solve a system of linear equations A*X = B with a Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF

cppcon - cppcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF

cppequ - cppequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

cpprfs - cpprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution

cppsv - cppsv - compute the solution to a complex system of linear equations A * X = B,

cppsvx - cppsvx - use the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations A * X = B,

cpptrf - cpptrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format

cpptri - cpptri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF

cpptrs - cpptrs - solve a system of linear equations A*X = B with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF

cptcon - cptcon - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization A = L*D*L**H or A = U**H*D*U computed by CPTTRF

cpteqr - cpteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor cptrfs - cptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

cptsv - cptsv - compute the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

cptsvx - cptsvx - use the factorization A = L*D*L**H to compute the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

cpttrf - cpttrf - compute the L*D*L' factorization of a complex Hermitian positive definite tridiagonal matrix A

cpttrs - cpttrs - solve a tridiagonal system of the form A * X = B using the factorization A = U'*D*U or A = L*D*L' computed by CPTTRF

cptts2 - cptts2 - solve a tridiagonal system of the form A * X = B using the factorization A = U'*D*U or A = L*D*L' computed by CPTTRF

crot - crot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex

crotg - crotg - Construct a Given's plane rotation

cscal - cscal - Compute y := alpha * y

csctr - csctr - Scatters elements from x into y.

cskymm - cskymm - Skyline format matrix-matrix multiply

cskysm - cskysm - Skyline format triangular solve

cspcon - cspcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF

csprfs - csprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

cspsv - cspsv - compute the solution to a complex system of linear equations A * X = B,

cspsvx - cspsvx - use the diagonal pivoting factorization A = U*D*U**T or A = L*D*L**T to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

csptrf - csptrf - compute the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

csptri - csptri - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF

csptrs - csptrs - solve a system of linear equations A*X = B with a complex symmetric matrix A stored in packed format using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF

csrot - csrot - Apply a plane rotation.

csscal - csscal - Compute y := alpha * y

cstedc - cstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

cstegr - cstegr - Compute T-sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T is a relatively robust representation

cstein - cstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

csteqr - csteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

cstsv - cstsv - compute the solution to a complex system of linear equations A * X = B where A is a Hermitian tridiagonal matrix

csttrf - csttrf - compute the factorization of a complex Hermitian tridiagonal matrix A

csttrs - csttrs - computes the solution to a complex system of linear equations A * X = B

cswap - cswap - Exchange vectors x and y.

csycon - csycon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF

csymm - csymm - perform one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C

csyr2k - csyr2k - perform one of the symmetric rank 2k operations C := alpha*A*B' + alpha*B*A' + beta*C or C :

= alpha*A'*B + alpha*B'*A + beta*C

csyrfs - csyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

csyrk - csyrk - perform one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C

csysv - csysv - compute the solution to a complex system of linear equations A * X = B,

csysvx - csysvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B,

csytf2 - csytf2 - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

csytrf - csytrf - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

csytri - csytri - compute the inverse of a complex symmetric indefinite matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF

csytrs - csytrs - solve a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF

ctbcon - ctbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

ctbmv - ctbmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

ctbrfs - ctbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

ctbsv - ctbsv - solve one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b

ctbtrs - ctbtrs - solve a triangular system of the form A * X = B, A**T * X = B, or A**H * X = B,

ctgevc - ctgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B)

ctgexc - ctgexc - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation (A, B) := Q * (A, B) * Z', so that the diagonal block of (A, B) with row index IFST is moved to row ILST ctgsen - ctgsen - reorder the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence trans- formation Q' * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B)

ctgsja - ctgsja - compute the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B

ctgsna - ctgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B)

ctgsyl - ctgsyl - solve the generalized Sylvester equation

ctpcon - ctpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

ctpmv - ctpmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

ctprfs - ctprfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

ctpsv - ctpsv - solve one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b

ctptri - ctptri - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

ctptrs - ctptrs - solve a triangular system of the form A * X = B, A**T * X = B, or A**H * X = B,

ctrans - ctrans - transpose and scale source matrix

ctrcon - ctrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

ctrevc - ctrevc - compute some or all of the right and/or left eigenvectors of a complex upper triangular matrix T

ctrexc - ctrexc - reorder the Schur factorization of a complex matrix A = Q*T*Q**H, so that the diagonal element of T with row index IFST is moved to row ILST

ctrmm - ctrmm - perform one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A) where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op (A) is one of op(A) = A or op(A) = A' or op(A) = conjg(A')

ctrmv - ctrmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x ctrrfs - ctrrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

ctrsen - ctrsen - reorder the Schur factorization of a complex matrix A = Q*T*Q**H, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace

ctrsm - ctrsm - solve one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B

ctrsna - ctrsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix Q*T*Q**H with Q unitary)

ctrsv - ctrsv - solve one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b

ctrsyl - ctrsyl - solve the complex Sylvester matrix equation

ctrti2 - ctrti2 - compute the inverse of a complex upper or lower triangular matrix

ctrtri - ctrtri - compute the inverse of a complex upper or lower triangular matrix A

ctrtrs - ctrtrs - solve a triangular system of the form A * X = B, A**T * X = B, or A**H * X = B,

ctzrqf - ctzrqf - routine is deprecated and has been replaced by routine CTZRZF

ctzrzf - ctzrzf - reduce the M-by-N (M<=N) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations

cung2l - cung2l - generate an m by n complex matrix Q with orthonormal columns,

cung2r - cung2r - generate an m by n complex matrix Q with orthonormal columns,

cungbr - cungbr - generate one of the complex unitary matrices Q or P**H determined by CGEBRD when reducing a complex matrix A to bidiagonal form

cunghr - cunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

cungl2 - cungl2 - generate an m-by-n complex matrix Q with orthonormal rows,

cunglq - cunglq - generate an M-by-N complex matrix Q with orthonormal rows,

cungql - cungql - generate an M-by-N complex matrix Q with orthonormal columns, cungqr - cungqr - generate an M-by-N complex matrix Q with orthonormal columns,

cungr2 - cungr2 - generate an m by n complex matrix Q with orthonormal rows,

cungrq - cungrq - generate an M-by-N complex matrix Q with orthonormal rows,

cungtr - cungtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

cunmbr - cunmbr - VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cunmhr - cunmhr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cunml2 - cunml2 - overwrite the general complex m-by-n matrix C with Q * C if SIDE = 'L' and TRANS = 'N', or Q'* C if SIDE = 'L' and TRANS = 'C', or C * Q if SIDE = 'R' and TRANS = 'N', or C * Q' if SIDE = 'R' and TRANS = 'C',

cunmlq - cunmlq - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cunmql - cunmql - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cunmqr - cunmqr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cunmr2 - cunmr2 - overwrite the general complex m-by-n matrix C with Q * C if SIDE = 'L' and TRANS = 'N', or Q'* C if SIDE = 'L' and TRANS = 'C', or C * Q if SIDE = 'R' and TRANS = 'N', or C * Q' if SIDE = 'R' and TRANS = 'C',

cunmrq - cunmrq - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cunmrz - cunmrz - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cunmtr - cunmtr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cupgtr - cupgtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

cupmtr - cupmtr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

cvbrmm - cvbrmm - variable block sparse row format matrix-matrix multiply

cvbrsm - cvbrsm - variable block sparse row format triangular solve cvmul - cvmul - compute the scaled product of complex vectors

dasum - dasum - Return the sum of the absolute values of a vector x.

daxpy - daxpy - compute y := alpha * x + y

daxpyi - daxpyi - Compute y := alpha * x + y

dbcomm - dbcomm - block coordinate matrix-matrix multiply

dbdimm - dbdimm - block diagonal format matrix-matrix multiply

dbdism - dbdism - block diagonal format triangular solve

dbdsdc - dbdsdc - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B

dbdsqr - dbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

dbelmm - dbelmm - block Ellpack format matrix-matrix multiply

dbelsm - dbelsm - block Ellpack format triangular solve

dbscmm - dbscmm - block sparse column matrix-matrix multiply

dbscsm - dbscsm - block sparse column format triangular solve

dbsrmm - dbsrmm - block sparse row format matrix-matrix multiply

dbsrsm - dbsrsm - block sparse row format triangular solve

dcnvcor - dcnvcor - compute the convolution or correlation of real vectors

dcnvcor2 - dcnvcor2 - compute the convolution or correlation of real matrices

dcoomm - dcoomm - coordinate matrix-matrix multiply

dcopy - dcopy - Copy x to y

dcosqb - dcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by 4 * N.

dcosqf - dcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by 4 * N.

dcosqi - dcosqi - initialize the array WSAVE, which is used in both COSQF and COSQB.

dcost - dcost - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by 2 * (N-1).

dcosti - dcosti - initialize the array WSAVE, which is used in COST.

dcscmm - dcscmm - compressed sparse column format matrix-matrix multiply

dcscsm - dcscsm - compressed sparse column format triangular solve

dcsrmm - dcsrmm - compressed sparse row format matrix-matrix multiply

dcsrsm - dcsrsm - compressed sparse row format triangular solve

ddiamm - ddiamm - diagonal format matrix-matrix multiply

ddiasm - ddiasm - diagonal format triangular solve

ddisna - ddisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

ddot - ddot - compute the dot product of two vectors x and y.

ddoti - ddoti - Compute the indexed dot product.

dellmm - dellmm - Ellpack format matrix-matrix multiply

dellsm - dellsm - Ellpack format triangular solve

dezftb - dezftb - computes a periodic sequence from its Fourier coefficients. DEZFTB is a simplified but slower version of DFFTB.

dezftf - dezftf - computes the Fourier coefficients of a periodic sequence. DEZFTF is a simplified but slower version of DFFTF.

dezfti - dezfti - initializes the array WSAVE, which is used in both DEZFTF and DEZFTB.

dfft2b - dfft2b - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFT2F followed by a call of DFFT2B will multiply the input sequence by M*N.

dfft2f - dfft2f - compute the Fourier coefficients of a periodic sequence. The DFFT operations are unnormalized, so a call of DFFT2F followed by a call of DFFT2B will multiply the input sequence by M*N.

dfft2i - dfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

dfft3b - dfft3b - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFT3F followed by a call of DFFT3B will multiply the input sequence by M*N*K.

dfft3f - dfft3f - compute the Fourier coefficients of a real periodic sequence. The DFFT operations are unnormalized, so a call of DFFT3F followed by a call of DFFT3B will multiply the input sequence by M*N*K.

dfft3i - dfft3i - initialize the array WSAVE, which is used in both DFFT3F and DFFT3B.

dfftb - dfftb - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFTF followed by a call of DFFTB will multiply the input sequence by N.

dfftf - dfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of DFFTF followed by a call of DFFTB will multiply the input sequence by N.

dffti - dffti - initialize the array WSAVE, which is used in both DFFTF and DFFTB.

dfftopt - dfftopt - compute the length of the closest fast FFT

dfftz - dfftz - initialize the trigonometric weight and factor tables or compute the forward Fast Fourier Transform of a double precision sequence.

dfftz2 - dfftz2 - initialize the trigonometric weight and factor tables or compute the two-dimensional forward Fast Fourier Transform of a two-dimensional double precision array.

dfftz3 - dfftz3 - initialize the trigonometric weight and factor tables or compute the three-dimensional forward Fast Fourier Transform of a three-dimensional double complex array.

dfftzm - dfftzm - initialize the trigonometric weight and factor tables or compute the one-dimensional forward Fast Fourier Transform of a set of double precision data sequences stored in a two-dimensional array.

dgbbrd - dgbbrd - reduce a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation

dgbcon - dgbcon - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

dgbequ - dgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

dgbmv - dgbmv - perform one of the matrix-vector operations y := alpha*A*x + beta*y or y := alpha*A'*x + beta*y

dgbrfs - dgbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

dgbsv - dgbsv - compute the solution to a real system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

dgbsvx - dgbsvx - use the LU factorization to compute the solution to a real system of linear equations A * X = B, A**T * X = B, or A**H * X = B,

dgbtf2 - dgbtf2 - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

dgbtrf - dgbtrf - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

dgbtrs - dgbtrs - solve a system of linear equations A * X = B or A' * X = B with a general band matrix A using the LU factorization computed by SGBTRF

dgebak - dgebak - form the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL

dgebal - dgebal - balance a general real matrix A

dgebrd - dgebrd - reduce a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation

dgecon - dgecon - estimate the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF

dgeequ - dgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number dgees - dgees - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

dgeesx - dgeesx - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

dgeev - dgeev - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

dgeevx - dgeevx - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

dgegs - dgegs - routine is deprecated and has been replaced by routine SGGES

dgegv - dgegv - routine is deprecated and has been replaced by routine SGGEV

dgehrd - dgehrd - reduce a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation

dgelqf - dgelqf - compute an LQ factorization of a real M-by-N matrix A

dgels - dgels - solve overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A

dgelsd - dgelsd - compute the minimum-norm solution to a real linear least squares problem

dgelss - dgelss - compute the minimum norm solution to a real linear least squares problem

dgelsx - dgelsx - routine is deprecated and has been replaced by routine SGELSY

dgelsy - dgelsy - compute the minimum-norm solution to a real linear least squares problem

dgemm - dgemm - perform one of the matrix-matrix operations C := alpha*op(A)*op(B) + beta*C

dgemv - dgemv - perform one of the matrix-vector operations y := alpha*A*x + beta*y or y := alpha*A'*x + beta*y

dgeqlf - dgeqlf - compute a QL factorization of a real M-by-N matrix A

dgeqp3 - dgeqp3 - compute a QR factorization with column pivoting of a matrix A

dgeqpf - dgeqpf - routine is deprecated and has been replaced by routine SGEQP3 dgeqrf - dgeqrf - compute a QR factorization of a real M-by-N matrix A

dger - dger - perform the rank 1 operation A := alpha*x*y' + A

dgerfs - dgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

dgerqf - dgerqf - compute an RQ factorization of a real M-by-N matrix A

dgesdd - dgesdd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors

dgesv - dgesv - compute the solution to a real system of linear equations A * X = B,

dgesvd - dgesvd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors

dgesvx - dgesvx - use the LU factorization to compute the solution to a real system of linear equations A * X = B,

dgetf2 - dgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

dgetrf - dgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

dgetri - dgetri - compute the inverse of a matrix using the LU factorization computed by SGETRF

dgetrs - dgetrs - solve a system of linear equations A * X = B or A' * X = B with a general N-by-N matrix A using the LU factorization computed by SGETRF

dggbak - dggbak - form the right or left eigenvectors of a real generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL

dggbal - dggbal - balance a pair of general real matrices (A,B)

dgges - dgges - compute for a pair of N-by-N real nonsymmetric matrices (A,B),

dggesx - dggesx - compute for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and,

dggev - dggev - compute for a pair of N-by-N real nonsymmetric matrices (A,B) dggevx - dggevx - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

dggglm - dggglm - solve a general Gauss-Markov linear model (GLM) problem

dgghrd - dgghrd - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

dgglse - dgglse - solve the linear equality-constrained least squares (LSE) problem

dggqrf - dggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

dggrqf - dggrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

dggsvd - dggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B

dggsvp - dggsvp - compute orthogonal matrices U, V and Q such that N-K-L K L U'*A*Q = K (0 A12 A13) if M-K-L >= 0

dgssco - dgssco - General sparse solver condition number estimate.

dgssda - dgssda - Deallocate working storage for the general sparse solver.

dgssfa - dgssfa - General sparse solver numeric factorization.

dgssfs - dgssfs - General sparse solver one call interface.

dgssin - dgssin - Initialize the general sparse solver.

dgssor - dgssor - General sparse solver ordering and symbolic factorization.

dgssps - dgssps - Print general sparse solver statics.

dgssrp - dgssrp - Return permutation used by the general sparse solver.

dgsssl - dgsssl - Solve routine for the general sparse solver.

dgssuo - dgssuo - User supplied permutation for ordering used in the general sparse solver.

dgtcon - dgtcon - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF dgthr - dgthr - Gathers specified elements from y into x.

dgthrz - dgthrz - Gather and zero.

dgtrfs - dgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

dgtsv - dgtsv - solve the equation A*X = B,

dgtsvx - dgtsvx - use the LU factorization to compute the solution to a real system of linear equations A * X = B or A**T * X = B,

dgttrf - dgttrf - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

dgttrs - dgttrs - solve one of the systems of equations A*X = B or A'*X = B,

dhgeqz - dhgeqz - implement a single-/double-shift version of the QZ method for finding the generalized eigenvalues w(j)=(ALPHAR(j) + i*ALPHAI(j))/BETAR(j) of the equation det(A-w(i) B) = 0 In addition, the pair A,B may be reduced to generalized Schur form

dhsein - dhsein - use inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H

dhseqr - dhseqr - compute the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition H = Z T Z**T, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors

djadmm - djadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

djadrp - djadrp - right permutation of a jagged diagonal matrix

djadsm - djadsm - Jagged-diagonal format triangular solve

dlagtf - dlagtf - factorize the matrix (T-lambda*I), where T is an n by n tridiagonal matrix and lambda is a scalar, as T-lambda*I = PLU

dlamrg - dlamrg - will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order

dlarz - dlarz - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right dlarzb - dlarzb - applies a real block reflector H or its transpose H**T to a real distributed M-by-N C from the left or the right

dlarzt - dlarzt - form the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors

dlasrt - dlasrt - the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D')

dlatzm - dlatzm - routine is deprecated and has been replaced by routine SORMRZ

dnrm2 - dnrm2 - Return the Euclidian norm of a vector.

dopgtr - dopgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by SSPTRD using packed storage

dopmtr - dopmtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dorg2l - dorg2l - generate an m by n real matrix Q with orthonormal columns,

dorg2r - dorg2r - generate an m by n real matrix Q with orthonormal columns,

dorgbr - dorgbr - generate one of the real orthogonal matrices Q or P**T determined by SGEBRD when reducing a real matrix A to bidiagonal form

dorghr - dorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD

dorgl2 - dorgl2 - generate an m by n real matrix Q with orthonormal rows,

dorglq - dorglq - generate an M-by-N real matrix Q with orthonormal rows,

dorgql - dorgql - generate an M-by-N real matrix Q with orthonormal columns,

dorgqr - dorgqr - generate an M-by-N real matrix Q with orthonormal columns,

dorgr2 - dorgr2 - generate an m by n real matrix Q with orthonormal rows,

dorgrq - dorgrq - generate an M-by-N real matrix Q with orthonormal rows,

dorgtr - dorgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD dormbr - dormbr - VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dormhr - dormhr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dormlq - dormlq - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dormql - dormql - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dormqr - dormqr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dormrq - dormrq - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dormrz - dormrz - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dormtr - dormtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

dpbcon - dpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPBTRF

dpbequ - dpbequ - compute row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm)

dpbrfs - dpbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution

dpbstf - dpbstf - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

dpbsv - dpbsv - compute the solution to a real system of linear equations A * X = B,

dpbsvx - dpbsvx - use the Cholesky factorization A = U**T*U or A = L*L**T to compute the solution to a real system of linear equations A * X = B,

dpbtf2 - dpbtf2 - compute the Cholesky factorization of a real symmetric positive definite band matrix A

dpbtrf - dpbtrf - compute the Cholesky factorization of a real symmetric positive definite band matrix A

dpbtrs - dpbtrs - solve a system of linear equations A*X = B with a symmetric positive definite band matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPBTRF

dpocon - dpocon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF dpoequ - dpoequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

dporfs - dporfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite,

dposv - dposv - compute the solution to a real system of linear equations A * X = B,

dposvx - dposvx - use the Cholesky factorization A = U**T*U or A = L*L**T to compute the solution to a real system of linear equations A * X = B,

dpotf2 - dpotf2 - compute the Cholesky factorization of a real symmetric positive definite matrix A

dpotrf - dpotrf - compute the Cholesky factorization of a real symmetric positive definite matrix A

dpotri - dpotri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF

dpotrs - dpotrs - solve a system of linear equations A*X = B with a symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF

dppcon - dppcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF

dppequ - dppequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

dpprfs - dpprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution

dppsv - dppsv - compute the solution to a real system of linear equations A * X = B,

dppsvx - dppsvx - use the Cholesky factorization A = U**T*U or A = L*L**T to compute the solution to a real system of linear equations A * X = B,

dpptrf - dpptrf - compute the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format

dpptri - dpptri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF

dpptrs - dpptrs - solve a system of linear equations A*X = B with a symmetric positive definite matrix A in packed storage using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF dptcon - dptcon - compute the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization A = L*D*L**T or A = U**T*D*U computed by SPTTRF

dpteqr - dpteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor

dptrfs - dptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

dptsv - dptsv - compute the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

dptsvx - dptsvx - use the factorization A = L*D*L**T to compute the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

dpttrf - dpttrf - compute the L*D*L' factorization of a real symmetric positive definite tridiagonal matrix A

dpttrs - dpttrs - solve a tridiagonal system of the form A * X = B using the L*D*L' factorization of A computed by SPTTRF

dptts2 - dptts2 - solve a tridiagonal system of the form A * X = B using the L*D*L' factorization of A computed by SPTTRF

dqdota - dqdota - compute a double precision constant plus an extended precision constant plus the extended precision dot product of two double precision vectors x and y.

dqdoti - dqdoti - compute a constant plus the extended precision dot product of two double precision vectors x and y.

drot - drot - Apply a Given's rotation constructed by SROTG.

drotg - drotg - Construct a Given's plane rotation

droti - droti - Apply an indexed Givens rotation.

drotm - drotm - Apply a Gentleman's modified Given's rotation constructed by SROTMG.

drotmg - drotmg - Construct a Gentleman's modified Given's plane rotation dsbev - dsbev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

dsbevd - dsbevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

dsbevx - dsbevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

dsbgst - dsbgst - reduce a real symmetric-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y,

dsbgv - dsbgv - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x

dsbgvd - dsbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x

dsbgvx - dsbgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x

dsbmv - dsbmv - perform the matrix-vector operation y := alpha*A*x + beta*y

dsbtrd - dsbtrd - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

dscal - dscal - Compute y := alpha * y

dsctr - dsctr - Scatters elements from x into y.

dsdot - dsdot - compute the double precision dot product of two single precision vectors x and y.

dsecnd - dsecnd - return the user time for a process in seconds

dsinqb - dsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by 4 * N.

dsinqf - dsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by 4 * N.

dsinqi - dsinqi - initialize the array xWSAVE, which is used in both SINQF and SINQB.

dsint - dsint - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by 2 * (N+1).

dsinti - dsinti - initialize the array WSAVE, which is used in subroutine SINT.

dskymm - dskymm - Skyline format matrix-matrix multiply

dskysm - dskysm - Skyline format triangular solve

dspcon - dspcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF

dspev - dspev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

dspevd - dspevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

dspevx - dspevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

dspgst - dspgst - reduce a real symmetric-definite generalized eigenproblem to standard form, using packed storage

dspgv - dspgv - compute all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

dspgvd - dspgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

dspgvx - dspgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

dspmv - dspmv - perform the matrix-vector operation y := alpha*A*x + beta*y

dspr - dspr - perform the symmetric rank 1 operation A := alpha*x*x' + A

dspr2 - dspr2 - perform the symmetric rank 2 operation A := alpha*x*y' + alpha*y*x' + A

dsprfs - dsprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

dspsv - dspsv - compute the solution to a real system of linear equations A * X = B, dspsvx - dspsvx - use the diagonal pivoting factorization A = U*D*U**T or A = L*D*L**T to compute the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

dsptrd - dsptrd - reduce a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation

dsptrf - dsptrf - compute the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

dsptri - dsptri - compute the inverse of a real symmetric indefinite matrix A in packed storage using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF

dsptrs - dsptrs - solve a system of linear equations A*X = B with a real symmetric matrix A stored in packed format using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF

dstebz - dstebz - compute the eigenvalues of a symmetric tridiagonal matrix T

dstedc - dstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

dstegr - dstegr - (a) Compute T-sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T is a relatively robust representation

dstein - dstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

dsteqr - dsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

dsterf - dsterf - compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm

dstev - dstev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

dstevd - dstevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix

dstevr - dstevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

dstevx - dstevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A dstsv - dstsv - compute the solution to a system of linear equations A * X = B where A is a symmetric tridiagonal matrix

dsttrf - dsttrf - compute the factorization of a symmetric tridiagonal matrix A

dsttrs - dsttrs - computes the solution to a real system of linear equations A * X = B

dswap - dswap - Exchange vectors x and y.

dsycon - dsycon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF

dsyev - dsyev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

dsyevd - dsyevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

dsyevr - dsyevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

dsyevx - dsyevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

dsygs2 - dsygs2 - reduce a real symmetric-definite generalized eigenproblem to standard form

dsygst - dsygst - reduce a real symmetric-definite generalized eigenproblem to standard form

dsygv - dsygv - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

dsygvd - dsygvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

dsygvx - dsygvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

dsymm - dsymm - perform one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C

dsymv - dsymv - perform the matrix-vector operation y := alpha*A*x + beta*y

dsyr - dsyr - perform the symmetric rank 1 operation A := alpha*x*x' + A

dsyr2 - dsyr2 - perform the symmetric rank 2 operation A := alpha*x*y' + alpha*y*x' + A dsyr2k - dsyr2k - perform one of the symmetric rank 2k operations C := alpha*A*B' + alpha*B*A' + beta*C or C := alpha*A'*B + alpha*B'*A + beta*C

dsyrfs - dsyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution

dsyrk - dsyrk - perform one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C

dsysv - dsysv - compute the solution to a real system of linear equations A * X = B,

dsysvx - dsysvx - use the diagonal pivoting factorization to compute the solution to a real system of linear equations A * X = B,

dsytd2 - dsytd2 - reduce a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

dsytf2 - dsytf2 - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

dsytrd - dsytrd - reduce a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation

dsytrf - dsytrf - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

dsytri - dsytri - compute the inverse of a real symmetric indefinite matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF

dsytrs - dsytrs - solve a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF

dtbcon - dtbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

dtbmv - dtbmv - perform one of the matrix-vector operations x := A*x, or x := A'*x

dtbrfs - dtbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

dtbsv - dtbsv - solve one of the systems of equations A*x = b, or A'*x = b

dtbtrs - dtbtrs - solve a triangular system of the form A * X = B or A**T * X = B, dtgevc - dtgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B)

dtgexc - dtgexc - reorder the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation (A, B) = Q * (A, B) * Z',

dtgsen - dtgsen - reorder the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence trans- formation Q' * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B

dtgsja - dtgsja - compute the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B

dtgsna - dtgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q*A*Z', Q*B*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z

dtgsyl - dtgsyl - solve the generalized Sylvester equation

dtpcon - dtpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

dtpmv - dtpmv - perform one of the matrix-vector operations x := A*x, or x := A'*x

dtprfs - dtprfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

dtpsv - dtpsv - solve one of the systems of equations A*x = b, or A'*x = b

dtptri - dtptri - compute the inverse of a real upper or lower triangular matrix A stored in packed format

dtptrs - dtptrs - solve a triangular system of the form A * X = B or A**T * X = B,

dtrans - dtrans - transpose and scale source matrix

dtrcon - dtrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

dtrevc - dtrevc - compute some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T

dtrexc - dtrexc - reorder the real Schur factorization of a real matrix A = Q*T*Q**T, so that the diagonal block of T with row index IFST is moved to row ILST dtrmm - dtrmm - perform one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A)

dtrmv - dtrmv - perform one of the matrix-vector operations x := A*x, or x := A'*x

dtrrfs - dtrrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

dtrsen - dtrsen - reorder the real Schur factorization of a real matrix A = Q*T*Q**T, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T,

dtrsm - dtrsm - solve one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B

dtrsna - dtrsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix Q*T*Q**T with Q orthogonal)

dtrsv - dtrsv - solve one of the systems of equations A*x = b, or A'*x = b

dtrsyl - dtrsyl - solve the real Sylvester matrix equation

dtrti2 - dtrti2 - compute the inverse of a real upper or lower triangular matrix

dtrtri - dtrtri - compute the inverse of a real upper or lower triangular matrix A

dtrtrs - dtrtrs - solve a triangular system of the form A * X = B or A**T * X = B,

dtzrqf - dtzrqf - routine is deprecated and has been replaced by routine STZRZF

dtzrzf - dtzrzf - reduce the M-by-N (M<=N) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations

dvbrmm - dvbrmm - variable block sparse row format matrix-matrix multiply

dvbrsm - dvbrsm - variable block sparse row format triangular solve

dwiener - dwiener - perform Wiener deconvolution of two signals

dzasum - dzasum - Return the sum of the absolute values of a vector x.

dznrm2 - dznrm2 - Return the Euclidian norm of a vector.

ezfftb - ezfftb - computes a periodic sequence from its Fourier coefficients. EZFFTB is a simplified but slower version of RFFTB.

ezfftf - ezfftf - computes the Fourier coefficients of a periodic sequence. EZFFTF is a simplified but slower version of RFFTF.

ezffti - ezffti - initializes the array WSAVE, which is used in both EZFFTF and EZFFTB.

fft - Overview of Fast Fourier Transform subroutines

icamax - icamax - return the index of the element with largest absolute value.

idamax - idamax - return the index of the element with largest absolute value.

ilaenv - The name of the calling subroutine, in either upper case or lower case.

isamax - isamax - return the index of the element with largest absolute value.

izamax - izamax - return the index of the element with largest absolute value.

lsame - lsame - returns .TRUE. if CA is the same letter as CB regardless of case

rfft2b - rfft2b - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by M*N.

rfft2f - rfft2f - compute the Fourier coefficients of a periodic sequence. The RFFT operations are unnormalized, so a call of RFFT2F followed by a call of RFFT2B will multiply the input sequence by M*N.

rfft2i - rfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

rfft3b - rfft3b - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by M*N*K.

rfft3f - rfft3f - compute the Fourier coefficients of a real periodic sequence. The RFFT operations are unnormalized, so a call of RFFT3F followed by a call of RFFT3B will multiply the input sequence by M*N*K.

rfft3i - rfft3i - initialize the array WSAVE, which is used in both RFFT3F and RFFT3B.

rfftb - rfftb - compute a periodic sequence from its Fourier coefficients. The RFFT operations are unnormalized, so a call of RFFTF followed by a call of RFFTB will multiply the input sequence by N.

rfftf - rfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of RFFTF followed by a call of RFFTB will multiply the input sequence by N.

rffti - rffti - initialize the array WSAVE, which is used in both RFFTF and RFFTB.

rfftopt - rfftopt - compute the length of the closest fast FFT

sasum - sasum - Return the sum of the absolute values of a vector x.

saxpy - saxpy - compute y := alpha * x + y

saxpyi - saxpyi - Compute y := alpha * x + y

sbcomm - sbcomm - block coordinate matrix-matrix multiply

sbdimm - sbdimm - block diagonal format matrix-matrix multiply

sbdism - sbdism - block diagonal format triangular solve

sbdsdc - sbdsdc - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B

sbdsqr - sbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

sbelmm - sbelmm - block Ellpack format matrix-matrix multiply

sbelsm - sbelsm - block Ellpack format triangular solve

sbscmm - sbscmm - block sparse column matrix-matrix multiply

sbscsm - sbscsm - block sparse column format triangular solve

sbsrmm - sbsrmm - block sparse row format matrix-matrix multiply

sbsrsm - sbsrsm - block sparse row format triangular solve

scasum - scasum - Return the sum of the absolute values of a vector x.

scnrm2 - scnrm2 - Return the Euclidian norm of a vector.

scnvcor - scnvcor - compute the convolution or correlation of real vectors

scnvcor2 - scnvcor2 - compute the convolution or correlation of real matrices scoomm - scoomm - coordinate matrix-matrix multiply

scopy - scopy - Copy x to y

scscmm - scscmm - compressed sparse column format matrix-matrix multiply

scscsm - scscsm - compressed sparse column format triangular solve

scsrmm - scsrmm - compressed sparse row format matrix-matrix multiply

scsrsm - scsrsm - compressed sparse row format triangular solve

sdiamm - sdiamm - diagonal format matrix-matrix multiply

sdiasm - sdiasm - diagonal format triangular solve

sdisna - sdisna - compute the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix

sdot - sdot - compute the dot product of two vectors x and y.

sdoti - sdoti - Compute the indexed dot product.

sdsdot - sdsdot - compute a constant plus the double precision dot product of two single precision vectors x and y

second - second - return the user time for a process in seconds

sellmm - sellmm - Ellpack format matrix-matrix multiply

sellsm - sellsm - Ellpack format triangular solve

sfftc - sfftc - initialize the trigonometric weight and factor tables or compute the forward Fast Fourier Transform of a real sequence.

sfftc2 - sfftc2 - initialize the trigonometric weight and factor tables or compute the two-dimensional forward Fast Fourier Transform of a two-dimensional real array.

sfftc3 - sfftc3 - initialize the trigonometric weight and factor tables or compute the three-dimensional forward Fast Fourier Transform of a three-dimensional complex array.

sfftcm - sfftcm - initialize the trigonometric weight and factor tables or compute the one-dimensional forward

Fast Fourier Transform of a set of real data sequences stored in a two-dimensional array.

sgbbrd - sgbbrd - reduce a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation

sgbcon - sgbcon - estimate the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm,

sgbequ - sgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

sgbmv - sgbmv - perform one of the matrix-vector operations y := alpha*A*x + beta*y or y := alpha*A'*x + beta*y

sgbrfs - sgbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

sgbsv - sgbsv - compute the solution to a real system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

sgbsvx - sgbsvx - use the LU factorization to compute the solution to a real system of linear equations A * X = B, A**T * X = B, or A**H * X = B,

sgbtf2 - sgbtf2 - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

sgbtrf - sgbtrf - compute an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges

sgbtrs - sgbtrs - solve a system of linear equations A * X = B or A' * X = B with a general band matrix A using the LU factorization computed by SGBTRF

sgebak - sgebak - form the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL

sgebal - sgebal - balance a general real matrix A

sgebrd - sgebrd - reduce a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation

sgecon - sgecon - estimate the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF sgeequ - sgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

sgees - sgees - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

sgeesx - sgeesx - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z

sgeev - sgeev - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

sgeevx - sgeevx - compute for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

sgegs - sgegs - routine is deprecated and has been replaced by routine SGGES

sgegv - sgegv - routine is deprecated and has been replaced by routine SGGEV

sgehrd - sgehrd - reduce a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation

sgelqf - sgelqf - compute an LQ factorization of a real M-by-N matrix A

sgels - sgels - solve overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A

sgelsd - sgelsd - compute the minimum-norm solution to a real linear least squares problem

sgelss - sgelss - compute the minimum norm solution to a real linear least squares problem

sgelsx - sgelsx - routine is deprecated and has been replaced by routine SGELSY

sgelsy - sgelsy - compute the minimum-norm solution to a real linear least squares problem

sgemm - sgemm - perform one of the matrix-matrix operations C := alpha*op(A)*op(B) + beta*C

sgemv - sgemv - perform one of the matrix-vector operations y := alpha*A*x + beta*y or y := alpha*A'*x + beta*y

sgeqlf - sgeqlf - compute a QL factorization of a real M-by-N matrix A sgeqp3 - sgeqp3 - compute a QR factorization with column pivoting of a matrix A

sgeqpf - sgeqpf - routine is deprecated and has been replaced by routine SGEQP3

sgeqrf - sgeqrf - compute a QR factorization of a real M-by-N matrix A

sger - sger - perform the rank 1 operation A := alpha*x*y' + A

sgerfs - sgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

sgerqf - sgerqf - compute an RQ factorization of a real M-by-N matrix A

sgesdd - sgesdd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors

sgesv - sgesv - compute the solution to a real system of linear equations A * X = B,

sgesvd - sgesvd - compute the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors

sgesvx - sgesvx - use the LU factorization to compute the solution to a real system of linear equations A * X = B,

sgetf2 - sgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

sgetrf - sgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

sgetri - sgetri - compute the inverse of a matrix using the LU factorization computed by SGETRF

sgetrs - sgetrs - solve a system of linear equations A * X = B or A' * X = B with a general N-by-N matrix A using the LU factorization computed by SGETRF

sggbak - sggbak - form the right or left eigenvectors of a real generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL

sggbal - sggbal - balance a pair of general real matrices (A,B)

sgges - sgges - compute for a pair of N-by-N real nonsymmetric matrices (A,B), sggesx - sggesx - compute for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and,

sggev - sggev - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

sggevx - sggevx - compute for a pair of N-by-N real nonsymmetric matrices (A,B)

sggglm - sggglm - solve a general Gauss-Markov linear model (GLM) problem

sgghrd - sgghrd - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

sgglse - sgglse - solve the linear equality-constrained least squares (LSE) problem

sggqrf - sggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

sggrqf - sggrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

sggsvd - sggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N real matrix A and P-by-N real matrix B

sggsvp - sggsvp - compute orthogonal matrices U, V and Q such that N-K-L K L U'*A*Q = K (0 A12 A13) if M-K-L >= 0

sgssco - sgssco - General sparse solver condition number estimate.

sgssda - sgssda - Deallocate working storage for the general sparse solver.

sgssfa - sgssfa - General sparse solver numeric factorization.

sgssfs - sgssfs - General sparse solver one call interface.

sgssin - sgssin - Initialize the general sparse solver.

sgssor - sgssor - General sparse solver ordering and symbolic factorization.

sgssps - sgssps - Print general sparse solver statics.

sgssrp - sgssrp - Return permutation used by the general sparse solver.

sgsssl - sgsssl - Solve routine for the general sparse solver.

sgssuo - sgssuo - User supplied permutation for ordering used in the general sparse solver.

sgtcon - sgtcon - estimate the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF

sgthr - sgthr - Gathers specified elements from y into x.

sgthrz - sgthrz - Gather and zero.

sgtrfs - sgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

sgtsv - sgtsv - solve the equation A*X = B,

sgtsvx - sgtsvx - use the LU factorization to compute the solution to a real system of linear equations A * X = B or A**T * X = B,

sgttrf - sgttrf - compute an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges

sgttrs - sgttrs - solve one of the systems of equations A*X = B or A'*X = B,

shgeqz - shgeqz - implement a single-/double-shift version of the QZ method for finding the generalized eigenvalues w(j)=(ALPHAR(j) + i*ALPHAI(j))/BETAR(j) of the equation det(A-w(i) B) = 0 In addition, the pair A,B may be reduced to generalized Schur form

shsein - shsein - use inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H

shseqr - shseqr - compute the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition H = Z T Z**T, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors

sinqb - sinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by 4 * N.

sinqf - sinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The SINQ operations are unnormalized inverses of themselves, so a call to SINQF followed by a call to SINQB will multiply the input sequence by 4 * N.

sinqi - sinqi - initialize the array xWSAVE, which is used in both SINQF and SINQB.

sint - sint - compute the discrete Fourier sine transform of an odd sequence. The SINT transforms are unnormalized inverses of themselves, so a call of SINT followed by another call of SINT will multiply the input sequence by 2 * (N+1).

sinti - sinti - initialize the array WSAVE, which is used in subroutine SINT.

sjadmm - sjadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

sjadrp - sjadrp - right permutation of a jagged diagonal matrix

sjadsm - sjadsm - Jagged-diagonal format triangular solve

slagtf - slagtf - factorize the matrix (T-lambda*I), where T is an n by n tridiagonal matrix and lambda is a scalar, as T-lambda*I = PLU

slamrg - slamrg - will create a permutation list which will merge the elements of A (which is composed of two independently sorted sets) into a single set which is sorted in ascending order

slarz - slarz - applies a real elementary reflector H to a real M-by-N matrix C, from either the left or the right

slarzb - slarzb - applies a real block reflector H or its transpose H**T to a real distributed M-by-N C from the left or the right

slarzt - slarzt - form the triangular factor T of a real block reflector H of order > n, which is defined as a product of k elementary reflectors

slasrt - slasrt - the numbers in D in increasing order (if ID = 'I') or in decreasing order (if ID = 'D')

slatzm - slatzm - routine is deprecated and has been replaced by routine SORMRZ

snrm2 - snrm2 - Return the Euclidian norm of a vector.

sopgtr - sopgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors H (i) of order n, as returned by SSPTRD using packed storage

sopmtr - sopmtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

sorg2l - sorg2l - generate an m by n real matrix Q with orthonormal columns,

sorg2r - sorg2r - generate an m by n real matrix Q with orthonormal columns,

sorgbr - sorgbr - generate one of the real orthogonal matrices Q or P**T determined by SGEBRD when reducing a real matrix A to bidiagonal form

sorghr - sorghr - generate a real orthogonal matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by SGEHRD

sorgl2 - sorgl2 - generate an m by n real matrix Q with orthonormal rows,

sorglq - sorglq - generate an M-by-N real matrix Q with orthonormal rows,

sorgql - sorgql - generate an M-by-N real matrix Q with orthonormal columns,

sorgqr - sorgqr - generate an M-by-N real matrix Q with orthonormal columns,

sorgr2 - sorgr2 - generate an m by n real matrix Q with orthonormal rows,

sorgrq - sorgrq - generate an M-by-N real matrix Q with orthonormal rows,

sorgtr - sorgtr - generate a real orthogonal matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by SSYTRD

sormbr - sormbr - VECT = 'Q', SORMBR overwrites the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

sormhr - sormhr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

sormlq - sormlq - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

sormql - sormql - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

sormqr - sormqr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

sormrq - sormrq - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

sormrz - sormrz - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

sormtr - sormtr - overwrite the general real M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

spbcon - spbcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite band matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPBTRF

spbequ - spbequ - compute row and column scalings intended to equilibrate a symmetric positive definite band matrix A and reduce its condition number (with respect to the two-norm) spbrfs - spbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and banded, and provides error bounds and backward error estimates for the solution

spbstf - spbstf - compute a split Cholesky factorization of a real symmetric positive definite band matrix A

spbsv - spbsv - compute the solution to a real system of linear equations A * X = B,

spbsvx - spbsvx - use the Cholesky factorization A = U**T*U or A = L*L**T to compute the solution to a real system of linear equations A * X = B,

spbtf2 - spbtf2 - compute the Cholesky factorization of a real symmetric positive definite band matrix A

spbtrf - spbtrf - compute the Cholesky factorization of a real symmetric positive definite band matrix A

spbtrs - spbtrs - solve a system of linear equations A*X = B with a symmetric positive definite band matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPBTRF

spocon - spocon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF

spoequ - spoequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A and reduce its condition number (with respect to the two-norm)

sporfs - sporfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite,

sposv - sposv - compute the solution to a real system of linear equations A * X = B,

sposvx - sposvx - use the Cholesky factorization A = U**T*U or A = L*L**T to compute the solution to a real system of linear equations A * X = B,

spotf2 - spotf2 - compute the Cholesky factorization of a real symmetric positive definite matrix A

spotrf - spotrf - compute the Cholesky factorization of a real symmetric positive definite matrix A

spotri - spotri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF

spotrs - spotrs - solve a system of linear equations A*X = B with a symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPOTRF

sppcon - sppcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite packed matrix using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF

sppequ - sppequ - compute row and column scalings intended to equilibrate a symmetric positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

spprfs - spprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and packed, and provides error bounds and backward error estimates for the solution

sppsv - sppsv - compute the solution to a real system of linear equations A * X = B,

sppsvx - sppsvx - use the Cholesky factorization A = U**T*U or A = L*L**T to compute the solution to a real system of linear equations A * X = B,

spptrf - spptrf - compute the Cholesky factorization of a real symmetric positive definite matrix A stored in packed format

spptri - spptri - compute the inverse of a real symmetric positive definite matrix A using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF

spptrs - spptrs - solve a system of linear equations A*X = B with a symmetric positive definite matrix A in packed storage using the Cholesky factorization A = U**T*U or A = L*L**T computed by SPPTRF

sptcon - sptcon - compute the reciprocal of the condition number (in the 1-norm) of a real symmetric positive definite tridiagonal matrix using the factorization A = L*D*L**T or A = U**T*D*U computed by SPTTRF

spteqr - spteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF, and then calling SBDSQR to compute the singular values of the bidiagonal factor

sptrfs - sptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

sptsv - sptsv - compute the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

sptsvx - sptsvx - use the factorization A = L*D*L**T to compute the solution to a real system of linear equations A*X = B, where A is an N-by-N symmetric positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

spttrf - spttrf - compute the L*D*L' factorization of a real symmetric positive definite tridiagonal matrix A

spttrs - spttrs - solve a tridiagonal system of the form A * X = B using the L*D*L' factorization of A computed by SPTTRF sptts2 - sptts2 - solve a tridiagonal system of the form A * X = B using the L*D*L' factorization of A computed by SPTTRF

srot - srot - Apply a Given's rotation constructed by SROTG.

srotg - srotg - Construct a Given's plane rotation

sroti - sroti - Apply an indexed Givens rotation.

srotm - srotm - Apply a Gentleman's modified Given's rotation constructed by SROTMG.

srotmg - srotmg - Construct a Gentleman's modified Given's plane rotation

ssbev - ssbev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

ssbevd - ssbevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

ssbevx - ssbevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric band matrix A

ssbgst - ssbgst - reduce a real symmetric-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y,

ssbgv - ssbgv - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x

ssbgvd - ssbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x

ssbgvx - ssbgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite banded eigenproblem, of the form A*x=(lambda)*B*x

ssbmv - ssbmv - perform the matrix-vector operation y := alpha*A*x + beta*y

ssbtrd - ssbtrd - reduce a real symmetric band matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

sscal - sscal - Compute y := alpha * y

ssctr - ssctr - Scatters elements from x into y.

sskymm - sskymm - Skyline format matrix-matrix multiply sskysm - sskysm - Skyline format triangular solve

sspcon - sspcon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF

sspev - sspev - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

sspevd - sspevd - compute all the eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

sspevx - sspevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A in packed storage

sspgst - sspgst - reduce a real symmetric-definite generalized eigenproblem to standard form, using packed storage

sspgv - sspgv - compute all the eigenvalues and, optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

sspgvd - sspgvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

sspgvx - sspgvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

sspmv - sspmv - perform the matrix-vector operation y := alpha*A*x + beta*y

sspr - sspr - perform the symmetric rank 1 operation A := alpha*x*x' + A

sspr2 - sspr2 - perform the symmetric rank 2 operation A := alpha*x*y' + alpha*y*x' + A

ssprfs - ssprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

sspsv - sspsv - compute the solution to a real system of linear equations A * X = B,

sspsvx - sspsvx - use the diagonal pivoting factorization A = U*D*U**T or A = L*D*L**T to compute the solution to a real system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices

ssptrd - ssptrd - reduce a real symmetric matrix A stored in packed form to symmetric tridiagonal form T by an orthogonal similarity transformation ssptrf - ssptrf - compute the factorization of a real symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

ssptri - ssptri - compute the inverse of a real symmetric indefinite matrix A in packed storage using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF

ssptrs - ssptrs - solve a system of linear equations A*X = B with a real symmetric matrix A stored in packed format using the factorization A = U*D*U**T or A = L*D*L**T computed by SSPTRF

sstebz - sstebz - compute the eigenvalues of a symmetric tridiagonal matrix T

sstedc - sstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

sstegr - sstegr - (a) Compute T-sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T is a relatively robust representation

sstein - sstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

ssteqr - ssteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

ssterf - ssterf - compute all eigenvalues of a symmetric tridiagonal matrix using the Pal-Walker-Kahan variant of the QL or QR algorithm

sstev - sstev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

sstevd - sstevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix

sstevr - sstevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

sstevx - sstevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix A

sstsv - sstsv - compute the solution to a system of linear equations A * X = B where A is a symmetric tridiagonal matrix

ssttrf - ssttrf - compute the factorization of a symmetric tridiagonal matrix A

ssttrs - ssttrs - computes the solution to a real system of linear equations A * X = B sswap - sswap - Exchange vectors x and y.

ssycon - ssycon - estimate the reciprocal of the condition number (in the 1-norm) of a real symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF

ssyev - ssyev - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

ssyevd - ssyevd - compute all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

ssyevr - ssyevr - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T

ssyevx - ssyevx - compute selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A

ssygs2 - ssygs2 - reduce a real symmetric-definite generalized eigenproblem to standard form

ssygst - ssygst - reduce a real symmetric-definite generalized eigenproblem to standard form

ssygv - ssygv - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

ssygvd - ssygvd - compute all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

ssygvx - ssygvx - compute selected eigenvalues, and optionally, eigenvectors of a real generalized symmetric-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

ssymm - ssymm - perform one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C

ssymv - ssymv - perform the matrix-vector operation y := alpha*A*x + beta*y

ssyr - ssyr - perform the symmetric rank 1 operation A := alpha*x*x' + A

ssyr2 - ssyr2 - perform the symmetric rank 2 operation A := alpha*x*y' + alpha*y*x' + A

ssyr2k - ssyr2k - perform one of the symmetric rank 2k operations C := alpha*A*B' + alpha*B*A' + beta*C or C := alpha*A'*B + alpha*B'*A + beta*C

ssyrfs - ssyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution ssyrk - ssyrk - perform one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C

ssysv - ssysv - compute the solution to a real system of linear equations A * X = B,

ssysvx - ssysvx - use the diagonal pivoting factorization to compute the solution to a real system of linear equations A * X = B,

ssytd2 - ssytd2 - reduce a real symmetric matrix A to symmetric tridiagonal form T by an orthogonal similarity transformation

ssytf2 - ssytf2 - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

ssytrd - ssytrd - reduce a real symmetric matrix A to real symmetric tridiagonal form T by an orthogonal similarity transformation

ssytrf - ssytrf - compute the factorization of a real symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

ssytri - ssytri - compute the inverse of a real symmetric indefinite matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF

ssytrs - ssytrs - solve a system of linear equations A*X = B with a real symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by SSYTRF

stbcon - stbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

stbmv - stbmv - perform one of the matrix-vector operations x := A*x, or x := A'*x

stbrfs - stbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

stbsv - stbsv - solve one of the systems of equations A*x = b, or A'*x = b

stbtrs - stbtrs - solve a triangular system of the form A * X = B or A**T * X = B,

stgevc - stgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of real upper triangular matrices (A,B)

stgexc - stgexc - reorder the generalized real Schur decomposition of a real matrix pair (A,B) using an orthogonal equivalence transformation (A, B) = Q * (A, B) * Z', stgsen - stgsen - reorder the generalized real Schur decomposition of a real matrix pair (A, B) (in terms of an orthonormal equivalence trans- formation Q' * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix A and the upper triangular B

stgsja - stgsja - compute the generalized singular value decomposition (GSVD) of two real upper triangular (or trapezoidal) matrices A and B

stgsna - stgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B) in generalized real Schur canonical form (or of any matrix pair (Q*A*Z', Q*B*Z') with orthogonal matrices Q and Z, where Z' denotes the transpose of Z

stgsyl - stgsyl - solve the generalized Sylvester equation

stpcon - stpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

stpmv - stpmv - perform one of the matrix-vector operations x := A*x, or x := A'*x

stprfs - stprfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

stpsv - stpsv - solve one of the systems of equations A*x = b, or A'*x = b

stptri - stptri - compute the inverse of a real upper or lower triangular matrix A stored in packed format

stptrs - stptrs - solve a triangular system of the form A * X = B or A**T * X = B,

strans - strans - transpose and scale source matrix

strcon - strcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

strevc - strevc - compute some or all of the right and/or left eigenvectors of a real upper quasi-triangular matrix T

strexc - strexc - reorder the real Schur factorization of a real matrix A = Q*T*Q**T, so that the diagonal block of T with row index IFST is moved to row ILST

strmm - strmm - perform one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A)

strmv - strmv - perform one of the matrix-vector operations x := A*x, or x := A'*x

strrfs - strrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

strsen - strsen - reorder the real Schur factorization of a real matrix A = Q*T*Q**T, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T,

strsm - strsm - solve one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B

strsna - strsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a real upper quasi-triangular matrix T (or of any matrix Q*T*Q**T with Q orthogonal)

strsv - strsv - solve one of the systems of equations A*x = b, or A'*x = b

strsyl - strsyl - solve the real Sylvester matrix equation

strti2 - strti2 - compute the inverse of a real upper or lower triangular matrix

strtri - strtri - compute the inverse of a real upper or lower triangular matrix A

strtrs - strtrs - solve a triangular system of the form A * X = B or A**T * X = B,

stzrqf - stzrqf - routine is deprecated and has been replaced by routine STZRZF

stzrzf - stzrzf - reduce the M-by-N (M<=N) real upper trapezoidal matrix A to upper triangular form by means of orthogonal transformations

sunperf_version - sunperf_version - gets library information .HP 1i SUBROUTINE SUNPERF_VERSION (VERSION, PATCH, UPDATE) .HP 1i INTEGER VERSION, PATCH, UPDATE .HP 1i

svbrmm - svbrmm - variable block sparse row format matrix-matrix multiply

svbrsm - svbrsm - variable block sparse row format triangular solve

swiener - swiener - perform Wiener deconvolution of two signals

use_threads - use_threads - set the upper bound on the number of threads that the calling thread wants used

using_threads - using_threads - returns the current Use number set by the USE_THREADS subroutine

vcfftb - vcfftb - compute a periodic sequence from its Fourier coefficients. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

vcfftf - vcfftf - compute the Fourier coefficients of a periodic sequence. The VCFFT operations are normalized, so a call of VCFFTF followed by a call of VCFFTB will return the original sequence.

vcffti - vcffti - initialize the array WSAVE, which is used in both VCFFTF and VCFFTB.

vcosqb - vcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

vcosqf - vcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

vcosqi - vcosqi - initialize the array WSAVE, which is used in both VCOSQF and VCOSQB.

vcost - vcost - compute the discrete Fourier cosine transform of an even sequence. The VCOST transform is normalized, so a call of VCOST followed by a call of VCOST will return the original sequence.

vcosti - vcosti - initialize the array WSAVE, which is used in VCOST.

vdcosqb - vdcosqb - synthesize a Fourier sequence from its representation in terms of a cosine series with odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

vdcosqf - vdcosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The VCOSQ operations are normalized, so a call of VCOSQF followed by a call of VCOSQB will return the original sequence.

vdcosqi - vdcosqi - initialize the array WSAVE, which is used in both VCOSQF and VCOSQB.

vdcost - vdcost - compute the discrete Fourier cosine transform of an even sequence. The VCOST transform is normalized, so a call of VCOST followed by a call of VCOST will return the original sequence.

vdcosti - vdcosti - initialize the array WSAVE, which is used in VCOST.

vdfftb - vdfftb - compute a periodic sequence from its Fourier coefficients. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

vdfftf - vdfftf - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

vdffti - vdffti - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

vdsinqb - vdsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

vdsinqf - vdsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

vdsinqi - vdsinqi - initialize the array WSAVE, which is used in both VSINQF and VSINQB.

vdsint - vdsint - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by 2 * (N+1). The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

vdsinti - vdsinti - initialize the array WSAVE, which is used in subroutine VSINT.

vrfftb - vrfftb - compute a periodic sequence from its Fourier coefficients. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

vrfftf - vrfftf - compute the Fourier coefficients of a periodic sequence. The VRFFT operations are normalized, so a call of VRFFTF followed by a call of VRFFTB will return the original sequence.

vrffti - vrffti - initialize the array WSAVE, which is used in both VRFFTF and VRFFTB.

vsinqb - vsinqb - synthesize a Fourier sequence from its representation in terms of a sine series with odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

vsinqf - vsinqf - compute the Fourier coefficients in a sine series representation with only odd wave numbers. The VSINQ operations are normalized, so a call of VSINQF followed by a call of VSINQB will return the original sequence.

vsinqi - vsinqi - initialize the array WSAVE, which is used in both VSINQF and VSINQB.

vsint - vsint - compute the discrete Fourier sine transform of an odd sequence. The VSINT transforms are unnormalized inverses of themselves, so a call of VSINT followed by another call of VSINT will multiply the input sequence by 2 * (N+1). The VSINT transforms are normalized, so a call of VSINT followed by a call of VSINT will return the original sequence.

vsinti - vsinti - initialize the array WSAVE, which is used in subroutine VSINT.

vzfftb - vzfftb - compute a periodic sequence from its Fourier coefficients. The VZFFT operations are normalized, so a call of VZFFTF followed by a call of VZFFTB will return the original sequence.

vzfftf - vzfftf - compute the Fourier coefficients of a periodic sequence. The VZFFT operations are normalized, so a call of VZFFTF followed by a call of VZFFTB will return the original sequence.

vzffti - vzffti - initialize the array WSAVE, which is used in both VZFFTF and VZFFTB.

zaxpy - zaxpy - compute y := alpha * x + y

zaxpyi - zaxpyi - Compute y := alpha * x + y

zbcomm - zbcomm - block coordinate matrix-matrix multiply

zbdimm - zbdimm - block diagonal format matrix-matrix multiply

zbdism - zbdism - block diagonal format triangular solve

zbdsqr - zbdsqr - compute the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B.

zbelmm - zbelmm - block Ellpack format matrix-matrix multiply

zbelsm - zbelsm - block Ellpack format triangular solve

zbscmm - zbscmm - block sparse column matrix-matrix multiply

zbscsm - zbscsm - block sparse column format triangular solve

zbsrmm - zbsrmm - block sparse row format matrix-matrix multiply

zbsrsm - zbsrsm - block sparse row format triangular solve

zcnvcor - zcnvcor - compute the convolution or correlation of complex vectors

zcnvcor2 - zcnvcor2 - compute the convolution or correlation of complex matrices

zcoomm - zcoomm - coordinate matrix-matrix multiply

zcopy - zcopy - Copy x to y

zcscmm - zcscmm - compressed sparse column format matrix-matrix multiply

zcscsm - zcscsm - compressed sparse column format triangular solve zcsrmm - zcsrmm - compressed sparse row format matrix-matrix multiply

zcsrsm - zcsrsm - compressed sparse row format triangular solve

zdiamm - zdiamm - diagonal format matrix-matrix multiply

zdiasm - zdiasm - diagonal format triangular solve

zdotc - zdotc - compute the dot product of two vectors conjg(x) and y.

zdotci - zdotci - Compute the complex conjugated indexed dot product.

zdotu - zdotu - compute the dot product of two vectors x and y.

zdotui - zdotui - Compute the complex unconjugated indexed dot product.

zdrot - zdrot - Apply a plane rotation.

zdscal - zdscal - Compute y := alpha * y

zellmm - zellmm - Ellpack format matrix-matrix multiply

zellsm - zellsm - Ellpack format triangular solve

zfft2b - zfft2b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by M*N.

zfft2f - zfft2f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFT2F followed by a call of ZFFT2B will multiply the input sequence by M*N.

zfft2i - zfft2i - initialize the array WSAVE, which is used in both the forward and backward transforms.

zfft3b - zfft3b - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFT3F followed by a call of ZFFT3B will multiply the input sequence by M*N*K.

zfft3f - zfft3f - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFT3F followed by a call of ZFFT3B will multiply the input sequence by M*N*K.

zfft3i - zfft3i - initialize the array WSAVE, which is used in both ZFFT3F and ZFFT3B.

zfftb - zfftb - compute a periodic sequence from its Fourier coefficients. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N.

zfftd - zfftd - initialize the trigonometric weight and factor tables or compute the inverse Fast Fourier Transform of a double complex sequence.

zfftd2 - zfftd2 - initialize the trigonometric weight and factor tables or compute the two-dimensional inverse Fast Fourier Transform of a two-dimensional double complex array.

zfftd3 - zfftd3 - initialize the trigonometric weight and factor tables or compute the three-dimensional inverse Fast Fourier Transform of a three-dimensional double complex array.

zfftdm - zfftdm - initialize the trigonometric weight and factor tables or compute the one-dimensional inverse Fast Fourier Transform of a set of double complex data sequences stored in a two-dimensional array.

zfftf - zfftf - compute the Fourier coefficients of a periodic sequence. The FFT operations are unnormalized, so a call of ZFFTF followed by a call of ZFFTB will multiply the input sequence by N.

zffti - zffti - initialize the array WSAVE, which is used in both ZFFTF and ZFFTB.

zfftopt - zfftopt - compute the length of the closest fast FFT

zfftz - zfftz - initialize the trigonometric weight and factor tables or compute the Fast Fourier transform (forward or inverse) of a double complex sequence.

zfftz2 - zfftz2 - initialize the trigonometric weight and factor tables or compute the two-dimensional Fast Fourier Transform (forward or inverse) of a two-dimensional double complex array.

zfftz3 - zfftz3 - initialize the trigonometric weight and factor tables or compute the three-dimensional Fast Fourier Transform (forward or inverse) of a three-dimensional double complex array.

zfftzm - zfftzm - initialize the trigonometric weight and factor tables or compute the one-dimensional Fast Fourier Transform (forward or inverse) of a set of data sequences stored in a two-dimensional double complex array.

zgbbrd - zgbbrd - reduce a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation

zgbcon - zgbcon - estimate the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm,

zgbequ - zgbequ - compute row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number

zgbmv - zgbmv - perform one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y zgbrfs - zgbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution

zgbsv - zgbsv - compute the solution to a complex system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices

zgbsvx - zgbsvx - use the LU factorization to compute the solution to a complex system of linear equations A * X = B, A**T * X = B, or A**H * X = B,

zgbtf2 - zgbtf2 - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

zgbtrf - zgbtrf - compute an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges

zgbtrs - zgbtrs - solve a system of linear equations A * X = B, A**T * X = B, or A**H * X = B with a general band matrix A using the LU factorization computed by CGBTRF

zgebak - zgebak - form the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL

zgebal - zgebal - balance a general complex matrix A

zgebrd - zgebrd - reduce a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation

zgecon - zgecon - estimate the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF

zgeequ - zgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

zgees - zgees - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

zgeesx - zgeesx - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z

zgeev - zgeev - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors

zgeevx - zgeevx - compute for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors zgegs - zgegs - routine is deprecated and has been replaced by routine CGGES

zgegv - zgegv - routine is deprecated and has been replaced by routine CGGEV

zgehrd - zgehrd - reduce a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation

zgelqf - zgelqf - compute an LQ factorization of a complex M-by-N matrix A

zgels - zgels - solve overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A

zgelsd - zgelsd - compute the minimum-norm solution to a real linear least squares problem

zgelss - zgelss - compute the minimum norm solution to a complex linear least squares problem

zgelsx - zgelsx - routine is deprecated and has been replaced by routine CGELSY

zgelsy - zgelsy - compute the minimum-norm solution to a complex linear least squares problem

zgemm - zgemm - perform one of the matrix-matrix operations C := alpha*op(A)*op(B) + beta*C

zgemv - zgemv - perform one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y

zgeqlf - zgeqlf - compute a QL factorization of a complex M-by-N matrix A

zgeqp3 - zgeqp3 - compute a QR factorization with column pivoting of a matrix A

zgeqpf - zgeqpf - routine is deprecated and has been replaced by routine CGEQP3

zgeqrf - zgeqrf - compute a QR factorization of a complex M-by-N matrix A

zgerc - zgerc - perform the rank 1 operation A := alpha*x*conjg(y') + A

zgerfs - zgerfs - improve the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution

zgerqf - zgerqf - compute an RQ factorization of a complex M-by-N matrix A

zgeru - zgeru - perform the rank 1 operation A := alpha*x*y' + A zgesdd - zgesdd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method

zgesv - zgesv - compute the solution to a complex system of linear equations A * X = B,

zgesvd - zgesvd - compute the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors

zgesvx - zgesvx - use the LU factorization to compute the solution to a complex system of linear equations A * X = B,

zgetf2 - zgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

zgetrf - zgetrf - compute an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges

zgetri - zgetri - compute the inverse of a matrix using the LU factorization computed by CGETRF

zgetrs - zgetrs - solve a system of linear equations A * X = B, A**T * X = B, or A**H * X = B with a general N-by-N matrix A using the LU factorization computed by CGETRF

zggbak - zggbak - form the right or left eigenvectors of a complex generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL

zggbal - zggbal - balance a pair of general complex matrices (A,B)

zgges - zgges - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR)

zggesx - zggesx - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T),

zggev - zggev - compute for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

zggevx - zggevx - compute for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors

zggglm - zggglm - solve a general Gauss-Markov linear model (GLM) problem zgghrd - zgghrd - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

zgglse - zgglse - solve the linear equality-constrained least squares (LSE) problem

zggqrf - zggqrf - compute a generalized QR factorization of an N-by-M matrix A and an N-by-P matrix B.

zggrqf - zggrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

zggsvd - zggsvd - compute the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B

zggsvp - zggsvp - compute unitary matrices U, V and Q such that N-K-L K L U'*A*Q = K (0 A12 A13) if M-K-L >= 0

zgssco - zgssco - General sparse solver condition number estimate.

zgssda - zgssda - Deallocate working storage for the general sparse solver.

zgssfa - zgssfa - General sparse solver numeric factorization.

zgssfs - zgssfs - General sparse solver one call interface.

zgssin - zgssin - Initialize the general sparse solver.

zgssor - zgssor - General sparse solver ordering and symbolic factorization.

zgssps - zgssps - Print general sparse solver statics.

zgssrp - zgssrp - Return permutation used by the general sparse solver.

zgsssl - zgsssl - Solve routine for the general sparse solver.

zgssuo - zgssuo - User supplied permutation for ordering used in the general sparse solver.

zgtcon - zgtcon - estimate the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF

zgthr - zgthr - Gathers specified elements from y into x.

zgthrz - zgthrz - Gather and zero.

zgtrfs - zgtrfs - improve the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution

zgtsv - zgtsv - solve the equation A*X = B,

zgtsvx - zgtsvx - use the LU factorization to compute the solution to a complex system of linear equations A * X = B, A**T * X = B, or A**H * X = B,

zgttrf - zgttrf - compute an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges

zgttrs - zgttrs - solve one of the systems of equations A * X = B, A**T * X = B, or A**H * X = B,

zhbev - zhbev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

zhbevd - zhbevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

zhbevx - zhbevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A

zhbgst - zhbgst - reduce a complex Hermitian-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y,

zhbgv - zhbgv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x

zhbgvd - zhbgvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x

zhbgvx - zhbgvx - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x

zhbmv - zhbmv - perform the matrix-vector operation y := alpha*A*x + beta*y

zhbtrd - zhbtrd - reduce a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

zhecon - zhecon - estimate the reciprocal of the condition number of a complex Hermitian matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF

zheev - zheev - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A zheevd - zheevd - compute all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

zheevr - zheevr - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T

zheevx - zheevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A

zhegs2 - zhegs2 - reduce a complex Hermitian-definite generalized eigenproblem to standard form

zhegst - zhegst - reduce a complex Hermitian-definite generalized eigenproblem to standard form

zhegv - zhegv - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

zhegvd - zhegvd - compute all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

zhegvx - zhegvx - compute selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

zhemm - zhemm - perform one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C

zhemv - zhemv - perform the matrix-vector operation y := alpha*A*x + beta*y

zher - zher - perform the hermitian rank 1 operation A := alpha*x*conjg(x') + A

zher2 - zher2 - perform the hermitian rank 2 operation A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A

zher2k - zher2k - perform one of the Hermitian rank 2k operations C := alpha*A*conjg(B') + conjg(alpha) *B*conjg(A') + beta*C or C := alpha*conjg(A')*B + conjg(alpha)*conjg(B')*A + beta*C

zherfs - zherfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution

zherk - zherk - perform one of the Hermitian rank k operations C := alpha*A*conjg(A') + beta*C or C := alpha*conjg(A')*A + beta*C

zhesv - zhesv - compute the solution to a complex system of linear equations A * X = B,

zhesvx - zhesvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, zhetf2 - zhetf2 - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

zhetrd - zhetrd - reduce a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation

zhetrf - zhetrf - compute the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method

zhetri - zhetri - compute the inverse of a complex Hermitian indefinite matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF

zhetrs - zhetrs - solve a system of linear equations A*X = B with a complex Hermitian matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF

zhgeqz - zhgeqz - implement a single-shift version of the QZ method for finding the generalized eigenvalues w(i) =ALPHA(i)/BETA(i) of the equation det(A-w(i) B) = 0 If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form (i.e., A and B are both upper triangular) by applying one unitary tranformation (usually called Q) on the left and another (usually called Z) on the right

zhpcon - zhpcon - estimate the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF

zhpev - zhpev - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage

zhpevd - zhpevd - compute all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

zhpevx - zhpevx - compute selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage

zhpgst - zhpgst - reduce a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage

zhpgv - zhpgv - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

zhpgvd - zhpgvd - compute all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x

zhpgvx - zhpgvx - compute selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x zhpmv - zhpmv - perform the matrix-vector operation y := alpha*A*x + beta*y

zhpr - zhpr - perform the hermitian rank 1 operation A := alpha*x*conjg(x') + A

zhpr2 - zhpr2 - perform the Hermitian rank 2 operation A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A

zhprfs - zhprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution

zhpsv - zhpsv - compute the solution to a complex system of linear equations A * X = B,

zhpsvx - zhpsvx - use the diagonal pivoting factorization A = U*D*U**H or A = L*D*L**H to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices

zhptrd - zhptrd - reduce a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation

zhptrf - zhptrf - compute the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method

zhptri - zhptri - compute the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF

zhptrs - zhptrs - solve a system of linear equations A*X = B with a complex Hermitian matrix A stored in packed format using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF

zhsein - zhsein - use inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H

zhseqr - zhseqr - compute the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition H = Z T Z**H, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors

zjadmm - zjadmm - Jagged diagonal matrix-matrix multiply (modified Ellpack)

zjadrp - zjadrp - right permutation of a jagged diagonal matrix

zjadsm - zjadsm - Jagged-diagonal format triangular solve

zlarz - zlarz - applie a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right zlarzb - zlarzb - applie a complex block reflector H or its transpose H**H to a complex distributed M-by-N C from the left or the right

zlarzt - zlarzt - form the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors

zlatzm - zlatzm - routine is deprecated and has been replaced by routine CUNMRZ

zpbcon - zpbcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPBTRF

zpbequ - zpbequ - compute row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm)

zpbrfs - zpbrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution

zpbstf - zpbstf - compute a split Cholesky factorization of a complex Hermitian positive definite band matrix A

zpbsv - zpbsv - compute the solution to a complex system of linear equations A * X = B,

zpbsvx - zpbsvx - use the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations A * X = B,

zpbtf2 - zpbtf2 - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

zpbtrf - zpbtrf - compute the Cholesky factorization of a complex Hermitian positive definite band matrix A

zpbtrs - zpbtrs - solve a system of linear equations A*X = B with a Hermitian positive definite band matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPBTRF

zpocon - zpocon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF

zpoequ - zpoequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm)

zporfs - zporfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite,

zposv - zposv - compute the solution to a complex system of linear equations A * X = B, zposvx - zposvx - use the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations A * X = B,

zpotf2 - zpotf2 - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

zpotrf - zpotrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A

zpotri - zpotri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF

zpotrs - zpotrs - solve a system of linear equations A*X = B with a Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF

zppcon - zppcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF

zppequ - zppequ - compute row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm)

zpprfs - zpprfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution

zppsv - zppsv - compute the solution to a complex system of linear equations A * X = B,

zppsvx - zppsvx - use the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations A * X = B,

zpptrf - zpptrf - compute the Cholesky factorization of a complex Hermitian positive definite matrix A stored in packed format

zpptri - zpptri - compute the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF

zpptrs - zpptrs - solve a system of linear equations A*X = B with a Hermitian positive definite matrix A in packed storage using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF

zptcon - zptcon - compute the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization A = L*D*L**H or A = U**H*D*U computed by CPTTRF

zpteqr - zpteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor zptrfs - zptrfs - improve the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution

zptsv - zptsv - compute the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

zptsvx - zptsvx - use the factorization A = L*D*L**H to compute the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix and X and B are N-by-NRHS matrices

zpttrf - zpttrf - compute the L*D*L' factorization of a complex Hermitian positive definite tridiagonal matrix A

zpttrs - zpttrs - solve a tridiagonal system of the form A * X = B using the factorization A = U'*D*U or A = L*D*L' computed by CPTTRF

zptts2 - zptts2 - solve a tridiagonal system of the form A * X = B using the factorization A = U'*D*U or A = L*D*L' computed by CPTTRF

zrot - zrot - apply a plane rotation, where the cos (C) is real and the sin (S) is complex, and the vectors X and Y are complex

zrotg - zrotg - Construct a Given's plane rotation

zscal - zscal - Compute y := alpha * y

zsctr - zsctr - Scatters elements from x into y.

zskymm - zskymm - Skyline format matrix-matrix multiply

zskysm - zskysm - Skyline format triangular solve

zspcon - zspcon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF

zsprfs - zsprfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution

zspsv - zspsv - compute the solution to a complex system of linear equations A * X = B,

zspsvx - zspsvx - use the diagonal pivoting factorization A = U*D*U**T or A = L*D*L**T to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices zsptrf - zsptrf - compute the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method

zsptri - zsptri - compute the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF

zsptrs - zsptrs - solve a system of linear equations A*X = B with a complex symmetric matrix A stored in packed format using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF

zstedc - zstedc - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method

zstegr - zstegr - Compute T-sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T is a relatively robust representation

zstein - zstein - compute the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration

zsteqr - zsteqr - compute all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method

zstsv - zstsv - compute the solution to a complex system of linear equations A * X = B where A is a Hermitian tridiagonal matrix

zsttrf - zsttrf - compute the factorization of a complex Hermitian tridiagonal matrix A

zsttrs - zsttrs - computes the solution to a complex system of linear equations A * X = B

zswap - zswap - Exchange vectors x and y.

zsycon - zsycon - estimate the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF

zsymm - zsymm - perform one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C

zsyr2k - zsyr2k - perform one of the symmetric rank 2k operations C := alpha*A*B' + alpha*B*A' + beta*C or C := alpha*A'*B + alpha*B'*A + beta*C

zsyrfs - zsyrfs - improve the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution zsyrk - zsyrk - perform one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C

zsysv - zsysv - compute the solution to a complex system of linear equations A * X = B,

zsysvx - zsysvx - use the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B,

zsytf2 - zsytf2 - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

zsytrf - zsytrf - compute the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method

zsytri - zsytri - compute the inverse of a complex symmetric indefinite matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF

zsytrs - zsytrs - solve a system of linear equations A*X = B with a complex symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF

ztbcon - ztbcon - estimate the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm

ztbmv - ztbmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

ztbrfs - ztbrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix

ztbsv - ztbsv - solve one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b

ztbtrs - ztbtrs - solve a triangular system of the form A * X = B, A**T * X = B, or A**H * X = B,

ztgevc - ztgevc - compute some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B)

ztgexc - ztgexc - reorder the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation (A, B) := Q * (A, B) * Z', so that the diagonal block of (A, B) with row index IFST is moved to row ILST

ztgsen - ztgsen - reorder the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence trans- formation Q' * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the pair (A,B) ztgsja - ztgsja - compute the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B

ztgsna - ztgsna - estimate reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B)

ztgsyl - ztgsyl - solve the generalized Sylvester equation

ztpcon - ztpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

ztpmv - ztpmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

ztprfs - ztprfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix

ztpsv - ztpsv - solve one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b

ztptri - ztptri - compute the inverse of a complex upper or lower triangular matrix A stored in packed format

ztptrs - ztptrs - solve a triangular system of the form A * X = B, A**T * X = B, or A**H * X = B,

ztrans - ztrans - transpose and scale source matrix

ztrcon - ztrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

ztrevc - ztrevc - compute some or all of the right and/or left eigenvectors of a complex upper triangular matrix T

ztrexc - ztrexc - reorder the Schur factorization of a complex matrix A = Q*T*Q**H, so that the diagonal element of T with row index IFST is moved to row ILST

ztrmm - ztrmm - perform one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A) where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op (A) is one of op(A) = A or op(A) = A' or op(A) = conjg(A')

ztrmv - ztrmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

ztrrfs - ztrrfs - provide error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix

ztrsen - ztrsen - reorder the Schur factorization of a complex matrix A = Q*T*Q**H, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace

ztrsm - ztrsm - solve one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B

ztrsna - ztrsna - estimate reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix Q*T*Q**H with Q unitary)

ztrsv - ztrsv - solve one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b

ztrsyl - ztrsyl - solve the complex Sylvester matrix equation

ztrti2 - ztrti2 - compute the inverse of a complex upper or lower triangular matrix

ztrtri - ztrtri - compute the inverse of a complex upper or lower triangular matrix A

ztrtrs - ztrtrs - solve a triangular system of the form A * X = B, A**T * X = B, or A**H * X = B,

ztzrqf - ztzrqf - routine is deprecated and has been replaced by routine CTZRZF

ztzrzf - ztzrzf - reduce the M-by-N (M<=N) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations

zung2l - zung2l - generate an m by n complex matrix Q with orthonormal columns,

zung2r - zung2r - generate an m by n complex matrix Q with orthonormal columns,

zungbr - zungbr - generate one of the complex unitary matrices Q or P**H determined by CGEBRD when reducing a complex matrix A to bidiagonal form

zunghr - zunghr - generate a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD

zungl2 - zungl2 - generate an m-by-n complex matrix Q with orthonormal rows,

zunglq - zunglq - generate an M-by-N complex matrix Q with orthonormal rows,

zungql - zungql - generate an M-by-N complex matrix Q with orthonormal columns,

zungqr - zungqr - generate an M-by-N complex matrix Q with orthonormal columns,

zungr2 - zungr2 - generate an m by n complex matrix Q with orthonormal rows, zungrq - zungrq - generate an M-by-N complex matrix Q with orthonormal rows,

zungtr - zungtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD

zunmbr - zunmbr - VECT = 'Q', CUNMBR overwrites the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zunmhr - zunmhr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zunml2 - zunml2 - overwrite the general complex m-by-n matrix C with Q * C if SIDE = 'L' and TRANS = 'N', or Q'* C if SIDE = 'L' and TRANS = 'C', or C * Q if SIDE = 'R' and TRANS = 'N', or C * Q' if SIDE = 'R' and TRANS = 'C',

zunmlq - zunmlq - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zunmql - zunmql - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zunmqr - zunmqr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zunmr2 - zunmr2 - overwrite the general complex m-by-n matrix C with Q * C if SIDE = 'L' and TRANS = 'N', or Q'* C if SIDE = 'L' and TRANS = 'C', or C * Q if SIDE = 'R' and TRANS = 'N', or C * Q' if SIDE = 'R' and TRANS = 'C',

zunmrq - zunmrq - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zunmrz - zunmrz - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zunmtr - zunmtr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zupgtr - zupgtr - generate a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage

zupmtr - zupmtr - overwrite the general complex M-by-N matrix C with SIDE = 'L' SIDE = 'R' TRANS = 'N'

zvbrmm - zvbrmm - variable block sparse row format matrix-matrix multiply

zvbrsm - zvbrsm - variable block sparse row format triangular solve

zvmul - zvmul - compute the scaled product of complex vectors

Contents

NAME

```
available_threads - returns information about current thread
usage
```

SYNOPSIS

```
SUBROUTINE AVAILABLE_THREADS(NTOTAL, NUSING)

INTEGER NTOTAL, NUSING

SUBROUTINE AVAILABLE_THREADS_64(NTOTAL, NUSING)

INTEGER*8 NTOTAL, NUSING
```

F95 INTERFACE

```
SUBROUTINE AVAILABLE_THREADS(NTOTAL, NUSING)

INTEGER :: NTOTAL, NUSING

SUBROUTINE AVAILABLE_THREADS_64(NTOTAL, NUSING)

INTEGER(8) :: NTOTAL, NUSING
```

C INTERFACE

```
#include <sunperf.h>

void available_threads(int *ntotal, int *nusing);

void available_threads_64(long *ntotal, long *nusing);
```

PURPOSE

available_threads threads returns NTOTAL, which is the total number of CPUs available to the job (generally the number of CPUs presently on-line in the partition), and NUSING, which is the sum of the current Use numbers for all threads specified in USE_THREADS. If NTOTAL < NUSING then the system is potentially overcommitted.

ARGUMENTS

NTOTAL (output)
Total number of CPUs available.

NUSING (output)
Sum of current Use numbers for all threads specified in USE_THREADS.

Contents

NAME

```
blas_dpermute - permutes a real (double precision) array  in
terms of the permutation vector P, output by dsortv
```

SYNOPSIS

```
SUBROUTINE BLAS_DPERMUTE (N, P, INCP, X, INCX)

INTEGER N
INTEGER P(*)
INTEGER INCP
REAL*8 X(*)
INTEGER INCX

SUBROUTINE BLAS_DPERMUTE_64 (N, P, INCP, X, INCX)

INTEGER*8 N
INTEGER*8 P(*)
INTEGER*8 INCP
REAL*8 X(*)
INTEGER*8  INCX
```

F95 INTERFACE

```
SUBROUTINE PERMUTE (X, P)

USE SUNPERF

SUBROUTINE PERMUTE_64 (X, P)

USE SUNPERF
```

ARGUMENTS

```
N (input) INTEGER, the number of elements to be permuted in X
          If  N  <= 1, the subroutine returns without trying
          to permute X.

P (input) INTEGER((N-1)*|INCP|+1), the permutation (index)
          vector defined follows  the  same  conventions  as
          that  for  DTYPE  SORTV. It records the details of
          the interchanges of the elements of X during sort-
          ing. That is X = P*X. In current implementation, P
          contains the index of sorted X.

INCP  (input) INTEGER, increment for P
          INCP must not be zero. INCP could be negative.  If
          INCP  < 0, the permutation is applied in the oppo-
          site direction.  That is
          If INCP > 0,
            if INCX > 0,
              sorted X((i-1)*INCX+1) = X(P((i-1)*INCP+1)),
            if INCX < 0,
              sorted X((N-i)*|INCX|+1) = X(P((i-1)*INCP+1));
          If INCP < 0,
            if INCX > 0,
              sorted X((i-1)*INCX+1) = X(P((N-i)*|INCP|+1)).
            if INCX < 0,
              sorted X((N-i)*|INCX|+1)
                   = X(P((N-i)*|INCP|+1)).

X (input/output) REAL*8(KIND)((N-1)*|INCX|+1), the array to
          be  permuted.  Minimum  size   (N-1)*|INCX|+1   is
          required

INCX  (input) INTEGER, increment for X
          INCX must not be zero. INCX could be negative.  If
          INCX < 0, X will be permuted in a reverse way (see
          the description for INCP above).
```

NAME

blas_spermute - permutes a real array in terms of the permutation vector P, output by dsortv

SYNOPSIS

```
SUBROUTINE BLAS_SPERMUTE (N, P, INCP, X, INCX)

INTEGER N
INTEGER P(*)
INTEGER INCP
REAL X(*)
INTEGER INCX

SUBROUTINE BLAS_SPERMUTE_64 (N, P, INCP, X, INCX)

INTEGER*8 N
INTEGER*8 P(*)
INTEGER*8 INCP
REAL X(*)
INTEGER*8  INCX
```

F95 INTERFACE

```
SUBROUTINE PERMUTE (X, P)

USE SUNPERF

SUBROUTINE PERMUTE_64 (X, P)

USE SUNPERF
```

ARGUMENTS

```
N (input) INTEGER, the number of elements to be permuted in X
          If  N  <= 1, the subroutine returns without trying
          to permute X.

P (input) INTEGER((N-1)*|INCP|+1), the permutation (index)
          vector defined follows  the  same  conventions  as
          that  for  DTYPE  SORTV. It records the details of
          the interchanges of the elements of X during sort-
          ing. That is X = P*X. In current implementation, P
          contains the index of sorted X.

INCP  (input) INTEGER, increment for P
          INCP must not be zero. INCP could be negative.  If
          INCP  < 0, the permutation is applied in the oppo-
          site direction.  That is
          If INCP > 0,
            if INCX > 0,
              sorted X((i-1)*INCX+1) = X(P((i-1)*INCP+1)),
            if INCX < 0,
              sorted X((N-i)*|INCX|+1) = X(P((i-1)*INCP+1));
          If INCP < 0,
            if INCX > 0,
              sorted X((i-1)*INCX+1) = X(P((N-i)*|INCP|+1)).
            if INCX < 0,
              sorted X((N-i)*|INCX|+1)
                   = X(P((N-i)*|INCP|+1)).

X (input/output) REAL(KIND)((N-1)*|INCX|+1), the array to be
          permuted. Minimum size (N-1)*|INCX|+1 is required

INCX  (input) INTEGER, increment for X
          INCX must not be zero. INCX could be negative.  If
          INCX < 0, X will be permuted in a reverse way (see
          the description for INCP above).

NAME

```
caxpy - compute y := alpha * x + y
```

SYNOPSIS

```
SUBROUTINE CAXPY(N, ALPHA, X, INCX, Y, INCY)

COMPLEX ALPHA
COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY

SUBROUTINE CAXPY_64(N, ALPHA, X, INCX, Y, INCY)

COMPLEX ALPHA
COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE AXPY([N], ALPHA, X, [INCX], Y, [INCY])

COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY

SUBROUTINE AXPY_64([N], ALPHA, X, [INCX], Y, [INCY])

COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void caxpy(int n, complex *alpha, complex *x, int incx, com-
          plex *y, int incy);

void caxpy_64(long n, complex *alpha, complex *x, long incx,
          complex *y, long incy);
```

PURPOSE

caxpy compute y := alpha * x + y where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
array of DIMENSION at least (1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
array of DIMENSION at least (1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

```
caxpyi - Compute y := alpha * x + y
```

SYNOPSIS

```
 SUBROUTINE CAXPYI(NZ, A, X, INDX, Y)

 COMPLEX A
 COMPLEX X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE CAXPYI_64(NZ, A, X, INDX, Y)

 COMPLEX A
 COMPLEX X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE AXPYI([NZ], [A], X, INDX, Y)

 COMPLEX :: A
 COMPLEX, DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE AXPYI_64([NZ], [A], X, INDX, Y)

 COMPLEX :: A
 COMPLEX, DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
CAXPYI Compute y := alpha * x + y where alpha is a scalar, x
is a sparse vector, and y is a vector in full storage form

 do i = 1, n
   y(indx(i)) = alpha * x(i) + y(indx(i))
 enddo
```

ARGUMENTS

```
NZ (input) - INTEGER
        Number of elements in the compressed form.
        Unchanged on exit.

A (input)
        On entry, A(LPHA) specifies the scaling value.
        Unchanged on exit. A is defaulted to (1.0E0, 0.0E0)
        for F95 INTERFACE.
X (input)
        Vector containing the values of the compressed form.
        Unchanged on exit.

INDX (input) - INTEGER
        Vector containing the indices of the compressed
        form.  It is assumed that the elements in INDX are
        distinct and greater than zero.  Unchanged on exit.

Y (output)
        Vector on input which contains the vector Y in full
        storage form.  On exit, only the elements
        corresponding to the indices in INDX have been
        modified.

```

DESCRIPTION

```
         C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block coordinate format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if the matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
```

```
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

VAL()          scalar array of length LB*LB*BNNZ consisting of
               the non-zero block entries of A, in any order.
               Each block is stored in standard column-major form.

BINDX()        integer array of length BNNZ consisting of the
               block row indices of the block entries of A.

BJNDX()        integer array of length BNNZ consisting of the
               block column indices of the block entries of A.

BNNZ           number of block entries

LB             dimension of dense blocks composing A.

B()            rectangular array with first dimension LDB.
LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK. WORK is not
               referenced in the current version.

LWORK          length of WORK array. LWORK is not referenced
               in the current version.

```

DESCRIPTION

```
         C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block diagonal format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                     ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix  is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
```

```
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
                consisting of the NBDIAG nonzero block diagonal in
                any order. Each dense block is stored in standard
                column-major form.

 BLDA           leading block dimension of VAL().

 IBDIAG()       integer array of length NBDIAG consisting of the
                corresponding diagonal offsets of the non-zero
                block diagonals of A in VAL.  Lower triangular
                block diagonals have negative offsets, the main
                block diagonal has offset 0, and upper triangular
                block diagonals have positive offset.

 NBDIAG         the number of non-zero block diagonals in A.
 LB             dimension of dense blocks composing A.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block diagonal format
and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)

DV()          Array of length MB*LB*LB containing the elements of
              the diagonal blocks of the matrix D.  The size of each
              square block is LB-by-LB and each block
              is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-identity blocks on the main diagonal
                 1 : identity diagonal blocks
                 2 : diagonal blocks are dense matrices
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          Two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
               consisting of the NBDIAG non-zero block diagonal.
               Each dense block is stored in standard column-major form.

BLDA           Leading block dimension of VAL().  Should be greater
               than or equal to MB.

IBDIAG()       integer array of length NBDIAG consisting of the
               corresponding diagonal offsets of the non-zero block
               diagonals of A in VAL.  Lower triangular block diagonals
               have negative offsets, the main block diagonal has offset
               0, and upper triangular block diagonals have positive offset.
               Elements of IBDIAG  MUST be sorted in  increasing order.

NBDIAG         The number of non-zero block diagonals in A.

LB             Dimension of dense blocks composing A.

B()            Rectangular array with first dimension LDB.

LDB            Leading dimension of B.

BETA           Scalar parameter.

C()            Rectangular array with first dimension LDC.

LDC            Leading dimension of C.
```

```
WORK()         scratch array of length LWORK.
               On exit, if LWORK= -1, WORK(1) returns the optimum  size
               of LWORK.

LWORK         length of WORK array. LWORK should be at least
              MB*LB.

              For good performance, LWORK should generally be larger.
              For optimum performance on multiple processors, LWORK
              >=MB*LB*N_CPUS where N_CPUS is the maximum number of
              processors available to the program.

              If LWORK=0, the routine is to allocate workspace needed.

              If LWORK = -1, then a workspace query is assumed; the
              routine only calculates the optimum size of the WORK array,
              returns this value as the first entry of the WORK array,
              and no error message related to LWORK is issued by XERBLA.
```

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BDI representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine.

WORK(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

#include <sunperf.h>

void cbdsqr(char uplo, int n, int ncvt, int  nru,  int  ncc,
          float *d, float *e, complex *vt, int ldvt, complex
          *u, int ldu, complex *c, int ldc, int *info);

void cbdsqr_64(char uplo, long n, long ncvt, long nru,  long
          ncc,  float  *d, float *e, complex *vt, long ldvt,
          complex *u, long ldu, complex *c, long  ldc,  long
          *info);
```

PURPOSE

cbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = Q * S * P' (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes U * Q, P' * VT, or Q' * C, for given complex input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

UPLO (input)
= 'U': B is upper bidiagonal;
= 'L': B is lower bidiagonal.

N (input) The order of the matrix B. N >= 0.

```
NCVT (input)
          The number of columns of the matrix VT. NCVT >= 0.

NRU (input)
          The number of rows of the matrix U. NRU >= 0.

NCC (input)
          The number of columns of the matrix C. NCC >= 0.

D (input/output)
          On entry, the n diagonal elements of the  bidiago-
          nal  matrix  B.   On exit, if INFO=0, the singular
          values of B in decreasing order.
E (input/output)
          On entry, the elements of E contain the  offdiago-
          nal elements of of the bidiagonal matrix whose SVD
          is desired. On normal exit (INFO = 0), E  is  des-
          troyed.   If the algorithm does not converge (INFO
          > 0), D and E will contain the diagonal and super-
          diagonal  elements of a bidiagonal matrix orthogo-
          nally equivalent to the one given as  input.  E(N)
          is used for workspace.

VT (input/output)
          On entry, an N-by-NCVT matrix VT.  On exit, VT  is
          overwritten  by  P' * VT.  VT is not referenced if
          NCVT = 0.

LDVT (input)
          The leading dimension of the array  VT.   LDVT  >=
          max(1,N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U (input/output)
          On entry, an NRU-by-N matrix U.   On  exit,  U  is
          overwritten  by U * Q.  U is not referenced if NRU
          = 0.

LDU (input)
          The leading dimension of  the  array  U.   LDU  >=
          max(1,NRU).

C (input/output)
          On entry, an N-by-NCC matrix C.   On  exit,  C  is
          overwritten by Q' * C.  C is not referenced if NCC
          = 0.

LDC (input)
          The leading dimension of  the  array  C.   LDC  >=
          max(1,N) if NCC > 0; LDC >=1 if NCC = 0.
```

WORK (workspace)
dimension (4*N)

INFO (output)
= 0: successful exit
< 0: If INFO = -i, the i-th argument had an illegal value
> 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block Ellpack format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
```

```
                   0 : non-unit
                   1 : unit
                 DESCRA(4) Array base  (NOT IMPLEMENTED)
                   0 : C/C++ compatible
                   1 : Fortran compatible
                 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                   0 : unknown
                   1 : no repeated indices

 VAL()           scalar array of length LB*LB*BLDA*MAXBNZ containing
                 matrix entries, stored column-major within each dense
                 block.

 BINDX()         two-dimensional integer BLDA-by-MAXBNZ array such
                 BINDX(i,:) consists of the block column indices of the
                 nonzero blocks in block row i, padded by the integer
                 value i if the number of nonzero blocks is less than
                 MAXBNZ.

 BLDA            leading dimension of BINDX(:,:).

 MAXBNZ          max number of nonzeros blocks per row.
 LB              row and column dimension of the dense blocks composing
                 VAL.

 B()             rectangular array with first dimension LDB.

 LDB             leading dimension of B

 BETA            Scalar parameter

 C()             rectangular array with first dimension LDC.

 LDC             leading dimension of C

 WORK()          scratch array of length LWORK. WORK is not
                 referenced in the current version.

 LWORK           length of WORK array. LWORK is not referenced
                 in the current version.

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block Ellpack format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                   1 : symmetric (A=A')
                   2 : Hermitian (A= CONJG(A'))
                   3 : Triangular
                   4 : Skew(Anti)-Symmetric (A=-A')
                   5 : Diagonal
                   6 : Skew-Hermitian (A= -CONJG(A'))
                 Note: For the routine, DESCRA(1)=3 is only supported.

                 DESCRA(2) upper/lower triangular indicator
                   1 : lower
                   2 : upper
                 DESCRA(3) main diagonal type
                   0 : non-identity blocks on the main diagonal
                   1 : identity diagonal blocks
                   2 : diagonal blocks are dense matrices
                 DESCRA(4) Array base  (NOT IMPLEMENTED)
                   0 : C/C++ compatible
                   1 : Fortran compatible
                 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                   0 : unknown
                   1 : no repeated indices
  VAL()          scalar array of length LB*LB*BLDA*MAXBNZ containing
                 matrix entries, stored column-major within each dense
                 block.

  BINDX()        two-dimensional integer BLDA-by-MAXBNZ array such
                 BINDX(i,:) consists of the block column indices of the
                 nonzero blocks in block row i, padded by the integer
                 value i if the number of nonzero blocks is less than
                 MAXBNZ.  The block column indices MUST be sorted
                 in increasing order for each block row.

  BLDA           leading dimension of BINDX(:,:).

  MAXBNZ         max number of nonzeros blocks per row.

  LB             row and column dimension of the dense blocks composing A.

  B()            rectangular array with first dimension LDB.

  LDB            leading dimension of B

  BETA           Scalar parameter

  C()            rectangular array with first dimension LDC.

  LDC            leading dimension of C

  WORK()         scratch array of length LWORK.
                 On exit, if LWORK= -1, WORK(1) returns the minimum
```

size of LWORK.

LWORK — length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BEL representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

NOTES/BUGS

It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
  CALL SBSCMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          scalar array of length LB*LB*BNNZ consisting of the block
               entries stored column-major within each dense block.

BINDX()        integer array of length BNNZ consisting of the
               block row indices of the block entries of A.
               The block row indices MUST be sorted
               in increasing order for each block column.

BPNTRB()       integer array of length MB such that
               BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
               of the first block entry of the J-th block column of A.

BPNTRE()       integer array of length MB such that
               BPNTRE(J)-BPNTRB(1) points to location in BINDX
               of the last block entry of the J-th block column of A.

LB             dimension of dense blocks composing A.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C
```

WORK() scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BSC representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed

successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

6. It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
  CALL SBSCSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block sparse row format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix A is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
```

```
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length LB*LB*BNNZ consisting
                of the block  entries stored column-major within
                each dense block.

 BINDX()        integer array of length BNNZ consisting of the
                block column indices of the block entries of A.

 BPNTRB()       integer array of length MB such that
                BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                of the first block entry of the J-th block row of A.
 BPNTRE()       integer array of length MB such that
                BPNTRE(J)-BPNTRB(1) points to location in BINDX
                of the last block entry of the J-th block row of A.

 LB             dimension of dense blocks composing A.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block sparse row format
format and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-identity blocks on the main diagonal
                  1 : identity diagonal blocks
                  2 : diagonal blocks are dense matrices
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           scalar array of length LB*LB*BNNZ consisting of the block
                entries stored column-major within each dense block.

BINDX()         integer array of length BNNZ consisting of the
                block column indices of the block entries of A.
                The block column indices MUST be sorted
                in increasing order for each block row.

BPNTRB()        integer array of length MB such that
                BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                of the first block entry of the J-th block row of A.

BPNTRE()        integer array of length MB such that
                BPNTRE(J)-BPNTRB(1) points to location in BINDX
                of the last block entry of the J-th block row of A.

LB              dimension of dense blocks composing A.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C
```

WORK()   scratch array of length LWORK.
On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK   length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

          inc2z, complex *work, long lwork);
```

PURPOSE

ccnvcor computes the convolution or correlation of complex vectors.

ARGUMENTS

CNVCOR (input)
CHARACTER
'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

FOUR (input)
CHARACTER
'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the real and imaginary parts of the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

NX (input)

Length of the filter vector. NX >= 0. CCNVCOR will return immediately if NX = 0.

X (input) dimension(*)

Filter vector.

IFX (input)

Index of the first element of X. NX >= IFX >= 1.

INCX (input)

Stride between elements of the filter vector in X. INCX > 0.

NY (input)

Length of the input vectors. NY >= 0. CCNVCOR will return immediately if NY = 0.

NPRE (input)

The number of implicit zeros prepended to the Y vectors. NPRE >= 0.

M (input)

Number of input vectors. M >= 0. CCNVCOR will return immediately if M = 0.

Y (input) dimension(*)

Input vectors.

IFY (input)

Index of the first element of Y. NY >= IFY >= 1.

INC1Y (input)

Stride between elements of the input vectors in Y. INC1Y > 0.

INC2Y (input)

Stride between the input vectors in Y. INC2Y > 0.

NZ (input)

Length of the output vectors. NZ >= 0. CCNVCOR will return immediately if NZ = 0. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

K (input)

Number of Z vectors. K >= 0. If K = 0 then CCNVCOR will return immediately. If K < M then only the first K input vectors will be processed. If K > M then M input vectors will be processed.

Z (output)
dimension(*)
Result vectors.

IFZ (input)
Index of the first element of Z. NZ >= IFZ >= 1.

INC1Z (input)
Stride between elements of the output vectors in Z. INC1Z > 0.

INC2Z (input)
Stride between the output vectors in Z. INC2Z > 0.

WORK (input/output)
(input/scratch) dimension(LWORK)
Scratch space. Before the first call to CCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to CCNVCOR or if CCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make CCNVCOR run faster.

LWORK (input)
Length of WORK. LWORK >= 2*MAX(NX,NY+NPRE,NZ)+8.

          mz, long nz, complex *z, long ldz, complex  *work,
          long lwork);
```

PURPOSE

ccnvcor2 computes the convolution or correlation of complex matrices.

ARGUMENTS

CNVCOR (input)
'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

METHOD (input)
'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' to compute directly from the definition.

```
TRANSX (input)
          'N' or 'n' if X is the filter matrix, 'T'  or  't'
          if transpose(X) is the filter matrix.

SCRATCHX (input)
          'N' or 'n' if X must be preserved, 'S' or 's' if X
          can  be  used as scratch space.  The contents of X
          are undefined after returning from a call in which
          X is allowed to be used for scratch.

TRANSY (input)
          'N' or 'n' if Y is the input matrix, 'T' or 't' if
          transpose(Y) is the input matrix.

SCRATCHY (input)
          'N' or 'n' if Y must be preserved, 'S' or 's' if Y
          can  be  used as scratch space.  The contents of Y
          are undefined after returning from a call in which
          Y is allowed to be used for scratch.

MX (input)
          Number of rows in the filter matrix.  MX >= 0.

NX (input)
          Number of columns in the filter matrix.  NX >= 0.

X (input)
          On entry, the filter matrix.  Unchanged on exit if
          SCRATCHX  is  'N'  or  'n',  undefined  on exit if
          SCRATCHX is 'S' or 's'.

LDX (input)
          Leading dimension of the array that  contains  the
          filter matrix.

MY (input)
          Number of rows in the input matrix.  MY >= 0.

NY (input)
          Number of columns in the input matrix.  NY >= 0.

MPRE (input)
          Number of implicit zeros to prepend to each row of
          the input matrix.  MPRE >= 0.

NPRE (input)
          Number of implicit zeros to prepend to each column
          of the input matrix.  NPRE >= 0.

Y (input)
```

Input matrix. Unchanged on exit if SCRATCHY is 'N' or 'n', undefined on exit if SCRATCHY is 'S' or 's'.

LDY (input)
Leading dimension of the array that contains the input matrix.

MZ (input)
Number of rows in the output matrix. MZ >= 0. CCNVCOR2 will return immediately if MZ = 0.

NZ (input)
Number of columns in the output matrix. NZ >= 0. CCNVCOR2 will return immediately if NZ = 0.

Z (output)
dimension(LDZ,*)
Result matrix.

LDZ (input)
Leading dimension of the array that contains the result matrix. LDZ >= MAX(1,MZ).

WORK (input/output)
(input/scratch) dimension(LWORK)
On entry for the first call to CCNVCOR2, WORK(1) must contain CMPLX(0.0,0.0). After the first call, WORK(1) must be set to CMPLX(0.0,0.0) iff WORK has been altered since the last call to this subroutine or if the sizes of the arrays have changed.

LWORK (input)
Length of the work vector. The upper bound of the workspace length requirement is 2 * (MYC + NYC) + 15, where MYC = MAX(MAX(MX,NX), MAX(MY,NY)+NPRE) and NYC = MAX(MAX(MX,NX), MAX(MY,NY)+MPRE). If LWORK indicates a workspace that is too small, the routine will allocate its own workspace. If the FFT is not used, the value of LWORK is unimportant.

 COMPLEX    ALPHA, BETA
 COMPLEX, DIMENSION(:) :: VAL
 COMPLEX, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in coordinate format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
```

```
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length NNZ consisting of the
                non-zero entries of A, in any order.

 INDX()         integer array of length NNZ consisting of the
                corresponding row indices of the entries of A.

 JNDX()         integer array of length NNZ consisting of the
                corresponding column indices of the entries of A.

 NNZ            number of non-zero elements in A.
 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY

SUBROUTINE COPY_64([N], X, [INCX], Y, [INCY])

COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ccopy(int n, complex *x,  int  incx,  complex  *y,  int
          incy);

void ccopy_64(long n, complex *x,  long  incx,  complex  *y,
```

```
          long incy);
```

PURPOSE

ccopy Copy x to y where x and y are n-vectors.

ARGUMENTS

```
N (input)
          On entry, N specifies the number  of  elements  in
          the  vector.   N must be at least one for the sub-
          routine to have any visible effect.  Unchanged  on
          exit.
X (input)
          of DIMENSION at least ( 1 + ( n - 1 )*abs( INCX  )
          ).   Before  entry,  the  incremented array X must
          contain the vector x.  Unchanged on exit.

INCX (input)
          On entry, INCX specifies  the  increment  for  the
          elements  of X.  INCX must not be zero.  Unchanged
          on exit.

Y (output)
          of DIMENSION at least ( 1 + ( m - 1 )*abs( INCY  )
          ).  On entry, the incremented array Y must contain
          the vector y. On exit, Y  is  overwritten  by  the
          vector x.

INCY (input)
          On entry, INCY specifies  the  increment  for  the
          elements  of Y.  INCY must not be zero.  Unchanged
          on exit.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
  SUBROUTINE SCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,
 *           C, LDC, WORK, LWORK )
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in compressed sparse column
format and op( A )  is one  of
op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic column scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
  VAL()         scalar array of length NNZ consisting of nonzero entries
                of A.

  INDX()        integer array of length NNZ consisting of the row indices
                of nonzero entries of A. (Row indices MUST be sorted in
                increasing order for each column).

  PNTRB()       integer array of length M such that PNTRB(J)-PNTRB(1)+1
                points to location in VAL of the first nonzero element
                in column J.

  PNTRE()       integer array of length M such that PNTRE(J)-PNTRB(1)
                points to location in VAL of the last nonzero element
                in column J.

  B()           rectangular array with first dimension LDB.

  LDB           leading dimension of B

  BETA          Scalar parameter

  C()           rectangular array with first dimension LDC.

  LDC           leading dimension of C

  WORK()        scratch array of length LWORK.

                On exit,  if LWORK = -1, WORK(1) returns the optimum  LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the columns of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the columns have been scaled. UNITD=3 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the column number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the CSC representation

of a sparse matrix. They are not used anyway in these cases.
But if UNITD=4, the unit diagonal elements MUST be
referenced in the CSC representation.

4. The routine can be applied for solving triangular systems
when the upper or lower triangle of the general sparse
matrix A is used. However *DESCRA*(1) must be equal to 3 in
this case.

5. It is known that there exists another representation of
the compressed sparse column format (see for example Y.Saad,
"Iterative Methods for Sparse Linear Systems", WPS, 1996).
Its data structure consists of three array instead of the
four used in the current implementation. The main
difference is that only one array, IA, containing the
pointers to the beginning of each column in the arrays VAL
and INDX is used instead of two arrays PNTRB and PNTRE. To
use the routine with this kind of sparse column format the
following calling sequence should be used

```
  SUBROUTINE SCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,
 *           C, LDC, WORK, LWORK )
```

 COMPLEX    ALPHA, BETA
 COMPLEX, DIMENSION(:, :) ::  VAL, B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in diagonal format and op( A ) is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)

TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
                0 : non-unit
                1 : unit
              DESCRA(4) Array base  (NOT IMPLEMENTED)
                0 : C/C++ compatible
                1 : Fortran compatible
              DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                0 : unknown
                1 : no repeated indices
```

VAL()	two-dimensional LDA-by-NDIAG array such that VAL(:,I) consists of non-zero elements on diagonal IDIAG(I) of A. Diagonals in the lower triangular part of A are padded from the top, and those in the upper triangular part are padded from the bottom.
LDA	leading dimension of VAL, must be .GE. MIN(M,K)
IDIAG()	integer array of length NDIAG consisting of the corresponding diagonal offsets of the non-zero diagonals of A in VAL. Lower triangular diagonals have negative offsets, the main diagonal has offset 0, and upper triangular diagonals have positive offset.
NDIAG	number of non-zero diagonals in A.
B()	rectangular array with first dimension LDB.
LDB	leading dimension of B
BETA	Scalar parameter
C()	rectangular array with first dimension LDC.
LDC	leading dimension of C
WORK()	scratch array of length LWORK. WORK is not referenced in the current version.
LWORK	length of WORK array. LWORK is not referenced in the current version.

 COMPLEX, DIMENSION(:, :) ::  VAL, B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
```

where ALPHA and BETA are scalar, C and B are m by n dense matrices, D is a diagonal scaling matrix, A is a unit, or non-unit, upper or lower triangular matrix represented in diagonal format and op(A) is one of

```
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))
                Note: For the routine, only DESCRA(1)=3 is supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           two-dimensional LDA-by-NDIAG array such that VAL(:,I)
                consists of non-zero elements on diagonal IDIAG(I)
                of A.  Diagonals in the lower triangular part of A
                are padded from the top, and those in the upper
                triangular part are padded from the bottom.

LDA             leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG()         integer array of length NDIAG consisting of the
                corresponding diagonal offsets of the non-zero
                diagonals of A in VAL.  Lower triangular diagonals
                have negative offsets, the main diagonal has offset
                0, and upper triangular diagonals have positive offset.
                Elements of IDIAG of MUST be sorted in  increasing order.

NDIAG           number of non-zero diagonals in A.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.
                On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the DIA representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the DIA representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

Contents

NAME

```
cdotc - compute the dot product of two vectors conjg(x)  and
y.
```

SYNOPSIS

```
COMPLEX FUNCTION CDOTC(N, X, INCX, Y, INCY)

COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY

COMPLEX FUNCTION CDOTC_64(N, X, INCX, Y, INCY)

COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
COMPLEX FUNCTION DOTC([N], X, [INCX], Y, [INCY])

COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY

COMPLEX FUNCTION DOTC_64([N], X, [INCX], Y, [INCY])

COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>

complex cdotc(int n, complex *x, int incx, complex  *y,  int
          incy);
```

```
complex cdotc_64(long n, complex *x, long incx, complex  *y,
          long incy);
```

PURPOSE

cdotc compute the dot product of conjg(x) and y where x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

X (input)
of DIMENSION at least (1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
of DIMENSION at least (1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
cdotci - Compute the complex conjugated indexed dot product.
```

SYNOPSIS

```
 COMPLEX FUNCTION CDOTCI(NZ, X, INDX, Y)

 COMPLEX X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 COMPLEX FUNCTION CDOTCI_64(NZ, X, INDX, Y)

 COMPLEX X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 COMPLEX FUNCTION DOTCI([NZ], X, INDX, Y)

 COMPLEX, DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 COMPLEX FUNCTION DOTCI_64([NZ], X, INDX, Y)

 COMPLEX, DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
CDOTCI Compute the complex conjugated indexed dot product of
a complex sparse vector x stored in compressed form with a
```

complex vector y in full storage form.

```
 dot = 0
 do i = 1, n
   dot = dot + conjg(x(i)) * y(indx(i))
 enddo
```

ARGUMENTS

NZ (input)
Number of elements in the compressed form.
Unchanged on exit.

X (input)
Vector in compressed form. Unchanged on exit.

INDX (input)
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)
Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

                 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                   0 : unknown
                   1 : no repeated indices

 VAL()           two-dimensional LDA-by-MAXNZ array such that VAL(I,:)
                 consists of non-zero elements in row I of A, padded by
                 zero values if the row contains less than MAXNZ.

 INDX()          two-dimensional integer LDA-by-MAXNZ array such
                 INDX(I,:) consists of the column indices of the
                 nonzero elements in row I, padded by the integer
                 value I if the number of nonzeros is less than MAXNZ.

 LDA             leading dimension of VAL and INDX.

 MAXNZ           max number of nonzeros elements per row.

 B()             rectangular array with first dimension LDB.
 LDB             leading dimension of B

 BETA            Scalar parameter

 C()             rectangular array with first dimension LDC.

 LDC             leading dimension of C

 WORK()          scratch array of length LWORK. WORK is not
                 referenced in the current version.

 LWORK           length of WORK array. LWORK is not referenced
                 in the current version.

NAME

```
cellsm - Ellpack format triangular solve
```

SYNOPSIS

```
  SUBROUTINE CELLSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, LDA, MAXNZ,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
  INTEGER    TRANSA, M, N, UNITD, DESCRA(5), LDA, MAXNZ,
 *           LDB, LDC, LWORK
  INTEGER    INDX(LDA,MAXNZ)
  COMPLEX    ALPHA, BETA
  COMPLEX    DV(M), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)

  SUBROUTINE CELLSM_64( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, LDA, MAXNZ,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
  INTEGER*8  TRANSA, M, N, UNITD, DESCRA(5), LDA, MAXNZ,
 *           LDB, LDC, LWORK
  INTEGER*8  INDX(LDA,MAXNZ)
  COMPLEX    ALPHA, BETA
  COMPLEX    DV(M), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

F95 INTERFACE

```
  SUBROUTINE ELLSM( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
 *    INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
  INTEGER    TRANSA, M,  MAXNZ
  INTEGER, DIMENSION(:) ::  DESCRA
  INTEGER, DIMENSION(:, :) ::    INDX
  COMPLEX    ALPHA, BETA
  COMPLEX, DIMENSION(:) ::  DV
  COMPLEX, DIMENSION(:, :) ::  VAL, B, C
```

```
 SUBROUTINE ELLSM_64( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
*    INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, M,  MAXNZ
 INTEGER*8, DIMENSION(:) ::  DESCRA
 INTEGER*8, DIMENSION(:, :) ::    INDX
 COMPLEX    ALPHA, BETA
 COMPLEX, DIMENSION(:) ::  DV
 COMPLEX, DIMENSION(:, :) ::  VAL, B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in Ellpack format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                    0 : general
                    1 : symmetric (A=A')
                    2 : Hermitian (A= CONJG(A'))
                    3 : Triangular
                    4 : Skew(Anti)-Symmetric (A=-A')
                    5 : Diagonal
                    6 : Skew-Hermitian (A= -CONJG(A'))

                  Note: For the routine, only DESCRA(1)=3 is supported.

                  DESCRA(2) upper/lower triangular indicator
                    1 : lower
                    2 : upper
                  DESCRA(3) main diagonal type
                    0 : non-unit
                    1 : unit
                  DESCRA(4) Array base  (NOT IMPLEMENTED)
                    0 : C/C++ compatible
                    1 : Fortran compatible
                  DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                    0 : unknown
                    1 : no repeated indices
    VAL()         two-dimensional LDA-by-MAXNZ array such that VAL(I,:)
                  consists of non-zero elements in row I of A, padded by
                  zero values if the row contains less than MAXNZ.

    INDX()        two-dimensional integer LDA-by-MAXNZ array such
                  INDX(I,:) consists of the column indices of the
                  nonzero elements in row I, padded by the integer
                  value I if the number of nonzeros is less than MAXNZ.
                  The column indices MUST be sorted in increasing order
                  for each row.

    LDA           leading dimension of VAL and INDX.

    MAXNZ         max number of nonzeros elements per row.

    B()           rectangular array with first dimension LDB.

    LDB           leading dimension of B

    BETA          Scalar parameter

    C()           rectangular array with first dimension LDC.

    LDC           leading dimension of C

    WORK()        scratch array of length LWORK.

                  On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK   length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the ELL representation of a sparse matrix. They are not used anyway in these cases.

But if UNITD=4, the unit diagonal elements MUST be referenced in the ELL representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

REAL, DIMENSION(:) :: WORK

SUBROUTINE FFT2B_64([M], [N], A, [LDA], WORK, LWORK)

COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LWORK
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void cfft2b(int m, int n, complex *a, int lda, float  *work,
          int lwork);

void cfft2b_64(long m, long n, complex *a, long  lda,  float
          *work, long lwork);
```

ARGUMENTS

```
M (input) Number of rows to be transformed.   These  subrou-
          tines  are  most  efficient when M is a product of
          small primes.  M >= 0.
N (input) Number of columns to be transformed.   These  sub-
          routines are most efficient when N is a product of
          small primes.  N >= 0.

A (input/output)
          On entry, a two-dimensional array A(M,N) that con-
          tains the sequences to be transformed.

LDA (input)
          Leading dimension of the array containing the data
          to be transformed.  LDA >= M.

WORK (input)
          On input, workspace WORK must have  been  initial-
          ized by CFFT2I.

LWORK (input)
          The dimension of the array WORK.  LWORK >= (4 * (M
          + N) + 30)
```

          *work, long lwork);
```

ARGUMENTS

```
M (input) Number of rows to be transformed.   These  subrou-
          tines  are  most  efficient when M is a product of
          small primes.  M >= 0.
N (input) Number of columns to be transformed.   These  sub-
          routines are most efficient when N is a product of
          small primes.  N >= 0.

A (input/output)
          On entry, a two-dimensional array A(M,N) that con-
          tains the sequences to be transformed.

LDA (input)
          Leading dimension of the array containing the data
          to be transformed.  LDA >= M.

WORK (input)
          On input, workspace WORK must have  been  initial-
          ized by CFFT2I.

LWORK (input)
          The dimension of the array WORK.  LWORK >= (4 * (M
          + N) + 30)
```

Contents

NAME

```
cfft2i - initialize the array WSAVE, which is used  in  both
the forward and backward transforms.
```

SYNOPSIS

```
SUBROUTINE CFFT2I(M, N, WORK)

INTEGER M, N
REAL WORK(*)

SUBROUTINE CFFT2I_64(M, N, WORK)

INTEGER*8 M, N
REAL WORK(*)
```

F95 INTERFACE

```
SUBROUTINE CFFT2I(M, N, WORK)

INTEGER :: M, N
REAL, DIMENSION(:) :: WORK

SUBROUTINE CFFT2I_64(M, N, WORK)

INTEGER(8) :: M, N
REAL, DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void cfft2i(int m, int n, float *work);

void cfft2i_64(long m, long n, float *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

WORK (input/output)
On entry, an array of dimension (4 * (M + N) + 30) or greater. CFFT2I needs to be called only once to initialize array WORK before calling CFFT2F and/or CFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

SUBROUTINE FFT_64(IOPT, [N], [SCALE], X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)
```

```
INTEGER(8), INTENT(IN) :: IOPT
INTEGER(8), INTENT(IN), OPTIONAL :: N, LWORK
REAL, INTENT(IN), OPTIONAL :: SCALE
COMPLEX, INTENT(IN), DIMENSION(:) :: X
COMPLEX, INTENT(OUT), DIMENSION(:) :: Y
REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS
INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
REAL, INTENT(OUT), DIMENSION(:) :: WORK
INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>

void cfftc_ (int *iopt, int *n, float  *scale,  complex  *x,
          complex  *y, float *trigs, int *ifac, float *work,
          int *lwork, int *ierr);

void cfftc_64_ (long *iopt, long *n, float  *scale,  complex
          *x,  complex  *y,  float *trigs, long *ifac, float
          *work, long *lwork, long *ierr);
```

PURPOSE

```
cfftc initializes the trigonometric weight and factor tables
or  computes the Fast Fourier transform (forward or inverse)
of a complex sequence as follows:

               N-1
Y(k) = scale * SUM  W*X(j)
               j=0

where
k ranges from 0 to N-1
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W = exp(isign*i*j*k*2*pi/N)
```

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = -1 computes forward FFT
          IOPT = +1 computes inverse FFT
```

N (input)
Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)
Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) On entry, X is a complex array of dimension at least N that contains the sequence to be transformed.

Y (output)
Complex array of dimension at least N that contains the transform results. X and Y may be the same array starting at the same memory location. Otherwise, it is assumed that there is no overlap between X and Y in memory.

TRIGS (input/output)
Real array of length 2*N that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)
Real array of dimension at least 2*N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0, 1 or -1
-2 = N < 0

```
-3 = (LWORK is not 0) and (LWORK is less than 2*N)
-4 = memory allocation for workspace failed
```

               *ldy, float *trigs, long *ifac, float *work,  long
               *lwork, long *ierr);
```

PURPOSE

cfftc2 initializes the trigonometric weight and factor tables or computes the two-dimensional Fast Fourier Transform (forward or inverse) of a two-dimensional complex array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the columns of the input array. One-dimensional FFTs are then computed along the rows of the intermediate results.

```
                   N2-1  N1-1
Y(k1,k2) = scale * SUM   SUM   W2*W1*X(j1,j2)
                   j2=0  j1=0
```

where
k1 ranges from 0 to N1-1 and k2 ranges from 0 to N2-1
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W1 = exp(isign*i*j1*k1*2*pi/N1)
W2 = exp(isign*i*j2*k2*2*pi/N2)

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT
IOPT = +1 computes inverse FFT

N1 (input)
Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. N2 >= 0. Unchanged on exit.

SCALE (input)
Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains input data to be transformed.

LDX (input)
Leading dimension of X. LDX >= N1 Unchanged on exit.

Y (output)
Y is a complex array of dimensions (LDY, N2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. If X and Y are the same array, LDY = LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)
Real array of length 2*(N1+N2) that contains the trigonometric weights. The weights are computed

when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)
Real array of dimension at least 2*MAX(N1,N2)*NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0, 1 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1)
-5 = (LDY < N1) or (LDY not equal LDX when X and Y are same array)
-6 = (LWORK not equal 0) and (LWORK < 2*MAX(N1,N2)*NCPUS)
-7 = memory allocation failed

SEE ALSO

fft

CAUTIONS

On exit, entire output array Y(1:LDY, 1:N2) is overwritten.

          long *ifac, float *work, long *lwork, long *ierr);
```

PURPOSE

cfftc3 initializes the trigonometric weight and factor tables or computes the three-dimensional Fast Fourier Transform (forward or inverse) of a three-dimensional complex array.

```
                      N3-1  N2-1  N1-1
Y(k1,k2,k3) = scale * SUM   SUM   SUM   W3*W2*W1*X(j1,j2,j3)
                      j3=0  j2=0  j1=0
```

where
k1 ranges from 0 to N1-1; k2 ranges from 0 to N2-1 and k3 ranges from 0 to N3-1

```
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W1 = exp(isign*i*j1*k1*2*pi/N1)
W2 = exp(isign*i*j2*k2*2*pi/N2)
W3 = exp(isign*i*j3*k3*2*pi/N3)
```

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = -1 computes forward FFT
          IOPT = +1 computes inverse FFT

N1 (input)
          Integer specifying length of the transform in  the
          first  dimension.  N1 is most efficient when it is
          a product of small primes.  N1 >= 0.  Unchanged on
          exit.

N2 (input)
          Integer specifying length of the transform in  the
          second dimension.  N2 is most efficient when it is
          a product of small primes.  N2 >= 0.  Unchanged on
          exit.

N3 (input)
          Integer specifying length of the transform in  the
          third  dimension.  N3 is most efficient when it is
          a product of small primes.  N3 >= 0.  Unchanged on
          exit.

SCALE (input)
          Real scalar by which transform results are scaled.
          Unchanged  on exit.  SCALE is defaulted to 1.0 for
          F95 INTERFACE.

X (input) X is a complex array of  dimensions  (LDX1,  LDX2,
          N3) that contains input data to be transformed.

LDX1 (input)
          first dimension of X.  LDX1  >=  N1  Unchanged  on
          exit.

LDX2 (input)
          second dimension of X.  LDX2 >=  N2  Unchanged  on
          exit.
```

Y (output)

Y is a complex array of dimensions (LDY1, LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)

first dimension of Y. If X and Y are the same array, LDY1 = LDX1 Else LDY1 >= N1 Unchanged on exit.

LDY2 (input)

second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)

Real array of length 2*(N1+N2+N3) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 3*128 that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least (2*MAX(N,N2,N3) + 32*N3) * NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return

-1 = IOPT is not 0, 1 or -1

```
-2 = N1 < 0
-3 = N2 < 0
-4 = N3 < 0
-5 = (LDX1 < N1)
-6 = (LDX2 < N2)
-7 = (LDY1 < N1) or (LDY1 not equal  LDX1  when  X
and Y are same array)
-8 = (LDY2 < N2) or (LDY2 not equal  LDX2  when  X
and Y are same array)
-9  =  (LWORK  not   equal   0)   and   (LWORK   <
(2*MAX(N,N2,N3) + 16*N3) * NCPUS)
-10 = memory allocation failed
```

SEE ALSO

fft

CAUTIONS

This routine uses Y(N1+1:LDY1,:,:) as scratch space. Therefore, the original contents of this subarray will be lost upon returning from routine while subarray Y(1:N1,1:N2,1:N3) contains the transform results.

```

PURPOSE

cfftcm initializes the trigonometric weight and factor tables or computes the one-dimensional Fast Fourier Transform (forward or inverse) of a set of data sequences stored in a two-dimensional complex array:

```
            N1-1
     Y(k,l) = SUM  W*X(j,l)
            j=0

     where
     k ranges from 0 to N1-1 and l ranges from 0 to N2-1
     i = sqrt(-1)
     isign = 1 for inverse transform or -1 for forward transform
     W = exp(isign*i*j*k*2*pi/N1)
```

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT
IOPT = +1 computes inverse FFT

N1 (input)
Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)
Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns.

LDX (input)
Leading dimension of X. LDX >= N1 Unchanged on exit.

Y (output)
Y is a complex array of dimensions (LDY, N2) that contains the transform results of the input sequences. X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. If X and Y are the same array, LDY = LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)
Real array of length 2*N1 that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1 or IOPT = -1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least 2*N1*NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0, 1 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1)

NAME

```
cfftf - compute  the  Fourier  coefficients  of  a  periodic
sequence.  The FFT operations are unnormalized, so a call of
CFFTF followed by a call of CFFTB will  multiply  the  input
sequence by N.
```

SYNOPSIS

```
SUBROUTINE CFFTF(N, X, WSAVE)

COMPLEX X(*)
INTEGER N
REAL WSAVE(*)

SUBROUTINE CFFTF_64(N, X, WSAVE)

COMPLEX X(*)
INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTF([N], X, WSAVE)

COMPLEX, DIMENSION(:) :: X
INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE FFTF_64([N], X, WSAVE)

COMPLEX, DIMENSION(:) :: X
INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cfftf(int n, complex *x, float *wsave);

void cfftf_64(long n, complex *x, float *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input) On entry, an array  of  length  N  containing  the
          sequence to be transformed.

WSAVE (input)
          On entry, WSAVE must be an array of dimension (4 *
          N  + 15) or greater and must have been initialized
          by CFFTI.
```

Contents

NAME

```
cffti - initialize the array WSAVE, which is  used  in  both
CFFTF and CFFTB.
```

SYNOPSIS

```
SUBROUTINE CFFTI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE CFFTI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE CFFTI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE CFFTI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cffti(int n, float *wsave);

void cffti_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input/output)
On entry, an array of dimension (4 * N + 15) or greater. CFFTI needs to be called only once to initialize array WORK before calling CFFTF and/or CFFTB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

```
cfftopt - compute the length of the closest fast FFT
```

SYNOPSIS

```
INTEGER FUNCTION CFFTOPT(LEN)

INTEGER LEN

INTEGER*8 FUNCTION CFFTOPT_64(LEN)

INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION CFFTOPT(LEN)

INTEGER :: LEN

INTEGER(8) FUNCTION CFFTOPT_64(LEN)

INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>

int cfftopt(int len);

long cfftopt_64(long len);
```

PURPOSE

```
cfftopt computes the length of the closest fast  FFT.   Fast
```

Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length 32=2**5 will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

CFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. CFFTOPT will return 16 for an input of N=16 and return 18=2*3*3 for an input of N=17.

Note that the length computed here is not guaranteed to be optimal, only to be a product of small primes. Also, the value returned may change as the underlying FFTs become capable of handling larger primes. For example, passing in N=51 today will return 52=2*2*13 rather than 51=3*17 because the FFTs in Performance Library do not have fast radix 17 code. In the future, radix 17 code may be added and then N=51 will return 51.

NAME

```
cffts -  initialize  the  trigonometric  weight  and  factor
tables  or  compute  the inverse Fast Fourier Transform of a
complex sequence as follows.
```

SYNOPSIS

```
SUBROUTINE CFFTS(IOPT, N, SCALE, X, Y, TRIGS, IFAC, WORK, LWORK, IERR)

INTEGER IOPT, N, IFAC(*), LWORK, IERR
COMPLEX X(*)
REAL SCALE, Y(*), TRIGS(*), WORK(*)

SUBROUTINE CFFTS_64(IOPT, N, SCALE, X, Y, TRIGS, IFAC, WORK, LWORK, IERR)

INTEGER*8 IOPT, N, IFAC(*), LWORK, IERR
REAL SCALE, Y(*), TRIGS(*), WORK(*)
COMPLEX X(*)
```

F95 INTERFACE

```
SUBROUTINE FFT(IOPT, N, [SCALE], X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)

INTEGER*4, INTENT(IN) :: IOPT, N
INTEGER*4, INTENT(IN), OPTIONAL :: LWORK
REAL, INTENT(IN), OPTIONAL :: SCALE
COMPLEX, INTENT(IN), DIMENSION(:) :: X
REAL, INTENT(OUT), DIMENSION(:) :: Y
REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS
INTEGER*4, INTENT(INOUT), DIMENSION(:) :: IFAC
REAL, INTENT(OUT), DIMENSION(:) :: WORK
INTEGER*4, INTENT(OUT) :: IERR

SUBROUTINE FFT_64(IOPT, N, [SCALE], X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)
```

```
INTEGER(8), INTENT(IN) :: IOPT, N
INTEGER(8), INTENT(IN), OPTIONAL :: LWORK
REAL, INTENT(IN), OPTIONAL :: SCALE
COMPLEX, INTENT(IN), DIMENSION(:) :: X
REAL, INTENT(OUT), DIMENSION(:) :: Y
REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS
INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
REAL, INTENT(OUT), DIMENSION(:) :: WORK
INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>

void cffts_ (int *iopt, int *n, float  *scale,  complex  *x,
          float  *y,  float  *trigs, int *ifac, float *work,
          int *lwork, int *ierr);

void cffts_64_ (long *iopt, long *n, float  *scale,  complex
          *x,  float  *y,  float  *trigs,  long *ifac, float
          *work, long *lwork, long *ierr);
```

PURPOSE

```
cffts initializes the trigonometric weight and factor tables
or  computes the inverse Fast Fourier Transform of a complex
sequence as follows:

               N-1
Y(k) = scale * SUM  W*X(j)
               j=0

where
k ranges from 0 to N-1
i = sqrt(-1)
isign = 1 for inverse transform or -1 for forward transform
W = exp(isign*i*j*k*2*pi/N)
In complex-to-real transform of length N, the  (N/2+1)  com-
plex  input  data  points  stored are the positive-frequency
half of the spectrum of the Discrete Fourier Transform.  The
other  half  can be obtained through complex conjugation and
therefore is not stored.  Furthermore, due to symmetries the
imaginary  of the component of X(0) and X(N/2) (if N is even
in the latter) is assumed to be zero and is not referenced.
```

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = 1 computes inverse FFT

N (input)
Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)
Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) On entry, X is a complex array whose first (N/2+1) elements are the input sequence to be transformed.

Y (output)
Real array of dimension at least N that contains the transform results. X and Y may be the same array starting at the same memory location. Otherwise, it is assumed that there is no overlap between X and Y in memory.

TRIGS (input/output)
Real array of length 2*N that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = 1. Unchanged on exit.

WORK (workspace)
Real array of dimension at least N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following

values:
0 = normal return
-1 = IOPT is not 0 or 1
-2 = N < 0
-3 = (LWORK is not 0) and (LWORK is less than N)
-4 = memory allocation for workspace failed

               *ldy, float *trigs, long *ifac, float *work,  long
               *lwork, long *ierr);
```

PURPOSE

```
     cffts2  initializes  the  trigonometric  weight  and  factor
     tables  or computes the two-dimensional inverse Fast Fourier
     Transform of a two-dimensional complex array.  In  computing
     the  two-dimensional  FFT, one-dimensional FFTs are computed
     along the rows of the input array.  One-dimensional FFTs are
     then computed along the columns of the intermediate results.

                        N1-1  N2-1
     Y(k1,k2) = scale * SUM   SUM   W2*W1*X(j1,j2)
                        j1=0  j2=0

     where
     k1 ranges from 0 to N1-1 and k2 ranges from 0 to N2-1
     i = sqrt(-1)
     isign = 1 for inverse transform
     W1 = exp(isign*i*j1*k1*2*pi/N1)
     W2 = exp(isign*i*j2*k2*2*pi/N2)
     In complex-to-real transform of length N1, the (N1/2+1) com-
     plex  input  data  points  stored are the positive-frequency
```

half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = 1 computes inverse FFT

N1 (input)
Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes. N2 >= 0. Unchanged on exit.

SCALE (input)
Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains input data to be transformed.

LDX (input)
Leading dimension of X. LDX >= (N1/2 + 1) Unchanged on exit.

Y (output)
Y is a real array of dimensions (LDY, N2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. If X and Y are the same array, LDY = 2*LDX Else LDY >= 2*LDX and LDY must

be even. Unchanged on exit.

TRIGS (input/output)

Real array of length 2*(N1+N2) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)

Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)

Real array of dimension at least MAX(N1,2*N2)*NCPUS, where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)

Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)

On exit, integer IERR has one of the following values:

0 = normal return
-1 = IOPT is not 0, 1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1/2+1)
-5 = LDY not equal 2*LDX when X and Y are same array
-6 = (LDY < 2*LDX or LDY odd) when X and Y are same array
-7 = (LWORK not equal 0) and (LWORK < MAX(N1,2*N2)*NCPUS)
-8 = memory allocation failed

SEE ALSO

fft

CAUTIONS

Y(N1+1:LDY,:) is used as scratch space. Upon returning, the original contents of Y(N1+1:LDY,:) will be lost, whereas Y(1:N1,1:N2) contains the transform results.

```

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = +1 computes inverse FFT

N1 (input)
          Integer specifying length of the transform in  the
          first  dimension.  N1 is most efficient when it is
          a product of small primes.  N1 >= 0.  Unchanged on
          exit.

N2 (input)
          Integer specifying length of the transform in  the
          second dimension.  N2 is most efficient when it is
          a product of small primes.  N2 >= 0.  Unchanged on
          exit.
N3 (input)
          Integer specifying length of the transform in  the
          third  dimension.  N3 is most efficient when it is
          a product of small primes.  N3 >= 0.  Unchanged on
          exit.

SCALE (input)
          Real scalar by which transform results are scaled.
          Unchanged  on exit.  SCALE is defaulted to 1.0 for
          F95 INTERFACE.

X (input) X is a complex array of  dimensions  (LDX1,  LDX2,
          N3) that contains input data to be transformed.

LDX1 (input)
          first dimension of X.  LDX1 >= N1/2+1 Unchanged on
          exit.

LDX2 (input)
          second dimension of X.  LDX2 >=  N2  Unchanged  on
          exit.

Y (output)
          Y is a complex array of  dimensions  (LDY1,  LDY2,
          N3)  that contains the transform results.  X and Y
          can be the same array starting at the same  memory
```

location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)
first dimension of Y. If X and Y are the same array, LDY1 = 2*LDX1 Else LDY1 >= 2*LDX1 and LDY1 is even Unchanged on exit.

LDY2 (input)
second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)
Real array of length 2*(N1+N2+N3) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 3*128 that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)
Real array of dimension at least (MAX(N,2*N2,2*N3) + 16*N3) * NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or 1
-2 = N1 < 0
-3 = N2 < 0
-4 = N3 < 0
-5 = (LDX1 < N1/2+1)
-6 = (LDX2 < N2)

-7 = LDY1 not equal 2*LDX1 when X and Y are same array
-8 = (LDY1 < 2*LDX1) or (LDY1 is odd) when X and Y are not same array
-9 = (LDY2 < N2) or (LDY2 not equal LDX2) when X and Y are same array
-10 = (LWORK not equal 0) and ((LWORK < MAX(N,2*N2,2*N3) + 16*N3)*NCPUS)
-11 = memory allocation failed

fft

CAUTIONS

This routine uses Y(N1+1:LDY1,:,:) as scratch space. Therefore, the original contents of this subarray will be lost upon returning from routine while subarray Y(1:N1,1:N2,1:N3) contains the transform results.

Contents

NAME

```
     cfftsm - initialize  the  trigonometric  weight  and  factor
     tables  or  compute the one-dimensional inverse Fast Fourier
     Transform of a set of complex data  sequences  stored  in  a
     two-dimensional array.
```

SYNOPSIS

```
     SUBROUTINE CFFTSM(IOPT, N1, N2, SCALE, X, LDX, Y, LDY, TRIGS, IFAC, WORK,
LWORK, IERR)

     INTEGER IOPT, N1, N2, LDX, LDY, IFAC(*), LWORK, IERR
     COMPLEX X(LDX, *)
     REAL SCALE, Y(LDY, *), TRIGS(*), WORK(*)

     SUBROUTINE CFFTSM_64(IOPT, N1, N2, SCALE, X, LDX, Y, LDY, TRIGS, IFAC, WORK,
LWORK, IERR)

     INTEGER*8 IOPT, N1, N2, LDX, LDY, IFAC(*), LWORK, IERR
     REAL SCALE, Y(LDY,*), TRIGS(*), WORK(*)
     COMPLEX X(LDX, *)
```

F95 INTERFACE

WORK, [LWORK], IERR)

     INTEGER(8), INTENT(IN) :: IOPT, N1
     INTEGER(8), INTENT(IN), OPTIONAL :: N2, LDX, LDY, LWORK
     REAL, INTENT(IN), OPTIONAL :: SCALE
     COMPLEX, INTENT(IN), DIMENSION(:,:) :: X
     REAL, INTENT(OUT), DIMENSION(:,:) :: Y
     REAL, INTENT(INOUT), DIMENSION(:) :: TRIGS
     INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
     REAL, INTENT(OUT), DIMENSION(:) :: WORK
     INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
     #include <sunperf.h>
     void cfftsm_ (int *iopt, int *n1,  int  *n2,  float  *scale,
               complex  *x,  int  *ldx, float *y, int *ldy, float
               *trigs, int *ifac, float *work,  int  *lwork,  int
               *ierr);

     void cfftsm_64_ (long  *iopt,  long  *n1,  long  *n2,  float
               *scale,  complex  *x,  long  *ldx,  float *y, long
               *ldy, float *trigs, long *ifac, float *work,  long
               *lwork, long *ierr);
```

PURPOSE

cfftsm initializes the trigonometric weight and factor tables or computes the one-dimensional inverse Fast Fourier Transform of a set of complex data sequences stored in a two-dimensional array:

```
                     N1-1
     Y(k,l) = scale * SUM  W*X(j,l)
                     j=0
```

where
k ranges from 0 to N1-1 and l ranges from 0 to N2-1
i = sqrt(-1)
isign = 1 for inverse transform
W = exp(isign*i*j*k*2*pi/N1)
In complex-to-real transform of length N1, the (N1/2+1) complex input data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored. Furthermore, due to symmetries the

imaginary of the component of X(0,0:N2-1) and X(N1/2,0:N2-1) (if N1 is even in the latter) is assumed to be zero and is not referenced.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = 1 computes inverse FFT

N1 (input)
Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)
Real scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0 for F95 INTERFACE.

X (input) X is a complex array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns in X(0:N1/2, 0:N2-1).

LDX (input)
Leading dimension of X. LDX >= (N1/2+1) Unchanged on exit.

Y (output)
Y is a real array of dimensions (LDY, N2) that contains the transform results of the input sequences in Y(0:N1-1,0:N2-1). X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. If X and Y are the same array, LDY = 2*LDX Else LDY >= N1 Unchanged on exit.

TRIGS (input/output)
Real array of length 2*N1 that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = 1. Unchanged on exit.

WORK (workspace)
Real array of dimension at least N1. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or 1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1/2+1)
-5 = (LDY < N1) or (LDY not equal 2*LDX when X and Y are same array)
-6 = (LWORK not equal 0) and (LWORK < N1)
-7 = memory allocation failed

             *e, complex *q, long ldq, complex *pt, long  ldpt,
             complex *c, long ldc, long *info);
```

PURPOSE

cgbbrd reduces a complex general m-by-n band matrix A to real upper bidiagonal form B by a unitary transformation: Q' * A * P = B.

The routine computes B, and optionally forms Q or P', or computes Q'*C for a given matrix C.

ARGUMENTS

VECT (input)
Specifies whether or not the matrices Q and P' are to be formed. = 'N': do not form Q or P';
= 'Q': form Q only;
= 'P': form P' only;
= 'B': form both.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NCC (input)
The number of columns of the matrix C. NCC >= 0.

KL (input)
The number of subdiagonals of the matrix A. KL >=

0.

KU (input)
The number of superdiagonals of the matrix A. KU >= 0.

AB (input/output)
On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl). On exit, A is overwritten by values generated during the reduction.

LDAB (input)
The leading dimension of the array A. LDAB >= KL+KU+1.

D (output)
The diagonal elements of the bidiagonal matrix B.

E (output)
The superdiagonal elements of the bidiagonal matrix B.

Q (output)
If VECT = 'Q' or 'B', the m-by-m unitary matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT (output)
If VECT = 'P' or 'B', the n-by-n unitary matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT (input)
The leading dimension of the array PT. LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C (input/output)
On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q'*C. C is not referenced if NCC = 0.

LDC (input)
The leading dimension of the array C. LDC >=

```
          max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.

WORK (workspace)
          dimension(MAX(M,N))

RWORK (workspace)
          dimension(MAX(M,N))

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.

COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, NSUB, NSUPER, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void cgbcon(char norm, int n, int nsub, int nsuper,  complex
          *a,  int  lda,  int  *ipivot,  float  anorm, float
          *rcond, int *info);

void cgbcon_64(char norm, long n, long  nsub,  long  nsuper,
          complex  *a,  long lda, long *ipivot, float anorm,
          float *rcond, long *info);
```

PURPOSE

cgbcon estimates the reciprocal of the condition number of a complex general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. N >= 0.

NSUB (input)
The number of subdiagonals within the band of A.
NSUB >= 0.

NSUPER (input)
The number of superdiagonals within the band of A.
NSUPER >= 0.

A (input) Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with NSUB+NSUPER superdiagonals in rows 1 to NSUB+NSUPER+1, and the multipliers used during the factorization are stored in rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDA (input)
The leading dimension of the array A. LDA >= 2*NSUB+NSUPER+1.

IPIVOT (input)
The pivot indices; for 1 <= i <= N, row i of the matrix was interchanged with row IPIVOT(i).

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension (N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
          ROWCND, COLCND, AMAX, [INFO])

COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, KL, KU, LDA, INFO
REAL :: ROWCND, COLCND, AMAX
REAL, DIMENSION(:) :: R, C
```

C INTERFACE

```
#include <sunperf.h>

void cgbequ(int m, int n, int kl, int ku,  complex  *a,  int
          lda,  float  *r,  float  *c,  float *rowcnd, float
          *colcnd, float *amax, int *info);
void cgbequ_64(long m, long n, long kl, long ku, complex *a,
          long lda, float *r, float *c, float *rowcnd, float
          *colcnd, float *amax, long *info);
```

PURPOSE

cgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

A (input) The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

R (output)
If INFO = 0, or INFO > M, R contains the row scale factors for A.

C (output)
If INFO = 0, C contains the column scale factors for A.

ROWCND (output)
If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND (output)
If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

       X, [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: TRANSA
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>

void cgbmv(char transa, int m, int n, int nsub, int  nsuper,
          complex  *alpha,  complex *a, int lda, complex *x,
          int incx, complex *beta, complex *y, int incy);
void cgbmv_64(char transa, long m, long n, long  nsub,  long
          nsuper, complex *alpha, complex *a, long lda, com-
          plex *x, long incx,  complex  *beta,  complex  *y,
          long incy);
```

PURPOSE

cgbmv performs one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with nsub sub-diagonals and nsuper super-diagonals.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:
TRANSA = 'N' or 'n'   y := alpha*A*x + beta*y.
TRANSA = 'T' or 't'   y := alpha*A'*x + beta*y.
TRANSA = 'C' or 'c'   y := alpha*conjg(A')*x + beta*y.
Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix A. M must be at least zero. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. N must be at least zero. Unchanged on exit.

NSUB (input)
On entry, NSUB specifies the number of sub-diagonals of the matrix A. NSUB must satisfy 0 .le. NSUB. Unchanged on exit.

NSUPER (input)
On entry, NSUPER specifies the number of super-diagonals of the matrix A. NSUPER must satisfy 0 .le. NSUPER. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry, the leading (nsub + nsuper + 1) by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (nsuper + 1) of the array, the first super-diagonal starting at position 2 in row nsuper, the first sub-diagonal starting at position 1 in row (nsuper + 2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left nsuper by nsuper triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
    DO 20, J = 1, N
      K = NSUPER + 1 - J
      DO 10, I = MAX( 1, J - NSUPER ), MIN( M, J +
NSUB )
        A( K + I, J ) = matrix( I, J )
10    CONTINUE
20 CONTINUE
```

Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA must be at least (nsub + nsuper + 1). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)) when TRANSA = 'N' or

'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (m - 1)*abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

          *info);
```

PURPOSE

cgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.
```

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input)
Details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL*KU+1.

IPIVOT (input)
The pivot indices from CGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CGBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >=

max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void cgbsv(int n, int kl, int ku, int nrhs, complex *a,  int
          lda, int *ipivot, complex *b, int ldb, int *info);

void cgbsv_64(long n, long kl, long ku, long  nrhs,  complex
          *a,  long lda, long *ipivot, complex *b, long ldb,
          long *info);
```

PURPOSE

cgbsv computes the solution to a complex system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as A = L * U, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the matrix A in band storage, in rows

KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: A(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL) On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDA (input)
The leading dimension of the array A. LDA >= 2*KL+KU+1.

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

On entry: On exit:

```
    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
```

```
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

          float  *c,  complex *b, long ldb, complex *x, long
          ldx, float *rcond, float *ferr, float *berr,  long
          *info);
```

PURPOSE

cgbsvx uses the LU factorization to compute the solution to a complex system of linear equations A * X = B, A**T * X = B, or A**H * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

```
1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X  =
diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X  =
diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X  =
diag(C)*B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(R)*A*diag(C) and B by  diag(R)*B  (if
TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').
2. If FACT = 'N' or 'E', the LU  decomposition  is  used  to
factor the
   matrix A (after equilibration if FACT = 'E') as
      A = L * U,
   where L is a product of permutation and unit  lower  tri-
angular
   matrices with KL subdiagonals, and U is upper  triangular
with
   KL+KU superdiagonals.

3. If some U(i,i)=0, so that U is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.

6. If equilibration was used, the matrix X is  premultiplied
```

```
by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS  =  'T'  or
'C') so
   that it solves the original system before equilibration.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored form of  the
          matrix A is supplied on entry, and if not, whether
          the matrix A should be equilibrated before  it  is
          factored.  = 'F':  On entry, AF and IPIVOT contain
          the factored form of A.  If EQUED is not 'N',  the
          matrix  A  has been equilibrated with scaling fac-
          tors given by R and C.  A, AF, and IPIVOT are  not
          modified.   = 'N':  The matrix A will be copied to
          AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

TRANSA (input)
          Specifies the form of the system of  equations.  =
          'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

KL (input)
          The number of subdiagonals within the band  of  A.
          KL >= 0.

KU (input)
          The number of superdiagonals within the band of A.
          KU >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the matrix A in band storage, in rows  1
          to KL+KU+1.  The j-th column of A is stored in the
          j-th column of the array A as follows:   A(KU+1+i-
          j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)
```

If FACT = 'F' and EQUED is not 'N', then A must have been equilibrated by the scaling factors in R and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A
EQUED = 'C': A := A * diag(C)
EQUED = 'B': A := diag(R) * A * diag(C).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by CGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL+KU+1.

IPIVOT (input)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by CGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the equilibrated matrix

A.

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input/output)
The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input/output)
The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)
On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))*X if TRANSA = 'N' and EQUED = 'C' or 'B', or inv(diag(R))*X if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N) On exit, WORK2(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is

<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

INTEGER*8 IPIV(*)
```

F95 INTERFACE

```
SUBROUTINE GBTF2([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])

COMPLEX, DIMENSION(:,:) :: AB
INTEGER :: M, N, KL, KU, LDAB, INFO
INTEGER, DIMENSION(:) :: IPIV

SUBROUTINE GBTF2_64([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])

COMPLEX, DIMENSION(:,:) :: AB
INTEGER(8) :: M, N, KL, KU, LDAB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>

void cgbtf2(int m, int n, int kl, int ku, complex  *ab,  int
          ldab, int *ipiv, int *info);

void cgbtf2_64(long m, long n, long  kl,  long  ku,  complex
          *ab, long ldab, long *ipiv, long *info);
```

PURPOSE

cgbtf2 computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

AB (input/output)
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input)
The leading dimension of the array AB. LDAB >=

2*KL+KU+1.

IPIV (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

```
On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U, because of fill-in resulting from the row interchanges.

          *ab, long ldab, long *ipivot, long *info);
```

PURPOSE

cgbtrf computes an LU factorization of a complex m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

M (input) Integer
The number of rows of the matrix A. M >= 0.

N (input) Integer
The number of columns of the matrix A. N >= 0.

KL (input) Integer
The number of subdiagonals within the band of A. KL >= 0.

KU (input) Integer
The number of superdiagonals within the band of A. KU >= 0.

AB (input/output) Complex array of dimension (LDAB,N).
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The J-th column of A is stored in the J-th column of the array AB as follows: AB(KL+KU+1+I-J,J) = A(I,J) for MAX(1,J-KU)<=I<=MIN(M,J+KL)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input) Integer
The leading dimension of the array AB. LDAB >= 2*KL+KU+1.

IPIVOT (output) Integer array of dimension MIN(M,N)
The pivot indices; for 1 <= I <= MIN(M,N), row I of the matrix was interchanged with row IPIVOT(I).

INFO (output) Integer
= 0: successful exit
< 0: if INFO = -I, the I-th argument had an illegal value
> 0: if INFO = +I, U(I,I) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

```
On entry:                      On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

             *b, int ldb, int *info);
   void cgbtrs_64(char transa, long n, long nsub, long  nsuper,
             long  nrhs,  complex  *a,  long lda, long *ipivot,
             complex *b, long ldb, long *info);
```

PURPOSE

cgbtrs solves a system of linear equations
A * X = B, A**T * X = B, or A**H * X = B with a general band matrix A using the LU factorization computed by CGBTRF.

ARGUMENTS

```
   TRANSA (input)
             Specifies the form of the system of equations.   =
             'N':  A * X = B     (No transpose)
             = 'T':  A**T * X = B  (Transpose)
             = 'C':  A**H * X = B  (Conjugate transpose)

             TRANSA is defaulted to 'N' for F95 INTERFACE.

   N (input) The order of the matrix A.  N >= 0.

   NSUB (input)
             The number of subdiagonals within the band  of  A.
             NSUB >= 0.

   NSUPER (input)
             The number of superdiagonals within the band of A.
             NSUPER >= 0.

   NRHS (input)
             The number of right hand sides, i.e.,  the  number
             of columns of the matrix B.  NRHS >= 0.
```

```
A (input) Details of the LU factorization of the band matrix
          A, as computed by CGBTRF.  U is stored as an upper
          triangular band matrix with NSUB+NSUPER superdiag-
          onals  in  rows 1 to NSUB+NSUPER+1, and the multi-
          pliers used during the factorization are stored in
          rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          2*NSUB+NSUPER+1.
IPIVOT (input)
          The pivot indices; for 1 <= i <= N, row i  of  the
          matrix was interchanged with row IPIVOT(i).

B (input/output)
          On entry, the right hand side matrix B.  On  exit,
          the solution matrix X.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

INTEGER :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: SCALE

SUBROUTINE GEBAK_64(JOB, SIDE, [N], ILO, IHI, SCALE, [M], V, [LDV],
       [INFO])
```

```
CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX, DIMENSION(:,:) :: V
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void cgebak(char job, char side, int n, int  ilo,  int  ihi,
          float  *scale,  int  m,  complex  *v, int ldv, int
          *info);

void cgebak_64(char job, char side, long n, long  ilo,  long
          ihi,  float  *scale, long m, complex *v, long ldv,
          long *info);
```

PURPOSE

cgebak forms the right or left eigenvectors of a complex general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by CGEBAL.

ARGUMENTS

JOB (input)
Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to CGEBAL.

SIDE (input)
= 'R': V contains right eigenvectors;
= 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. N >= 0.

ILO (input)
The integer ILO determined by CGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
The integer IHI determined by CGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

SCALE (input)
Details of the permutation and scaling factors, as returned by CGEBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)
On entry, the matrix of right or left eigenvectors to be transformed, as returned by CHSEIN or CTREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)
The leading dimension of the array V. LDV >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

NAME

```
cgebal - balance a general complex matrix A
```

SYNOPSIS

```
SUBROUTINE CGEBAL(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)

CHARACTER * 1 JOB
COMPLEX A(LDA,*)
INTEGER N, LDA, ILO, IHI, INFO
REAL SCALE(*)

SUBROUTINE CGEBAL_64(JOB, N, A, LDA, ILO, IHI, SCALE, INFO)

CHARACTER * 1 JOB
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, ILO, IHI, INFO
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE GEBAL(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])

CHARACTER(LEN=1) :: JOB
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, ILO, IHI, INFO
REAL, DIMENSION(:) :: SCALE

SUBROUTINE GEBAL_64(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])

CHARACTER(LEN=1) :: JOB
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, ILO, IHI, INFO
```

```
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void cgebal(char job, int n, complex *a, int lda, int  *ilo,
          int *ihi, float *scale, int *info);

void cgebal_64(char job, long n, complex *a, long lda,  long
          *ilo, long *ihi, float *scale, long *info);
```

PURPOSE

cgebal balances a general complex matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input)
Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ILO (output)

ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)

ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

SCALE (output)

Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The permutations consist of row and column interchanges which put the matrix in the form

```
          ( T1   X   Y  )
  P A P = (  0   B   Z  )
          (  0   0   T2 )
```

where T1 and T2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ILO and IHI mark the starting and ending columns of the submatrix B. Balancing consists of applying a diagonal similarity transformation inv(D) * B * D to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

```
  ( T1     X*D          Y    )
  (  0  inv(D)*B*D  inv(D)*Z ).
  (  0      0           T2   )
```

Information about the permutations P and the diagonal matrix D is returned in the vector SCALE.

This subroutine is based on the EISPACK routine CBAL.

       [INFO])

COMPLEX, DIMENSION(:) :: TAUQ, TAUP, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: D, E

SUBROUTINE GEBRD_64([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],
       [LWORK], [INFO])

COMPLEX, DIMENSION(:) :: TAUQ, TAUP, WORK
```

```
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL, DIMENSION(:) :: D, E
```

C INTERFACE

```
#include <sunperf.h>

void cgebrd(int m, int n, complex *a,  int  lda,  float  *d,
          float   *e,  complex  *tauq,  complex  *taup,  int
          *info);

void cgebrd_64(long m, long n, complex *a, long  lda,  float
          *d,  float  *e, complex *tauq, complex *taup, long
          *info);
```

PURPOSE

cgebrd reduces a general complex M-by-N matrix A to upper or lower bidiagonal form B by a unitary transformation: Q**H * A * P = B.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

ARGUMENTS

M (input) The number of rows in the matrix A. M >= 0.

N (input) The number of columns in the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the unitary matrix P as a product of elementary reflec-

tors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

D (output)
The diagonal elements of the bidiagonal matrix B: D(i) = A(i,i).

E (output)
The off-diagonal elements of the bidiagonal matrix B: if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Q. See Further Details.

TAUP (output)
The scalar factors of the elementary reflectors which represent the unitary matrix P. See Further Details.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. LWORK >= max(1,M,N). For optimum performance LWORK >= (M+N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrices Q and P are represented as products of elementary reflectors:

If m >= n,

```
   Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)

Each H(i) and G(i) has the form:

   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

where tauq and taup are complex scalars, and  v  and  u  are
complex  vectors;  v(1:i-1)  =  0, v(i) = 1, and v(i+1:m) is
stored on exit in A(i+1:m,i); u(1:i) = 0, u(i+1)  =  1,  and
u(i+2:n)  is stored on exit in A(i,i+2:n); tauq is stored in
TAUQ(i) and taup in TAUP(i).
If m < n,

   Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)

Each H(i) and G(i) has the form:

   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'

where tauq and taup are complex scalars, and  v  and  u  are
complex  vectors;  v(1:i)  =  0, v(i+1) = 1, and v(i+2:m) is
stored on exit in A(i+2:m,i); u(1:i-1) = 0, u(i)  =  1,  and
u(i+1:n)  is stored on exit in A(i,i+1:n); tauq is stored in
TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by  the  following
examples:

m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

  (  d   e   u1  u1  u1 )           (  d   u1   u1   u1   u1
u1 )
  (  v1  d   e   u2  u2 )           (  e   d    u2   u2   u2
u2 )
  (  v1  v2  d   e   u3 )           (  v1  e    d    u3   u3
u3 )
  (  v1  v2  v3  d   e  )           (  v1  v2   e    d    u4
u4 )
  (  v1  v2  v3  v4  d  )           (  v1   v2   v3   e    d
u5 )
  (  v1  v2  v3  v4  v5 )

where d and e denote diagonal and off-diagonal  elements  of
B, vi denotes an element of the vector defining H(i), and ui
an element of the vector defining G(i).

          float anorm, float *rcond, long *info);
```

PURPOSE

cgecon estimates the reciprocal of the condition number of a general complex matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by CGETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

```
   RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

N (input) The order of the matrix A.  N >= 0.

A (input) The factors L and U from  the  factorization  A  =
          P*L*U as computed by CGETRF.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).
```

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE GEEQU_64([M], [N], A, [LDA], R, C, ROWCND, COLCND,
       AMAX, [INFO])
```

```
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, INFO
REAL :: ROWCND, COLCND, AMAX
REAL, DIMENSION(:) :: R, C
```

C INTERFACE

```
#include <sunperf.h>

void cgeequ(int m, int n, complex *a,  int  lda,  float  *r,
          float  *c,  float  *rowcnd,  float  *colcnd, float
          *amax, int *info);

void cgeequ_64(long m, long n, complex *a, long  lda,  float
          *r,  float *c, float *rowcnd, float *colcnd, float
          *amax, long *info);
```

PURPOSE

cgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input) The M-by-N matrix whose equilibration factors are to be computed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

R (output)
If INFO = 0 or INFO > M, R contains the row scale factors for A.

C (output)
If INFO = 0, C contains the column scale factors for A.

ROWCND (output)
If INFO = 0 or INFO > M, ROWCND contains the ratio of the smallest R(i) to the largest R(i). If ROWCND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCND (output)
If INFO = 0, COLCND contains the ratio of the smallest C(i) to the largest C(i). If COLCND >= 0.1, it is not worth scaling by C.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

C INTERFACE

```
#include <sunperf.h>

void cgees(char jobz,  char  sortev,  int(*select)(complex),
          int n, complex *a, int lda, int *nout, complex *w,
          complex *z, int ldz, int *info);

void      cgees_64(char       jobz,       char       sortev,
          long(*select)(complex),  long  n, complex *a, long
          lda, long *nout, complex *w, complex *z, long ldz,
          long *info);
```

PURPOSE

cgees computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z**H).

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

JOBZ (input)
 = 'N': Schur vectors are not computed;

= 'V': Schur vectors are computed.

SORTEV (input)
Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered:
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. The eigenvalue W(j) is selected if SELECT(W(j)) is true.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the N-by-N matrix A. On exit, A has been overwritten by its Schur form T.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

NOUT (output)
If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues for which SELECT is true.

W (output)
W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

Z (output)
If JOBZ = 'V', Z contains the unitary matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1; if JOBZ = 'V', LDZ >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,2*N). For good performance, LDWORK must

generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(N)

WORK3 (workspace)
dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is
<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT = .TRUE.. This could also be caused by underflow due to scaling.

          plex *a, long lda, long *nout, complex *w, complex
          *z,  long  ldz,  float  *rcone, float *rconv, long
          *info);
```

PURPOSE

cgeesx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues, the Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z**H).

Optionally, it also orders the eigenvalues on the diagonal of the Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A complex matrix is in Schur form if it is upper triangular.

ARGUMENTS

JOBZ (input)
= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

SORTEV (input)
Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to order to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue W(j) is selected if SELECT(W(j)) is true.

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for average of selected eigenvalues only;
= 'V': Computed for selected right invariant subspace only;
= 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORTEV must equal 'S'.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the N-by-N matrix A. On exit, A is overwritten by its Schur form T.

LDA (input)
The leading dimension of the array A. LDA >=

max(1,N).

NOUT (output)
If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues for which SELECT is true.

W (output)
W contains the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T.

Z (output)
If JOBZ = 'V', Z contains the unitary matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

RCONE (output)
If SENSE = 'E' or 'B', RCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONV (output)
If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
dimension(LDWORK) On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,2*N). Also, if SENSE = 'E' or 'V' or 'B', LDWORK >= 2*NOUT*(N-NOUT), where NOUT is the number of selected eigenvalues computed by this routine. Note that 2*NOUT*(N-NOUT) <= N*N/2. For good performance, LDWORK must generally be larger.

WORK2 (workspace)
dimension(N)

BWORK3 (workspace)
dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, and i is

<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of W contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the transformation which reduces A to its partially converged Schur form.
= N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

          long lda, complex *w, complex *vl, long ldvl, com-
          plex *vr, long ldvr, long *info);
```

PURPOSE

cgeev computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

The right eigenvector v(j) of A satisfies

A * v(j) = lambda(j) * v(j)

where lambda(j) is its eigenvalue.
The left eigenvector u(j) of A satisfies

u(j)**H * A = lambda(j) * u(j)**H

where u(j)**H denotes the conjugate transpose of u(j).

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

ARGUMENTS

JOBVL (input)
= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of are computed.

JOBVR (input)
= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed.

N (input) The order of the matrix A. N >= 0.

```
A (input/output)
          On entry, the N-by-N matrix A.   On  exit,  A  has
          been overwritten.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

W (output)
          W contains the computed eigenvalues.

VL (input)
          If JOBVL = 'V', the  left  eigenvectors  u(j)  are
          stored  one after another in the columns of VL, in
          the same order as their eigenvalues.  If  JOBVL  =
          'N',  VL  is  not referenced.  u(j) = VL(:,j), the
          j-th column of VL.

LDVL (input)
          The leading dimension of the array VL.  LDVL >= 1;
          if JOBVL = 'V', LDVL >= N.

VR (input)
          If JOBVR = 'V', the right  eigenvectors  v(j)  are
          stored  one after another in the columns of VR, in
          the same order as their eigenvalues.  If  JOBVR  =
          'N',  VR  is  not referenced.  v(j) = VR(:,j), the
          j-th column of VR.

LDVR (input)
          The leading dimension of the array VR.  LDVR >= 1;
          if JOBVR = 'V', LDVR >= N.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The  dimension  of  the  array  WORK.   LDWORK  >=
          max(1,2*N).   For  good  performance,  LDWORK must
          generally be larger.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.

WORK2 (workspace)
          dimension(2*N)
```

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements and i+1:N of W contain eigenvalues which have converged.

          long*,  long*,  float*,  float*,  float*,  float*,
          long*);
```

PURPOSE

cgeevx computes for an N-by-N complex nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right
eigenvectors (RCONDV).

```
The right eigenvector v(j) of A satisfies
                 A * v(j) = lambda(j) * v(j)
where lambda(j) is its eigenvalue.
The left eigenvector u(j) of A satisfies
              u(j)**H * A = lambda(j) * u(j)**H
where u(j)**H denotes the conjugate transpose of u(j).
```

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input)
Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute;
= 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, ie. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)
= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input)
= 'N': right eigenvectors of A are not computed;
= 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for eigenvalues only;

```
          = 'V': Computed for right eigenvectors only;
          = 'B': Computed for eigenvalues and  right  eigen-
          vectors.

          If SENSE = 'E' or 'B', both left and right  eigen-
          vectors  must  also  be  computed (JOBVL = 'V' and
          JOBVR = 'V').

N (input) The order of the matrix A. N >= 0.

A (input/output)
          On entry, the N-by-N matrix A.   On  exit,  A  has
          been  overwritten.  If JOBVL = 'V' or JOBVR = 'V',
          A contains the Schur form of the balanced  version
          of the matrix A.
LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

W (output)
          W contains the computed eigenvalues.

VL (input)
          If JOBVL = 'V', the  left  eigenvectors  u(j)  are
          stored  one after another in the columns of VL, in
          the same order as their eigenvalues.  If  JOBVL  =
          'N',  VL  is  not referenced.  u(j) = VL(:,j), the
          j-th column of VL.

LDVL (input)
          The leading dimension of the array VL.  LDVL >= 1;
          if JOBVL = 'V', LDVL >= N.

VR (input)
          If JOBVR = 'V', the right  eigenvectors  v(j)  are
          stored  one after another in the columns of VR, in
          the same order as their eigenvalues.  If  JOBVR  =
          'N',  VR  is  not referenced.  v(j) = VR(:,j), the
          j-th column of VR.

LDVR (input)
          The leading dimension of the array VR.  LDVR >= 1;
          if JOBVR = 'V', LDVR >= N.

ILO (output)
          ILO and IHI are integer values determined  when  A
          was  balanced.   The  balanced A(i,j) = 0 if I > J
          and J = 1,...,ILO-1 or I = IHI+1,...,N.

IHI (output)
```

ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

SCALE (output)
Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)
The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONE (output)
RCONE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONV (output)
RCONV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (output)
The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK >= max(1,2*N), and if SENSE = 'V' or 'B', LDWORK >= N*N+2*N. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of W contain eigenvalues which have converged.

          *vsr, long ldvsr, long *info);
```

PURPOSE

cgegs routine is deprecated and has been replaced by routine CGGES.

CGEGS computes for a pair of N-by-N complex nonsymmetric matrices A, B: the generalized eigenvalues (alpha, beta), the complex Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver CGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one unitary matrix and both on the right by another unitary matrix, these two unitary matrices being chosen so as to bring the pair of matrices into upper triangular form with the diagonal elements of B being non-negative real numbers (this is also called complex Schur form.)

The left and right Schur vectors are the columns of VSL and VSR, respectively, where VSL and VSR are the unitary matrices
which reduce A and B to Schur form:

Schur form of (A,B) = ((VSL)**H A (VSR), (VSL)**H B (VSR))

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of A.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) Schur vectors are to be computed. On exit, the generalized Schur form of B.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) output by CGEGS. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
See the description of ALPHA.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL >= 1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

LDVSR (input)
The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,2*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for CGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the blocksizes for CGEQRF, CUNMQR, and CUNGQR; the optimal LDWORK is N*(NB+1).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(3*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from CGGBAL
=N+2: error return from CGEQRF
=N+3: error return from CUNMQR
=N+4: error return from CUNGQR
=N+5: error return from CGGHRD
=N+6: error return from CHGEQZ (other than failed iteration) =N+7: error return from CGGBAK (computing VSL)
=N+8: error return from CGGBAK (computing VSR)
=N+9: error return from CLASCL (various places)

```

PURPOSE

cgegv routine is deprecated and has been replaced by routine CGGEV.

CGEGV computes for a pair of N-by-N complex nonsymmetric matrices A and B, the generalized eigenvalues (alpha, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that (A - w B) r = 0 . A left generalized eigenvector is a vector l such that l**H * (A - w B) = 0, where l**H is the
conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B. See "Further Details", below.

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHA (output)
On exit, ALPHA(j)/VL(j), j=1,...,N, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/VL(j) may easily over- or underflow, and VL(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and VL always less than and usually comparable with norm(B).

VL (output)
If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVL = 'N'.

BETA (output)
If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVL = 'N'.

LDVL (input)
The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (output)
If JOBVR = 'V', the right generalized eigenvectors. (See "Purpose", above.) Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVR = 'N'.

LDVR (input)
The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,2*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for CGEQRF, CUNMQR, and CUNGQR.) Then compute: NB as the MAX of the blocksizes for CGEQRF, CUNMQR, and

CUNGQR; The optimal LDWORK is MAX(2*N, N*(NB+1)).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(8*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and VL(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from CGGBAL
=N+2: error return from CGEQRF
=N+3: error return from CUNMQR
=N+4: error return from CUNGQR
=N+5: error return from CGGHRD
=N+6: error return from CHGEQZ (other than failed iteration) =N+7: error return from CTGEVC
=N+8: error return from CGGBAK (computing VL)
=N+9: error return from CGGBAK (computing VR)
=N+10: error return from CLASCL (various calls)

FURTHER DETAILS

Balancing

This driver calls CGGBAL to both permute and scale rows and columns of A and B. The permutations PL and PR are chosen so that PL*A*PR and PL*B*R will be upper triangular except for the diagonal blocks A(i:j,i:j) and B(i:j,i:j), with i and j as close together as possible. The diagonal scaling matrices DL and DR are chosen so that the pair DL*PL*A*PR*DR, DL*PL*B*PR*DR have elements close to one (except for the elements that start out zero.)

After the eigenvalues and eigenvectors of the balanced matrices have been computed, CGGBAK transforms the eigenvectors back to what they would have been (in perfect arithmetic) if they had not been balanced.

Contents of A and B on Exit

-------- -- - --- - -- ----

If any eigenvectors are computed (either JOBVL='V' or JOBVR='V' or both), then on exit the arrays A and B will contain the complex Schur form[*] of the "balanced" versions of A and B. If no eigenvectors are computed, then only the diagonal blocks will be correct.

[*] In other words, upper triangular form.

       [INFO])

COMPLEX, DIMENSION(:) :: TAU, WORKIN
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO

SUBROUTINE GEHRD_64([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
       [INFO])

COMPLEX, DIMENSION(:) :: TAU, WORKIN
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cgehrd(int n, int ilo, int ihi, complex  *a,  int  lda,
          complex *tau, int *info);

void cgehrd_64(long n, long ilo, long ihi, complex *a,  long
          lda, complex *tau, long *info);
```

PURPOSE

cgehrd reduces a complex general matrix A to upper Hessenberg form H by a unitary similarity transformation: Q' * A * Q = H .

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

IHI (input)
See the description of ILO.

A (input/output)
On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)
The length of the array WORKIN. LWORKIN >= max(1,N). For optimum performance LWORKIN >= N*NB, where NB is the optimal blocksize.

If LWORKIN = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of (ihi-ilo) elementary reflectors

```
   Q = H(ilo) H(ilo+1) . . . H(ihi-1).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a complex scalar, and v is a complex vector with v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with n = 7, ilo = 2 and ihi = 6:

```
on entry,                        on exit,

( a   a   a   a   a   a   a )    (  a   a   h    h    h    h
a  )  (      a   a   a   a   a   a )    (      a   h   h   h
h   a ) (     a   a   a   a   a   a )    (       h    h    h
h    h    h  ) (     a   a   a   a   a   a )    (      v2  h
h   h   h   h ) (     a   a   a   a   a   a )     (       v2
v3   h    h    h    h  )  (     a   a   a   a   a   a )    (
v2  v3  v4  h   h   h ) (                         a  )     (
a )
```

where a denotes an element of the original matrix A, h denotes a modified element of the upper Hessenberg matrix H, and vi denotes an element of the vector defining H(i).

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgelqf(int m, int n, complex *a, int lda, complex *tau,
          int *info);

void cgelqf_64(long m, long n, complex *a, long lda, complex
          *tau, long *info);
```

PURPOSE

cgelqf computes an LQ factorization of a complex M-by-N matrix A: A = L * Q.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(k)' . . . H(2)' H(1)', where k = min(m,n).

Each H(i) has the form
   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with v(1:i-1) = 0 and v(i) = 1; conjg(v(i+1:n)) is stored on
exit in A(i,i+1:n), and tau in TAU(i).
```

INTEGER*8 M, N, NRHS, LDA, LDB, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GELS([TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB], [WORK],
       LDWORK, [INFO])

CHARACTER(LEN=1) :: TRANSA
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER :: M, N, NRHS, LDA, LDB, LDWORK, INFO

SUBROUTINE GELS_64([TRANSA], [M], [N], [NRHS], A, [LDA], B, [LDB],
       [WORK], LDWORK, [INFO])
```

```
CHARACTER(LEN=1) :: TRANSA
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, NRHS, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cgels (char, int, int, int,  complex*,  int,  complex*,
          int, int*);

void cgels_64 (char, long, long, long, complex*, long,  com-
          plex*, long, long*);
```

PURPOSE

cgels solves overdetermined or underdetermined complex linear systems involving an M-by-N matrix A, or its conjugate-transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

1. If TRANS = 'N' and m >= n: find the least squares solution of
   an overdetermined system, i.e., solve the least squares problem
   minimize || B - A*X ||.

2. If TRANS = 'N' and m < n: find the minimum norm solution of
   an underdetermined system A * X = B.

3. If TRANS = 'C' and m >= n: find the minimum norm solution of
   an undetermined system A**H * X = B.

4. If TRANS = 'C' and m < n: find the least squares solution of
   an overdetermined system, i.e., solve the least squares problem
   minimize || B - A**H * X ||.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

TRANSA (input)
= 'N': the linear system involves A;
= 'C': the linear system involves A**H.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. if M >= N, A is overwritten by details of its QR factorization as returned by CGEQRF; if M < N, A is overwritten by details of its LQ factorization as returned by CGELQF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the matrix B of right hand side vectors, stored columnwise; B is M-by-NRHS if TRANSA = 'N', or N-by-NRHS if TRANSA = 'C'. On exit, B is overwritten by the solution vectors, stored columnwise: if TRANSA = 'N' and m >= n, rows 1 to n of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements N+1 to M in that column; if TRANSA = 'N' and m < n, rows 1 to N of B contain the minimum norm solution vectors; if TRANSA = 'C' and m >= n, rows 1 to M of B contain the minimum norm solution vectors; if TRANSA = 'C' and m < n, rows 1 to M of B contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements M+1 to N in that column.

LDB (input)
The leading dimension of the array B. LDB >= MAX(1,M,N).

```
WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (output)
          The dimension of the array WORK.  LDWORK  >=  max(
          1,  MN  +  max( MN, NRHS ) ).  For optimal perfor-
          mance, LDWORK >= max( 1, MN + max( MN,  NRHS  )*NB
          ).   where  MN  =  min(M,N)  and NB is the optimum
          block size.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

INTEGER(8) :: M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL :: RCOND
REAL, DIMENSION(:) :: S, RWORK
```

C INTERFACE

```
#include <sunperf.h>
void cgelsd(int m, int n, int nrhs,  complex  *a,  int  lda,
          complex  *b,  int  ldb, float *s, float rcond, int
          *rank, int *info);

void cgelsd_64(long m, long n, long nrhs, complex  *a,  long
          lda,  complex *b, long ldb, float *s, float rcond,
          long *rank, long *info);
```

PURPOSE

```
cgelsd computes the minimum-norm solution to a  real  linear
least squares problem:
    minimize 2-norm(| b - A*x |)
using the singular value decomposition (SVD) of A. A  is  an
M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can
be  handled in a single call; they are stored as the columns
of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
solution matrix X.

The problem is solved in three steps:
(1) Reduce the coefficient matrix A to bidiagonal form with
    Householder tranformations, reducing the original  prob-
lem
    into a "bidiagonal least squares problem" (BLS)
(2) Solve the BLS using a divide and conquer approach.
(3) Apply back all the Householder tranformations to solve
    the original least squares problem.

The effective rank of A is determined by  treating  as  zero
those  singular  values  which are less than RCOND times the
largest singular value.
```

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)
The leading dimension of the array B. LDB >= max(1,M,N).

S (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND (input)
RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK (output)
The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. The exact minimum amount of workspace needed depends on M, N and NRHS. If M >= N, LWORK >= 2*N + N*NRHS. If M < N, LWORK >= 2*M + M*NRHS. For good performance, LWORK should generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
If M >= N, LRWORK >= 8*N + 2*N*SMLSIZ + 8*N*NLVL + N*NRHS. If M < N, LRWORK >= 8*M + 2*M*SMLSIZ + 8*M*NLVL + M*NRHS. SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25), and NLVL = INT(LOG_2(MIN(M,N)/(SMLSIZ+1))) + 1

IWORK (workspace)
LIWORK >= 3 * MINMN * NLVL + 11 * MINMN, where MINMN = MIN(M,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

          lda,  complex  *b,  long  ldb,  float *sing, float
          rcond, long *irank, long *info);
```

PURPOSE

cgelss computes the minimum norm solution to a complex linear least squares problem:

Minimize 2-norm(| b - A*x |).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)

On entry, the M-by-N matrix A. On exit, the first min(m,n) rows of A are overwritten with its right singular vectors, stored rowwise.

LDA (input)

The leading dimension of the array A. LDA >= max(1,M).

B (input/output)

On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)

The leading dimension of the array B. LDB >= max(1,M,N).

SING (output)

The singular values of A in decreasing order. The condition number of A in the 2-norm = SING(1)/SING(min(m,n)).

RCOND (input)

RCOND is used to determine the effective rank of A. Singular values SING(i) <= RCOND*SING(1) are treated as zero. If RCOND < 0, machine precision is used instead.

IRANK (output)

The effective rank of A, i.e., the number of singular values which are greater than RCOND*SING(1).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK >= 1, and also: LDWORK >= 2*min(M,N) + max(M,N,NRHS) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(5*min(M,N))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

```
#include <sunperf.h>
void cgelsx(int m, int n, int nrhs,  complex  *a,  int  lda,
          complex *b, int ldb, int *jpivot, float rcond, int
          *irank, int *info);

void cgelsx_64(long m, long n, long nrhs, complex  *a,  long
          lda,  complex  *b,  long  ldb, long *jpivot, float
          rcond, long *irank, long *info);
```

PURPOSE

```
cgelsx routine is deprecated and has been replaced  by  rou-
tine CGELSY.

CGELSX computes  the  minimum-norm  solution  to  a  complex
linear least squares problem:
    minimize || A * X - B ||
using a complete orthogonal factorization of A.  A is an  M-
by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can
be  handled in a single call; they are stored as the columns
of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
solution matrix X.

The routine first computes a QR  factorization  with  column
pivoting:
    A * P = Q * [ R11 R12 ]
                [  0  R22 ]
with R11 defined as  the  largest  leading  submatrix  whose
estimated  condition number is less than 1/RCOND.  The order
of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihi-
lated by unitary transformations from the right, arriving at
the complete orthogonal factorization:
```

```
   A * P = Q * [ T11 0 ] * Z
               [  0  0 ]
The minimum-norm solution is then
   X = P * Z' [ inv(T11)*Q1'*B ]
              [        0       ]
where Q1 consists of the first RANK columns of Q.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of matrices B and X. NRHS >= 0.

A (input/output)
          On entry, the M-by-N matrix A.   On  exit,  A  has
          been   overwritten  by  details  of  its  complete
          orthogonal factorization.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

B (input/output)
          On entry, the M-by-NRHS right hand side matrix  B.
          On exit, the N-by-NRHS solution matrix X.  If m >=
          n and IRANK = n, the residual  sum-of-squares  for
          the  solution  in  the i-th column is given by the
          sum of squares of elements N+1:M in that column.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,M,N).

JPIVOT (input/output)
          On entry, if JPIVOT(i) .ne. 0, the i-th column  of
          A  is  an  initial  column, otherwise it is a free
          column.  Before the QR  factorization  of  A,  all
          initial  columns are permuted to the leading posi-
          tions; only the remaining free columns  are  moved
          as a result of column pivoting during the factori-
          zation.  On exit, if JPIVOT(i) = k, then the  i-th
          column of A*P was the k-th column of A.

RCOND (input)
```

RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

IRANK (output)
The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)

          complex  *b,  int ldb, int *jpvt, float rcond, int
          *rank, int *info);

void cgelsy_64(long m, long n, long nrhs, complex  *a,  long
          lda,  complex  *b,  long  ldb,  long  *jpvt, float
          rcond, long *rank, long *info);
```

PURPOSE

```
cgelsy computes  the  minimum-norm  solution  to  a  complex
linear least squares problem:
    minimize || A * X - B ||
using a complete orthogonal factorization of A.  A is an  M-
by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can
be  handled in a single call; they are stored as the columns
of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
solution matrix X.

The routine first computes a QR  factorization  with  column
pivoting:
    A * P = Q * [ R11 R12 ]
                [  0  R22 ]
with R11 defined as  the  largest  leading  submatrix  whose
estimated  condition number is less than 1/RCOND.  The order
of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihi-
lated by unitary transformations from the right, arriving at
the complete orthogonal factorization:
   A * P = Q * [ T11 0 ] * Z
               [  0  0 ]
```

The minimum-norm solution is then
```
   X = P * Z' [ inv(T11)*Q1'*B ]
              [        0       ]
```
where Q1 consists of the first RANK columns of Q.

This routine is basically identical to the original xGELSX except three differences:
- o The permutation of matrix B (the right hand side) is faster and more simple.
- o The call to the subroutine xGEQPF has been substituted by the the call to the subroutine xGEQP3. This subroutine is a Blas-3 version of the QR factorization with column pivoting.
- o Matrix B (the right hand side) is updated with Blas-3.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been overwritten by details of its complete orthogonal factorization.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,M,N).

JPVT (input/output)
On entry, if JPVT(i) .ne. 0, the i-th column of A is permuted to the front of AP, otherwise column i is a free column. On exit, if JPVT(i) = k, then

the i-th column of A*P was the k-th column of A.

RCOND (input)
RCOND is used to determine the effective rank of A, which is defined as the order of the largest leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

RANK (output)
The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. The unblocked strategy requires that: LWORK >= MN + MAX(2*MN, N+1, MN+NRHS) where MN = min(M,N). The block algorithm requires that: LWORK >= MN + MAX(2*MN, NB*(N+1), MN+MN*NB, MN+NB*NRHS) where NB is an upper bound on the blocksize returned by ILAENV for the routines CGEQP3, CTZRZF, CTZRQF, CUNMQR, and CUNMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

       B, [LDB], BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: TRANSA, TRANSB
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,:) :: A, B, C
INTEGER(8) :: M, N, K, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>

void cgemm(char transa, char transb, int m, int  n,  int  k,
          complex  *alpha,  complex *a, int lda, complex *b,
          int ldb, complex *beta, complex *c, int ldc);

void cgemm_64(char transa, char transb, long m, long n, long
          k,  complex  *alpha, complex *a, long lda, complex
          *b, long ldb,  complex  *beta,  complex  *c,  long
          ldc);
```

PURPOSE

cgemm performs one of the matrix-matrix operations

C := alpha*op(A)*op(B) + beta*C

where op(X) is one of

op(X) = X   or   op(X) = X'   or   op(X) = conjg(X'), alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

ARGUMENTS

TRANSA (input)

On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', op(A) = A.

TRANSA = 'T' or 't', op(A) = A'.

TRANSA = 'C' or 'c', op(A) = conjg(A').

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

```
TRANSB (input)
          On entry, TRANSB specifies the form of op( B )  to
          be used in the matrix multiplication as follows:

          TRANSB = 'N' or 'n',  op( B ) = B.

          TRANSB = 'T' or 't',  op( B ) = B'.

          TRANSB = 'C' or 'c',  op( B ) = conjg( B' ).

          Unchanged on exit.

          TRANSB is defaulted to 'N' for F95 INTERFACE.

M (input)
          On entry,  M  specifies  the number  of  rows   of
          the   matrix op( A )  and of the  matrix  C.  M >=
          0.  Unchanged on exit.

N (input)
          On entry,  N  specifies the number  of columns  of
          the  matrix  op(  B ) and the number of columns of
          the matrix C. N >= 0.  Unchanged on exit.

K (input)
          On entry,  K  specifies  the number of columns  of
          the  matrix  op( A ) and the number of rows of the
          matrix op( B ). K >= 0.  Unchanged on exit.

ALPHA (input)
          On  entry,  ALPHA  specifies  the  scalar   alpha.
          Unchanged on exit.

A (input)
          COMPLEX array of DIMENSION ( LDA, ka ),  where  ka
          is K when TRANSA = 'N' or 'n', and is M otherwise.
          Before entry with TRANSA = 'N' or 'n', the leading
          M by K part of the array A must contain the matrix
          A, otherwise the leading K by M part of the  array
          A must contain the matrix A.  Unchanged on exit.

LDA (input)
          On entry, LDA specifies the first dimension  of  A
          as  declared  in  the  calling (sub) program. When
          TRANSA = 'N' or 'n' then LDA >= max(1, M),  other-
          wise LDA >= max(1, K).  Unchanged on exit.

B (input)
          COMPLEX array of DIMENSION ( LDB, kb ),  where  kb
          is  n  when  TRANSB = 'N' or 'n',  and is  k  oth-
```

erwise. Before entry with TRANSB = 'N' or 'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then LDB >= max(1, k), otherwise LDB >= max(1, n). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)
COMPLEX array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta*C).

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC >= max(1, m). Unchanged on exit.

          BETA, Y, [INCY])

   CHARACTER(LEN=1) :: TRANSA
   COMPLEX :: ALPHA, BETA
   COMPLEX, DIMENSION(:) :: X, Y
   COMPLEX, DIMENSION(:,:) :: A
   INTEGER(8) :: M, N, LDA, INCX, INCY
```

C INTERFACE

```
   #include <sunperf.h>

   void cgemv(char transa, int m, int n, complex  *alpha,  com-
             plex  *a,  int  lda, complex *x, int incx, complex
             *beta, complex *y, int incy);
   void cgemv_64(char transa, long m, long n,  complex  *alpha,
             complex  *a, long lda, complex *x, long incx, com-
             plex *beta, complex *y, long incy);
```

PURPOSE

cgemv performs one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, or y := alpha*conjg(A')*x + beta*y where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   y := alpha*A*x + beta*y.

TRANSA = 'T' or 't'   y := alpha*A'*x + beta*y.

TRANSA = 'C' or 'c'   y := alpha*conjg(A')*x + beta*y.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (m - 1)*abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

SUBROUTINE GEQLF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeqlf(int m, int n, complex *a, int lda, complex *tau,
          int *info);

void cgeqlf_64(long m, long n, complex *a, long lda, complex
          *tau, long *info);
```

PURPOSE

cgeqlf computes a QL factorization of a complex M-by-N matrix A: A = Q * L.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if m >= n, the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N). For optimum performance LDWORK >= N*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(k) . . . H(2) H(1), where k = min(m,n).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a complex scalar, and v is a complex vector with v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in A(1:m-k+i-1,n-k+i), and tau in TAU(i).

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
REAL, DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>

void cgeqp3(int m, int n, complex *a, int  lda,  int  *jpvt,
          complex *tau, int *info);

void cgeqp3_64(long m, long n, complex *a,  long  lda,  long
          *jpvt, complex *tau, long *info);
```

PURPOSE

cgeqp3 computes a QR factorization with column pivoting of a matrix A: A*P = Q*R using Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M,N)-by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of min(M,N) elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

JPVT (input/output)
On entry, if JPVT(J).ne.0, the J-th column of A is permuted to the front of A*P (a leading column); if JPVT(J)=0, the J-th column of A is a free column. On exit, if JPVT(J)=K, then the J-th column of A*P was the the K-th column of A.

```
TAU (output)
          The scalar factors of the elementary reflectors.

WORK (workspace)
          On exit, if INFO=0, WORK(1)  returns  the  optimal
          LWORK.

LWORK (input)
          The dimension of the array  WORK.  LWORK  >=  N+1.
          For optimal performance LWORK >= ( N+1 )*NB, where
          NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

RWORK (workspace)
          dimension(2*N)

INFO (output)
          = 0: successful exit.
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value.
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real/complex scalar, and v is a  real/complex
vector with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on
exit in A(i+1:m,i), and tau in TAU(i).

          *jpivot, complex *tau, long *info);
```

PURPOSE

cgeqpf routine is deprecated and has been replaced by routine CGEQP3.

CGEQPF computes a QR factorization with column pivoting of a complex M-by-N matrix A: A*P = Q*R.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M,N)-by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

JPIVOT (input/output)
On entry, if JPIVOT(i) .ne. 0, the i-th column of A is permuted to the front of A*P (a leading column); if JPIVOT(i) = 0, the i-th column of A is a free column. On exit, if JPIVOT(i) = k, then

```
            the i-th column of A*P was the k-th column of A.

TAU (output)
            The scalar factors of the elementary reflectors.

WORK (workspace)
            dimension(N)

WORK2 (workspace)
            dimension(2*N)

INFO (output)
            = 0:  successful exit
            < 0:  if INFO =  -i,  the  i-th  argument  had  an
            illegal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(n)

Each H(i) has the form

   H = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(1:i-1)  = 0 and v(i) = 1; v(i+1:m) is stored on exit
in A(i+1:m,i).

The matrix P is represented in jpvt as follows: If
   jpvt(j) = i
then the jth column of P is the ith canonical unit vector.
```

SUBROUTINE CGEQRF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER M, N, LDA, LDWORK, INFO

SUBROUTINE CGEQRF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, LDA, LDWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE GEQRF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, LDWORK, INFO

SUBROUTINE GEQRF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgeqrf(int m, int n, complex *a, int lda, complex *tau,
          int *info);

void cgeqrf_64(long m, long n, complex *a, long lda, complex
          *tau, long *info);
```

PURPOSE

cgeqrf computes a QR factorization of a complex M-by-N matrix A: A = Q * R.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M,N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N). For optimum performance LDWORK >= N*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
Q = H(1) H(2) . . . H(k), where k = min(m,n).
```

Each H(i) has the form

```
H(i) = I - tau * v * v'
```

where tau is a complex scalar, and v is a complex vector with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i), and tau in TAU(i).

COMPLEX ALPHA
COMPLEX X(*), Y(*), A(LDA,*)
INTEGER M, N, INCX, INCY, LDA

SUBROUTINE CGERC_64(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)

COMPLEX ALPHA
COMPLEX X(*), Y(*), A(LDA,*)
INTEGER*8 M, N, INCX, INCY, LDA
```

F95 INTERFACE

```
SUBROUTINE GERC([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: M, N, INCX, INCY, LDA

SUBROUTINE GERC_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>

void cgerc(int m, int n, complex  *alpha,  complex  *x,  int
          incx, complex *y, int incy, complex *a, int lda);

void cgerc_64(long m, long n, complex  *alpha,  complex  *x,
          long incx, complex *y, long incy, complex *a, long
          lda);
```

PURPOSE

cgerc performs the rank 1 operation A := alpha*x*conjg(y') + A where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the

elements of Y. INCY must not be zero. Unchanged on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

          complex *b, long ldb, complex *x, long ldx,  float
          *ferr, float *berr, long *info);
```

PURPOSE

cgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
```

A (input) The original N-by-N matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CGETRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

```
WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO =  -i,  the  i-th  argument  had  an
          illegal value
```

SUBROUTINE GERQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgerqf(int m, int n, complex *a, int lda, complex *tau,
          int *info);

void cgerqf_64(long m, long n, complex *a, long lda, complex
          *tau, long *info);
```

PURPOSE

cgerqf computes an RQ factorization of a complex M-by-N matrix A: A = R * Q.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the unitary matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(1)' H(2)' . . . H(k)', where k = min(m,n).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a complex scalar, and v is a complex vector with v(n-k+i+1:n) = 0 and v(n-k+i) = 1; conjg(v(1:n-k+i-1)) is stored on exit in A(m-k+i,1:n-k+i-1), and tau in TAU(i).

COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, INCX, INCY, LDA
```

C INTERFACE

```
#include <sunperf.h>

void cgeru(int m, int n, complex  *alpha,  complex  *x,  int
          incx, complex *y, int incy, complex *a, int lda);

void cgeru_64(long m, long n, complex  *alpha,  complex  *x,
          long incx, complex *y, long incy, complex *a, long
          lda);
```

PURPOSE

cgeru performs the rank 1 operation A := alpha*x*y' + A where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged

on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

#include <sunperf.h>

void cgesdd(char jobz, int m, int n, complex  *a,  int  lda,
          float  *s,  complex  *u, int ldu, complex *vt, int
          ldvt, int *info);

void cgesdd_64(char jobz, long m, long n, complex  *a,  long
          lda,  float *s, complex *u, long ldu, complex *vt,
          long ldvt, long *info);
```

PURPOSE

cgesdd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors, by using divide-and-conquer method. The SVD is written

= U * SIGMA * conjugate-transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V**H, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
Specifies options for computing all or part of the matrix U:
= 'A': all M columns of U and all N rows of V**H are returned in the arrays U and VT; = 'S': the first min(M,N) columns of U and the first min(M,N) rows of V**H are returned in the arrays U and VT; = 'O': If M >= N, the first N columns of U are overwritten on the array A and all rows of V**H are returned in the array VT; otherwise, all columns of U are returned in the array U and the first M rows of V**H are overwritten in the array VT; = 'N': no columns of U or rows of V**H are computed.

M (input) The number of rows of the input matrix A. M >= 0.

N (input) The number of columns of the input matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if JOBZ = 'O', A is overwritten with the first N columns of U (the left singular vectors, stored columnwise) if M >= N; A is overwritten with the first M rows of V**H (the right singular vectors, stored row-wise) otherwise. if JOBZ .ne. 'O', the contents of A are destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

S (output)
The singular values of A, sorted so that S(i) >= S(i+1).

U (output)
UCOL = M if JOBZ = 'A' or JOBZ = 'O' and M < N; UCOL = min(M,N) if JOBZ = 'S'. If JOBZ = 'A' or JOBZ = 'O' and M < N, U contains the M-by-M unitary matrix U; if JOBZ = 'S', U contains the first min(M,N) columns of U (the left singular vectors, stored columnwise); if JOBZ = 'O' and M >= N, or

JOBZ = 'N', U is not referenced.

LDU (input)

The leading dimension of the array U. LDU >= 1; if JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU >= M.

VT (output)

If JOBZ = 'A' or JOBZ = 'O' and M >= N, VT contains the N-by-N unitary matrix V**H; if JOBZ = 'S', VT contains the first min(M,N) rows of V**H (the right singular vectors, stored rowwise); if JOBZ = 'O' and M < N, or JOBZ = 'N', VT is not referenced.

LDVT (input)

The leading dimension of the array VT. LDVT >= 1; if JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N; if JOBZ = 'S', LDVT >= min(M,N).

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= 1. if JOBZ = 'N', LWORK >= 2*min(M,N)+max(M,N). if JOBZ = 'O', LWORK >= 2*min(M,N)*min(M,N)+2*min(M,N)+max(M,N). if JOBZ = 'S' or 'A', LWORK >= min(M,N)*min(M,N)+2*min(M,N)+max(M,N). For good performance, LWORK should generally be larger. If LWORK < 0 but other input arguments are legal, WORK(1) returns optimal LWORK.

RWORK (workspace)

If JOBZ = 'N', LRWORK >= 7*min(M,N). Otherwise, LRWORK >= 5*min(M,N)*min(M,N) + 5*min(M,N)

IWORK (workspace)

dimension(8*MIN(M,N))

INFO (output)

= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The updating process of SBDSDC did not converge.

          *ipivot, complex *b, int ldb, int *info);

void cgesv_64(long n, long nrhs, complex *a, long lda,  long
          *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cgesv computes the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as
   A = P * L * U,
where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the N-by-NRHS matrix of right hand side

matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

          plex  *a,  long lda, float *sing, complex *u, long
          ldu, complex *vt, long ldvt, long *info);
```

PURPOSE

cgesvd computes the singular value decomposition (SVD) of a complex M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written
 = U * SIGMA * conjugate-transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M unitary matrix, and V is an N-by-N unitary matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**H, not V.

ARGUMENTS

JOBU (input)
Specifies options for computing all or part of the matrix U:
= 'A': all M columns of U are returned in array U:
= 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A;

= 'N': no columns of U (no left singular vectors) are computed.

JOBVT (input)
Specifies options for computing all or part of the matrix V**H:
= 'A': all N rows of V**H are returned in the array VT;
= 'S': the first min(m,n) rows of V**H (the right singular vectors) are returned in the array VT; = 'O': the first min(m,n) rows of V**H (the right singular vectors) are overwritten on the array A;
= 'N': no rows of V**H (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M (input) The number of rows of the input matrix A. M >= 0.

N (input) The number of columns of the input matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if JOBU = 'O',   A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V**H (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

SING (output)
The singular values of A, sorted so that SING(i) >= SING(i+1).

U (input) (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M unitary matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= 1; if JOBU = 'S' or 'A', LDU >= M.

VT (input)

If JOBVT = 'A', VT contains the N-by-N unitary matrix V**H; if JOBVT = 'S', VT contains the first min(m,n) rows of V**H (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT (input)
The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= 1. LDWORK >= 2*MIN(M,N)+MAX(M,N) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
DIMENSION(5*MIN(M,N)). On exit, if INFO > 0, WORK2(1:MIN(M,N)-1) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies A = U * B * VT, so it has the same singular values as A, and singular vectors related by U and VT.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if CBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of WORK2 above for details.

#include <sunperf.h>

void cgesvx(char fact, char transa, int n, int nrhs, complex
          *a,  int  lda, complex *af, int ldaf, int *ipivot,
          char equed, float *r, float *c,  complex  *b,  int
          ldb,  complex  *x,  int  ldx,  float *rcond, float
          *ferr, float *berr, int *info);

void cgesvx_64(char fact, char transa, long  n,  long  nrhs,
          complex *a, long lda, complex *af, long ldaf, long
          *ipivot, char equed, float *r, float  *c,  complex
          *b,  long ldb, complex *x, long ldx, float *rcond,
          float *ferr, float *berr, long *info);
```

PURPOSE

```
cgesvx uses the LU factorization to compute the solution  to
a complex system of linear equations
   A * X = B, where A is an N-by-N matrix and X  and  B  are
N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
```

```
   the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X  =
diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X  =
diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X  =
diag(C)*B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(R)*A*diag(C) and B by  diag(R)*B  (if
TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU  decomposition  is  used  to
factor the
   matrix A (after equilibration if FACT = 'E') as
      A = P * L * U,
   where P is a permutation matrix, L is a unit  lower  tri-
angular
   matrix, and U is upper triangular.

3. If some U(i,i)=0, so that U is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.

6. If equilibration was used, the matrix X is  premultiplied
by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS  =  'T'  or
'C') so
   that it solves the original system before equilibration.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored form of  the
          matrix A is supplied on entry, and if not, whether
          the matrix A should be equilibrated before  it  is
          factored.  = 'F':  On entry, AF and IPIVOT contain
          the factored form of A.  If EQUED is not 'N',  the
          matrix  A  has been equilibrated with scaling fac-
          tors given by R and C.  A, AF, and IPIVOT are  not
          modified.   = 'N':  The matrix A will be copied to
          AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the N-by-N matrix A.  If FACT = 'F'  and
          EQUED  is  not  'N', then A must have been equili-
          brated by the scaling factors in R and/or C.  A is
          not  modified  if  FACT = 'F' or 'N', or if FACT =
          'E' and EQUED = 'N' on exit.

          On exit, if EQUED .ne. 'N', A is  scaled  as  fol-
          lows:  EQUED = 'R':  A := diag(R) * A
          EQUED = 'C':  A := A * diag(C)
          EQUED = 'B':  A := diag(R) * A * diag(C).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

AF (input/output)
          If FACT = 'F', then AF is an input argument and on
```

entry contains the factors L and U from the factorization A = P*L*U as computed by CGETRF. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by CGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED (input/output)
Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input/output)
The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an

input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input/output)
The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))*X if TRANSA = 'N' and EQUED = 'C' or 'B', or inv(diag(R))*X if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest ele-

ment in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(2*N) On exit, WORK2(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK2(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK2(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is

<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV

SUBROUTINE GETF2_64([M], [N], A, [LDA], IPIV, [INFO])

COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgetf2(int m, int n, complex *a, int  lda,  int  *ipiv,
          int *info);

void cgetf2_64(long m, long n, complex *a,  long  lda,  long
          *ipiv, long *info);
```

PURPOSE

cgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form
   A = P * L * U
where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

IPIV (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is

exactly singular, and division by zero will occur if it is used to solve a system of equations.

INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cgetrf(int m, int n, complex *a, int lda, int  *ipivot,
          int *info);

void cgetrf_64(long m, long n, complex *a,  long  lda,  long
          *ipivot, long *info);
```

PURPOSE

cgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form
   A = P * L * U
where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

IPIVOT (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U

is exactly singular, and division by zero will occur if it is used to solve a system of equations.

SUBROUTINE GETRI([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])

COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, LDWORK, INFO
INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE GETRI_64([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])

COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void cgetri(int n, complex *a, int  lda,  int  *ipivot,  int
          *info);

void cgetri_64(long n, complex *a, long lda,  long  *ipivot,
          long *info);
```

PURPOSE

cgetri computes the inverse of a matrix using the LU factorization computed by CGETRF.

This method inverts U and then computes inv(A) by solving the system inv(A)*L = inv(U) for inv(A).

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the factors L and U from the factorization A = P*L*U as computed by CGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
The pivot indices from CGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

WORK (workspace)
On exit, if INFO=0, then WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N). For optimal performance LDWORK >= N*NB, where NB is the optimal blocksize returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

```

C INTERFACE

```
#include <sunperf.h>

void cgetrs(char transa, int n, int nrhs,  complex  *a,  int
          lda, int *ipivot, complex *b, int ldb, int *info);

void cgetrs_64(char transa, long n, long nrhs,  complex  *a,
          long lda, long *ipivot, complex *b, long ldb, long
          *info);
```

PURPOSE

cgetrs solves a system of linear equations
   A * X = B, A**T * X = B, or A**H * X = B with a general N-by-N matrix A using the LU factorization computed by CGETRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B   (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The factors L and U from the factorization A = P*L*U as computed by CGETRF.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

IPIVOT (input)
The pivot indices from CGETRF; for 1<=i<=N, row i

of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

CHARACTER(LEN=1) :: JOB, SIDE
COMPLEX, DIMENSION(:,:) :: V
INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE
```

C INTERFACE

```
#include <sunperf.h>

void cggbak(char job, char side, int n, int  ilo,  int  ihi,
          float  *lscale,  float *rscale, int m, complex *v,
          int ldv, int *info);
void cggbak_64(char job, char side, long n, long  ilo,  long
          ihi, float *lscale, float *rscale, long m, complex
          *v, long ldv, long *info);
```

PURPOSE

cggbak forms the right or left eigenvectors of a complex generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by CGGBAL.

ARGUMENTS

```
JOB (input)
          Specifies  the  type  of  backward  transformation
          required:
          = 'N':  do nothing, return immediately;
          = 'P':  do backward transformation for permutation
          only;
          = 'S':  do  backward  transformation  for  scaling
          only;
          = 'B':  do backward transformations for both  per-
          mutation and scaling.  JOB must be the same as the
          argument JOB supplied to CGGBAL.

SIDE (input)
          = 'R':  V contains right eigenvectors;
          = 'L':  V contains left eigenvectors.

N (input) The number of rows of the matrix V.  N >= 0.

ILO (input)
```

The integers ILO and IHI determined by CGGBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
The integers ILO and IHI determined by CGGBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

LSCALE (input)
Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by CGGBAL.

RSCALE (input)
Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by CGGBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)
On entry, the matrix of right or left eigenvectors to be transformed, as returned by CTGEVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)
The leading dimension of the matrix V. LDV >= max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: N, LDA, LDB, ILO, IHI, INFO
REAL, DIMENSION(:) :: LSCALE, RSCALE, WORK
```

C INTERFACE

```
#include <sunperf.h>

void cggbal(char job, int n, complex *a,  int  lda,  complex
          *b,  int  ldb,  int *ilo, int *ihi, float *lscale,
          float *rscale, int *info);

void cggbal_64(char job, long n, complex *a, long lda,  com-
          plex  *b,  long  ldb,  long *ilo, long *ihi, float
          *lscale, float *rscale, long *info);
```

PURPOSE

cggbal balances a pair of general complex matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem A*x = lambda*B*x.

ARGUMENTS

```
JOB (input)
          Specifies the operations to be performed on A  and
          B:
          = 'N':  none:  simply  set  ILO  =  1,  IHI  =  N,
          LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i=1,...,N;
          = 'P':  permute only;
          = 'S':  scale only;
          = 'B':  both permute and scale.

N (input) The order of the matrices A and B.  N >= 0.

A (input/output)
          On entry, the input  matrix  A.   On  exit,  A  is
          overwritten by the balanced matrix.  If JOB = 'N',
```

A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) On entry, the input matrix B. On exit, B is overwritten by the balanced matrix. If JOB = 'N', B is not referenced.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

ILO (output)
ILO and IHI are set to integers such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
ILO and IHI are set to integers such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N.

LSCALE (input)
Details of the permutations and scaling factors applied to the left side of A and B. If P(j) is the index of the row interchanged with row j, and D(j) is the scaling factor applied to row j, then LSCALE(j) = P(j) for J = 1,...,ILO-1 = D(j) for J = ILO,...,IHI = P(j) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (input)
Details of the permutations and scaling factors applied to the right side of A and B. If P(j) is the index of the column interchanged with column j, and D(j) is the scaling factor applied to column j, then RSCALE(j) = P(j) for J = 1,...,ILO-1 = D(j) for J = ILO,...,IHI = P(j) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

WORK (workspace)
dimension(6*N)

INFO (output)

```
= 0:  successful exit
< 0:  if INFO = -i, the i-th argument had an ille-
gal value.
```

          complex  *alpha, complex *beta, complex *vsl, long
          ldvsl, complex *vsr, long ldvsr, long *info);
```

PURPOSE

cgges computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized complex Schur form (S, T), and optionally left and/or right Schur vectors (VSL and VSR). This gives the generalized Schur factorization

```
(A,B) = ( (VSL)*S*(VSR)**H, (VSL)*T*(VSR)**H )
```

where (VSR)**H is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T. The leading columns of VSL and VSR then form an unitary basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver CGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.
A pair of matrices (S,T) is in generalized complex Schur form if S and T are upper triangular and, in addition, the diagonal elements of T are non-negative real numbers.

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELCTG).

SELCTG (input)
SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue ALPHA(j)/BETA(j) is selected if SELCTG(ALPHA(j),BETA(j)) is true.

Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+2 (See INFO below).

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j), j=1,...,N and BETA(j), j=1,...,N are the diagonals of the complex Schur form (A,B) output by CGGES. The BETA(j) will be non-negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
See description of ALPHA.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)

The leading dimension of the matrix VSL. LDVSL >= 1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)
The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(8*N)

BWORK (workspace)
dimension(N) Not referenced if SORT = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ
=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy SELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering falied in CTGSEN.

```

PURPOSE

cggesx computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, the complex Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization A,B) = ((VSL) S (VSR)**H, (VSL) T (VSR)**H)

where (VSR)**H is the conjugate-transpose of VSR.

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized complex Schur form if T is upper triangular with non-negative diagonal and S is upper triangular.

ARGUMENTS

JOBVSL (input)
        = 'N': do not compute the left Schur vectors;
        = 'V': compute the left Schur vectors.

JOBVSR (input)
        = 'N': do not compute the right Schur vectors;
        = 'V': compute the right Schur vectors.

SORT (input)
        Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
        = 'S': Eigenvalues are ordered (see SELCTG).

SELCTG (input)

SELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', SELCTG is not referenced. If SORT = 'S', SELCTG is used to select eigenvalues to sort to the top left of the Schur form. Note that a selected complex eigenvalue may no longer satisfy SELCTG(ALPHA(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3 see INFO below).

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N' : None are computed;
= 'E' : Computed for average of selected eigenvalues only;
= 'V' : Computed for selected deflating subspaces only;
= 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which SELCTG is true.

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHA(j) and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T). BETA(j) will be non-

negative real.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
See description of ALPHA.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)
The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE (output)
If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV (output)
If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition number for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 2*N. If SENSE = 'E', 'V', or 'B', LWORK >= MAX(2*N, 2*SDIM*(N-SDIM)).

RWORK (workspace)

```
          dimension(8*N) Real workspace.
IWORK (workspace/output)
          Not referenced if SENSE = 'N'.  On exit, if INFO =
          0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
          The dimension of the array WORK. LIWORK >= N+2.

BWORK (workspace)
          dimension(N) Not referenced if SORT = 'N'.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          = 1,...,N:  The QZ iteration  failed.   (A,B)  are
          not in Schur form, but ALPHA(j) and BETA(j) should
          be correct for j=INFO+1,...,N.  > N:  =N+1:  other
          than QZ iteration failed in CHGEQZ
          =N+2: after reordering, roundoff changed values of
          some  complex  eigenvalues  so that leading eigen-
          values in the Generalized  Schur  form  no  longer
          satisfy  SELCTG=.TRUE.   This could also be caused
          due  to  scaling.   =N+3:  reordering  failed   in
          CTGSEN.

```

PURPOSE

cggev computes for a pair of N-by-N complex nonsymmetric matrices (A,B), the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right generalized eigenvector v(j) corresponding to the generalized eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j).
```

The left generalized eigenvector u(j) corresponding to the generalized eigenvalues lambda(j) of (A,B) satisfies

```
u(j)**H * A = lambda(j) * u(j)**H * B
```

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues.

Note: the quotients ALPHA(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
See description of ALPHA.

VL (input)
If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag.

part) = 1. Not referenced if JOBVL = 'N'.

LDVL (input)
The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (input)
If JOBVR = 'V', the right generalized eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR (input)
The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,2*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(8*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
=1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other then QZ iteration failed in SHGEQZ,
=N+2: error return from STGEVC.

```

PURPOSE

cggevx computes for a pair of N-by-N complex nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally, it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.
The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
                 A * v(j) = lambda(j) * B * v(j) .
```

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
                 u(j)**H * A  = lambda(j) * u(j)**H * B.
```

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

BALANC (input)
Specifies the balance option to be performed:
= 'N': do not diagonally scale or permute;
= 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

SENSE (input)

Determines which reciprocal condition numbers are computed. = 'N': none are computed;
= 'E': computed for eigenvalues only;
= 'V': computed for eigenvectors only;
= 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the matrix A in the pair (A,B). On exit, A has been overwritten. If JOBVL='V' or JOBVR='V' or both, then A contains the first part of the complex Schur form of the "balanced" versions of the input A and B.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the matrix B in the pair (A,B). On exit, B has been overwritten. If JOBVL='V' or JOBVR='V' or both, then B contains the second part of the complex Schur form of the "balanced" versions of the input A and B.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHA (output)
On exit, ALPHA(j)/BETA(j), j=1,...,N, will be the generalized eigenvalues.

Note: the quotient ALPHA(j)/BETA(j)) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio ALPHA/BETA. However, ALPHA will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

BETA (output)
See description of ALPHA.

VL (output)
If JOBVL = 'V', the left generalized eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag.

```
          part) = 1.  Not referenced if JOBVL = 'N'.

LDVL (input)
          The leading dimension of the matrix VL. LDVL >= 1,
          and if JOBVL = 'V', LDVL >= N.
VR (input)
          If JOBVR = 'V', the right generalized eigenvectors
          v(j)  are  stored one after another in the columns
          of VR, in the same  order  as  their  eigenvalues.
          Each  eigenvector  will  be  scaled so the largest
          component will have  abs(real  part)  +  abs(imag.
          part) = 1.  Not referenced if JOBVR = 'N'.

LDVR (input)
          The leading dimension of the matrix VR. LDVR >= 1,
          and if JOBVR = 'V', LDVR >= N.

ILO (output)
          ILO is an integer value such that on exit A(i,j) =
          0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i
          = IHI+1,...,N.  If BALANC = 'N' or 'S',  ILO  =  1
          and IHI = N.

IHI (output)
          IHI is an integer value such that on exit A(i,j) =
          0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i
          = IHI+1,...,N.  If BALANC = 'N' or 'S',  ILO  =  1
          and IHI = N.

LSCALE (output)
          Details of the permutations  and  scaling  factors
          applied  to the left side of A and B.  If PL(j) is
          the index of the row interchanged with row j,  and
          DL(j) is the scaling factor applied to row j, then
          LSCALE(j) = PL(j)  for j  =  1,...,ILO-1  =  DL(j)
          for  j = ILO,...,IHI = PL(j)  for j = IHI+1,...,N.
          The order in which the interchanges are made is  N
          to IHI+1, then 1 to ILO-1.

RSCALE (output)
          Details of the permutations  and  scaling  factors
          applied to the right side of A and B.  If PR(j) is
          the index of the column interchanged  with  column
          j,  and  DR(j)  is  the  scaling factor applied to
          column  j,  then  RSCALE(j)  =  PR(j)   for  j   =
          1,...,ILO-1  =  DR(j)  for j = ILO,...,IHI = PR(j)
          for j = IHI+1,...,N The order in which the  inter-
          changes are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)
```

The one-norm of the balanced matrix A.

BBNRM (output)
The one-norm of the balanced matrix B.

RCONDE (output)
If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If SENSE = 'V', RCONDE is not referenced.

RCONDV (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced. Not referenced if JOB = 'E'.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,2*N). If SENSE = 'N' or 'E', LWORK >= 2*N. If SENSE = 'V' or 'B', LWORK >= 2*N*N+2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(6*N) Real workspace.

IWORK (workspace)
dimension(N+2) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)
dimension(N) If SENSE = 'N', BWORK is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvec-

tors have been calculated, but ALPHA(j) and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in CHGEQZ.
=N+2: error return from CTGEVC.

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue lambda is
hord(w, lambda) <= EPS * norm(ABNRM, BBNRM) / RCONDE(I)

An approximate error bound for the angle between the i-th computed eigenvector VL(i) or VR(i) is given by
PS * norm(ABNRM, BBNRM) / DIF(i).

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see section 4.11 of LAPACK User's Guide.

COMPLEX, DIMENSION(:) :: D, X, Y, WORK
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: N, M, P, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cggglm(int n, int m, int p, complex *a, int  lda,  com-
          plex  *b, int ldb, complex *d, complex *x, complex
          *y, int *info);

void cggglm_64(long n, long m, long p, complex *a, long lda,
          complex *b, long ldb, complex *d, complex *x, com-
          plex *y, long *info);
```

PURPOSE

```
cggglm solves a  general  Gauss-Markov  linear  model  (GLM)
problem:
        minimize || y ||_2   subject to   d = A*x + B*y
            x

where A is an N-by-M matrix, B is an N-by-P matrix, and d is
a given N-vector. It is assumed that M <= N <= M+P, and

           rank(A) = M    and    rank( A B ) = N.

Under these assumptions, the constrained equation is  always
consistent,  and  there is a unique solution x and a minimal
2-norm solution y, which is obtained using a generalized  QR
factorization of A and B.

In particular, if matrix B is square nonsingular,  then  the
problem  GLM  is equivalent to the following weighted linear
least squares problem

             minimize || inv(B)*(d-A*x) ||_2
                 x

where inv(B) denotes the inverse of B.
```

ARGUMENTS

```
N (input) The number of rows of the matrices A and B.  N  >=
          0.

M (input) The number of columns of the matrix A.  0 <= M  <=
          N.

P (input) The number of columns of the matrix B.  P >= N-M.
```

A (input/output)
On entry, the N-by-M matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-P matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

D (input/output)
On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X (output)
On exit, X and Y are the solutions of the GLM problem.

Y (output)
On exit, X and Y are the solutions of the GLM problem.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N+M+P). For optimum performance, LDWORK >= M+min(N,P)+max(N,P)*NB, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

NAME

cgghrd - reduce a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular

SYNOPSIS

```
SUBROUTINE CGGHRD(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ,
      Z, LDZ, INFO)

CHARACTER * 1 COMPQ, COMPZ
COMPLEX A(LDA,*), B(LDB,*), Q(LDQ,*), Z(LDZ,*)
INTEGER N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO

SUBROUTINE CGGHRD_64(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q,
      LDQ, Z, LDZ, INFO)

CHARACTER * 1 COMPQ, COMPZ
COMPLEX A(LDA,*), B(LDB,*), Q(LDQ,*), Z(LDZ,*)
INTEGER*8 N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
```

F95 INTERFACE

```
SUBROUTINE GGHRD(COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB], Q,
       [LDQ], Z, [LDZ], [INFO])

CHARACTER(LEN=1) :: COMPQ, COMPZ
COMPLEX, DIMENSION(:,:) :: A, B, Q, Z
INTEGER :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO

SUBROUTINE GGHRD_64(COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB],
       Q, [LDQ], Z, [LDZ], [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ, COMPZ
COMPLEX, DIMENSION(:,:) :: A, B, Q, Z
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cgghrd(char compq, char compz, int n, int ilo, int ihi,
          complex  *a, int lda, complex *b, int ldb, complex
          *q, int ldq, complex *z, int ldz, int *info);

void cgghrd_64(char compq, char compz,  long  n,  long  ilo,
          long  ihi,  complex *a, long lda, complex *b, long
          ldb, complex *q, long ldq, complex *z,  long  ldz,
          long *info);
```

PURPOSE

cgghrd reduces a pair of complex matrices (A,B) to generalized upper Hessenberg form using unitary transformations, where A is a general matrix and B is upper triangular: Q' * A * Z = H and Q' * B * Z = T, where H is upper Hessenberg, T is upper triangular, and Q and Z are unitary, and ' means conjugate transpose.

The unitary matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that
1 * A * Z1' = (Q1*Q) * H * (Z1*Z)'

ARGUMENTS

COMPQ (input)
= 'N': do not compute Q;
= 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product Q1*Q is returned.

COMPZ (input)
= 'N': do not compute Q;
= 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'V': Q must contain a unitary matrix Q1 on entry, and the product Q1*Q is returned.

N (input) The order of the matrices A and B. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to CGGBAL; otherwise they should be set to 1 and N respectively. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See description of ILO.

A (input/output)
On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the rest is set to zero.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-N upper triangular matrix B. On exit, the upper triangular matrix T = Q' B Z. The elements below the diagonal are set to zero.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

Q (input/output)
If COMPQ='N': Q is not referenced.
If COMPQ='I': on entry, Q need not be set, and on exit it contains the unitary matrix Q, where Q' is the product of the Givens transformations which are applied to A and B on the left. If COMPQ='V': on entry, Q must contain a unitary matrix Q1, and on exit this is overwritten by Q1*Q.

LDQ (input)
The leading dimension of the array Q. LDQ >= N if COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z (input/output)
If COMPZ='N': Z is not referenced.
If COMPZ='I': on entry, Z need not be set, and on exit it contains the unitary matrix Z, which is the product of the Givens transformations which

are applied to A and B on the right. If COMPZ='V': on entry, Z must contain a unitary matrix Z1, and on exit this is overwritten by Z1*Z.

LDZ (input)
The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in _Matrix_Computations_, by Golub and van Loan (Johns Hopkins Press).

COMPLEX, DIMENSION(:,:) :: A, B
INTEGER :: M, N, P, LDA, LDB, LDWORK, INFO

SUBROUTINE GGLSE_64([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],
       [LDWORK], [INFO])

COMPLEX, DIMENSION(:) :: C, D, X, WORK
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cgglse(int m, int n, int p, complex *a, int  lda,  com-
          plex  *b, int ldb, complex *c, complex *d, complex
          *x, int *info);

void cgglse_64(long m, long n, long p, complex *a, long lda,
          complex *b, long ldb, complex *c, complex *d, com-
          plex *x, long *info);
```

PURPOSE

```
cgglse solves the linear equality-constrained least  squares
(LSE) problem:
        minimize || c - A*x ||_2   subject to   B*x = d

where A is an M-by-N matrix, B is a P-by-N matrix,  c  is  a
given  M-vector,  and  d  is a given P-vector. It is assumed
that
P <= N <= M+P, and

         rank(B) = P and  rank( ( A ) ) = N.
                              ( ( B ) )

These conditions ensure that the LSE problem  has  a  unique
solution, which is obtained using a GRQ factorization of the
matrices B and A.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrices A and  B.  N
          >= 0.

P (input) The number of rows of the matrix B. 0 <= P <= N <=
          M+P.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, A is des-
          troyed.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).
```

B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

C (input/output)
On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D (input/output)
On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X (output)
On exit, X is the solution of the LSE problem.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M+N+P). For optimum performance LDWORK >= P+min(M,N)+max(M,N)*NB, where NB is an upper bound for the optimal blocksizes for CGEQRF, CGERQF, CUNMQR and CUNMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

SUBROUTINE GGQRF_64([N], [M], [P], A, [LDA], TAUA, B, [LDB], TAUB,
       [WORK], [LWORK], [INFO])

COMPLEX, DIMENSION(:) :: TAUA, TAUB, WORK
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: N, M, P, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cggqrf(int n, int m, int p, complex *a, int  lda,  com-
          plex  *taua,  complex  *b, int ldb, complex *taub,
          int *info);

void cggqrf_64(long n, long m, long p, complex *a, long lda,
          complex  *taua,  complex  *b,  long  ldb,  complex
          *taub, long *info);
```

PURPOSE

```
cggqrf computes a generalized QR factorization of an  N-by-M
matrix A and an N-by-P matrix B:
            A = Q*R,        B = Q*T*Z,

where Q is an N-by-N unitary matrix, Z is a  P-by-P  unitary
matrix, and R and T assume one of the forms:

if N >= M,  R = ( R11 ) M  ,   or if N < M,  R = ( R11   R12
) N,
                (  0  ) N-M                         N   M-N
                   M

where R11 is upper triangular, and

if N <= P,  T = ( 0  T12 ) N,   or if N > P,  T =  (  T11  )
N-P,
                 P-N  N                           ( T21 ) P
                                                     P

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR  fac-
torization  of A and B implicitly gives the QR factorization
of inv(B)*A:

             inv(B)*A = Z'*(inv(T)*R)

where inv(B) denotes the inverse of the  matrix  B,  and  Z'
denotes the conjugate transpose of matrix Z.
```

ARGUMENTS

N (input) The number of rows of the matrices A and B. N >=

0.

M (input) The number of columns of the matrix A. M >= 0.

P (input) The number of columns of the matrix B. P >= 0.

A (input/output)
On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N,M)-by-M upper trapezoidal matrix R (R is upper triangular if N >= M); the elements below the diagonal, with the array TAUA, represent the unitary matrix Q as a product of min(N,M) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAUA (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B (input/output)
On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

TAUB (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >=

max(1,N,M,P). For optimum performance LWORK >= max(N,M,P)*max(NB1,NB2,NB3), where NB1 is the optimal blocksize for the QR factorization of an N-by-M matrix, NB2 is the optimal blocksize for the RQ factorization of an N-by-P matrix, and NB3 is the optimal blocksize for a call of CUNMQR.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
Q = H(1) H(2) . . . H(k), where k = min(n,m).
```

Each H(i) has the form

```
H(i) = I - taua * v * v'
```

where taua is a complex scalar, and v is a complex vector with v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is stored on exit in A(i+1:n,i), and taua in TAUA(i).
To form Q explicitly, use LAPACK subroutine CUNGQR.
To use Q to update another matrix, use LAPACK subroutine CUNMQR.

The matrix Z is represented as a product of elementary reflectors

```
Z = H(1) H(2) . . . H(k), where k = min(n,p).
```

Each H(i) has the form

```
H(i) = I - taub * v * v'
```

where taub is a complex scalar, and v is a complex vector with v(p-k+i+1:p) = 0 and v(p-k+i) = 1; v(1:p-k+i-1) is stored on exit in B(n-k+i,1:p-k+i-1), and taub in TAUB(i).
To form Z explicitly, use LAPACK subroutine CUNGRQ.
To use Z to update another matrix, use LAPACK subroutine CUNMRQ.

INTEGER :: M, P, N, LDA, LDB, LWORK, INFO

SUBROUTINE GGRQF_64([M], [P], [N], A, [LDA], TAUA, B, [LDB], TAUB,
       [WORK], [LWORK], [INFO])

COMPLEX, DIMENSION(:) :: TAUA, TAUB, WORK
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: M, P, N, LDA, LDB, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cggrqf(int m, int p, int n, complex *a, int  lda,  com-
          plex  *taua,  complex  *b, int ldb, complex *taub,
          int *info);

void cggrqf_64(long m, long p, long n, complex *a, long lda,
          complex  *taua,  complex  *b,  long  ldb,  complex
          *taub, long *info);
```

PURPOSE

```
cggrqf computes a generalized RQ factorization of an  M-by-N
matrix A and a P-by-N matrix B:
            A = R*Q,        B = Z*T*Q,

where Q is an N-by-N unitary matrix, Z is a  P-by-P  unitary
matrix, and R and T assume one of the forms:

if M <= N,  R = ( 0  R12 ) M,   or if M > N,  R =  (  R11  )
M-N,
                 N-M  M                           ( R21 ) N
                                                     N

where R12 or R21 is upper triangular, and

if P >= N,  T = ( T11 ) N  ,   or if P < N,  T = ( T11   T12
) P,
                (  0  ) P-N                         P   N-P
                   N

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ  fac-
torization  of A and B implicitly gives the RQ factorization
of A*inv(B):

             A*inv(B) = (R*inv(T))*Z'

where inv(B) denotes the inverse of the  matrix  B,  and  Z'
denotes the conjugate transpose of the matrix Z.
```

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if M <= N, the upper triangle of the subarray A(1:M,N-M+1:N) contains the M-by-M upper triangular matrix R; if M > N, the elements on and above the (M-N)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAUA, represent the unitary matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAUA (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Q (see Further Details).

B (input/output)
On entry, the P-by-N matrix B. On exit, the elements on and above the diagonal of the array contain the min(P,N)-by-N upper trapezoidal matrix T (T is upper triangular if P >= N); the elements below the diagonal, with the array TAUB, represent the unitary matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

TAUB (output)
The scalar factors of the elementary reflectors which represent the unitary matrix Z (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,N,M,P). For optimum performance LWORK >=

```
          max(N,M,P)*max(NB1,NB2,NB3),  where  NB1  is   the
          optimal  blocksize  for the RQ factorization of an
          M-by-N matrix, NB2 is the  optimal  blocksize  for
          the  QR  factorization of a P-by-N matrix, and NB3
          is the optimal blocksize for a call of CUNMRQ.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.
INFO (output)
          = 0:  successful exit
          < 0:  if INFO=-i, the i-th argument had an illegal
          value.
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form

   H(i) = I - taua * v * v'

where taua is a complex scalar, and v is  a  complex  vector
with  v(n-k+i+1:n)  =  0  and  v(n-k+i) = 1; v(1:n-k+i-1) is
stored on exit in A(m-k+i,1:n-k+i-1), and taua in TAUA(i).
To form Q explicitly, use LAPACK subroutine CUNGRQ.
To use Q to update another  matrix,  use  LAPACK  subroutine
CUNMRQ.

The matrix Z is  represented  as  a  product  of  elementary
reflectors

   Z = H(1) H(2) . . . H(k), where k = min(p,n).

Each H(i) has the form

   H(i) = I - taub * v * v'

where taub is a complex scalar, and v is  a  complex  vector
with  v(1:i-1)  = 0 and v(i) = 1; v(i+1:p) is stored on exit
in B(i+1:p,i), and taub in TAUB(i).
To form Z explicitly, use LAPACK subroutine CUNGQR.
To use Z to update another  matrix,  use  LAPACK  subroutine
CUNMQR.

          plex *q, long ldq, long *iwork3, long *info);
```

PURPOSE

cggsvd computes the generalized singular value decomposition (GSVD) of an M-by-N complex matrix A and P-by-N complex matrix B:

```
      U'*A*Q = D1*( 0 R ),    V'*B*Q = D2*( 0 R )
```

where U, V and Q are unitary matrices, and Z' means the conjugate transpose of Z. Let K+L = the effective numerical rank of the matrix (A',B')', then R is a (K+L)-by-(K+L) nonsingular upper triangular matrix, D1 and D2 are M-by-(K+L) and P-by-(K+L) "diagonal" matrices and of the following structures, respectively:

If M-K-L >= 0,

```
                    K  L
```

```
       D1 =     K ( I  0 )
                L ( 0  C )
            M-K-L ( 0  0 )

                  K  L
       D2 =   L ( 0  S )
            P-L ( 0  0 )

                N-K-L  K    L
  ( 0 R ) = K (  0   R11  R12 )
            L (  0    0   R22 )
where

  C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
  S = diag( BETA(K+1),  ... , BETA(K+L) ),
  C**2 + S**2 = I.

  R is stored in A(1:K+L,N-K-L+1:N) on exit.
If M-K-L < 0,

                  K M-K K+L-M
       D1 =   K ( I  0    0   )
            M-K ( 0  C    0   )

                    K M-K K+L-M
       D2 =   M-K ( 0  S    0  )
            K+L-M ( 0  0    I  )
              P-L ( 0  0    0  )

                   N-K-L  K   M-K  K+L-M
  ( 0 R ) =     K ( 0    R11  R12  R13  )
              M-K ( 0     0   R22  R23  )
            K+L-M ( 0     0    0   R33  )

where

  C = diag( ALPHA(K+1), ... , ALPHA(M) ),
  S = diag( BETA(K+1),  ... , BETA(M) ),
  C**2 + S**2 = I.

  (R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33  is
stored
  ( 0  R22 R23 )
  in B(M-K+1:L,N+M-K-L+1:N) on exit.

The routine computes C, S, R, and optionally the unitary
transformation matrices U, V and Q.

In particular, if B is an N-by-N  nonsingular  matrix,  then
the GSVD of A and B implicitly gives the SVD of A*inv(B):
```

```
                     A*inv(B) = U*(D1*inv(D2))*V'.
```

If (A',B')' has orthnormal columns, then the GSVD of A and B is also equal to the CS decomposition of A and B. Furthermore, the GSVD can be used to derive the solution of the eigenvalue problem:

```
                     A'*A x = lambda* B'*B x.
```

In some literature, the GSVD of A and B is presented in the form

```
                 U'*A*X = ( 0 D1 ),   V'*B*X = ( 0 D2 )
```

where U and V are orthogonal and X is nonsingular, and D1 and D2 are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

```
                      X = Q*(  I   0    )
                            (  0 inv(R) )
```

ARGUMENTS

JOBU (input)
- = 'U': Unitary matrix U is computed;
- = 'N': U is not computed.

JOBV (input)
- = 'V': Unitary matrix V is computed;
- = 'N': V is not computed.

JOBQ (input)
- = 'Q': Unitary matrix Q is computed;
- = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. P >= 0.

K (output)
On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of (A',B')'.

L (output)
On exit, K and L specify the dimension of the subblocks described in Purpose. K + L = effective numerical rank of (A',B')'.

A (input/output)

On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains part of the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

ALPHA (output)
On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1,
ALPHA(1:K) = 1,
BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = C,
BETA(K+1:K+L) = S, or if M-K-L < 0, ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0
BETA(K+1:M) = S, BETA(M+1:K+L) = 1 and
ALPHA(K+L+1:N) = 0
BETA(K+L+1:N) = 0

BETA (output)
See description of ALPHA.

U (output)
If JOBU = 'U', U contains the M-by-M unitary matrix U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (output)
If JOBV = 'V', V contains the P-by-P unitary matrix V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (output)
If JOBQ = 'Q', Q contains the N-by-N unitary

matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)
dimension(MAX(3*N,M,P)+N)

WORK2 (workspace)
dimension(2*N)

IWORK3 (output)
dimension(N) On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK3(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine CTGSJA.

          M-K-L ( 0     0    0  )

                 N-K-L  K    L
        =     K ( 0    A12  A13 )  if M-K-L < 0;
            M-K ( 0     0   A23 )

               N-K-L  K    L
```

```
 V'*B*Q =   L ( 0     0   B13 )
          P-L ( 0     0    0  )
```

where the K-by-K matrix A12 and L-by-L matrix B13 are non-singular upper triangular; A23 is L-by-L upper triangular if M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal. K+L = the effective numerical rank of the (M+P)-by-N matrix (A',B')'. Z' denotes the conjugate transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine CGGSVD.

ARGUMENTS

```
JOBU (input)
          = 'U':  Unitary matrix U is computed;
          = 'N':  U is not computed.
JOBV (input)
          = 'V':  Unitary matrix V is computed;
          = 'N':  V is not computed.

JOBQ (input)
          = 'Q':  Unitary matrix Q is computed;
          = 'N':  Q is not computed.
```

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB (input)

The leading dimension of the array B. LDB >= max(1,P).

TOLA (input)
TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a sub-block of A. Generally, they are set to TOLA = MAX(M,N)*norm(A)*MACHEPS, TOLB = MAX(P,N)*norm(B)*MACHEPS. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
See description of TOLA.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in Purpose section. K + L = effective numerical rank of (A',B')'.

L (output)
See the description of K.

U (input) If JOBU = 'U', U contains the unitary matrix U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) If JOBV = 'V', V contains the unitary matrix V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) If JOBQ = 'Q', Q contains the unitary matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

IWORK (workspace)
dimension(N)

RWORK (workspace)
dimension(2*N)

TAU (workspace)

dimension(N)

WORK (workspace)
dimension(MAX(3*N,M,P))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine CGEQPF for the QR factorization with column pivoting to detect the effective numerical rank of the a matrix. It may be replaced by a better rank determination strategy.

NAME

cgssco - General sparse solver condition number estimate.

SYNOPSIS

```
SUBROUTINE CGSSCO ( COND, HANDLE, IER )

INTEGER             IER
REAL                COND
DOUBLE PRECISION    HANDLE(150)
```

PURPOSE

CGSSCO - Condition number estimate.

PARAMETERS

```
COND      - REAL
        On exit, an estimate of the condition number of the
        factored matrix.  Must be called after the numerical
        factorization subroutine, CGSSFA().

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -700 : Invalid calling sequence - need to call CGSSFA first.
```

-710 : Condition number estimate not available (not implemented
for this HANDLE's matix type).

Contents

NAME

```
cgssda - Deallocate working storage for the general sparse
solver.
```

SYNOPSIS

```
 SUBROUTINE CGSSDA ( HANDLE, IER )

 INTEGER           IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

CGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

```
HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         none
```

Contents

NAME

```
cgssfa - General sparse solver numeric factorization.
```

SYNOPSIS

```
 SUBROUTINE CGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )

 INTEGER            NEQNS, COLSTR(*), ROWIND(*), IER
 COMPLEX            VALUES(*)
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

CGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

```
NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        coefficient matrix.  Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.

ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

VALUES(*) - COMPLEX array
        On entry, VALUES(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the numeric values of
```

```
        the sparse matrix to be factored.  Unchanged on
        exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER        - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -300 : Invalid calling sequence - need to call CGSSOR first.
         -301 : Failure to dynamically allocate memory.
         -666 : Internal error.
```

NAME

cgssfs - General sparse solver one call interface.

SYNOPSIS

```
 SUBROUTINE CGSSFS ( MTXTYP, PIVOT , NEQNS, COLSTR, ROWIND,
                     VALUES, NRHS  , RHS   , LDRHS , ORDMTHD,
                     OUTUNT, MSGLVL, HANDLE, IER )

 CHARACTER*2        MTXTYP
 CHARACTER*1        PIVOT
 INTEGER            NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,
                    OUTUNT, MSGLVL, IER
 CHARACTER*3        ORDMTHD
 COMPLEX            VALUES(*), RHS(*)
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

CGSSFS - General sparse solver one call interface.

PARAMETERS

```
MTXTYP    - CHARACTER*2
        On entry, MTXTYP specifies the coefficient matrix
        type.  Specifically, the valid options are:

         'sp' or 'SP' - symmetric structure, Hermitian positive definite
values
         'ss' or 'SS' - symmetric structure, symmetric values
         'su' or 'SU' - symmetric structure, unsymmetric values
         'uu' or 'UU' - unsymmetric structure, unsymmetric values

        Unchanged on exit.
```

```
PIVOT     - CHARACTER*1
        On entry, pivot specifies whether or not pivoting is
        used in the course of the numeric factorization.
        The valid options are:

         'n' or 'N' - no pivoting is used
         (Pivoting is not supported for this release).

        Unchanged on exit.

NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        the coefficient matrix.  NEQNS must be at least one.
        Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.
ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

VALUES(*) - COMPLEX array
        On entry, VALUES(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the non-zero numeric
        values of the sparse matrix to be factored.
        Unchanged on exit.

NRHS      - INTEGER
        On entry, NRHS specifies the number of right hand
        sides to solve for.  Unchanged on exit.

RHS(*)    - COMPLEX array
        On entry, RHS(LDRHS,NRHS) contains the NRHS right
        hand sides.  On exit, it contains the solutions.

LDRHS     - INTEGER
        On entry, LDRHS specifies the leading dimension of
        the RHS array. Unchanged on exit.

ORDMTHD   - CHARACTER*3
        On entry, ORDMTHD specifies the fill-reducing
        ordering to be used by the sparse solver.
        Specifically, the valid options are:

         'nat' or 'NAT' - natural ordering (no ordering)
         'mmd' or 'MMD' - multiple minimum degree
```

```
         'gnd' or 'GND' - general nested dissection
         'uso' or 'USO' - user specified ordering (see CGSSUO)

        Unchanged on exit.

OUTUNT    - INTEGER
        Output unit.  Unchanged on exit.

MSGLVL    - INTEGER
        Message level.

         0 - no output from solver.
         (No messages supported for this release.)

        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array of containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.
IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -101 : Failure to dynamically allocate memory.
         -102 : Invalid matrix type.
         -103 : Invalid pivot option.
         -104 : Number of nonzeros is less than NEQNS.
         -105 : NEQNS < 1
         -201 : Failure to dynamically allocate memory.
         -301 : Failure to dynamically allocate memory.
         -401 : Failure to dynamically allocate memory.
         -402 : NRHS < 1
         -403 : NEQNS > LDRHS
         -666 : Internal error.
```

Contents

NAME

```
cgssin - Initialize the general sparse solver.
```

SYNOPSIS

```
 SUBROUTINE CGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,
                     MSGLVL, HANDLE, IER )

 CHARACTER*2       MTXTYP
 CHARACTER*1       PIVOT
 INTEGER           NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGLVL, IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

CGSSIN - Initialize the sparse solver and input the matrix
structure.

PARAMETERS

```
MTXTYP    - CHARACTER*2
        On entry, MTXTYP specifies the coefficient matrix
        type.  Specifically, the valid options are:

         'sp' or 'SP' - symmetric structure, Hermitian positive definite
values
         'ss' or 'SS' - symmetric structure, symmetric values
         'su' or 'SU' - symmetric structure, unsymmetric values
         'uu' or 'UU' - unsymmetric structure, unsymmetric values

        Unchanged on exit.

PIVOT     - CHARACTER*1
        On entry, PIVOT specifies whether or not pivoting is
```

```
        used in the course of the numeric factorization.
        The valid options are:

         'n' or 'N' - no pivoting is used
         (Pivoting is not supported for this release).

        Unchanged on exit.

NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        the coefficient matrix.  NEQNS must be at least one.
        Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.

ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

OUTUNT    - INTEGER
        Output unit.  Unchanged on exit.

MSGLVL    - INTEGER
        Message level.

         0 - no output from solver.
         (No messages supported for this release.)

        Unchanged on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -101 : Failure to dynamically allocate memory.
         -102 : Invalid matrix type.
         -103 : Invalid pivot option.
         -104 : Number of nonzeros less than NEQNS.
         -105 : NEQNS < 1
```

NAME

```
cgssor - General sparse solver ordering and symbolic
factorization.
```

SYNOPSIS

```
 SUBROUTINE CGSSOR ( ORDMTHD, HANDLE, IER )

 CHARACTER*3       ORDMTHD
 INTEGER           IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

CGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

```
ORDMTHD   - CHARACTER*3
        On entry, ORDMTHD specifies the fill-reducing
        ordering to be used by the sparse solver.
        Specifically, the valid options are:

         'nat' or 'NAT' - natural ordering (no ordering)
         'mmd' or 'MMD' - multiple minimum degree
         'gnd' or 'GND' - general nested dissection
         'uso' or 'USO' - user specified ordering (see CGSSUO)

        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
```

Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-200 : Invalid calling sequence - need to call CGSSIN first.
-201 : Failure to dynamically allocate memory.
-666 : Internal error.

Contents

NAME

```
cgssps - Print general sparse solver statics.
```

SYNOPSIS

```
 SUBROUTINE CGSSPS ( HANDLE, IER )

 INTEGER            IER
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

CGSSPS - Print solver statistics.

PARAMETERS

```
HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -800 : Invalid calling sequence - need to call CGSSSL first.
         -899 : Printed solver statistics not supported this release.
```

Contents

NAME

```
cgssrp - Return permutation used by the general sparse
solver.
```

SYNOPSIS

```
 SUBROUTINE CGSSRP ( PERM, HANDLE, IER )

 INTEGER            PERM(*), IER
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

CGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

```
PERM(NEQNS)  - INTEGER array
        Undefined on entry.  PERM(NEQNS) is the permutation
        array used by the sparse solver for the fill-
        reducing ordering.  Modified on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:
```

-600 : Invalid calling sequence - need to call CGSSOR first.

Contents

NAME

cgsssl - Solve routine for the general sparse solver.

SYNOPSIS

```
SUBROUTINE CGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )

INTEGER            NRHS, LDRHS, IER
COMPLEX            RHS(LDRHS,NRHS)
DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

CGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

```
NRHS      - INTEGER
        On entry, NRHS specifies the number of right hand
        sides to solve for.  Unchanged on exit.

RHS(LDRHS,*) - COMPLEX array
        On entry, RHS(LDRHS,NRHS) contains the NRHS right
        hand sides.  On exit, it contains the solutions.

LDRHS     - INTEGER
        On entry, LDRHS specifies the leading dimension of
        the RHS array. Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.
```

```
IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -400 : Invalid calling sequence - need to call CGSSFA first.
         -401 : Failure to dynamically allocate memory.
         -402 : NRHS < 1
         -403 : NEQNS > LDRHS
```

Contents

NAME

```
cgssuo - User supplied permutation for ordering used in the
general sparse solver.
```

SYNOPSIS

```
 SUBROUTINE CGSSUO ( PERM, HANDLE, IER )

 INTEGER            PERM(*), IER
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

CGSSUO - User supplied permutation for ordering. Must be
called after *CGSSIN*() (sparse solver initialization) and
before *CGSSOR*() (sparse solver ordering).

PARAMETERS

```
PERM(NEQNS)  - INTEGER array
        On entry, PERM(NEQNS) is a permutation array
        supplied by the user for the fill-reducing ordering.
        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:
```

-500 : Invalid calling sequence - need to call CGSSIN first.

Contents

NAME

```
cgtcon - estimate the reciprocal of the condition number  of
a complex tridiagonal matrix A using the LU factorization as
computed by CGTTRF
```

SYNOPSIS

```
SUBROUTINE CGTCON(NORM, N, LOW, DIAG, UP1, UP2, IPIVOT, ANORM, RCOND,

       RCOND, [WORK], [INFO])

CHARACTER(LEN=1) :: NORM
COMPLEX, DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
INTEGER :: N, INFO
INTEGER, DIMENSION(:) :: IPIVOT
```

```
REAL :: ANORM, RCOND

SUBROUTINE GTCON_64(NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
       RCOND, [WORK], [INFO])

CHARACTER(LEN=1) :: NORM
COMPLEX, DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
void cgtcon(char norm, int n, complex *low,  complex  *diag,
          complex  *up1,  complex  *up2,  int *ipivot, float
          anorm, float *rcond, int *info);

void cgtcon_64(char norm,  long  n,  complex  *low,  complex
          *diag,  complex  *up1, complex *up2, long *ipivot,
          float anorm, float *rcond, long *info);
```

PURPOSE

cgtcon estimates the reciprocal of the condition number of a complex tridiagonal matrix A using the LU factorization as computed by CGTTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I':   Infinity-norm.

N (input) The order of the matrix A. N >= 0.

LOW (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by CGTTRF.

DIAG (input)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input)
The (n-1) elements of the first superdiagonal of U.

UP2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

NAME

```
cgthr - Gathers specified elements from y into x.
```

SYNOPSIS

```
 SUBROUTINE CGTHR(NZ, Y, X, INDX)

 COMPLEX Y(*), X(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE CGTHR_64(NZ, Y, X, INDX)

 COMPLEX Y(*), X(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE GTHR([NZ], Y, X, INDX)

 COMPLEX, DIMENSION(:) :: Y, X
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE GTHR_64([NZ], Y, X, INDX)

 COMPLEX, DIMENSION(:) :: Y, X
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
CGTHR - Gathers the specified elements from a vector y in
full storage form into a vector x in compressed form.  Only
```

the elements of y whose indices are listed in indx are referenced.

```
 do i = 1, n
   x(i) = y(indx(i))
 enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form. Unchanged on exit.

Y (input)
Vector in full storage form. Unchanged on exit.

X (output)
Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

          ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations:

```
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

LOW (input)
          The (n-1) subdiagonal elements of A.
DIAG (input)
          The diagonal elements of A.

UP (input)
          The (n-1) superdiagonal elements of A.

LOWF (input)
          The (n-1) multipliers that  define  the  matrix  L
          from  the  LU  factorization  of  A as computed by
          CGTTRF.

DIAGF (input)
          The n diagonal elements of  the  upper  triangular
          matrix U from the LU factorization of A.

UPF1 (input)
          The (n-1) elements of the first  superdiagonal  of
          U.

UPF2 (input)
          The (n-2) elements of the second superdiagonal  of
          U.

IPIVOT (input)
          The pivot indices; for 1 <= i <= n, row i  of  the
          matrix   was   interchanged  with  row  IPIVOT(i).
          IPIVOT(i)  will  always  be  either  i   or   i+1;
          IPIVOT(i)  = i indicates a row interchange was not
          required.

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).
```

X (input/output)
On entry, the solution matrix X, as computed by CGTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          *info);
```

PURPOSE

cgtsv solves the equation

where A is an N-by-N tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation A'*X = B may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input/output)
On entry, LOW must contain the (n-1) subdiagonal elements of A. On exit, LOW is overwritten by the (n-2) elements of the second superdiagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A. On exit, DIAG is overwritten by the n diagonal elements of U.

UP (input/output)
On entry, UP must contain the (n-1) superdiagonal elements of A. On exit, UP is overwritten by the (n-1) elements of the first superdiagonal of U.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >=

max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

          *x, long ldx, float  *rcond,  float  *ferr,  float
          *berr, long *info);
```

PURPOSE

cgtsvx uses the LU factorization to compute the solution to a complex system of linear equations A * X = B, A**T * X = B, or A**H * X = B, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A
   as A = L * U, where L is a product of permutation and unit lower
   bidiagonal matrices and U is upper triangular with nonzeros in
   only the main diagonal and first two superdiagonals.

2. If some U(i,i)=0, so that U is exactly singular, then the routine
   returns with INFO = i. Otherwise, the factored form of A is used
   to estimate the condition number of the matrix A. If the
   reciprocal of the condition number is less than machine precision,
   INFO = N+1 is returned as a warning, but the routine still goes on
   to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form
   of A.

4. Iterative refinement is applied to improve the computed solution
   matrix and calculate error bounds and backward error estimates
   for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': LOWF, DIAGF, UPF1, UPF2, and IPIVOT contain the factored form of A; LOW, DIAG, UP, LOWF, DIAGF, UPF1, UPF2 and IPIVOT will not be modified. = 'N': The matrix will be copied to LOWF, DIAGF, and UPF1 and factored.

TRANSA (input)
Specifies the form of the system of equations:

```
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

LOW (input)
          The (n-1) subdiagonal elements of A.

DIAG (input)
          The n diagonal elements of A.

UP (input)
          The (n-1) superdiagonal elements of A.

LOWF (input/output)
          If FACT = 'F', then LOWF is an input argument  and
          on  entry  contains  the  (n-1)  multipliers  that
          define the matrix L from the LU factorization of A
          as computed by CGTTRF.

          If FACT = 'N', then LOWF is an output argument and
          on exit contains the (n-1) multipliers that define
          the matrix L from the LU factorization of A.

DIAGF (input/output)
          If FACT = 'F', then DIAGF is an input argument and
          on  entry  contains the n diagonal elements of the
          upper triangular matrix U from the  LU  factoriza-
          tion of A.

          If FACT = 'N', then DIAGF is  an  output  argument
          and  on  exit  contains the n diagonal elements of
          the upper triangular matrix U from the LU factori-
          zation of A.

UPF1 (input/output)
          If FACT = 'F', then UPF1 is an input argument  and
          on  entry contains the (n-1) elements of the first
          superdiagonal of U.

          If FACT = 'N', then UPF1 is an output argument and
          on  exit  contains the (n-1) elements of the first
          superdiagonal of U.
```

UPF2 (input/output)
If FACT = 'F', then UPF2 is an input argument and on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIVOT (input/output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by CGTTRF.

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest ele-

ment in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is

<= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

          *up1, complex *up2, int *ipivot, int *info);

void cgttrf_64(long n, complex *low, complex *diag,  complex
          *up1, complex *up2, long *ipivot, long *info);
```

PURPOSE

cgttrf computes an LU factorization of a complex tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form
   A = L * U
where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)
On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)
On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)

On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

   COMPLEX, DIMENSION(:,:) :: B
   INTEGER(8) :: N, NRHS, LDB, INFO
   INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
   #include <sunperf.h>

   void cgttrs(char transa, int n, int nrhs, complex *low, com-
             plex   *diag,  complex  *up1,  complex  *up2,  int
             *ipivot, complex *b, int ldb, int *info);
   void cgttrs_64(char transa, long n, long nrhs, complex *low,
             complex  *diag,  complex  *up1, complex *up2, long
             *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cgttrs solves one of the systems of equations
   A * X = B, A**T * X = B, or A**H * X = B, with a tri-
diagonal matrix A using the LU factorization computed by
CGTTRF.

ARGUMENTS

TRANSA (input)
          Specifies the form of the system of equations.   =
          'N': A * X = B   (No transpose)
          = 'T': A**T * X = B (Transpose)
          = 'C': A**H * X = B (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.

NRHS (input)
          The number of right hand sides, i.e., the number
          of columns of the matrix B. NRHS >= 0.

LOW (input)
          The (n-1) multipliers that define the matrix L
          from the LU factorization of A.

DIAG (input)
          The n diagonal elements of the upper triangular

matrix U from the LU factorization of A.

UP1 (input)
The (n-1) elements of the first super-diagonal of U.

UP2 (input)
The (n-2) elements of the second super-diagonal of U.

IPIVOT (input)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input/output)
On entry, the matrix of right hand side vectors B. On exit, B is overwritten by the solution vectors X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value

#include <sunperf.h>

void chbev(char jobz, char uplo, int n, int kd, complex  *a,
          int  lda,  float  *w,  complex  *z,  int  ldz, int
          *info);
void chbev_64(char jobz, char uplo, long n, long kd, complex
          *a, long lda, float *w, complex *z, long ldz, long
          *info);
```

PURPOSE

chbev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  A,  stored in the first KD+1
          rows of the array.  The j-th column of A is stored
          in  the j-th column of the array A as follows:  if
          UPLO = 'U', A(kd+1+i-j,j) =  A(i,j)  for  max(1,j-
          kd)<=i<=j;  if  UPLO = 'L', A(1+i-j,j)    = A(i,j)
```

for j<=i<=min(n,j+kd).

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of A, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of A.

LDA (input)
The leading dimension of the array A. LDA >= KD + 1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(N)

WORK2 (workspace)
dimension(max(1,3*N-2))

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```

C INTERFACE

```
#include <sunperf.h>
void chbevd(char jobz, char uplo, int  n,  int  kd,  complex
          *ab,  int ldab, float *w, complex *z, int ldz, int
          *info);

void chbevd_64(char jobz, char uplo, long n, long  kd,  com-
          plex  *ab,  long  ldab, float *w, complex *z, long
          ldz, long *info);
```

PURPOSE

chbevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).
On exit, AB is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the first superdiagonal and the diagonal of the tridiagonal matrix T are returned in rows KD and KD+1 of AB, and if UPLO = 'L', the diagonal and first subdiagonal of T are returned in the first two rows of AB.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD + 1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N**2.

If LWORK = -1, then a workspace query is assumed;

the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N .

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

          abtol,  long  *nfound,  float *w, complex *z, long
          ldz, long *ifail, long *info);
```

PURPOSE

chbevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian band matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;

= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

= 'A': all eigenvalues will be found;
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found; = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)

= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)

The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input/output)

On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, A is overwritten by values generated during the reduction to tridiagonal form.

LDA (input)

The leading dimension of the array A. LDA >= KD + 1.

Q (output)

If JOBZ = 'V', the N-by-N unitary matrix used in the reduction to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)

The leading dimension of the array Q. If JOBZ = 'V', then LDQ >= max(1,N).

VL (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tri- diagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
The first NFOUND elements contain the selected eigenvalues in ascending order.

```
Z (input) If JOBZ = 'V', then if INFO = 0, the first  NFOUND
          columns  of Z contain the orthonormal eigenvectors
          of the matrix  A  corresponding  to  the  selected
          eigenvalues, with the i-th column of Z holding the
          eigenvector associated with W(i).  If an eigenvec-
          tor  fails to converge, then that column of Z con-
          tains the latest approximation to the eigenvector,
          and  the  index  of the eigenvector is returned in
          IFAIL.  If JOBZ = 'N', then Z is  not  referenced.
          Note:   the   user   must  ensure  that  at  least
          max(1,NFOUND) columns are supplied in the array Z;
          if  RANGE  = 'V', the exact value of NFOUND is not
          known in advance and an upper bound must be used.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          dimension(N)

WORK2 (workspace)
          dimension(7*N)

IWORK3 (workspace)
          dimension(5*N)

IFAIL (output)
          If JOBZ = 'V', then if INFO = 0, the first  NFOUND
          elements  of  IFAIL  are  zero.  If INFO > 0, then
          IFAIL contains the  indices  of  the  eigenvectors
          that  failed  to  converge.   If  JOBZ = 'N', then
          IFAIL is not referenced.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, then i eigenvectors  failed  to
          converge.   Their  indices  are  stored  in  array
          IFAIL.

          plex *x, int ldx, int *info);
void chbgst_64(char vect, char uplo, long n, long  ka,  long
          kb,  complex  *ab,  long  ldab,  complex *bb, long
          ldbb, complex *x, long ldx, long *info);
```

PURPOSE

chbgst reduces a complex Hermitian-definite banded generalized eigenproblem A*x = lambda*B*x to standard form C*y = lambda*y, such that C has the same bandwidth as A.

B must have been previously factorized as S**H*S by CPBSTF, using a split Cholesky factorization. A is overwritten by C = X**H*A*X, where X = S**(-1)*Q and Q is a unitary matrix chosen to preserve the bandwidth of A.

ARGUMENTS

VECT (input)
= 'N': do not form the transformation matrix X;
= 'V': form X.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrices A and B. N >= 0.

KA (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= 0.

KB (input)
The number of superdiagonals of the matrix B if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KA >= KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).
On exit, the transformed matrix X**H*A*X, stored in the same format as A.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input)
The banded factor S from the split Cholesky factorization of B, as returned by CPBSTF, stored in the first kb+1 rows of the array.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

X (output)
If VECT = 'V', the n-by-n matrix X. If VECT = 'N', the array X is not referenced.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N) if VECT = 'V'; LDX >= 1 otherwise.

WORK (workspace)
dimension(N)

RWORK (workspace)

```

PURPOSE

chbgv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

KA (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'. KA >= 0.

KB (input)
          The number of superdiagonals of the  matrix  B  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
```

= 'L'. KB >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first ka+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(ka+1+i-j,j) = A(i,j) for max(1,j-ka)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+ka).

On exit, the contents of AB are destroyed.

LDAB (input)
The leading dimension of the array AB. LDAB >= KA+1.

BB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix B, stored in the first kb+1 rows of the array. The j-th column of B is stored in the j-th column of the array BB as follows: if UPLO = 'U', BB(kb+1+i-j,j) = B(i,j) for max(1,j-kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S**H*S, as returned by CPBSTF.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z**H*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

```

PURPOSE

chbgvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

KA (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'. KA >= 0.
KB (input)
          The number of superdiagonals of the  matrix  B  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'. KB >= 0.

AB (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  A,  stored in the first ka+1
          rows of the array.  The j-th column of A is stored
          in the j-th column of the array AB as follows:  if
          UPLO = 'U', AB(ka+1+i-j,j) = A(i,j)  for  max(1,j-
          ka)<=i<=j;  if UPLO = 'L', AB(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+ka).

          On exit, the contents of AB are destroyed.

LDAB (input)
          The leading dimension of the array  AB.   LDAB  >=
          KA+1.

BB (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  B,  stored in the first kb+1
          rows of the array.  The j-th column of B is stored
          in the j-th column of the array BB as follows:  if
          UPLO = 'U', BB(kb+1+i-j,j) = B(i,j)  for  max(1,j-
          kb)<=i<=j;  if UPLO = 'L', BB(1+i-j,j)    = B(i,j)
          for j<=i<=min(n,j+kb).

          On exit, the factor S from the split Cholesky fac-
          torization B = S**H*S, as returned by CPBSTF.

LDBB (input)
```

The leading dimension of the array BB. LDBB >= KB+1.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the matrix Z of eigenvectors, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized so that Z**H*B*Z = I. If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

WORK (workspace)
On exit, if INFO=0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N. If JOBZ = 'V' and N > 1, LWORK >= 2*N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
On exit, if INFO=0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO=0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is:
<= N: the algorithm failed to converge: i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then CPBSTF
returned INFO = i: B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

PURPOSE

chbgvx computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite banded eigenproblem, of the form A*x=(lambda)*B*x. Here A and B are assumed to be Hermitian and banded, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either all eigenvalues, a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found;
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be  found; = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.
N (input) The order of the matrices A and B.  N >= 0.

KA (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'. KA >= 0.

KB (input)
          The number of superdiagonals of the  matrix  B  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'. KB >= 0.

AB (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  A,  stored in the first ka+1
          rows of the array.  The j-th column of A is stored
          in the j-th column of the array AB as follows:  if
          UPLO = 'U', AB(ka+1+i-j,j) = A(i,j)  for  max(1,j-
          ka)<=i<=j;  if UPLO = 'L', AB(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+ka).

          On exit, the contents of AB are destroyed.

LDAB (input)
          The leading dimension of the array  AB.   LDAB  >=
          KA+1.

BB (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  B,  stored in the first kb+1
          rows of the array.  The j-th column of B is stored
          in the j-th column of the array BB as follows:  if
          UPLO = 'U', BB(kb+1+i-j,j) = B(i,j)  for  max(1,j-
```

kb)<=i<=j; if UPLO = 'L', BB(1+i-j,j) = B(i,j) for j<=i<=min(n,j+kb).

On exit, the factor S from the split Cholesky factorization B = S**H*S, as returned by CPBSTF.

LDBB (input)
The leading dimension of the array BB. LDBB >= KB+1.

Q (output)
If JOBZ = 'V', the n-by-n matrix used in the reduction of A*x = (lambda)*B*x to standard form, i.e. C*x = (lambda)*x, and consequently C to tridiagonal form. If JOBZ = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. If JOBZ = 'N', LDQ >= 1. If JOBZ = 'V', LDQ >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

```
          ABSTOL + EPS *   max( |a|,|b| ) ,

          where EPS is the machine precision.  If ABSTOL  is
          less than or equal to zero, then  EPS*|T|  will be
          used in its place, where |T| is the 1-norm of  the
          tridiagonal matrix obtained by reducing AP to tri-
          diagonal form.
          Eigenvalues will be computed most accurately  when
          ABSTOL  is  set  to  twice the underflow threshold
          2*SLAMCH('S'), not zero.  If this routine  returns
          with INFO>0, indicating that some eigenvectors did
          not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
          The total number of eigenvalues found.  0 <= M  <=
          N.  If RANGE = 'A', M = N, and if RANGE = 'I', M =
          IU-IL+1.

W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          matrix  Z of eigenvectors, with the i-th column of
          Z holding the eigenvector  associated  with  W(i).
          The eigenvectors are normalized so that Z**H*B*Z =
          I.  If JOBZ = 'N', then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= N.

WORK (workspace)
          dimension(N)

RWORK (workspace)
          dimension(7*N)

IWORK (workspace)
          dimension(5*N)

IFAIL (output)
          If JOBZ = 'V', then if INFO = 0, the first M  ele-
          ments  of IFAIL are zero.  If INFO > 0, then IFAIL
          contains the  indices  of  the  eigenvectors  that
          failed  to converge.  If JOBZ = 'N', then IFAIL is
          not referenced.

INFO (output)
          = 0:  successful exit
```

< 0: if INFO = -i, the i-th argument had an ille-
gal value
> 0: if INFO = i, and i is:
<= N: then i eigenvectors failed to converge.
Their indices are stored in array IFAIL. > N:
if INFO = N + i, for 1 <= i <= N, then CPBSTF
returned INFO = i: B is not positive definite.
The factorization of B could not be completed and
no eigenvalues or eigenvectors were computed.

INTEGER*8 N, K, LDA, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE HBMV(UPLO, [N], K, ALPHA, A, [LDA], X, [INCX], BETA,
       Y, [INCY])

CHARACTER(LEN=1) :: UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, K, LDA, INCX, INCY

SUBROUTINE HBMV_64(UPLO, [N], K, ALPHA, A, [LDA], X, [INCX],
```

```
          BETA, Y, [INCY])

     CHARACTER(LEN=1) :: UPLO
     COMPLEX :: ALPHA, BETA
     COMPLEX, DIMENSION(:) :: X, Y
     COMPLEX, DIMENSION(:,:) :: A
     INTEGER(8) :: N, K, LDA, INCX, INCY
```

C INTERFACE

```
     #include <sunperf.h>

     void chbmv(char uplo, int n, int k, complex *alpha,  complex
               *a,  int lda, complex *x, int incx, complex *beta,
               complex *y, int incy);
     void chbmv_64(char uplo, long n,  long  k,  complex  *alpha,
               complex  *a, long lda, complex *x, long incx, com-
               plex *beta, complex *y, long incy);
```

PURPOSE

chbmv performs the matrix-vector operation y := alpha*A*x + beta*y where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian band matrix, with k super-diagonals.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the band matrix A is being supplied as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is being supplied.

UPLO = 'L' or 'l'   The lower triangular part of A is being supplied.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry, K specifies the number of super-diagonals of the matrix A. K must satisfy 0 .le.

K. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer the upper triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
    DO 20, J = 1, N
      M = K + 1 - J
      DO 10, I = MAX( 1, J - K ), J
        A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the hermitian matrix, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer the lower triangular part of a hermitian band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

```
#include <sunperf.h>

void chbtrd(char vect, char uplo, int  n,  int  kd,  complex
          *ab, int ldab, float *d, float *e, complex *q, int
          ldq, int *info);
void chbtrd_64(char vect, char uplo, long n, long  kd,  com-
          plex  *ab,  long ldab, float *d, float *e, complex
          *q, long ldq, long *info);
```

PURPOSE

chbtrd reduces a complex Hermitian band matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: Q**H * A * Q = T.

ARGUMENTS

```
VECT (input)
          = 'N':  do not form Q;
          = 'V':  form Q;
          = 'U':  update a matrix X, by forming X*Q.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

AB (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  A,  stored in the first KD+1
```

rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). On exit, the diagonal elements of AB are overwritten by the diagonal elements of the tridiagonal matrix T; if KD > 0, the elements on the first superdiagonal (if UPLO = 'U') or the first subdiagonal (if UPLO = 'L') are overwritten by the off-diagonal elements of T; the rest of AB is overwritten by values generated during the reduction.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

D (output)
The diagonal elements of the tridiagonal matrix T.

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = T(i,i+1) if UPLO = 'U'; E(i) = T(i+1,i) if UPLO = 'L'.

Q (input/output)
On entry, if VECT = 'U', then Q must contain an N-by-N matrix X; if VECT = 'N' or 'V', then Q need not be set.

On exit: if VECT = 'V', Q contains the N-by-N unitary matrix Q; if VECT = 'U', Q contains the product X*Q; if VECT = 'N', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1, and LDQ >= N if VECT = 'V' or 'U'.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

void checon_64(char uplo, long n, complex *a, long lda, long
          *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

checon estimates the reciprocal of the condition number of a complex Hermitian matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHETRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
#include <sunperf.h>

void cheev(char jobz, char uplo, int n, complex *a, int lda,
          float *w, int *info);

void cheev_64(char jobz, char uplo, long n, complex *a, long
          lda, float *w, long *info);
```

PURPOSE

cheev computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the  matrix  A.   On  exit, if JOBZ = 'V', then if
          INFO = 0, A contains the orthonormal  eigenvectors
          of  the matrix A.  If JOBZ = 'N', then on exit the
          lower triangle (if UPLO='L') or the upper triangle
          (if  UPLO='U')  of  A,  including the diagonal, is
          destroyed.

LDA (input)
```

The leading dimension of the array A. LDA >= max(1,N).

W (output)

If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The length of the array WORK. LDWORK >= max(1,2*N-1). For optimal efficiency, LDWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)

dimension(max(1,3*N-2))

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: W, RWORK
```

C INTERFACE

```
#include <sunperf.h>
void cheevd(char jobz, char uplo, int  n,  complex  *a,  int
          lda, float *w, int *info);

void cheevd_64(char jobz, char uplo,  long  n,  complex  *a,
          long lda, float *w, long *info);
```

PURPOSE

cheevd computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

JOBZ (input)
 = 'N': Compute eigenvalues only;
 = 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, if JOBZ = 'V', then if INFO = 0, A contains the orthonormal eigenvectors of the matrix A. If JOBZ = 'N', then on exit the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N + 1. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of the array RWORK. If N <= 1, LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message

```
            related to LRWORK is issued by XERBLA.

    IWORK (workspace/output)
            On exit, if INFO = 0, IWORK(1) returns the optimal
            LIWORK.

    LIWORK (input)
            The dimension of the array  IWORK.   If  N  <=  1,
            LIWORK must be at least 1.  If JOBZ  = 'N' and N >
            1, LIWORK must be at least 1.  If JOBZ  = 'V'  and
            N > 1, LIWORK must be at least 3 + 5*N.

            If LIWORK = -1, then a workspace query is assumed;
            the  routine  only  calculates the optimal size of
            the IWORK array, returns this value as  the  first
            entry  of  the  IWORK  array, and no error message
            related to LIWORK is issued by XERBLA.

    INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  if INFO = i, the algorithm  failed  to  con-
            verge;  i off-diagonal elements of an intermediate
            tridiagonal form did not converge to zero.

```

PURPOSE

cheevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian tridiagonal matrix T. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

Whenever possible, CHEEVR calls CSTEGR to compute the eigenspectrum using Relatively Robust Representations. CSTEGR computes eigenvalues by the dqds algorithm, while orthogonal eigenvectors are computed from various "good" L D

L^T representations (also known as Relatively Robust Representations). Gram-Schmidt orthogonalization is avoided as far as possible. More specifically, the various steps of the algorithm are as follows. For the i-th unreduced block of T,
   (a) Compute T - sigma_i = L_i D_i L_i^T, such that L_i D_i L_i^T
        is a relatively robust representation,
   (b) Compute the eigenvalues, lambda_j, of L_i D_i L_i^T to high
       relative accuracy by the dqds algorithm,
   (c) If there is a cluster of close eigenvalues, "choose" sigma_i
       close to the cluster, and go to step (a),
   (d) Given the approximate eigenvalue lambda_j of L_i D_i L_i^T,
       compute the corresponding eigenvector by forming a
       rank-revealing twisted factorization.
The desired accuracy of the output can be specified by the input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for the symmetric tridiagonal eigenvalue/eigenvector problem", by Inderjit Dhillon, Computer Science Division Technical Report No. UCB//CSD-97-971, UC Berkeley, May 1997.

Note 1 : CHEEVR calls CSTEGR when the full spectrum is requested on machines which conform to the ieee-754 floating point standard. CHEEVR calls SSTEBZ and CSTEIN on non-ieee machines and
when partial spectrum requests are made.

Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not handle NaNs and infinities in the ieee standard default manner.

ARGUMENTS

JOBZ (input)
          = 'N': Compute eigenvalues only;
          = 'V': Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the  matrix  A.   On  exit, the lower triangle (if
          UPLO='L') or the upper triangle (if  UPLO='U')  of
          A, including the diagonal, is destroyed.
LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

VU (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

IL (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.

IU (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.

ABSTOL (input)
          The absolute error tolerance for the  eigenvalues.
          An approximate eigenvalue is accepted as converged
          when it is determined to lie in an interval  [a,b]
          of width less than or equal to
```

```
          ABSTOL + EPS *   max( |a|,|b| ) ,

          where EPS is the machine precision.  If ABSTOL  is
          less than or equal to zero, then  EPS*|T|  will be
          used in its place, where |T| is the 1-norm of  the
          tridiagonal  matrix obtained by reducing A to tri-
          diagonal form.

          See "Computing Small Singular Values of Bidiagonal
          Matrices  with Guaranteed High Relative Accuracy,"
          by Demmel and Kahan, LAPACK Working Note #3.

          If high relative accuracy is important, set ABSTOL
          to  SLAMCH(  'Safe  minimum'  ).   Doing  so  will
          guarantee that eigenvalues are  computed  to  high
          relative   accuracy   when   possible   in  future
          releases.  The current  code  does  not  make  any
          guarantees about high relative accuracy, but furu-
          tre releases will. See J. Barlow  and  J.  Demmel,
          "Computing  Accurate Eigensystems of Scaled Diago-
          nally Dominant Matrices", LAPACK Working Note  #7,
          for  a  discussion  of which matrices define their
          eigenvalues to high relative accuracy.

M (output)
          The total number of eigenvalues found.  0 <= M  <=
          N.  If RANGE = 'A', M = N, and if RANGE = 'I', M =
          IU-IL+1.

W (output)
          The first M elements contain the  selected  eigen-
          values in ascending order.

Z (output)
          If JOBZ = 'V', then if  INFO  =  0,  the  first  M
          columns  of Z contain the orthonormal eigenvectors
          of the matrix  A  corresponding  to  the  selected
          eigenvalues, with the i-th column of Z holding the
          eigenvector associated with W(i).  If JOBZ =  'N',
          then  Z  is  not  referenced.  Note: the user must
          ensure that at least max(1,M) columns are supplied
          in the array Z; if RANGE = 'V', the exact value of
          M is not known in advance and an upper bound  must
          be used.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

ISUPPZ (output)
```

The support of the eigenvectors in Z, i.e., the indices indicating the nonzero elements in Z. The i-th eigenvector is nonzero only in elements ISUPPZ(2*i-1) through ISUPPZ(2*i).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. LWORK >= max(1,2*N). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the max of the blocksize for CHETRD and for CUNMTR as returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
On exit, if INFO = 0, RWORK(1) returns the optimal (and minimal) LRWORK.

LRWORK (input)
The length of the array RWORK. LRWORK >= max(1,24*N).

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal (and minimal) LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= max(1,10*N).

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
> 0: Internal error

```

PURPOSE

cheevx computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

RANGE (input)

= 'A': all eigenvalues will be found.
= 'V': all eigenvalues in the half-open interval (VL,VU] will be found. = 'I': the IL-th through IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A. On exit, the lower triangle (if UPLO='L') or the upper triangle (if UPLO='U') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
On normal exit, the first NFOUND elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

```
WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (input)
          The  length  of  the  array   WORK.    LDWORK   >=
          max(1,2*N).   For  optimal  efficiency,  LDWORK >=
          (NB+1)*N, where NB is the max of the blocksize for
          CHETRD and for CUNMTR as returned by ILAENV.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.

WORK2 (workspace)
          dimension(7*N)

IWORK3 (workspace)
          dimension(5*N)

IFAIL (output)
          If JOBZ = 'V', then if INFO = 0, the first  NFOUND
          elements  of  IFAIL  are  zero.  If INFO > 0, then
          IFAIL contains the  indices  of  the  eigenvectors
          that  failed  to  converge.   If  JOBZ = 'N', then
          IFAIL is not referenced.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, then i eigenvectors  failed  to
          converge.   Their  indices  are  stored  in  array
          IFAIL.
```

INTEGER*8 ITYPE, N, LDA, LDB, INFO
```

F95 INTERFACE

```
SUBROUTINE HEGS2(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER :: ITYPE, N, LDA, LDB, INFO

SUBROUTINE HEGS2_64(ITYPE, UPLO, N, A, [LDA], B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: ITYPE, N, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void chegs2(int itype, char uplo, int  n,  complex  *a,  int
          lda, complex *b, int ldb, int *info);

void chegs2_64(long itype, char uplo, long  n,  complex  *a,
          long lda, complex *b, long ldb, long *info);
```

PURPOSE

chegs2 reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U')*A*inv(U) or inv(L)*A*inv(L')
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U` or L'*A*L.

B must have been previously factorized as U'*U or L*L' by CPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U')*A*inv(U) or inv(L)*A*inv(L');
= 2 or 3: compute U*A*U' or L'*A*L.

UPLO (input)
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored, and how B has been factorized. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The triangular factor from the Cholesky factorization of B, as returned by CPOTRF.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

void chegst_64(long itype, char uplo, long  n,  complex  *a,
          long lda, complex *b, long ldb, long *info);
```

PURPOSE

chegst reduces a complex Hermitian-definite generalized eigenproblem to standard form.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U**H)*A*inv(U) or inv(L)*A*inv(L**H)
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U**H or L**H*A*L.

B must have been previously factorized as U**H*U or L*L**H by CPOTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U**H)*A*inv(U) or inv(L)*A*inv(L**H);
= 2 or 3: compute U*A*U**H or L**H*A*L.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as U**H*U; = 'L': Lower triangle of A is stored and B is factored as L*L**H.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the transformed matrix,

```
          stored in the same format as A.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input) The triangular factor from the Cholesky factoriza-
          tion of B, as returned by CPOTRF.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

```
#include <sunperf.h>

void chegv(int itype, char jobz, char uplo, int  n,  complex
          *a,  int  lda,  complex *b, int ldb, float *w, int
          *info);

void chegv_64(long itype, char jobz, char uplo, long n, com-
          plex *a, long lda, complex *b, long ldb, float *w,
          long *info);
```

PURPOSE

chegv computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.
```

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A.

On exit, if JOBZ = 'V', then if INFO = 0, A contains the matrix Z of eigenvectors. The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I. If JOBZ = 'N', then on exit the upper triangle (if UPLO='U') or the lower triangle (if UPLO='L') of A, including the diagonal, is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the Hermitian positive definite matrix B. If UPLO = 'U', the leading N-by-N upper triangular part of B contains the upper triangular part of the matrix B. If UPLO = 'L', the leading N-by-N lower triangular part of B contains the lower triangular part of the matrix B.

On exit, if INFO <= N, the part of B containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization B = U**H*U or B = L*L**H.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of the array WORK. LDWORK >= max(1,2*N-1). For optimal efficiency, LDWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(max(1,3*N-2))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or CHEEV returned an error code:
<= N: if INFO = i, CHEEV failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

          complex  *a, long lda, complex *b, long ldb, float
          *w, long *info);
```

PURPOSE

chegvd computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

```
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.
A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the matrix A.

          On exit, if JOBZ = 'V', then if INFO = 0,  A  con-
          tains the matrix Z of eigenvectors.  The eigenvec-
          tors are normalized as follows:  if ITYPE =  1  or
          2,  Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I.
          If JOBZ = 'N', then on exit the upper triangle (if
          UPLO='U')  or  the lower triangle (if UPLO='L') of
          A, including the diagonal, is destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input/output)
          On entry, the Hermitian matrix B.  If UPLO =  'U',
          the leading N-by-N upper triangular part of B con-
          tains the upper triangular part of the  matrix  B.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of B contains the lower  triangular  part  of
          the matrix B.

          On exit, if INFO <= N, the part  of  B  containing
          the matrix is overwritten by the triangular factor
          U or L from the Cholesky factorization B =  U**H*U
          or B = L*L**H.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).
```

W (output)
If INFO = 0, the eigenvalues in ascending order.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. If N <= 1, LWORK >= 1. If JOBZ = 'N' and N > 1, LWORK >= N + 1. If JOBZ = 'V' and N > 1, LWORK >= 2*N + N**2.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of the array RWORK. If N <= 1, LRWORK >= 1. If JOBZ = 'N' and N > 1, LRWORK >= N. If JOBZ = 'V' and N > 1, LRWORK >= 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If N <= 1, LIWORK >= 1. If JOBZ = 'N' and N > 1, LIWORK >= 1. If JOBZ = 'V' and N > 1, LIWORK >= 3 + 5*N.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: CPOTRF or CHEEVD returned an error code:

<= N: if INFO = i, CHEEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero; > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

PURPOSE

chegvx computes selected eigenvalues, and optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of A contains the lower  triangular  part  of
          the matrix A.

          On exit,  the lower triangle (if UPLO='L') or  the
          upper  triangle  (if UPLO='U') of A, including the
          diagonal, is destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input/output)
          On entry, the Hermitian matrix B.  If UPLO =  'U',
          the leading N-by-N upper triangular part of B con-
          tains the upper triangular part of the  matrix  B.
          If UPLO = 'L', the leading N-by-N lower triangular
          part of B contains the lower  triangular  part  of
          the matrix B.
```

```
          On exit, if INFO <= N, the part  of  B  containing
          the matrix is overwritten by the triangular factor
          U or L from the Cholesky factorization B =  U**H*U
          or B = L*L**H.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.
VU (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

IL (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.

IU (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and  largest  eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.

ABSTOL (input)
          The absolute error tolerance for the  eigenvalues.
          An approximate eigenvalue is accepted as converged
          when it is determined to lie in an interval  [a,b]
          of width less than or equal to

          ABSTOL + EPS *   max( |a|,|b| ) ,

          where EPS is the machine precision.  If ABSTOL  is
          less than or equal to zero, then  EPS*|T|  will be
          used in its place, where |T| is the 1-norm of  the
          tridiagonal  matrix obtained by reducing A to tri-
          diagonal form.

          Eigenvalues will be computed most accurately  when
          ABSTOL  is  set  to  twice the underflow threshold
          2*SLAMCH('S'), not zero.  If this routine  returns
          with INFO>0, indicating that some eigenvectors did
```

not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (output)
If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**T*B*Z = I; if ITYPE = 3, Z**T*inv(B)*Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace/output)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of the array WORK. LWORK >= max(1,2*N-1). For optimal efficiency, LWORK >= (NB+1)*N, where NB is the blocksize for CHETRD returned by ILAENV.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)

dimension(7*N)

IWORK (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPOTRF or CHEEVX returned an error code:
<= N: if INFO = i, CHEEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= N, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

NAME

```
chemm - perform one of the  matrix-matrix  operations  C  :=
alpha*A*B + beta*C or C := alpha*B*A + beta*C
```

SYNOPSIS

```
SUBROUTINE CHEMM(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
      LDC)

CHARACTER * 1 SIDE, UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER M, N, LDA, LDB, LDC

SUBROUTINE CHEMM_64(SIDE, UPLO, M, N, ALPHA, A, LDA, B, LDB, BETA, C,
      LDC)

CHARACTER * 1 SIDE, UPLO
COMPLEX ALPHA, BETA
COMPLEX A(LDA,*), B(LDB,*), C(LDC,*)
INTEGER*8 M, N, LDA, LDB, LDC
```

F95 INTERFACE

```
SUBROUTINE HEMM(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])

CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,:) :: A, B, C
INTEGER :: M, N, LDA, LDB, LDC

SUBROUTINE HEMM_64(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,:) :: A, B, C
INTEGER(8) :: M, N, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>

void chemm(char side, char  uplo,  int  m,  int  n,  complex
          *alpha,  complex *a, int lda, complex *b, int ldb,
          complex *beta, complex *c, int ldc);

void chemm_64(char side, char uplo, long m, long n,  complex
          *alpha,  complex  *a,  long  lda, complex *b, long
          ldb, complex *beta, complex *c, long ldc);
```

PURPOSE

chemm performs one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C where alpha and beta are scalars, A is an hermitian matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether the hermitian matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the hermitian matrix A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of the hermitian matrix is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of the hermitian matrix is to be referenced.

Unchanged on exit.

M (input)
On entry, M specifies the number of rows of the matrix C. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix C. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.
A (input)
COMPLEX array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the hermitian matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1, m), otherwise LDA >= max(1, n). Unchanged on exit.

B (input)

COMPLEX array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB must be at least max(1, m). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

COMPLEX array of DIMENSION (LDC, n).

Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry.

On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, m). Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>

void chemv(char uplo, int n, complex *alpha, complex *a, int
          lda,  complex *x, int incx, complex *beta, complex
          *y, int incy);

void chemv_64(char uplo, long n, complex *alpha, complex *a,
          long  lda,  complex  *x, long incx, complex *beta,
          complex *y, long incy);
```

PURPOSE

chemv performs the matrix-vector operation y := alpha*A*x + beta*y where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading

n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

X (input)

(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

void cher_64(char uplo, long n,  float  alpha,  complex  *x,
          long incx, complex *a, long lda);
```

PURPOSE

cher performs the hermitian rank 1 operation A := alpha*x*conjg(x') + A where alpha is a real scalar, x is an n element vector and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

          long incx, complex *y, long incy, complex *a, long
          lda);
```

PURPOSE

cher2 performs the hermitian rank 2 operation A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A where alpha is a scalar, x and y are n element vectors and A is an n by n hermitian matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of A is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of A is to be referenced.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element

vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

Y (input)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

A (input/output)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the hermitian matrix and the strictly lower triangular part of A is not referenced. On exit, the upper triangular part of the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the hermitian matrix and the strictly upper triangular part of A is not referenced. On exit, the lower triangular part of the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

       [LDB], BETA, C, [LDC])

CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,:) :: A, B, C
INTEGER(8) :: N, K, LDA, LDB, LDC
REAL :: BETA
```

C INTERFACE

```
#include <sunperf.h>
void cher2k(char uplo, char transa, int n, int  k,  complex*
          alpha,  complex  *a, int lda, complex *b, int ldb,
          float beta, complex *c, int ldc);

void cher2k_64(char uplo, char transa, long n, long k,  com-
          plex  *alpha,  complex  *a,  long lda, complex *b,
          long ldb, float beta, complex *c, long ldc);
```

PURPOSE

cher2k performs one of the Hermitian rank 2k operations C := alpha*A*conjg(B') + conjg(alpha)*B*conjg(A') + beta*C or C := alpha*conjg(A')*B + conjg(alpha)*conjg(B')*A + beta*C where alpha and beta are scalars with beta real, C is an n by n Hermitian matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)

On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)

On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   C := alpha*A*conjg(B') + conjg(alpha)*B*conjg(A') + beta*C.

TRANSA = 'C' or 'c'   C := alpha*conjg(A')*B + conjg(alpha)*conjg(B')*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

B (input)

COMPLEX array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)
COMPLEX array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

          *ferr, float *berr, long *info);
```

PURPOSE

cherfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHETRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHETRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CHETRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

+ beta*C
```

SYNOPSIS

```
SUBROUTINE CHERK(UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)

CHARACTER * 1 UPLO, TRANSA
COMPLEX A(LDA,*), C(LDC,*)
INTEGER N, K, LDA, LDC
REAL ALPHA, BETA

SUBROUTINE CHERK_64(UPLO, TRANSA, N, K, ALPHA, A, LDA, BETA, C, LDC)

CHARACTER * 1 UPLO, TRANSA
COMPLEX A(LDA,*), C(LDC,*)
INTEGER*8 N, K, LDA, LDC
REAL ALPHA, BETA
```

F95 INTERFACE

```
SUBROUTINE HERK(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA, C,
       [LDC])

CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX, DIMENSION(:,:) :: A, C
INTEGER :: N, K, LDA, LDC
REAL :: ALPHA, BETA

SUBROUTINE HERK_64(UPLO, [TRANSA], [N], [K], ALPHA, A, [LDA], BETA,
       C, [LDC])
```

```
CHARACTER(LEN=1) :: UPLO, TRANSA
COMPLEX, DIMENSION(:,:) :: A, C
INTEGER(8) :: N, K, LDA, LDC
REAL :: ALPHA, BETA
```

C INTERFACE

```
#include <sunperf.h>

void cherk(char uplo, char  transa,  int  n,  int  k,  float
          alpha,  complex  *a,  int lda, float beta, complex
          *c, int ldc);

void cherk_64(char uplo, char transa, long n, long k,  float
          alpha,  complex  *a, long lda, float beta, complex
          *c, long ldc);
```

PURPOSE

cherk performs one of the Hermitian rank k operations C := alpha*A*conjg(A') + beta*C or C := alpha*conjg(A')*A + beta*C where alpha and beta are real scalars, C is an n by n Hermitian matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   C := alpha*A*conjg(A') + beta*C.

TRANSA = 'C' or 'c'   C := alpha*conjg(A')*A +

beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)
On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'C' or 'c', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)
COMPLEX array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the Hermitian matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated

matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the Hermitian matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

```

C INTERFACE

```
   #include <sunperf.h>

   void chesv(char uplo, int n, int nrhs, complex *a, int  lda,
             int *ipivot, complex *b, int ldb, int *info);
   void chesv_64(char uplo, long n, long nrhs, complex *a, long
             lda,  long  *ipivot,  complex  *b,  long ldb, long
             *info);
```

PURPOSE

chesv computes the solution to a complex system of linear equations
A * X = B, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
A = U * D * U**H, if UPLO = 'U', or
A = L * D * L**H, if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)

On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHETRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
Details of the interchanges and the block structure of D, as determined by CHETRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >= 1, and for best performance LDWORK >= N*NB, where NB is the optimal blocksize for CHETRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

          *a,  int  lda, complex *af, int ldaf, int *ipivot,
          complex *b, int ldb, complex *x,  int  ldx,  float
          *rcond, float *ferr, float *berr, int *info);

void chesvx_64(char fact, char uplo, long n, long nrhs, com-
          plex  *a,  long  lda, complex *af, long ldaf, long
          *ipivot, complex *b, long ldb,  complex  *x,  long
          ldx,  float *rcond, float *ferr, float *berr, long
          *info);
```

PURPOSE

chesvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A.
   The form of the factorization is
      A = U * D * U**H, if UPLO = 'U', or

```
      A = L * D * L**H,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper
(lower)
   triangular matrices, and D is Hermitian and block  diago-
nal with
   1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.
3. The system of equations is solved for X  using  the  fac-
tored form
   of A.

4. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored  form  of  A
          has  been supplied on entry.  = 'F':  On entry, AF
          and IPIVOT contain the factored form of A.  A,  AF
          and  IPIVOT  will  not  be  modified.  = 'N':  The
          matrix A will be copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
```

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHETRF.

If FACT = 'N', then AF is an output argument and on exit returns the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHETRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHETRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >= 2*N, and for best performance LDWORK >= N*NB, where NB is the optimal blocksize for CHETRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

COMPLEX, DIMENSION(:,:) :: A
```

```
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>

void chetf2(char uplo, int  n,  complex  *a,  int  lda,  int
          *ipiv, int *info);

void chetf2_64(char uplo, long n, complex *a, long lda, long
          *ipiv, long *info);
```

PURPOSE

chetf2 computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method:

```
   A = U*D*U'  or  A = L*D*L'
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the conjugate transpose of U, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)
Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by
J. Lewis, Boeing Computer Services Company
A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

If UPLO = 'U', then A = U*D*U', where
U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where

```
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
```

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

```

C INTERFACE

```
#include <sunperf.h>

void chetrd(char uplo, int n, complex *a, int lda, float *d,
          float *e, complex *tau, int *info);

void chetrd_64(char uplo, long  n,  complex  *a,  long  lda,
          float *d, float *e, complex *tau, long *info);
```

PURPOSE

chetrd reduces a complex Hermitian matrix A to real symmetric tridiagonal form T by a unitary similarity transformation: Q**H * A * Q = T.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

D (output)
The diagonal elements of the tridiagonal matrix T: D(i) = A(i,i).

E (output)
The off-diagonal elements of the tridiagonal matrix T: E(i) = A(i,i+1) if UPLO = 'U', E(i) = A(i+1,i) if UPLO = 'L'.

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. For optimum performance LWORK >= N*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

If UPLO = 'U', the matrix Q is represented as a product of elementary reflectors

Q = H(n-1) . . . H(2) H(1).

Each H(i) has the form

```
   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(i+1:n)  = 0 and v(i) = 1; v(1:i-1) is stored on exit
in
A(1:i-1,i+1), and tau in TAU(i).

If UPLO = 'L', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(1:i)  = 0 and v(i+1) = 1; v(i+2:n) is stored on exit
in A(i+2:n,i), and tau in TAU(i).

The contents of A on exit are illustrated by  the  following
examples with n = 5:

if UPLO = 'U':                       if UPLO = 'L':

  (    d     e     v2    v3    v4   )                (     d
)
  (       d    e    v3    v4   )                (    e     d
)
  (           d    e    v4  )                (   v1   e     d
)
  (              d   e  )                (   v1   v2   e    d
)
  (                  d  )              (  v1  v2  v3  e    d
)

where d and e denote diagonal and off-diagonal  elements  of
T, and vi denotes an element of the vector defining H(i).

SUBROUTINE HETRF_64(UPLO, [N], A, [LDA], IPIVOT, [WORK], [LDWORK],
       [INFO])
```

```
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void chetrf(char uplo, int  n,  complex  *a,  int  lda,  int
          *ipivot, int *info);

void chetrf_64(char uplo, long n, complex *a, long lda, long
          *ipivot, long *info);
```

PURPOSE

chetrf computes the factorization of a complex Hermitian matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the Hermitian matrix A.  If UPLO =  'U',
          the leading N-by-N upper triangular part of A con-
          tains the upper triangular part of the  matrix  A,
          and the strictly lower triangular part of A is not
          referenced.  If UPLO =  'L',  the  leading  N-by-N
          lower triangular part of A contains the lower tri-
          angular part of the matrix  A,  and  the  strictly
          upper triangular part of A is not referenced.
```

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >=1. For best performance LDWORK >= N*NB, where NB is the block size returned by ILAENV.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

```
If UPLO = 'U', then A = U*D*U', where
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where  k  decreases
from  n  to  1 in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation matrix as defined by IPIVOT(k), and U(k) is a
unit upper triangular matrix,  such  that  if  the  diagonal
```

block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where
L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

          *ipivot, int *info);

void chetri_64(char uplo, long n, complex *a, long lda, long
          *ipivot, long *info);
```

PURPOSE

chetri computes the inverse of a complex Hermitian indefinite matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHETRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHETRF.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHETRF.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

PURPOSE

chgeqz implements a single-shift version of the QZ method for finding the generalized eigenvalues w(i)=ALPHA(i)/BETA(i) of the equation A are then ALPHA(1),...,ALPHA(N), and of B are BETA(1),...,BETA(N).

If JOB='S' and COMPQ and COMPZ are 'V' or 'I', then the unitary transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:
(in) A(in) Z(in)* = Q(out) A(out) Z(out)*

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrixigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

```
JOB (input)
          = 'E': compute only ALPHA and BETA.  A and B  will
          not  necessarily  be  put  into  generalized Schur
          form.  = 'S': put A and B into  generalized  Schur
          form, as well as computing ALPHA and BETA.

COMPQ (input)
          = 'N': do not modify Q.
          = 'V': multiply the array Q on the  right  by  the
          conjugate  transpose  of the unitary tranformation
          that is applied to the left side of  A  and  B  to
          reduce them to Schur form.  = 'I': like COMPQ='V',
          except that Q will be initialized to the  identity
          first.

COMPZ (input)
          = 'N': do not modify Z.
          = 'V': multiply the array Z on the  right  by  the
          unitary tranformation that is applied to the right
          side of A and B to reduce them to Schur  form.   =
          'I':  like  COMPZ='V',  except that Z will be ini-
          tialized to the identity first.

N (input) The order of the matrices A, B, Q, and Z.  N >= 0.

ILO (input)
          It is assumed that A is already  upper  triangular
          in rows and columns 1:ILO-1 and IHI+1:N.  1 <= ILO
          <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
          It is assumed that A is already  upper  triangular
          in rows and columns 1:ILO-1 and IHI+1:N.  1 <= ILO
          <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

A (input) On entry, the N-by-N upper  Hessenberg  matrix  A.
          Elements  below  the subdiagonal must be zero.  If
          JOB='S', then on exit  A  and  B  will  have  been
          simultaneously  reduced  to upper triangular form.
          If JOB='E', then on exit A  will  have  been  des-
          troyed.

LDA (input)
          The leading dimension of the array A.  LDA >= max(
          1, N ).

B (input) On entry, the N-by-N upper  triangular  matrix  B.
          Elements  below  the  diagonal  must  be zero.  If
          JOB='S', then on exit  A  and  B  will  have  been
```

simultaneously reduced to upper triangular form. If JOB='E', then on exit B will have been destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

ALPHA (output)
The diagonal elements of A when the pair (A,B) has been reduced to Schur form. ALPHA(i)/BETA(i) i=1,...,N are the generalized eigenvalues.

BETA (output)
The diagonal elements of B when the pair (A,B) has been reduced to Schur form. ALPHA(i)/BETA(i) i=1,...,N are the generalized eigenvalues. A and B are normalized so that BETA(1),...,BETA(N) are non-negative real numbers.

Q (input/output)
If COMPQ='N', then Q will not be referenced. If COMPQ='V' or 'I', then the conjugate transpose of the unitary transformations which are applied to A and B on the left will be applied to the array Q on the right.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1. If COMPQ='V' or 'I', then LDQ >= N.

Z (input/output)
If COMPZ='N', then Z will not be referenced. If COMPZ='V' or 'I', then the unitary transformations which are applied to A and B on the right will be applied to the array Z on the right.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If COMPZ='V' or 'I', then LDZ >= N.

WORK (workspace)
On exit, if INFO >= 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
= 1,...,N: the QZ iteration did not converge. (A,B) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (A,B) is not in Schur form, but ALPHA(i) and BETA(i), i=INFO-N+1,...,N should be correct. > 2*N: various "impossible" errors.

FURTHER DETAILS

We assume that complex ABS works as long as its value is less than overflow.

```
#include <sunperf.h>

void chpcon(char uplo, int n, complex *a, int *ipivot, float
          anorm, float *rcond, int *info);

void chpcon_64(char uplo, long n, complex *a, long  *ipivot,
          float anorm, float *rcond, long *info);
```

PURPOSE

chpcon estimates the reciprocal of the condition number of a complex Hermitian packed matrix A using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHPTRF.

ANORM (input)
The 1-norm of the original matrix A.

```
RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix  A, computed as RCOND = 1/(ANORM * AINVNM),
          where AINVNM is  an  estimate  of  the  1-norm  of
          inv(A) computed in this routine.

WORK (workspace)
          dimension(2*N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

          *w, complex *z, int ldz, int *info);

void chpev_64(char jobz, char  uplo,  long  n,  complex  *a,
          float *w, complex *z, long ldz, long *info);
```

PURPOSE

chpev computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix in packed storage.

ARGUMENTS

JOBZ (input)
= 'N': Compute eigenvalues only;
= 'V': Compute eigenvalues and eigenvectors.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

```
W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          orthonormal eigenvectors of the matrix A, with the
          i-th column of Z holding the  eigenvector  associ-
          ated  with  W(i).   If  JOBZ  = 'N', then Z is not
          referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).
WORK (workspace)
          dimension(MAX(1,2*N-1))

WORK2 (workspace)
          dimension(max(1,3*N-2))

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  if INFO = i, the algorithm  failed  to  con-
          verge;  i off-diagonal elements of an intermediate
          tridiagonal form did not converge to zero.

```
#include <sunperf.h>
void chpevd(char jobz, char uplo, int n, complex *ap,  float
          *w, complex *z, int ldz, int *info);

void chpevd_64(char jobz, char uplo, long  n,  complex  *ap,
          float *w, complex *z, long ldz, long *info);
```

PURPOSE

chpevd computes all the eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A in packed storage. If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.
```

AP (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

On exit, AP is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

W (output)
If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, Z contains the orthonormal eigenvectors of the matrix A, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of array WORK. If N <= 1, LWORK must be at least 1. If JOBZ = 'N' and N > 1, LWORK must be at least N. If JOBZ = 'V' and N > 1, LWORK must be at least 2*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of array RWORK. If N <= 1,

LRWORK must be at least 1. If JOBZ = 'N' and N > 1, LRWORK must be at least N. If JOBZ = 'V' and N > 1, LRWORK must be at least 1 + 5*N + 2*N**2.

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of array IWORK. If JOBZ = 'N' or N <= 1, LIWORK must be at least 1. If JOBZ = 'V' and N > 1, LIWORK must be at least 3 + 5*N.

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the algorithm failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not converge to zero.

```
#include <sunperf.h>

void chpevx(char jobz, char range, char uplo, int n, complex
          *a,  float  vl,  float  vu,  int il, int iu, float
          abtol, int *nfound, float *w, complex *z, int ldz,
          int *ifail, int *info);

void chpevx_64(char jobz, char range,  char  uplo,  long  n,
          complex  *a, float vl, float vu, long il, long iu,
          float abtol, long *nfound, float *w,  complex  *z,
          long ldz, long *ifail, long *info);
```

PURPOSE

chpevx computes selected eigenvalues and, optionally, eigen- vectors of a complex Hermitian matrix A in packed storage. Eigenvalues/vectors can be selected by specifying either a range of values or a range of indices for the desired eigen- values.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found;
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be  found; = 'I': the IL-th through
```

IU-th eigenvalues will be found.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.
On exit, A is overwritten by values generated during the reduction to tridiagonal form. If UPLO = 'U', the diagonal and first superdiagonal of the tridiagonal matrix T overwrite the corresponding elements of A, and if UPLO = 'L', the diagonal and first subdiagonal of T overwrite the corresponding elements of A.

VL (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

VU (input)
If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged

when it is determined to lie in an interval [a,b] of width less than or equal to

ABTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing A to tri-diagonal form.

Eigenvalues will be computed most accurately when ABTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABTOL to 2*SLAMCH('S').

See "Computing Small Singular Values of Bidiagonal Matrices with Guaranteed High Relative Accuracy," by Demmel and Kahan, LAPACK Working Note #3.

NFOUND (output)
The total number of eigenvalues found. 0 <= NFOUND <= N. If RANGE = 'A', NFOUND = N, and if RANGE = 'I', NFOUND = IU-IL+1.

W (output)
If INFO = 0, the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0, the first NFOUND columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If an eigenvec-tor fails to converge, then that column of Z con-tains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,NFOUND) columns are supplied in the array Z; if RANGE = 'V', the exact value of NFOUND is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(7*N)

IWORK3 (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first NFOUND elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, then i eigenvectors failed to converge. Their indices are stored in array IFAIL.

          plex *bp, int *info);

void chpgst_64(long itype, char uplo, long n,  complex  *ap,
          complex *bp, long *info);
```

PURPOSE

chpgst reduces a complex Hermitian-definite generalized eigenproblem to standard form, using packed storage.

If ITYPE = 1, the problem is A*x = lambda*B*x,
and A is overwritten by inv(U**H)*A*inv(U) or inv(L)*A*inv(L**H)
If ITYPE = 2 or 3, the problem is A*B*x = lambda*x or
B*A*x = lambda*x, and A is overwritten by U*A*U**H or L**H*A*L.

B must have been previously factorized as U**H*U or L*L**H by CPPTRF.

ARGUMENTS

ITYPE (input)
= 1: compute inv(U**H)*A*inv(U) or inv(L)*A*inv(L**H);
= 2 or 3: compute U*A*U**H or L**H*A*L.

UPLO (input)
= 'U': Upper triangle of A is stored and B is factored as U**H*U; = 'L': Lower triangle of A is stored and B is factored as L*L**H.

N (input) The order of the matrices A and B. N >= 0.

AP (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, if INFO = 0, the transformed matrix, stored in the same format as A.

BP (input)
The triangular factor from the Cholesky factorization of B, stored in the same format as A, as returned by CPPTRF.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
#include <sunperf.h>

void chpgv(int itype, char jobz, char uplo, int  n,  complex
          *a, complex *b, float *w, complex *z, int ldz, int
          *info);

void chpgv_64(long itype, char jobz, char uplo, long n, com-
          plex  *a,  complex  *b, float *w, complex *z, long
          ldz, long *info);
```

PURPOSE

chpgv computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.
```

```
A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  A  as  follows:   if  UPLO = 'U', A(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i +
          (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

          On exit, the contents of A are destroyed.

B (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  B,  packed  columnwise in a linear
          array.  The j-th column of  B  is  stored  in  the
          array  B  as  follows:   if  UPLO = 'U', B(i + (j-
          1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L', B(i +
          (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

          On exit, the triangular factor U  or  L  from  the
          Cholesky  factorization  B = U**H*U or B = L*L**H,
          in the same storage format as B.

W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          matrix  Z  of  eigenvectors.  The eigenvectors are
          normalized  as  follows:   if  ITYPE  =  1  or  2,
          Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I.  If
          JOBZ = 'N', then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
          dimension(MAX(1,2*N-1))

WORK2 (workspace)
          dimension(MAX(1,3*N-2))

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  CPPTRF or CHPEV returned an error code:
          <= N:  if INFO = i, CHPEV failed  to  converge;  i

          complex  *ap,  complex  *bp, float *w, complex *z,
          long ldz, long *info);
```

PURPOSE

chpgvd computes all the eigenvalues and, optionally, the eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite.
If eigenvectors are desired, it uses a divide and conquer algorithm.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

ITYPE (input)

```
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.
AP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  AP  as  follows:  if UPLO = 'U', AP(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L',  AP(i
          + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

          On exit, the contents of AP are destroyed.

BP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  B,  packed  columnwise in a linear
          array.  The j-th column of  B  is  stored  in  the
          array  BP  as  follows:  if UPLO = 'U', BP(i + (j-
          1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L',  BP(i
          + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

          On exit, the triangular factor U  or  L  from  the
          Cholesky  factorization  B = U**H*U or B = L*L**H,
          in the same storage format as B.

W (output)
          If INFO = 0, the eigenvalues in ascending order.

Z (input) If JOBZ = 'V', then if INFO = 0,  Z  contains  the
          matrix  Z  of  eigenvectors.  The eigenvectors are
          normalized  as  follows:   if  ITYPE  =  1  or  2,
          Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I.  If
          JOBZ = 'N', then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
```

```
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The  dimension  of  array  WORK.   If  N   <=   1,
          LWORK  >= 1.  If JOBZ = 'N' and N > 1, LWORK >= N.
          If JOBZ = 'V' and N > 1, LWORK >= 2*N.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

RWORK (workspace)
          On exit, if INFO = 0, RWORK(1) returns the optimal
          LRWORK.

LRWORK (input)
          The  dimension  of  array  RWORK.   If  N  <=   1,
          LRWORK  >=  1.  If JOBZ = 'N' and N > 1, LRWORK >=
          N.  If JOBZ = 'V' and N > 1, LRWORK >= 1 +  5*N  +
          2*N**2.

          If LRWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the RWORK array, returns this value as  the  first
          entry  of  the  RWORK  array, and no error message
          related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LIWORK.

LIWORK (input)
          The dimension of array IWORK.  If JOBZ  = 'N' or N
          <=  1,  LIWORK  >=  1.   If JOBZ  = 'V' and N > 1,
          LIWORK >= 3 + 5*N.

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  CPPTRF or CHPEVD returned an error code:
```

<= N: if INFO = i, CHPEVD failed to converge; i off-diagonal elements of an intermediate tridiagonal form did not convergeto zero; > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

          *w,  complex  *z,  long  ldz,  long  *ifail,  long
          *info);
```

PURPOSE

chpgvx computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian-definite eigenproblem, of the form A*x=(lambda)*B*x, A*Bx=(lambda)*x, or B*A*x=(lambda)*x. Here A and B are assumed to be Hermitian, stored in packed format, and B is also positive definite. Eigenvalues and eigenvectors can be selected by specifying either a range of values or a range of indices for the desired eigenvalues.

ARGUMENTS

```
ITYPE (input)
          Specifies the problem type to be solved:
          = 1:  A*x = (lambda)*B*x
          = 2:  A*B*x = (lambda)*x
          = 3:  B*A*x = (lambda)*x

JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.

RANGE (input)
          = 'A': all eigenvalues will be found;
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be  found; = 'I': the IL-th through
          IU-th eigenvalues will be found.
UPLO (input)
          = 'U':  Upper triangles of A and B are stored;
          = 'L':  Lower triangles of A and B are stored.

N (input) The order of the matrices A and B.  N >= 0.

AP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  AP  as  follows:  if UPLO = 'U', AP(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L',  AP(i
          + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

          On exit, the contents of AP are destroyed.

BP (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  B,  packed  columnwise in a linear
          array.  The j-th column of  B  is  stored  in  the
          array  BP  as  follows:  if UPLO = 'U', BP(i + (j-
          1)*j/2) = B(i,j) for 1<=i<=j; if UPLO = 'L',  BP(i
          + (j-1)*(2*n-j)/2) = B(i,j) for j<=i<=n.

          On exit, the triangular factor U  or  L  from  the
          Cholesky  factorization  B = U**H*U or B = L*L**H,
          in the same storage format as B.

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

VU (input)
```

If RANGE='V', the lower and upper bounds of the interval to be searched for eigenvalues. VL < VU. Not referenced if RANGE = 'A' or 'I'.

IL (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [a,b] of width less than or equal to

ABSTOL + EPS * max(|a|,|b|) ,

where EPS is the machine precision. If ABSTOL is less than or equal to zero, then EPS*|T| will be used in its place, where |T| is the 1-norm of the tridiagonal matrix obtained by reducing AP to tri-diagonal form.

Eigenvalues will be computed most accurately when ABSTOL is set to twice the underflow threshold 2*SLAMCH('S'), not zero. If this routine returns with INFO>0, indicating that some eigenvectors did not converge, try setting ABSTOL to 2*SLAMCH('S').

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
On normal exit, the first M elements contain the selected eigenvalues in ascending order.

Z (input) If JOBZ = 'N', then Z is not referenced. If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix A corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). The eigenvectors are normalized as follows: if ITYPE = 1 or 2, Z**H*B*Z = I; if ITYPE = 3, Z**H*inv(B)*Z = I.

If an eigenvector fails to converge, then that column of Z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in IFAIL. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

WORK (workspace)
dimension(2*N)

RWORK (workspace)
dimension(7*N)

IWORK (workspace)
dimension(5*N)

IFAIL (output)
If JOBZ = 'V', then if INFO = 0, the first M elements of IFAIL are zero. If INFO > 0, then IFAIL contains the indices of the eigenvectors that failed to converge. If JOBZ = 'N', then IFAIL is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: CPPTRF or CHPEVX returned an error code:
<= N: if INFO = i, CHPEVX failed to converge; i eigenvectors failed to converge. Their indices are stored in array IFAIL. > N: if INFO = N + i, for 1 <= i <= n, then the leading minor of order i of B is not positive definite. The factorization of B could not be completed and no eigenvalues or eigenvectors were computed.

COMPLEX, DIMENSION(:) :: A, X, Y
```

```
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>

void chpmv(char uplo, int n,  complex  *alpha,  complex  *a,
          complex  *x,  int incx, complex *beta, complex *y,
          int incy);

void chpmv_64(char uplo, long n, complex *alpha, complex *a,
          complex  *x, long incx, complex *beta, complex *y,
          long incy);
```

PURPOSE

chpmv performs the matrix-vector operation y := alpha*A*x + beta*y where alpha and beta are scalars, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u'   The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l'   The lower triangular part of A is supplied in A.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed

sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that the imaginary parts of the diagonal elements need not be set and are assumed to be zero. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

          long incx, complex *a);
```

PURPOSE

chpr performs the hermitian rank 1 operation A := alpha*x*conjg(x') + A where alpha is a real scalar, x is an n element vector and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array A as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in A.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in A.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

A (input/output)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array A is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array A is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

void chpr2_64(char uplo, long n, complex *alpha, complex *x,
          long incx, complex *y, long incy, complex *ap);
```

PURPOSE

chpr2 performs the Hermitian rank 2 operation A := alpha*x*conjg(y') + conjg(alpha)*y*conjg(x') + A where alpha is a scalar, x and y are n element vectors and A is an n by n hermitian matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the matrix A is supplied in the packed array AP as follows:

UPLO = 'U' or 'u' The upper triangular part of A is supplied in AP.

UPLO = 'L' or 'l' The lower triangular part of A is supplied in AP.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the n element vector x. Unchanged on exit.

INCX (input)

On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

Y (input)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

AP (input/output)

((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array AP must contain the upper triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(1, 2) and a(2, 2) respectively, and so on. On exit, the array AP is overwritten by the upper triangular part of the updated matrix. Before entry with UPLO = 'L' or 'l', the array AP must contain the lower triangular part of the hermitian matrix packed sequentially, column by column, so that AP(1) contains a(1, 1), AP(2) and AP(3) contain a(2, 1) and a(3, 1) respectively, and so on. On exit, the array AP is overwritten by the lower triangular part of the updated matrix. Note that the imaginary parts of the diagonal elements need not be set, they are assumed to be zero, and on exit they are set to zero.

              complex *x, long ldx, float  *ferr,  float  *berr,
              long *info);
```

PURPOSE

chprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
    UPLO (input)
              = 'U':  Upper triangle of A is stored;
              = 'L':  Lower triangle of A is stored.

    N (input) The order of the matrix A.  N >= 0.

    NRHS (input)
              The number of right hand sides, i.e.,  the  number
              of columns of the matrices B and X.  NRHS >= 0.

    A (input) The upper  or  lower  triangle  of  the  Hermitian
              matrix  A,  packed  columnwise  in a linear array.
              The j-th column of A is stored in the array  A  as
```

follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AF (input)
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHPTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CHPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)

```
            dimension(N)

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
```

INTEGER, DIMENSION(:) :: IPIVOT

SUBROUTINE HPSV_64(UPLO, N, [NRHS], A, IPIVOT, B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO
```

```
COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:,:) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void chpsv(char uplo, int  n,  int  nrhs,  complex  *a,  int
          *ipivot, complex *b, int ldb, int *info);

void chpsv_64(char uplo, long n, long nrhs, complex *a, long
          *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

chpsv computes the solution to a complex system of linear equations
A * X = B, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
A = U * D * U**H, if UPLO = 'U', or
A = L * D * L**H, if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the

array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (output)
Details of the interchanges and the block structure of D, as determined by CHPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```
   a11 a12 a13 a14
```

```
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44
```

Packed storage of the upper triangle of A:

```
A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

C INTERFACE

```
#include <sunperf.h>

void chpsvx(char fact, char uplo, int n, int  nrhs,  complex
          *a, complex *af, int *ipivot, complex *b, int ldb,
          complex *x, int ldx, float  *rcond,  float  *ferr,
          float *berr, int *info);

void chpsvx_64(char fact, char uplo, long n, long nrhs, com-
          plex  *a,  complex  *af, long *ipivot, complex *b,
          long ldb, complex  *x,  long  ldx,  float  *rcond,
          float *ferr, float *berr, long *info);
```

PURPOSE

chpsvx uses the diagonal pivoting factorization A = U*D*U**H or A = L*D*L**H to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N Hermitian matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
      A = U * D * U**H,  if UPLO = 'U', or
```

```
      A = L * D * L**H,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper
(lower)
   triangular matrices and D is Hermitian and block diagonal
with
   1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.
3. The system of equations is solved for X  using  the  fac-
tored form
   of A.

4. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored  form  of  A
          has  been supplied on entry.  = 'F':  On entry, AF
          and IPIVOT contain the factored form of A.  AF and
          IPIVOT will not be modified.  = 'N':  The matrix A
          will be copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
```

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.
If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**H or A = L*D*L**H as computed by CHPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CHPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CHPTRF.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

```
LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

RCOND (output)
          The estimate of the reciprocal condition number of
          the  matrix  A.  If RCOND is less than the machine
          precision (in  particular,  if  RCOND  =  0),  the
          matrix  is  singular  to  working precision.  This
          condition is indicated by a return code of INFO  >
          0.

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          > 0:  if INFO = i, and i is
          <= N:  D(i,i) is exactly zero.  The  factorization
          has  been  completed  but  the factor D is exactly
          singular, so the solution and error  bounds  could
          not  be computed. RCOND = 0 is returned.  = N+1: D
          is nonsingular, but RCOND  is  less  than  machine
          precision,  meaning that the matrix is singular to
          working precision.  Nevertheless, the solution and
          error  bounds  are  computed  because  there are a
          number of situations where the  computed  solution
```

can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

```

C INTERFACE

```
#include <sunperf.h>

void chptrd(char uplo, int n, complex *ap, float  *d,  float
          *e, complex *tau, int *info);

void chptrd_64(char uplo, long n,  complex  *ap,  float  *d,
          float *e, complex *tau, long *info);
```

PURPOSE

chptrd reduces a complex Hermitian matrix A stored in packed form to real symmetric tridiagonal form T by a unitary similarity transformation: Q**H * A * Q = T.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input)
On entry, the upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. On exit, if UPLO = 'U', the diagonal and first superdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements above the first superdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors; if UPLO = 'L', the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T, and the elements below the first subdiagonal, with the array TAU, represent the unitary matrix Q as a product of elementary reflectors. See Further Details.

```
D (output)
          The diagonal elements of the tridiagonal matrix T:
          D(i) = A(i,i).

E (output)
          The  off-diagonal  elements  of  the   tridiagonal
          matrix  T:   E(i) = A(i,i+1) if UPLO = 'U', E(i) =
          A(i+1,i) if UPLO = 'L'.

TAU (output)
          The scalar factors of  the  elementary  reflectors
          (see Further Details).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
If UPLO = 'U', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(n-1) . . . H(2) H(1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(i+1:n)  = 0 and v(i) = 1; v(1:i-1) is stored on exit
in AP,  overwriting  A(1:i-1,i+1),  and  tau  is  stored  in
TAU(i).

If UPLO = 'L', the matrix Q is represented as a  product  of
elementary reflectors

   Q = H(1) H(2) . . . H(n-1).

Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a complex scalar, and v  is  a  complex  vector
with  v(1:i)  = 0 and v(i+1) = 1; v(i+2:n) is stored on exit
in AP, overwriting A(i+2:n,i), and tau is stored in TAU(i).

```
#include <sunperf.h>

void chptrf(char uplo, int n, complex *a, int  *ipivot,  int
          *info);

void chptrf_64(char uplo, long n, complex *a, long  *ipivot,
          long *info);
```

PURPOSE

chptrf computes the factorization of a complex Hermitian packed matrix A using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**H  or  A = L*D*L**H
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is Hermitian and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  A  as  follows:   if  UPLO = 'U', A(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i +
          (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

          On exit, the block diagonal matrix D and the  mul-
          tipliers  used to obtain the factor U or L, stored
          as a packed triangular matrix overwriting  A  (see
          below for further details).

IPIVOT (output)
```

```
          Details of the interchanges and the  block  struc-
          ture  of  D.   If  IPIVOT(k)  >  0,  then rows and
          columns k  and  IPIVOT(k)  were  interchanged  and
          D(k,k)  is a 1-by-1 diagonal block.  If UPLO = 'U'
          and IPIVOT(k) = IPIVOT(k-1) <  0,  then  rows  and
          columns  k-1  and -IPIVOT(k) were interchanged and
          D(k-1:k,k-1:k) is a  2-by-2  diagonal  block.   If
          UPLO  =  'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then
          rows and columns k+1 and  -IPIVOT(k)  were  inter-
          changed  and  D(k:k+1,k:k+1)  is a 2-by-2 diagonal
          block.

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          > 0: if INFO = i, D(i,i)  is  exactly  zero.   The
          factorization  has  been  completed, but the block
          diagonal matrix D is exactly singular,  and  divi-
          sion  by  zero will occur if it is used to solve a
          system of equations.
```

FURTHER DETAILS

```
5-96 - Based on modifications by J. Lewis,  Boeing  Computer
Services
       Company

If UPLO = 'U', then A = U*D*U', where
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where  k  decreases
from  n  to  1 in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation matrix as defined by IPIVOT(k), and U(k) is a
unit upper triangular matrix,  such  that  if  the  diagonal
block D(k) is of order s (s = 1 or 2), then

           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k

If s = 1, D(k) overwrites A(k,k), and  v  overwrites  A(1:k-
1,k).   If s = 2, the upper triangle of D(k) overwrites A(k-
1,k-1), A(k-1,k), and A(k,k), and  v  overwrites  A(1:k-2,k-
1:k).

If UPLO = 'L', then A = L*D*L', where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where  k  increases
```

from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

          *info);

void chptri_64(char uplo, long n, complex *a, long  *ipivot,
          long *info);
```

PURPOSE

chptri computes the inverse of a complex Hermitian indefinite matrix A in packed storage using the factorization A = U*D*U**H or A = L*D*L**H computed by CHPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**H;
= 'L': Lower triangular, form is A = L*D*L**H.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CHPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (Hermitian) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CHPTRF.

WORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) = 0; the matrix is singular and its inverse could not be computed.

```

C INTERFACE

```
#include <sunperf.h>

void chsein(char side, char eigsrc, char initv, int *select,
          int  n,  complex  *h, int ldh, complex *w, complex
          *vl, int ldvl, complex *vr, int ldvr, int mm,  int
          *m, int *ifaill, int *ifailr, int *info);

void chsein_64(char side,  char  eigsrc,  char  initv,  long
          *select, long n, complex *h, long ldh, complex *w,
          complex *vl, long ldvl, complex  *vr,  long  ldvr,
          long mm, long *m, long *ifaill, long *ifailr, long
          *info);
```

PURPOSE

chsein uses inverse iteration to find specified right and/or left eigenvectors of a complex upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

```
H * x = w * x,     y**h * H = w * y**h
```

where y**h denotes the conjugate transpose of the vector y.

ARGUMENTS

SIDE (input)

```
          = 'R': compute right eigenvectors only;
          = 'L': compute left eigenvectors only;
          = 'B': compute both right and left eigenvectors.

EIGSRC (input)
          Specifies the source of eigenvalues supplied in W:
          = 'Q': the eigenvalues were  found  using  CHSEQR;
          thus,  if  H has zero subdiagonal elements, and so
          is block-triangular, then the j-th eigenvalue  can
          be  assumed  to be an eigenvalue of the block con-
          taining the j-th row/column.  This property allows
          CHSEIN  to  perform  inverse iteration on just one
          diagonal block.  = 'N': no assumptions are made on
          the  correspondence between eigenvalues and diago-
          nal blocks.  In this case, CHSEIN must always per-
          form inverse iteration using the whole matrix H.

INITV (input)
          = 'N': no initial vectors are supplied;
          = 'U': user-supplied initial vectors are stored in
          the arrays VL and/or VR.

SELECT (input)
          Specifies the  eigenvectors  to  be  computed.  To
          select the eigenvector corresponding to the eigen-
          value W(j), SELECT(j) must be set to .TRUE..

N (input) The order of the matrix H.  N >= 0.

H (input) The upper Hessenberg matrix H.

LDH (input)
          The leading dimension of  the  array  H.   LDH  >=
          max(1,N).

W (input/output)
          On entry, the eigenvalues of H.  On exit, the real
          parts  of  W  may  have  been  altered since close
          eigenvalues are perturbed  slightly  in  searching
          for independent eigenvectors.

VL (input/output)
          On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL
          must  contain  starting  vectors  for  the inverse
          iteration for the left eigenvectors; the  starting
          vector  for  each  eigenvector must be in the same
          column in which the eigenvector  will  be  stored.
          On  exit, if SIDE = 'L' or 'B', the left eigenvec-
          tors specified by SELECT will be  stored  consecu-
          tively  in the columns of VL, in the same order as
```

their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR required to store the eigenvectors (= the number of .TRUE. elements in SELECT).

WORK (workspace)
dimension(N*N)

RWORK (workspace)
dimension(N)

IFAILL (output)
If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'R', IFAILL is not referenced.

IFAILR (output)
If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the

right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If SIDE = 'L', IFAILR is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

FURTHER DETAILS

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x|+|y|.

   CHARACTER(LEN=1) :: JOB, COMPZ
   COMPLEX, DIMENSION(:) :: W, WORK
   COMPLEX, DIMENSION(:,:) :: H, Z
   INTEGER(8) :: N, ILO, IHI, LDH, LDZ, LWORK, INFO
```

C INTERFACE

```
   #include <sunperf.h>

   void chseqr (char, char, int, int, int, complex*, int,  com-
             plex*, complex*, int, int*);

   void chseqr_64 (char,  char,  long,  long,  long,  complex*,
             long, complex*, complex*, long, long*);
```

PURPOSE

chseqr computes the eigenvalues of a complex upper Hessenberg matrix H, and, optionally, the matrices T and Z from the Schur decomposition H = Z T Z**H, where T is an upper triangular matrix (the Schur form), and Z is the unitary matrix of Schur vectors.

Optionally Z may be postmultiplied into an input unitary matrix Q, so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the unitary matrix Q: A = Q*H*Q**H = (QZ)*T*(QZ)**H.

ARGUMENTS

JOB (input)
= 'E': compute eigenvalues only;
= 'S': compute eigenvalues and the Schur form T.

COMPZ (input)
= 'N': no Schur vectors are computed;
= 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an unitary matrix Q on entry, and the product Q*Z is returned.

N (input) The order of the matrix H. N >= 0.

ILO (input)
It is assumed that H is already upper triangular

```
          in  rows  and columns 1:ILO-1 and IHI+1:N. ILO and
          IHI are normally set by a previous call to CGEBAL,
          and  then  passed to CGEHRD when the matrix output
          by CGEBAL is reduced to Hessenberg form. Otherwise
          ILO and IHI should be set to 1 and N respectively.
          1 <= ILO <= IHI <= N, if N > 0; ILO=1  and  IHI=0,
          if N=0.

IHI (input)
          See the description of ILO.

H (input/output)
          On entry, the upper Hessenberg matrix H.  On exit,
          if  JOB  =  'S',  H  contains the upper triangular
          matrix T from the Schur decomposition  (the  Schur
          form).  If  JOB  =  'E',  the  contents  of  H are
          unspecified on exit.

LDH (input)
          The leading dimension  of  the  array  H.  LDH  >=
          max(1,N).

W (output)
          The computed eigenvalues. If JOB = 'S', the eigen-
          values  are  stored  in  the  same order as on the
          diagonal of the Schur form  returned  in  H,  with
          W(i) = H(i,i).

Z (input) If COMPZ = 'N': Z is not referenced.
          If COMPZ = 'I': on entry, Z need not be  set,  and
          on  exit,  Z  contains the unitary matrix Z of the
          Schur vectors of H.  If COMPZ = 'V':  on  entry  Z
          must  contain an N-by-N matrix Q, which is assumed
          to be equal to the unit matrix except for the sub-
          matrix Z(ILO:IHI,ILO:IHI); on exit Z contains Q*Z.
          Normally Q is  the  unitary  matrix  generated  by
          CUNGHR  after  the call to CGEHRD which formed the
          Hessenberg matrix H.

LDZ (input)
          The leading dimension of  the  array  Z.   LDZ  >=
          max(1,N)  if  COMPZ  = 'I' or 'V'; LDZ >= 1 other-
          wise.

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (output)
          The  dimension  of  the  array  WORK.   LWORK   >=
```

max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, CHSEQR failed to compute all the eigenvalues in a total of 30*(IHI-ILO+1) iterations; elements 1:ilo-1 and i+1:n of W contain those eigenvalues which have been successfully computed.

 COMPLEX    ALPHA, BETA
 COMPLEX, DIMENSION(:) ::  VAL
 COMPLEX, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in jagged-diagonal format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
```

```
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

VAL()          array of length NNZ consisting of entries of A.
               VAL can be viewed as a column major ordering of a
               row permutation of the Ellpack representation of A,
               where the Ellpack representation is permuted so that
               the rows are non-increasing in the number of nonzero
               entries.  Values added for padding in Ellpack are
               not included in the Jagged-Diagonal format.

INDX()         array of length NNZ consisting of the column indices
               of the corresponding entries in VAL.
PNTR()         array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
               points to the location in VAL of the first element
               in the row-permuted Ellpack represenation of A.

MAXNZ          max number of nonzeros elements per row.

IPERM()        integer array of length M such that I = IPERM(I'),
               where row I in the original Ellpack representation
               corresponds to row I' in the permuted representation.
               If IPERM(1) = 0, it is assumed by convention that
               IPERM(I) = I. IPERM is used to determine the order
               in which rows of C are updated.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK. WORK is not
               referenced in the current version.

LWORK          length of WORK array. LWORK is not referenced
               in the current version.
```

NAME

cjadrp - right permutation of a jagged diagonal matrix

SYNOPSIS

```
 SUBROUTINE CJADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, WORK, LWORK )
 INTEGER    TRANSP, M, K, MAXNZ, LWORK
 INTEGER    INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
 COMPLEX    VAL(*)

 SUBROUTINE CJADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, WORK, LWORK )
 INTEGER*8  TRANSP, M, K, MAXNZ, LWORK
 INTEGER*8  INDX(*), PNTR(MAXNZ+1), IPERM(K), WORK(LWORK)
 COMPLEX    VAL(*)
```

F95 INTERFACE

```
 SUBROUTINE JADRP( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
 INTEGER TRANSP, M, K,  MAXNZ
 INTEGER, DIMENSION(:) :: INDX, PNTR, IPERM
 COMPLEX, DIMENSION(:) :: VAL

 SUBROUTINE JADRP_64( TRANSP, M, K, VAL, INDX, PNTR, MAXNZ,
*                   IPERM, [WORK], [LWORK] )
 INTEGER*8 TRANSP, M, K,  MAXNZ
 INTEGER*8, DIMENSION(:) :: INDX, PNTR, IPERM
 COMPLEX, DIMENSION(:) :: VAL
```

DESCRIPTION

A <- A P
A <- A P'
(' indicates matrix transpose)

where permutation P is represented by an integer vector IPERM, such that IPERM(I) is equal to the position of the only nonzero element in row I of permutation matrix P.

NOTE: In order to get a symetrically permuted jagged diagonal matrix P A P', one can explicitly permute the columns P A by calling

```
SJADRP(0, M, M, VAL, INDX, PNTR, MAXNZ, IPERM, WORK, LWORK)
```

where parameters VAL, INDX, PNTR, MAXNZ, IPERM are the representation of A in the jagged diagonal format. The operation makes sense if the original matrix A is square.

ARGUMENTS

TRANSP — Indicates how to operate with the permutation matrix
  0 : operate with matrix
  1 : operate with transpose matrix

M — Number of rows in matrix A

K — Number of columns in matrix A

VAL() — array of length PNTR(MAXNZ+1)-PNTR(1) consisting of entries of A. VAL can be viewed as a column major ordering of a row permutation of the Ellpack representation of A, where the Ellpack representation is permuted so that the rows are non-increasing in the number of nonzero entries. Values added for padding in Ellpack are not included in the Jagged-Diagonal format.

INDX() — array of length PNTR(MAXNZ+1)-PNTR(1) consisting of the column indices of the corresponding entries in VAL.

PNTR() — array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1 points to the location in VAL of the first element in the row-permuted Ellpack represenation of A.

MAXNZ — max number of nonzeros elements per row.

IPERM() — integer array of length K such that I = IPERM(I').

```
                Array IPERM represents a permutation P, such that
                IPERM(I) is equal to the position of the only nonzero
                element in row I of permutation matrix P.
                For example, if
                               | 0 0 1 |
                           P  =| 1 0 0 |
                               | 0 1 0 |
                then IPERM = (3, 1, 2).

 WORK()         scratch array of length LWORK.  LWORK should be at
                least K.

 LWORK          length of WORK array

                If LWORK = -1, then a workspace query is assumed;
                the routine only calculates the optimal size of the
                WORK array, returns this value as the first entry of
                the WORK array, and no error message related to LWORK
                is issued by XERBLA.
```

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in jagged-diagonal format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))
                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           array of length NNZ consisting of entries of A.
                VAL can be viewed as a column major ordering of a
                row permutation of the Ellpack representation of A,
                where the Ellpack representation is permuted so that
                the rows are non-increasing in the number of nonzero
                entries.  Values added for padding in Ellpack are
                not included in the Jagged-Diagonal format.

INDX()          array of length NNZ consisting of the column indices
                of the corresponding entries in VAL.

PNTR()          array of length MAXNZ+1, where PNTR(I)-PNTR(1)+1
                points to the location in VAL of the first element
                in the row-permuted Ellpack represenation of A.

MAXNZ           max number of nonzeros elements per row.

IPERM()         integer array of length M such that I = IPERM(I'),
                where row I in the original Ellpack representation
                corresponds to row I' in the permuted representation.
                If IPERM(1)=0,   it's assumed by convention that
                IPERM(I)=I. IPERM is used to determine the order
                in which rows of C are updated.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter
```

```
C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.
               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK          length of WORK array.  LWORK should be at least 2*M.

               For good performance, LWORK should generally be larger.
               For optimum performance on multiple processors, LWORK
               >=2*M*N_CPUS where N_CPUS is the maximum number of
               processors available to the program.

               If LWORK=0, the routine is to allocate workspace needed.

               If LWORK = -1, then a workspace query is assumed; the
               routine only calculates the optimum size of the WORK
               array, returns this value as the first entry of the WORK
               array, and no error message related to LWORK is issued
               by XERBLA.
```

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the JAD representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the JAD representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

SUBROUTINE LARZ_64(SIDE, [M], [N], L, V, [INCV], TAU, C, [LDC], [WORK])

CHARACTER(LEN=1) :: SIDE
```

```
COMPLEX :: TAU
COMPLEX, DIMENSION(:) :: V, WORK
COMPLEX, DIMENSION(:,:) :: C
INTEGER(8) :: M, N, L, INCV, LDC
```

C INTERFACE

```
#include <sunperf.h>

void clarz(char side, int m, int n, int l, complex  *v,  int
          incv, complex *tau, complex *c, int ldc);

void clarz_64(char side, long m, long n, long l, complex *v,
          long incv, complex *tau, complex *c, long ldc);
```

PURPOSE

clarz applies a complex elementary reflector H to a complex M-by-N matrix C, from either the left or the right. H is represented in the form

H = I - tau * v * v'

where tau is a complex scalar and v is a complex vector.

If tau = 0, then H is taken to be the unit matrix.

To apply H' (the conjugate transpose of H), supply conjg(tau) instead tau.

H is a product of k elementary reflectors as returned by CTZRZF.

ARGUMENTS

SIDE (input)
= 'L': form H * C
= 'R': form C * H

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

L (input) The number of entries of the vector V containing the meaningful part of the Householder vectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V (input) The vector v in the representation of H as returned by CTZRZF. V is not used if TAU = 0.

INCV (input)
The increment between elements of v. INCV <> 0.

TAU (input)
The value tau in the representation of H.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by the matrix H * C if SIDE = 'L', or C * H if SIDE = 'R'.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
(N) if SIDE = 'L' or (M) if SIDE = 'R'

void clarzb(char side, char trans, char direct, char storev,
          int  m,  int n, int k, int l, complex *v, int ldv,
          complex *t, int ldt,  complex  *c,  int  ldc,  int
          ldwork);

void clarzb_64(char side,  char  trans,  char  direct,  char
          storev,  long  m,  long n, long k, long l, complex
          *v, long ldv, complex *t, long  ldt,  complex  *c,
          long ldc, long ldwork);
```

PURPOSE

clarzb applies a complex block reflector H or its transpose H**H to a complex distributed M-by-N C from the left or the right.

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

SIDE (input)
= 'L': apply H or H' from the Left
= 'R': apply H or H' from the Right

TRANS (input)
= 'N': apply H (No transpose)
= 'C': apply H' (Conjugate transpose)

DIRECT (input)
Indicates how H is formed from a product of elementary reflectors = 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet)
= 'B': H = H(k) . . . H(2) H(1) (Backward)

STOREV (input)
Indicates how the vectors which define the elementary reflectors are stored:
= 'C': Columnwise (not supported yet)
= 'R': Rowwise

M (input) The number of rows of the matrix C.

N (input) The number of columns of the matrix C.

K (input) The order of the matrix T (= the number of elementary reflectors whose product defines the block reflector).

L (input) The number of columns of the matrix V containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

V (input) If STOREV = 'C', NV = K; if STOREV = 'R', NV = L.

LDV (input)
The leading dimension of the array V. If STOREV = 'C', LDV >= L; if STOREV = 'R', LDV >= K.

T (input) The triangular K-by-K matrix T in the representation of the block reflector.

LDT (input)
The leading dimension of the array T. LDT >= K.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by H*C or H'*C or C*H or C*H'.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
dimension(MAX(M,N),K)

LDWORK (input)
The leading dimension of the array WORK. If SIDE = 'L', LDWORK >= max(1,N); if SIDE = 'R', LDWORK >= max(1,M).

NAME

```
clarzt - form the triangular factor T  of  a  complex  block
reflector H of order > n, which is defined as a product of k
elementary reflectors
```

SYNOPSIS

```
SUBROUTINE CLARZT(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)

CHARACTER * 1 DIRECT, STOREV
COMPLEX V(LDV,*), TAU(*), T(LDT,*)
INTEGER N, K, LDV, LDT

SUBROUTINE CLARZT_64(DIRECT, STOREV, N, K, V, LDV, TAU, T, LDT)

CHARACTER * 1 DIRECT, STOREV
COMPLEX V(LDV,*), TAU(*), T(LDT,*)
INTEGER*8 N, K, LDV, LDT
```

F95 INTERFACE

```
SUBROUTINE LARZT(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])

CHARACTER(LEN=1) :: DIRECT, STOREV
COMPLEX, DIMENSION(:) :: TAU
COMPLEX, DIMENSION(:,:) :: V, T
INTEGER :: N, K, LDV, LDT

SUBROUTINE LARZT_64(DIRECT, STOREV, N, K, V, [LDV], TAU, T, [LDT])

CHARACTER(LEN=1) :: DIRECT, STOREV
COMPLEX, DIMENSION(:) :: TAU
COMPLEX, DIMENSION(:,:) :: V, T
```

```
INTEGER(8) :: N, K, LDV, LDT
```

C INTERFACE

```
#include <sunperf.h>

void clarzt(char direct, char storev, int n, int k,  complex
          *v, int ldv, complex *tau, complex *t, int ldt);

void clarzt_64(char direct, char storev,  long  n,  long  k,
          complex  *v,  long  ldv, complex *tau, complex *t,
          long ldt);
```

PURPOSE

clarzt forms the triangular factor T of a complex block reflector H of order > n, which is defined as a product of k elementary reflectors.

If DIRECT = 'F', H = H(1) H(2) . . . H(k) and T is upper triangular;

If DIRECT = 'B', H = H(k) . . . H(2) H(1) and T is lower triangular.

If STOREV = 'C', the vector which defines the elementary reflector H(i) is stored in the i-th column of the array V, and

H = I - V * T * V'

If STOREV = 'R', the vector which defines the elementary reflector H(i) is stored in the i-th row of the array V, and

H = I - V' * T * V

Currently, only STOREV = 'R' and DIRECT = 'B' are supported.

ARGUMENTS

DIRECT (input)
Specifies the order in which the elementary reflectors are multiplied to form the block reflector:
= 'F': H = H(1) H(2) . . . H(k) (Forward, not supported yet)
= 'B': H = H(k) . . . H(2) H(1) (Backward)

```
STOREV (input)
          Specifies how the vectors which define the elemen-
          tary  reflectors  are  stored  (see  also  Further
          Details):
          = 'R': rowwise

N (input) The order of the block reflector H. N >= 0.

K (input) The order of the triangular factor T (= the number
          of elementary reflectors). K >= 1.

V (input) (LDV,K) if STOREV = 'C' (LDV,N) if  STOREV  =  'R'
          The matrix V. See further details.

LDV (input)
          The leading dimension of the array V.  If STOREV =
          'C', LDV >= max(1,N); if STOREV = 'R', LDV >= K.

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i).

T (input) The k by  k  triangular  factor  T  of  the  block
          reflector.   If  DIRECT = 'F', T is upper triangu-
          lar; if DIRECT = 'B', T is lower  triangular.  The
          rest of the array is not used.

LDT (input)
          The leading dimension of the array T. LDT >= K.
```

FURTHER DETAILS

```
Based on contributions by
  A. Petitet, Computer Science Dept., Univ. of Tenn.,  Knox-
ville, USA

The shape of the matrix V and the  storage  of  the  vectors
which  define  the H(i) is best illustrated by the following
example with n = 5 and k = 3. The elements equal  to  1  are
not  stored;  the  corresponding array elements are modified
but restored on exit. The rest of the array is not used.

DIRECT = 'F' and STOREV =  'C':          DIRECT  =  'F'  and
STOREV = 'R':

                                              ______V_____
       (    v1    v2    v3    )                            /
( v1 v2 v3 )                        ( v1 v1 v1 v1 v1 . . . . 1
)
   V = ( v1 v2 v3 )                        ( v2 v2 v2 v2 v2  .
```

```
. . 1   )
       ( v1 v2 v3 )                       ( v3 v3 v3 v3 v3  .
. 1     )
       ( v1 v2 v3 )
          .  .  .
          1  .  .
             1  .
                1

DIRECT = 'B' and STOREV =  'C':           DIRECT  =  'B'  and
STOREV = 'R':

                                                    ______V_____
          1                                              /
.  1                            ( 1 . . . . v1 v1 v1 v1 v1 )
          .  .  1                         ( . 1 . . .  v2  v2
v2 v2 v2 )

```

PURPOSE

```
clatzm routine is deprecated and has been replaced  by  rou-
tine CUNMRZ.

CLATZM applies a Householder matrix generated by CTZRQF to a
matrix.

Let P = I - tau*u*u',   u = ( 1 ),
                            ( v )
where v is an (m-1) vector if SIDE = 'L', or a (n-1)  vector
if SIDE = 'R'.

If SIDE equals 'L', let
       C = [ C1 ] 1
           [ C2 ] m-1
             n
Then C is overwritten by P*C.

If SIDE equals 'R', let
       C = [ C1, C2 ] m
              1  n-1
Then C is overwritten by C*P.
```

ARGUMENTS

```
SIDE (input)
          = 'L': form P * C
          = 'R': form C * P

M (input) The number of rows of the matrix C.
```

N (input) The number of columns of the matrix C.

V (input) (1 + (M-1)*abs(INCV)) if SIDE = 'L' (1 + (N-1)*abs(INCV)) if SIDE = 'R' The vector v in the representation of P. V is not used if TAU = 0.

INCV (input)
The increment between elements of v. INCV <> 0

TAU (input)
The value tau in the representation of P.

C1 (input/output)
(LDC,N) if SIDE = 'L' (M,1) if SIDE = 'R' On entry, the n-vector C1 if SIDE = 'L', or the m-vector C1 if SIDE = 'R'.

On exit, the first row of P*C if SIDE = 'L', or the first column of C*P if SIDE = 'R'.

C2 (input/output)
(LDC, N) if SIDE = 'L' (LDC, N-1) if SIDE = 'R' On entry, the (m - 1) x n matrix C2 if SIDE = 'L', or the m x (n - 1) matrix C2 if SIDE = 'R'.

On exit, rows 2:m of P*C if SIDE = 'L', or columns 2:m of C*P if SIDE = 'R'.

LDC (input)
The leading dimension of the arrays C1 and C2. LDC >= max(1,M).

WORK (workspace)
(N) if SIDE = 'L' (M) if SIDE = 'R'

```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence   to   be   transformed.   On  exit,  the
          quarter-wave cosine synthesis of the input.
WSAVE (input)
          On entry, an array with dimension of at least (3 *
          N + 15) that has been initialized by COSQI.
```

Contents

NAME

cosqf - compute the Fourier coefficients in a cosine series representation with only odd wave numbers. The COSQ operations are unnormalized inverses of themselves, so a call to COSQF followed by a call to COSQB will multiply the input sequence by 4 * N.

SYNOPSIS

```
SUBROUTINE COSQF(N, X, WSAVE)

INTEGER N
REAL X(*), WSAVE(*)

SUBROUTINE COSQF_64(N, X, WSAVE)

INTEGER*8 N
REAL X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQF(N, X, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: X, WSAVE

SUBROUTINE COSQF_64(N, X, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cosqf(int n, float *x, float *wsave);
```

```
void cosqf_64(long n, float *x, float *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence   to   be   transformed.   On  exit,  the
          quarter-wave cosine transform of the input.
WSAVE (input)
          On entry, an array with dimension of at least   (3
          * N + 15) that has been initialized by COSQI.
```

Contents

NAME

```
cosqi - initialize the array WSAVE, which is  used  in  both
COSQF and COSQB.
```

SYNOPSIS

```
SUBROUTINE COSQI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE COSQI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE COSQI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void cosqi(int n, float *wsave);

void cosqi_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array of dimension (3 * N + 15) or greater. COSQI needs to be called only once to initialize WSAVE before calling COSQF and/or COSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

cost - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by 2 * (N-1).

SYNOPSIS

```

```

```
void cost_64(long n, float *x, float *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines  are  most  efficient  when N - 1 is a
          product of small primes.  N >= 2.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence  to  be transformed.  On exit, the cosine
          transform of the input.
WSAVE (input)
          On entry, an array with dimension of at least   (3
          * N + 15), initialized by COSTI.
```

Contents

NAME

```
costi - initialize the array WSAVE, which is used in COST.
```

SYNOPSIS

```
SUBROUTINE COSTI(N, WSAVE)

INTEGER N
REAL WSAVE(*)

SUBROUTINE COSTI_64(N, WSAVE)

INTEGER*8 N
REAL WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSTI(N, WSAVE)

INTEGER :: N
REAL, DIMENSION(:) :: WSAVE

SUBROUTINE COSTI_64(N, WSAVE)

INTEGER(8) :: N
REAL, DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void costi(int n, float *wsave);

void costi_64(long n, float *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N - 1 is a product of small primes. N >= 2.

WSAVE (input)
On entry, an array of dimension (3 * N + 15) or greater. COSTI is called once to initialize WSAVE before calling COST and need not be called again between calls to COST if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void cpbcon(char uplo, int n, int kd, complex *a,  int  lda,
          float anorm, float *rcond, int *info);

void cpbcon_64(char uplo, long n, long kd, complex *a,  long
          lda, float anorm, float *rcond, long *info);
```

PURPOSE

cpbcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite band matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangular factor stored in A;
= 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO ='U', A(kd+1+i-j,j) = U(i,j) for max(1,j-kd)<=i<=j; if UPLO ='L', A(1+i-j,j) = L(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

ANORM (input)
The 1-norm (or infinity-norm) of the Hermitian band matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

SUBROUTINE PBEQU(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,
       [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, KD, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE PBEQU_64(UPLO, [N], KD, A, [LDA], SCALE, SCOND, AMAX,
       [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, KD, LDA, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void cpbequ(char uplo, int n, int kd, complex *a,  int  lda,
          float  *scale,  float  *scond,  float  *amax,  int
          *info);

void cpbequ_64(char uplo, long n, long kd, complex *a,  long
          lda, float *scale, float *scond, float *amax, long
          *info);
```

PURPOSE

cpbequ computes row and column scalings intended to equilibrate a Hermitian positive definite band matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
- = 'U': Upper triangular of A is stored;
- = 'L': Lower triangular of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input) The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          plex *a, long lda, complex *af, long ldaf, complex
          *b, long ldb, complex *x, long ldx,  float  *ferr,
          float *berr, long *info);
```

PURPOSE

cpbrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A as computed by CPBTRF, in the same storage format as A (see A).

LDAF (input)
The leading dimension of the array AF. LDAF >= KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CPBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative

```
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cpbstf(char uplo, int n, int kd, complex *ab, int ldab,
          int *info);

void cpbstf_64(char uplo, long n, long kd, complex *ab, long
          ldab, long *info);
```

PURPOSE

```
cpbstf computes a split Cholesky factorization of a  complex
Hermitian positive definite band matrix A.

This routine is designed to  be  used  in  conjunction  with
CHBGST.
The factorization has the form  A = S**H*S   where  S  is  a
band  matrix  of  the  same bandwidth as A and the following
structure:

  S = ( U    )
      ( M  L )

where U is upper triangular of order m = (n+kd)/2, and L  is
lower triangular of order n-m.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals of the  matrix  A  if
          UPLO  = 'U', or the number of subdiagonals if UPLO
          = 'L'.  KD >= 0.

AB (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  band  matrix  A,  stored in the first kd+1
          rows of the array.  The j-th column of A is stored
          in the j-th column of the array AB as follows:  if
          UPLO = 'U', AB(kd+1+i-j,j) = A(i,j)  for  max(1,j-
          kd)<=i<=j;  if UPLO = 'L', AB(1+i-j,j)    = A(i,j)
          for j<=i<=min(n,j+kd).
```

On exit, if INFO = 0, the factor S from the split Cholesky factorization A = S**H*S. See Further Details.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the factorization could not be completed, because the updated element a(i,i) was negative; the matrix A is not positive definite.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 7, KD = 2:

```
S = ( s11  s12  s13                     )
    (      s22  s23  s24                )
    (           s33  s34                )
    (                s44                )
    (           s53  s54  s55           )
    (                s64  s65  s66      )
    (                     s75  s76  s77 )
```

If UPLO = 'U', the array AB holds:

```
on entry:                          on exit:

 *    *   a13  a24  a35  a46  a57   *    *   s13  s24   s53'
s64' s75'
 *   a12  a23  a34  a45  a56  a67   *   s12  s23  s34   s54'
s65'  s76'  a11  a22  a33  a44  a55  a66  a77  s11  s22  s33
s44  s55  s66  s77
```

If UPLO = 'L', the array AB holds:

```
on entry:                          on exit:

a11  a22  a33  a44  a55  a66  a77  s11  s22  s33   s44   s55
s66   s77  a21  a32  a43  a54  a65  a76   *   s12' s23' s34'
s54  s65  s76   * a31  a42  a53  a64  a64    *     *    s13'
s24' s53  s64  s75   *    *
```

Array elements marked * are not used by the routine; s12' denotes conjg(s12); the diagonal elements of S are real.

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: N, NDIAG, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cpbsv(char uplo, int n, int ndiag,  int  nrhs,  complex
          *a, int lda, complex *b, int ldb, int *info);

void cpbsv_64(char uplo, long n, long ndiag, long nrhs, com-
          plex  *a,  long  lda,  complex  *b, long ldb, long
          *info);
```

PURPOSE

cpbsv computes the solution to a complex system of linear equations
A * X = B, where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.
The Cholesky decomposition is used to factor A as
A = U**H * U, if UPLO = 'U', or
A = L * L**H, if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower triangular band matrix, with the same number of superdiagonals or subdiagonals as A. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NDIAG (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if

UPLO = 'U', A(NDIAG+1+i-j,j) = A(i,j) for max(1,j-NDIAG)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(N,j+NDIAG). See below for further details.

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, in the same storage format as A.

LDA (input)
The leading dimension of the array A. LDA >= NDIAG+1.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, NDIAG = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
```

```
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

Array elements marked * are not used by the routine.

          complex  *x,  long ldx, float *rcond, float *ferr,
          float *berr, long *info);
```

PURPOSE

cpbsvx uses the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N Hermitian positive definite band matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B

Whether or not the system will be equilibrated depends on the
scaling of the matrix A, but if equilibration is used, A is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
factor the matrix A (after equilibration if FACT = 'E') as
A = U**H * U, if UPLO = 'U', or
A = L * L**H, if UPLO = 'L',
where U is an upper triangular band matrix, and L is a lower
triangular band matrix.

3. If the leading i-by-i principal minor is not positive definite,
then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.

4. The system of equations is solved for X using the factored form
of A.

5. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

6. If equilibration was used, the matrix X is premultiplied by
diag(S) so that it solves the original system before
equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the

matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S. A and AF will not be modified. = 'N': The matrix A will be copied to AF and factored.
= 'E': The matrix A will be equilibrated if necessary, then copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NDIAG (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. NDIAG >= 0.

NRHS (input)
The number of right-hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first NDIAG+1 rows of the array, except if FACT = 'F' and EQUED = 'Y', then A must contain the equilibrated matrix diag(S)*A*diag(S). The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(NDIAG+1+i-j,j) = A(i,j) for max(1,j-NDIAG)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(N,j+NDIAG). See below for further details.

On exit, if FACT = 'E' and EQUED = 'Y', A is overwritten by diag(S)*A*diag(S).

LDA (input)
The leading dimension of the array A. LDA >= NDIAG+1.

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, in the same storage

format as A (see A). If EQUED = 'Y', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H.

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= NDIAG+1.

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

```
The band storage scheme  is  illustrated  by  the  following
example, when N = 6, NDIAG = 2, and UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

   a11  a12  a13
        a22  a23  a24
             a33  a34  a35
                  a44  a45  a46
                       a55  a56
   (aij=conjg(aji))         a66

Band storage of the upper triangle of A:

    *    *   a13  a24  a35  a46
    *   a12  a23  a34  a45  a56
   a11  a22  a33  a44  a55  a66

Similarly, if UPLO = 'L' the format of A is as follows:

   a11  a22  a33  a44  a55  a66
   a21  a32  a43  a54  a65   *
   a31  a42  a53  a64   *    *

Array elements marked * are not used by the routine.
```

COMPLEX, DIMENSION(:,:) :: AB
INTEGER :: N, KD, LDAB, INFO

SUBROUTINE PBTF2_64(UPLO, [N], KD, AB, [LDAB], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: AB
INTEGER(8) :: N, KD, LDAB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cpbtf2(char uplo, int n, int kd, complex *ab, int ldab,
          int *info);

void cpbtf2_64(char uplo, long n, long kd, complex *ab, long
          ldab, long *info);
```

PURPOSE

cpbtf2 computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form
```
   A = U' * U ,  if UPLO = 'U', or
   A = L  * L',  if UPLO = 'L',
```
where U is an upper triangular matrix, U' is the conjugate transpose of U, and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of super-diagonals of the matrix A if UPLO = 'U', or the number of sub-diagonals if UPLO = 'L'. KD >= 0.

AB (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array AB as follows: if UPLO = 'U', AB(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', AB(1+i-j,j)   = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L

from the Cholesky factorization A = U'*U or A = L*L' of the band matrix A, in the same storage format as A.

LDAB (input)
The leading dimension of the array AB. LDAB >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

```
On entry:                       On exit:

    *    *   a13  a24  a35  a46      *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
```

Similarly, if UPLO = 'L' the format of A is as follows:

```
On entry:                       On exit:

   a11  a22  a33  a44  a55  a66     l11  l22  l33  l44   l55
l66
   a21  a32  a43  a54  a65   *      l21  l32  l43  l54   l65
*
   a31  a42  a53  a64   *    *      l31  l42  l53   l64    *
*
```

Array elements marked * are not used by the routine.

          lda, long *info);
```

PURPOSE

cpbtrf computes the Cholesky factorization of a complex Hermitian positive definite band matrix A.

The factorization has the form

```
   A = U**H * U,  if UPLO = 'U', or
   A = L  * L**H,  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

A (input/output)
On entry, the upper or lower triangle of the Hermitian band matrix A, stored in the first KD+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd).

On exit, if INFO = 0, the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, in the same storage format as A.

LDA (input)

The leading dimension of the array A. LDA >= KD+1.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when N = 6, KD = 2, and UPLO = 'U':

```
On entry:                       On exit:

PURPOSE

cpbtrs solves a system of linear equations A*X = B with a Hermitian positive definite band matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPBTRF.

ARGUMENTS

UPLO (input)
  = 'U': Upper triangular factor stored in A;
  = 'L': Lower triangular factor stored in A.

N (input) The order of the matrix A. N >= 0.

KD (input)
  The number of superdiagonals of the matrix A if UPLO = 'U', or the number of subdiagonals if UPLO = 'L'. KD >= 0.

NRHS (input)
  The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the band matrix A, stored in the first KD+1 rows of the array. The j-th column of U or L is stored in the j-th column of the array A as follows: if UPLO ='U',   A(kd+1+i-j,j)   =   U(i,j)   for max(1,j-kd)<=i<=j; if UPLO ='L', A(1+i-j,j)   = L(i,j) for j<=i<=min(n,j+kd).

LDA (input)
  The leading dimension of the array A.   LDA >= KD+1.

B (input/output)

On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

void cpocon_64(char uplo, long  n,  complex  *a,  long  lda,
          float anorm, float *rcond, long *info);
```

PURPOSE

cpocon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, as computed by CPOTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ANORM (input)
The 1-norm (or infinity-norm) of the Hermitian matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

SUBROUTINE POEQU_64([N], A, [LDA], SCALE, SCOND, AMAX, [INFO])

COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
```

```
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void cpoequ(int n, complex *a, int lda, float *scale,  float
          *scond, float *amax, int *info);

void cpoequ_64(long n, complex *a, long lda,  float  *scale,
          float *scond, float *amax, long *info);
```

PURPOSE

cpoequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i) = 1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j) = S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

A (input) The N-by-N Hermitian positive definite matrix whose scaling factors are to be computed. Only the diagonal elements of A are referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)

Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

          *berr, long *info);
```

PURPOSE

cporfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular

part of the matrix A, and the strictly upper tri-
angular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, as computed by CPOTRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CPOTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

#include <sunperf.h>
```

```
void cposv(char uplo, int n, int nrhs, complex *a, int  lda,
          complex *b, int ldb, int *info);

void cposv_64(char uplo, long n, long nrhs, complex *a, long
          lda, complex *b, long ldb, long *info);
```

PURPOSE

cposv computes the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

The Cholesky decomposition is used to factor A as
   A = U**H* U, if UPLO = 'U', or
   A = L * L**H, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower triangular matrix.   The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
          = 'U': Upper triangle of A is stored;
          = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
          The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
          On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

          On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed.

void cposvx(char fact, char uplo, int n, int  nrhs,  complex
          *a,  int  lda,  complex *af, int ldaf, char equed,
          float *s, complex *b, int  ldb,  complex  *x,  int
          ldx,  float  *rcond, float *ferr, float *berr, int
          *info);

void cposvx_64(char fact, char uplo, long n, long nrhs, com-
          plex  *a,  long  lda, complex *af, long ldaf, char
          equed, float *s, complex *b, long ldb, complex *x,
          long  ldx, float *rcond, float *ferr, float *berr,
          long *info);
```

PURPOSE

cposvx uses the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N Hermitian positive definite matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A

is
overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used
to
factor the matrix A (after equilibration if FACT = 'E')
as
A = U**H* U, if UPLO = 'U', or
A = L * L**H, if UPLO = 'L',
where U is an upper triangular matrix and L is a lower
triangular
matrix.

3. If the leading i-by-i principal minor is not positive
definite,
then the routine returns with INFO = i. Otherwise, the
factored
form of A is used to estimate the condition number of the
matrix
A. If the reciprocal of the condition number is less
than machine
precision, INFO = N+1 is returned as a warning, but the
routine
still goes on to solve for X and compute error bounds as
described below.

4. The system of equations is solved for X using the fac-
tored form
of A.

5. Iterative refinement is applied to improve the computed
solution
matrix and calculate error bounds and backward error
estimates
for it.

6. If equilibration was used, the matrix X is premultiplied
by
diag(S) so that it solves the original system before
equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the
matrix A is supplied on entry, and if not, whether
the matrix A should be equilibrated before it is
factored. = 'F': On entry, AF contains the fac-

```
          tored form of A.  If EQUED = 'Y', the matrix A has
          been equilibrated with scaling factors given by S.
          A and AF will not be modified.  = 'N':  The matrix
          A will be copied to AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
A (input/output)
          On entry, the Hermitian matrix A, except if FACT =
          'F'  and  EQUED  =  'Y',  then  A must contain the
          equilibrated matrix diag(S)*A*diag(S).  If UPLO  =
          'U', the leading N-by-N upper triangular part of A
          contains the upper triangular part of  the  matrix
          A,  and the strictly lower triangular part of A is
          not referenced.  If UPLO = 'L', the leading N-by-N
          lower triangular part of A contains the lower tri-
          angular part of the matrix  A,  and  the  strictly
          upper  triangular  part of A is not referenced.  A
          is not modified if FACT = 'F' or 'N', or if FACT =
          'E' and EQUED = 'N' on exit.

          On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
          overwritten by diag(S)*A*diag(S).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

AF (input/output)
          If FACT = 'F', then AF is an input argument and on
          entry  contains  the triangular factor U or L from
          the Cholesky factorization  A  =  U**H*U  or  A  =
          L*L**H, in the same storage format as A.  If EQUED
          .ne. 'N', then AF is  the  factored  form  of  the
          equilibrated matrix diag(S)*A*diag(S).

          If FACT = 'N', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
          the Cholesky factorization  A  =  U**H*U  or  A  =
          L*L**H of the original matrix A.
```

If FACT = 'E', then AF is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)
On entry, the N-by-NRHS righthand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If

RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

Hermitian positive definite matrix A
```

SYNOPSIS

```
SUBROUTINE CPOTF2(UPLO, N, A, LDA, INFO)

CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER N, LDA, INFO

SUBROUTINE CPOTF2_64(UPLO, N, A, LDA, INFO)

CHARACTER * 1 UPLO
COMPLEX A(LDA,*)
INTEGER*8 N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE POTF2(UPLO, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, INFO

SUBROUTINE POTF2_64(UPLO, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpotf2(char uplo, int  n,  complex  *a,  int  lda,  int
          *info);

void cpotf2_64(char uplo, long n, complex *a, long lda, long
          *info);
```

PURPOSE

cpotf2 computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

The factorization has the form

```
   A = U' * U ,  if UPLO = 'U', or
   A = L  * L',  if UPLO = 'L',
```

where U is an upper triangular matrix and L is lower triangular.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored. = 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading n by n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U'*U or A = L*L'.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite, and the factorization could not be completed.

```

C INTERFACE

```
#include <sunperf.h>
```

```
void cpotrf(char uplo, int  n,  complex  *a,  int  lda,  int
          *info);

void cpotrf_64(char uplo, long n, complex *a, long lda, long
          *info);
```

PURPOSE

cpotrf computes the Cholesky factorization of a complex Hermitian positive definite matrix A.

```
The factorization has the form
   A = U**H * U,  if UPLO = 'U', or
   A = L  * L**H,  if UPLO = 'L',
where U is an upper triangular matrix and L  is  lower  tri-
angular.
```

This is the block version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.
```

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the Hermitian matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the factorization could not be completed.

          *info);

void cpotri_64(char uplo, long n, complex *a, long lda, long
          *info);
```

PURPOSE

cpotri computes the inverse of a complex Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF.

ARGUMENTS

UPLO (input)
- = 'U': Upper triangle of A is stored;
- = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, as computed by CPOTRF. On exit, the upper or lower triangle of the (Hermitian) inverse of A, overwriting the input factor U or L.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

INFO (output)
- = 0: successful exit
- < 0: if INFO = -i, the i-th argument had an illegal value
- > 0: if INFO = i, the (i,i) element of the factor U or L is zero, and the inverse could not be computed.

void cpotrs_64(char uplo, long n,  long  nrhs,  complex  *a,
          long lda, complex *b, long ldb, long *info);
```

PURPOSE

cpotrs solves a system of linear equations A*X = B with a Hermitian positive definite matrix A using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPOTRF.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, as computed by CPOTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
SUBROUTINE PPCON_64(UPLO, N, A, ANORM, RCOND, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
REAL :: ANORM, RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void cppcon(char uplo, int n, complex *a, float anorm, float
          *rcond, int *info);
void cppcon_64(char uplo, long n, complex *a,  float  anorm,
          float *rcond, long *info);
```

PURPOSE

cppcon estimates the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite packed matrix using the Cholesky factorization A = U**H*U or A = L*L**H computed by CPPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The triangular factor U or L from the Cholesky factorization A = U**H*U or A = L*L**H, packed columnwise in a linear array. The j-th column of U or L is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = U(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = L(i,j) for j<=i<=n.

ANORM (input)
The 1-norm (or infinity-norm) of the Hermitian matrix A.

```
RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix  A, computed as RCOND = 1/(ANORM * AINVNM),
          where AINVNM is  an  estimate  of  the  1-norm  of
          inv(A) computed in this routine.

WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

Contents

NAME

```
cppequ - compute row and column scalings intended to equili-
brate  a  Hermitian  positive  definite  matrix  A in packed
storage and reduce its condition number (with respect to the
two-norm)
```

SYNOPSIS

```
SUBROUTINE CPPEQU(UPLO, N, A, SCALE, SCOND, AMAX, INFO)

CHARACTER * 1 UPLO
COMPLEX A(*)
INTEGER N, INFO
REAL SCOND, AMAX
REAL SCALE(*)

SUBROUTINE CPPEQU_64(UPLO, N, A, SCALE, SCOND, AMAX, INFO)

CHARACTER * 1 UPLO
COMPLEX A(*)
INTEGER*8 N, INFO
REAL SCOND, AMAX
REAL SCALE(*)
```

F95 INTERFACE

```
SUBROUTINE PPEQU(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

```
SUBROUTINE PPEQU_64(UPLO, [N], A, SCALE, SCOND, AMAX, [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: A
INTEGER(8) :: N, INFO
REAL :: SCOND, AMAX
REAL, DIMENSION(:) :: SCALE
```

C INTERFACE

```
#include <sunperf.h>

void cppequ(char uplo, int  n,  complex  *a,  float  *scale,
          float *scond, float *amax, int *info);
void cppequ_64(char uplo, long n, complex *a, float  *scale,
          float *scond, float *amax, long *info);
```

PURPOSE

cppequ computes row and column scalings intended to equilibrate a Hermitian positive definite matrix A in packed storage and reduce its condition number (with respect to the two-norm). S contains the scale factors, S(i)=1/sqrt(A(i,i)), chosen so that the scaled matrix B with elements B(i,j)=S(i)*A(i,j)*S(j) has ones on the diagonal. This choice of S puts the condition number of B within a factor N of the smallest possible condition number over all possible diagonal scalings.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

SCALE (output)
If INFO = 0, SCALE contains the scale factors for A.

SCOND (output)
If INFO = 0, SCALE contains the ratio of the smallest SCALE(i) to the largest SCALE(i). If SCOND >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by SCALE.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element is nonpositive.

```

C INTERFACE

```
#include <sunperf.h>

void cpprfs(char uplo, int n, int nrhs, complex *a,  complex
          *af,  complex  *b,  int  ldb, complex *x, int ldx,
          float *ferr, float *berr, int *info);

void cpprfs_64(char uplo, long n,  long  nrhs,  complex  *a,
          complex  *af,  complex  *b,  long ldb, complex *x,
          long ldx, float *ferr, float *berr, long *info);
```

PURPOSE

cpprfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangle of the Hermitian matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

```
AF (input)
          The triangular factor U or  L  from  the  Cholesky
          factorization  A  =  U**H*U or A = L*L**H, as com-
          puted by SPPTRF/CPPTRF,  packed  columnwise  in  a
          linear array in the same format as A (see A).

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).
X (input/output)
          On entry, the solution matrix X,  as  computed  by
          CPPTRS.  On exit, the improved solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

          *b, int ldb, int *info);

void cppsv_64(char uplo, long n, long nrhs, complex *a, com-
          plex *b, long ldb, long *info);
```

PURPOSE

```
cppsv computes the solution to a complex  system  of  linear
equations
   A * X = B, where A is an N-by-N Hermitian positive defin-
ite matrix stored in packed format and X and B are N-by-NRHS
matrices.

The Cholesky decomposition is used to factor A as
   A = U**H* U,  if UPLO = 'U', or
   A = L * L**H,  if UPLO = 'L',
where U is an upper triangular matrix and L is a lower  tri-
angular  matrix.   The  factored  form  of A is then used to
solve the system of equations A * X = B.
```

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input/output)
          On entry, the upper or lower triangle of the  Her-
          mitian  matrix  A,  packed  columnwise in a linear
          array.  The j-th column of  A  is  stored  in  the
          array  A  as  follows:   if  UPLO = 'U', A(i + (j-
          1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i +
          (j-1)*(2n-j)/2)  =  A(i,j) for j<=i<=n.  See below
          for further details.
```

```
            On exit, if INFO = 0, the factor U or L  from  the
            Cholesky  factorization  A = U**H*U or A = L*L**H,
            in the same storage format as A.

B (input/output)
            On entry, the N-by-NRHS right hand side matrix  B.
            On  exit,  if  INFO  =  0,  the N-by-NRHS solution
            matrix X.

LDB (input)
            The leading dimension of  the  array  B.   LDB  >=
            max(1,N).

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
            > 0:  if INFO = i, the leading minor of order i of
            A  is  not positive definite, so the factorization
            could not be completed, and the solution  has  not
            been computed.
```

FURTHER DETAILS

```
The packed storage scheme is illustrated  by  the  following
example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44

Packed storage of the upper triangle of A:

A = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

          *rcond, float *ferr, float *berr, long *info);
```

PURPOSE

cppsvx uses the Cholesky factorization A = U**H*U or A = L*L**H to compute the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N Hermitian positive definite matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate
   the system:
      diag(S) * A * diag(S) * inv(diag(S)) * X = diag(S) * B
   Whether or not the system will be equilibrated depends on the
   scaling of the matrix A, but if equilibration is used, A is
   overwritten by diag(S)*A*diag(S) and B by diag(S)*B.

2. If FACT = 'N' or 'E', the Cholesky decomposition is used to
factor the matrix A (after equilibration if FACT = 'E') as
A = U'* U , if UPLO = 'U', or
A = L * L', if UPLO = 'L',
where U is an upper triangular matrix, L is a lower triangular
matrix, and ' indicates conjugate transpose.

3. If the leading i-by-i principal minor is not positive definite,
then the routine returns with INFO = i. Otherwise, the factored
form of A is used to estimate the condition number of the matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as
described below.

4. The system of equations is solved for X using the factored form
of A.

5. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

6. If equilibration was used, the matrix X is premultiplied by
diag(S) so that it solves the original system before
equilibration.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored. = 'F': On entry, AF contains the factored form of A. If EQUED = 'Y', the matrix A has been equilibrated with scaling factors given by S.

```
          A and AF will not be modified.  = 'N':  The matrix
          A will be copied to AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the  upper  or  lower  triangle  of  the
          Hermitian  matrix A, packed columnwise in a linear
          array, except if FACT = 'F' and EQUED = 'Y',  then
          A    must    contain   the   equilibrated   matrix
          diag(S)*A*diag(S).  The j-th column of A is stored
          in  the  array A as follows:  if UPLO = 'U', A(i +
          (j-1)*j/2) = A(i,j) for 1<=i<=j; if  UPLO  =  'L',
          A(i  +  (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.  See
          below for further details.  A is not  modified  if
          FACT  =  'F'  or 'N', or if FACT = 'E' and EQUED =
          'N' on exit.

          On exit, if FACT = 'E'  and  EQUED  =  'Y',  A  is
          overwritten by diag(S)*A*diag(S).

AF (input/output)
          If FACT = 'F', then AF is an input argument and on
          entry  contains  the triangular factor U or L from
          the Cholesky factorization  A  =  U**H*U  or  A  =
          L*L**H, in the same storage format as A.  If EQUED
          .ne. 'N', then AF is  the  factored  form  of  the
          equilibrated matrix A.

          If FACT = 'N', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
          the Cholesky factorization  A  =  U**H*U  or  A  =
          L*L**H of the original matrix A.

          If FACT = 'E', then AF is an output  argument  and
          on  exit returns the triangular factor U or L from
          the Cholesky factorization  A  =  U**H*U  or  A  =
          L*L**H  of  the  equilibrated  matrix  A  (see the
          description of A for the form of the  equilibrated
```

matrix).

EQUED (input)
Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'Y': Equilibration was done, i.e., A has been replaced by diag(S) * A * diag(S). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

S (input/output)
The scale factors for A; not accessed if EQUED = 'N'. S is an input argument if FACT = 'F'; otherwise, S is an output argument. If FACT = 'F' and EQUED = 'Y', each element of S must be positive.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if EQUED = 'Y', B is overwritten by diag(S) * B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that if EQUED = 'Y', A and B are modified on exit, and the solution to the equilibrated system is inv(diag(S))*X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest ele-

ment in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)

dimension(2*N)

WORK2 (workspace)

dimension(N)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, and i is

<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the Hermitian matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = conjg(aji))
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

          float *rcond, int *info);

void cptcon_64(long n, float  *diag,  complex  *offd,  float
          anorm, float *rcond, long *info);
```

PURPOSE

cptcon computes the reciprocal of the condition number (in the 1-norm) of a complex Hermitian positive definite tridiagonal matrix using the factorization A = L*D*L**H or A = U**H*D*U computed by CPTTRF.

Norm(inv(A)) is computed by a direct method, and the reciprocal of the condition number is computed as

RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

DIAG (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization of A, as computed by CPTTRF.

OFFD (input)
The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization of A, as computed by CPTTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is the 1-norm of inv(A) computed in this routine.

WORK (workspace)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void cpteqr(char compz, int n, float *d, float  *e,  complex
          *z, int ldz, int *info);

void cpteqr_64(char compz, long n, float *d, float *e,  com-
          plex *z, long ldz, long *info);
```

PURPOSE

cpteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric positive definite tridiagonal matrix by first factoring the matrix using SPTTRF and then calling CBDSQR to compute the singular values of the bidiagonal factor.

This routine computes the eigenvalues of the positive definite tridiagonal matrix to high relative accuracy. This means that if the eigenvalues range over many orders of magnitude in size, then the small eigenvalues and corresponding eigenvectors will be computed more accurately than, for example, with the standard QR method.

The eigenvectors of a full or band positive definite Hermitian matrix can also be found if CHETRD, CHPTRD, or CHBTRD has been used to reduce this matrix to tridiagonal form. (The reduction to tridiagonal form, however, may preclude the possibility of obtaining high relative accuracy in the small eigenvalues of the original matrix, if these eigenvalues range over many orders of magnitude.)

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvectors of original Hermitian matrix also. Array Z contains the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvectors of tridiagonal matrix also.

```
N (input) The order of the matrix.  N >= 0.

D (input/output)
          On entry, the n diagonal elements of the tridiago-
          nal matrix.  On normal exit, D contains the eigen-
          values, in descending order.

E (input/output)
          On entry, the (n-1) subdiagonal  elements  of  the
          tridiagonal  matrix.   On  exit,  E  has been des-
          troyed.

Z (input) On entry, if COMPZ = 'V', the unitary matrix  used
          in the reduction to tridiagonal form.  On exit, if
          COMPZ = 'V', the orthonormal eigenvectors  of  the
          original  Hermitian  matrix;  if  COMPZ = 'I', the
          orthonormal  eigenvectors   of   the   tridiagonal
          matrix.   If  INFO  >  0  on  exit, Z contains the
          eigenvectors  associated  with  only  the   stored
          eigenvalues.   If   COMPZ  =  'N',  then  Z is not
          referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and if COMPZ = 'V' or 'I', LDZ >= max(1,N).

WORK (workspace)
          dimension(4*N)

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  if INFO = i, and i is:  <= N   the  Cholesky
          factorization of the matrix could not be performed
          because the i-th principal minor was not  positive
          definite.   > N   the SVD algorithm failed to con-
          verge; if INFO = N+i, i off-diagonal  elements  of
          the bidiagonal factor did not converge to zero.

```

PURPOSE

cptrfs improves the computed solution to a system of linear equations when the coefficient matrix is Hermitian positive definite and tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization:
= 'U': OFFD is the superdiagonal of A, and A = U**H*DIAG*U;
= 'L': OFFD is the subdiagonal of A, and A = L*DIAG*L**H. (The two forms are equivalent if A is real.)

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input)
The n real diagonal elements of the tridiagonal matrix A.

OFFD (input)
The (n-1) off-diagonal elements of the tridiagonal matrix A (see UPLO).

DIAGF (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization computed by CPTTRF.

OFFDF (input)
The (n-1) off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by CPTTRF (see UPLO).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CPTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(N)

WORK2 (workspace)

```
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

C INTERFACE

```
#include <sunperf.h>

void cptsv(int n, int nrhs, float *diag, complex *sub,  com-
          plex *b, int ldb, int *info);

void cptsv_64(long n, long nrhs, float *diag, complex  *sub,
          complex *b, long ldb, long *info);
```

PURPOSE

cptsv computes the solution to a complex system of linear equations A*X = B, where A is an N-by-N Hermitian positive definite tridiagonal matrix, and X and B are N-by-NRHS matrices.

A is factored as A = L*D*L**H, and the factored form of A is then used to solve the system of equations.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the factorization A = L*DIAG*L**H.

SUB (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**H factorization of A. SUB can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U**H*DIAG*U factorization of A.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution

matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the leading minor of order i is not positive definite, and the solution has not been computed. The factorization has not been completed unless i = N.

C INTERFACE

```
#include <sunperf.h>

void cptsvx(char fact, int n, int nrhs, float *diag, complex
          *sub, float *diagf, complex *subf, complex *b, int
          ldb, complex *x,  int  ldx,  float  *rcond,  float
          *ferr, float *berr, int *info);

void cptsvx_64(char fact, long n, long  nrhs,  float  *diag,
          complex *sub, float *diagf, complex *subf, complex
          *b, long ldb, complex *x, long ldx, float  *rcond,
          float *ferr, float *berr, long *info);
```

PURPOSE

```
cptsvx uses the factorization A = L*D*L**H  to  compute  the
solution  to  a  complex system of linear equations A*X = B,
where A is an N-by-N Hermitian positive definite tridiagonal
matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'N', the matrix A is factored as A =  L*D*L**H,
where L
   is a unit lower bidiagonal matrix and D is diagonal.  The
   factorization can also be regarded as having the form
   A = U**H*D*U.

2. If the leading i-by-i principal  minor  is  not  positive
definite,
   then the routine returns with INFO =  i.  Otherwise,  the
factored
   form of A is used to estimate the condition number of the
```

matrix
A. If the reciprocal of the condition number is less than machine
precision, INFO = N+1 is returned as a warning, but the routine
still goes on to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form
of A.

4. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of the matrix A is supplied on entry. = 'F': On entry, DIAGF and SUBF contain the factored form of A. DIAG, SUB, DIAGF, and SUBF will not be modified. = 'N': The matrix A will be copied to DIAGF and SUBF and factored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

DIAG (input)
The n diagonal elements of the tridiagonal matrix A.

SUB (input)
The (n-1) subdiagonal elements of the tridiagonal matrix A.

DIAGF (input/output)
If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the diagonal matrix DIAG from the L*DIAG*L**H factorization of A. If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal

elements of the diagonal matrix DIAG from the L*DIAG*L**H factorization of A.

SUBF (input/output)
If FACT = 'F', then SUBF is an input argument and on entry contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**H factorization of A. If FACT = 'N', then SUBF is an output argument and on exit contains the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L**H factorization of A.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j).

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: the leading minor of order i of A is not positive definite, so the factorization could not be completed, and the solution has not been computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

          *info);
```

PURPOSE

cpttrf computes the L*D*L' factorization of a complex Hermitian positive definite tridiagonal matrix A. The factorization may also be regarded as having the form A = U'*D*U.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

DIAG (input/output)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix DIAG from the L*DIAG*L' factorization of A.

OFFD (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix A. On exit, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the L*DIAG*L' factorization of A. OFFD can also be regarded as the superdiagonal of the unit bidiagonal factor U from the U'*DIAG*U factorization of A.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, the leading minor of order k is not positive definite; if k < N, the factorization could not be completed, while if k = N, the factorization was completed, but DIAG(N) = 0.

          *offd, complex *b, int ldb, int *info);

void cpttrs_64(char uplo, long n, long  nrhs,  float  *diag,
          complex *offd, complex *b, long ldb, long *info);
```

PURPOSE

cpttrs solves a tridiagonal system of the form
A * X = B using the factorization A = U'*D*U or A = L*D*L' computed by CPTTRF. D is a diagonal matrix specified in the vector D, U (or L) is a unit bidiagonal matrix whose superdiagonal (subdiagonal) is specified in the vector E, and X and B are N by NRHS matrices.

ARGUMENTS

UPLO (input)
Specifies the form of the factorization and whether the vector OFFD is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 'U': A = U'*DIAG*U, OFFD is the superdiagonal of U
= 'L': A = L*DIAG*L', OFFD is the subdiagonal of L

N (input) The order of the tridiagonal matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

DIAG (input)
The n diagonal elements of the diagonal matrix DIAG from the factorization A = U'*DIAG*U or A = L*DIAG*L'.

OFFD (input/output)
If UPLO = 'U', the (n-1) superdiagonal elements of

the unit bidiagonal factor U from the factorization A = U'*DIAG*U. If UPLO = 'L', the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization A = L*DIAG*L'.

B (input/output)
On entry, the right hand side vectors B for the system of linear equations. On exit, the solution vectors, X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value

          plex *e, complex *b, long ldb);
```

PURPOSE

cptts2 solves a tridiagonal system of the form
   A * X = B using the factorization A = U'*D*U or A =
L*D*L' computed by CPTTRF. D is a diagonal matrix specified
in the vector D, U (or L) is a unit bidiagonal matrix whose
superdiagonal (subdiagonal) is specified in the vector E,
and X and B are N by NRHS matrices.

ARGUMENTS

IUPLO (input)
Specifies the form of the factorization and whether the vector E is the superdiagonal of the upper bidiagonal factor U or the subdiagonal of the lower bidiagonal factor L. = 1: A = U'*D*U, E is the superdiagonal of U
= 0: A = L*D*L', E is the subdiagonal of L

N (input) The order of the tridiagonal matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

D (input) The n diagonal elements of the diagonal matrix D from the factorization A = U'*D*U or A = L*D*L'.

E (input) If IUPLO = 1, the (n-1) superdiagonal elements of the unit bidiagonal factor U from the factorization A = U'*D*U. If IUPLO = 0, the (n-1) subdiagonal elements of the unit bidiagonal factor L from the factorization A = L*D*L'.

B (input/output)
On entry, the right hand side vectors B for the system of linear equations. On exit, the solution

vectors, X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

          The number of elements in the vectors X and Y.

X (input/output)
          On input, the vector X.  On output, X is overwrit-
          ten with C*X + S*Y.

INCX (input)
          The increment  between  successive  values  of  Y.
          INCX <> 0.

Y (input/output)
          On input, the vector Y.  On output, Y is overwrit-
          ten with -CONJG(S)*X + C*Y.

INCY (input)
          The increment  between  successive  values  of  Y.
          INCY <> 0.

C (input)

S (input)
               C and S define a rotation
               [  C          S  ]
               [ -conjg(S)   C  ]

               where C*C + S*CONJG(S) = 1.0.

NAME

```
crotg - Construct a Given's plane rotation
```

SYNOPSIS

```
SUBROUTINE CROTG(A, B, C, S)

COMPLEX A, B, S
REAL C

SUBROUTINE CROTG_64(A, B, C, S)

COMPLEX A, B, S
REAL C
```

F95 INTERFACE

```
SUBROUTINE ROTG(A, B, C, S)

COMPLEX :: A, B, S
REAL :: C

SUBROUTINE ROTG_64(A, B, C, S)

COMPLEX :: A, B, S
REAL :: C
```

C INTERFACE

```
#include <sunperf.h>

void crotg(complex *a, complex *b, float *c, complex *s);

void crotg_64(complex *a, complex *b, float *c, complex *s);
```

PURPOSE

crotg Construct a Given's plane rotation that will annihilate an element of a vector.

ARGUMENTS

A (input/output)
: On entry, A contains the entry in the first vector that corresponds to the element to be annihilated in the second vector. On exit, contains the nonzero element of the rotated vector.

B (input)
: On entry, B contains the entry to be annihilated in the second vector. Unchanged on exit.

C (output)
: On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

S (output)
: On exit, C and S are the elements of the rotation matrix that will be applied to annihilate B.

NAME

```
cscal - Compute y := alpha * y
```

SYNOPSIS

```
SUBROUTINE CSCAL(N, ALPHA, Y, INCY)

COMPLEX ALPHA
COMPLEX Y(*)
INTEGER N, INCY

SUBROUTINE CSCAL_64(N, ALPHA, Y, INCY)

COMPLEX ALPHA
COMPLEX Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])

COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: Y
INTEGER :: N, INCY

SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])

COMPLEX :: ALPHA
COMPLEX, DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cscal(int n, complex *alpha, complex *y, int incy);

void cscal_64(long  n,  complex  *alpha,  complex  *y,  long
          incy);
```

PURPOSE

cscal Compute y := alpha * y where alpha is a scalar and y is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the sub- routine to have any visible effect. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

NAME

```
csctr - Scatters elements from x into y.
```

SYNOPSIS

```
 SUBROUTINE CSCTR(NZ, X, INDX, Y)

 COMPLEX X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE CSCTR_64(NZ, X, INDX, Y)

 COMPLEX X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE SCTR([NZ], X, INDX, Y)

 COMPLEX, DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE SCTR_64([NZ], X, INDX, Y)

 COMPLEX, DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
CSCTR - Scatters the components of a sparse vector x stored
in compressed form into specified components of a vector y
```

in full storage form.

```
 do i = 1, n
   y(indx(i)) = x(i)
 enddo
```

ARGUMENTS

```
NZ (input) - INTEGER
        Number of elements in the compressed form.
        Unchanged on exit.

X (input)
        Vector containing the values to be scattered from
        compressed form into full storage form.  Unchanged
        on exit.

INDX (input) - INTEGER
        Vector containing the indices of the compressed
        form.  It is assumed that the elements in INDX are
        distinct and greater than zero.  Unchanged on exit.

Y (output)
        Vector whose elements specified by indx have been
        set to the corresponding entries of x.  Only the
        elements corresponding to the indices in indx have
        been modified.

```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in skyline format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general (NOT SUPPORTED)
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
```

```
                   2 : upper
                 DESCRA(3) main diagonal type
                   0 : non-unit
                   1 : unit
                 DESCRA(4) Array base  (NOT IMPLEMENTED)
                   0 : C/C++ compatible
                   1 : Fortran compatible
                 DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                   0 : unknown
                   1 : no repeated indices

 VAL()           array contain the nonzeros of A in skyline profile form.
                 Row-oriented if DESCRA(2) = 1 (lower triangular),
                 column oriented if DESCRA(2) = 2 (upper triangular).

 PNTR()          integer array of length M+1 (lower triangular) or
                 K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
                 points to the location in VAL of the first element of
                 the skyline profile in row (column) I.

 B()             rectangular array with first dimension LDB.
 LDB             leading dimension of B

 BETA            Scalar parameter

 C()             rectangular array with first dimension LDC.

 LDC             leading dimension of C

 WORK()          scratch array of length LWORK. WORK is not
                 referenced in the current version.

 LWORK           length of WORK array. LWORK is not referenced
                 in the current version.

lower triangular matrix represented in skyline format and
op( A )  is one  of

 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' )).
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row or column scaling (see section
                    NOTES for further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter
```

```
DESCRA()       Descriptor argument.  Five element integer array
               DESCRA(1) matrix structure
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))

               Note: For the routine, DESCRA(1)=3 is only supported.
               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

VAL()          array contain the nonzeros of A in skyline profile form.
               Row-oriented if DESCRA(2) = 1 (lower triangular),
               column oriented if DESCRA(2) = 2 (upper triangular).

PNTR()         integer array of length M+1 (lower triangular) or
               K+1 (upper triangular) such that PNTR(I)-PNTR(1)+1
               points to the location in VAL of the first element of
               the skyline profile in row (column) I.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK.
               On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.

LWORK          length of WORK array.  LWORK should be at least M.

               For good performance, LWORK should generally be larger.
```

For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

SEE ALSO

NIST FORTRAN Sparse Blas User's Guide available at:

http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. Also not supported:
   a. lower triangular matrix A of size m by n where m > n
   b. upper triangular matrix A of size m by n where m < n

2. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

3. If UNITD =4, the routine scales the rows of A if *DESCRA*(2)=1 and the columns of A if *DESCRA*(2)=2 such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in this particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows (columns) have been scaled. UNITD=2 if *DESCRA*(2)=1 and UNITD=3 if *DESCRA*(2)=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row (column) number which 2-norm is exactly zero.

4. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements

might or might not be referenced in the SKY representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the SKY representation.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

SUBROUTINE SPCON_64(UPLO, N, AP, IPIVOT, ANORM, RCOND, [WORK], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: AP, WORK
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>

void cspcon(char uplo, int  n,  complex  *ap,  int  *ipivot,
          float anorm, float *rcond, int *info);
void cspcon_64(char uplo, long n, complex *ap, long *ipivot,
          float anorm, float *rcond, long *info);
```

PURPOSE

cspcon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric packed matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

AP (input)
Complex array, dimension (N*(N+1)/2) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by CSPTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
Complex array, dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

Contents

```

C INTERFACE

```
#include <sunperf.h>

void csprfs(char uplo, int n, int nrhs, complex *a,  complex
          *af, int *ipivot, complex *b, int ldb, complex *x,
          int ldx, float *ferr, float *berr, int *info);

void csprfs_64(char uplo, long n,  long  nrhs,  complex  *a,
          complex  *af,  long *ipivot, complex *b, long ldb,
          complex *x, long ldx, float  *ferr,  float  *berr,
          long *info);
```

PURPOSE

csprfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite and packed, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

UPLO (input)
          = 'U': Upper triangle of A is stored;
          = 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
          The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) Complex array, dimension (N*(N+1)/2) The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of

A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n.

AF (input)
Complex array, dimension (N*(N+1)/2) The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by CSPTRF.

B (input) Complex array, dimension (LDB,NRHS) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
Complex array, dimension (LDX,NRHS) On entry, the solution matrix X, as computed by CSPTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
Real array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Real array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solu-

tion).

WORK (workspace)
Complex array, dimension(2*N)

WORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

#include <sunperf.h>

void cspsv(char uplo, int n,  int  nrhs,  complex  *ap,  int
          *ipivot, complex *b, int ldb, int *info);

void cspsv_64(char uplo, long n,  long  nrhs,  complex  *ap,
          long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

cspsv computes the solution to a complex system of linear equations
   A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

The diagonal pivoting method is used to factor A as
   A = U * D * U**T, if UPLO = 'U', or
   A = L * D * L**T, if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower) triangular matrices, D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

UPLO (input)
 = 'U': Upper triangle of A is stored;
 = 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
 The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP (input/output)
 Complex array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th

column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (output)

Integer array, dimension (N) Details of the interchanges and the block structure of D, as determined by CSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)

Complex array, dimension (LDB,NRHS) On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44

Packed storage of the upper triangle of A:

AP = [ a11, a12, a22, a13, a23, a33, a14, a24, a34, a44 ]
```

#include <sunperf.h>

void cspsvx(char fact, char uplo, int n, int  nrhs,  complex
          *a, complex *af, int *ipivot, complex *b, int ldb,
          complex *x, int ldx, float  *rcond,  float  *ferr,
          float *berr, int *info);

void cspsvx_64(char fact, char uplo, long n, long nrhs, com-
          plex  *a,  complex  *af, long *ipivot, complex *b,
          long ldb, complex  *x,  long  ldx,  float  *rcond,
          float *ferr, float *berr, long *info);
```

PURPOSE

cspsvx uses the diagonal pivoting factorization A = U*D*U**T or A = L*D*L**T to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix stored in packed format and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A as

```
      A = U * D * U**T,  if UPLO = 'U', or
```

A = L * D * L**T, if UPLO = 'L',
where U (or L) is a product of permutation and unit upper (lower)
triangular matrices and D is symmetric and block diagonal with
1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the routine
returns with INFO = i. Otherwise, the factored form of A is used
to estimate the condition number of the matrix A. If the
reciprocal of the condition number is less than machine precision,
INFO = N+1 is returned as a warning, but the routine still goes on
to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form
of A.

4. Iterative refinement is applied to improve the computed solution
matrix and calculate error bounds and backward error estimates
for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': On entry, AF and IPIVOT contain the factored form of A. A, AF and IPIVOT will not be modified. = 'N': The matrix A will be copied to AF and factored.

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) Complex array, dimension (N*(N+1)/2) The upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2*n-j)/2) = A(i,j) for j<=i<=n. See below for further details.

AF (input/output)

Complex array, dimension (N*(N+1)/2) If FACT = 'F', then AF is an input argument and on entry contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A. If FACT = 'N', then AF is an output argument and on exit contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSPTRF, stored as a packed triangular matrix in the same storage format as A.

IPIVOT (input or output)

Integer array, dimension (N) If FACT = 'F', then IPIVOT is an input argument and on entry contains details of the interchanges and the block structure of D, as determined by CSPTRF. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

If FACT = 'N', then IPIVOT is an output argument and on exit contains details of the interchanges and the block structure of D, as determined by CSPTRF.

B (input) Complex array, dimension (LDB,NRHS) The N-by-NRHS right hand side matrix B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
Complex array, dimension (LDX,NRHS) The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
Complex array, dimension (NRHS) The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
Complex array, dimension (NRHS) The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
Complex array, dimension(2*N)

WORK2 (workspace)
Integer array, dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D

is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

FURTHER DETAILS

The packed storage scheme is illustrated by the following example when N = 4, UPLO = 'U':

Two-dimensional storage of the symmetric matrix A:

```
   a11 a12 a13 a14
       a22 a23 a24
           a33 a34     (aij = aji)
               a44
```

Packed storage of the upper triangle of A:

A = [a11, a12, a22, a13, a23, a33, a14, a24, a34, a44]

void csptrf(char uplo, int n, complex *ap, int *ipivot,  int
          *info);

void csptrf_64(char uplo, long n, complex *ap, long *ipivot,
          long *info);
```

PURPOSE

csptrf computes the factorization of a complex symmetric matrix A stored in packed format using the Bunch-Kaufman diagonal pivoting method:

```
A = U*D*U**T  or  A = L*D*L**T
```

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Complex array, dimension (N*(N+1)/2) On entry, the upper or lower triangle of the symmetric matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L, stored as a packed triangular matrix overwriting A (see below for further details).

IPIVOT (output)
Integer array, dimension (N) Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

5-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then A = U*D*U', where
   U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,

i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

          long *info);
```

PURPOSE

csptri computes the inverse of a complex symmetric indefinite matrix A in packed storage using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

AP (input/output)
Complex array, dimension (N*(N+1)/2) On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix, stored as a packed triangular matrix. The j-th column of inv(A) is stored in the array AP as follows: if UPLO = 'U', AP(i + (j-1)*j/2) = inv(A)(i,j) for 1<=i<=j; if UPLO = 'L', AP(i + (j-1)*(2n-j)/2) = inv(A)(i,j) for j<=i<=n.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by CSPTRF.

WORK (workspace)

Complex array, dimension (N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

```
CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: AP
COMPLEX, DIMENSION(:,:) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
```

C INTERFACE

```
#include <sunperf.h>

void csptrs(char uplo, int n, int  nrhs,  complex  *ap,  int
          *ipivot, complex *b, int ldb, int *info);

void csptrs_64(char uplo, long n, long  nrhs,  complex  *ap,
          long *ipivot, complex *b, long ldb, long *info);
```

PURPOSE

csptrs solves a system of linear equations A*X = B with a complex symmetric matrix A stored in packed format using the factorization A = U*D*U**T or A = L*D*L**T computed by CSPTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

AP (input)
Complex array, dimension (N*(N+1)/2) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSPTRF, stored as a packed triangular matrix.

IPIVOT (input)
Integer array, dimension (N) Details of the interchanges and the block structure of D as determined by CSPTRF.

B (input/output)
Complex array, dimension (LDB,NRHS) On entry, the right hand side matrix B. On exit, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

```
csrot - Apply a plane rotation.
```

SYNOPSIS

```
SUBROUTINE CSROT(N, X, INCX, Y, INCY, C, S)

REAL C, S
COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY

SUBROUTINE CSROT_64(N, X, INCX, Y, INCY, C, S)

REAL C, S
COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE ROT([N], X, [INCX], Y, [INCY], C, S)

REAL :: C, S
COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY

SUBROUTINE ROT_64([N], X, [INCX], Y, [INCY], C, S)

REAL :: C, S
COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csrot(int n, complex *x,  int  incx,  complex  *y,  int
          incy, float c, float s);

void csrot_64(long n, complex *x,  long  incx,  complex  *y,
          long incy, float c, float s);
```

PURPOSE

csrot Apply a plane rotation, where the cos and sin (c and s) are real and the vectors x and y are complex.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)
Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

C (input)
On entry, the cosine. Unchanged on exit.

S (input)
On entry, the sin. Unchanged on exit.

NAME

```
csscal - Compute y := alpha * y
```

SYNOPSIS

```
SUBROUTINE CSSCAL(N, ALPHA, Y, INCY)

COMPLEX Y(*)
INTEGER N, INCY
REAL ALPHA

SUBROUTINE CSSCAL_64(N, ALPHA, Y, INCY)

COMPLEX Y(*)
INTEGER*8 N, INCY
REAL ALPHA
```

F95 INTERFACE

```
SUBROUTINE SCAL([N], ALPHA, Y, [INCY])

COMPLEX, DIMENSION(:) :: Y
INTEGER :: N, INCY
REAL :: ALPHA

SUBROUTINE SCAL_64([N], ALPHA, Y, [INCY])

COMPLEX, DIMENSION(:) :: Y
INTEGER(8) :: N, INCY
REAL :: ALPHA
```

C INTERFACE

```
#include <sunperf.h>
```

```
void csscal(int n, float alpha, complex *y, int incy);

void csscal_64(long n, float alpha, complex *y, long incy);
```

PURPOSE

csscal Compute y := alpha * y where alpha is a scalar and y is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

```

F95 INTERFACE

```
SUBROUTINE STEDC(COMPZ, [N], D, E, Z, [LDZ], [WORK], [LWORK], [RWORK],
       [LRWORK], [IWORK], [LIWORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: Z
```

```
INTEGER :: N, LDZ, LWORK, LRWORK, LIWORK, INFO
INTEGER, DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: D, E, RWORK

SUBROUTINE STEDC_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [LWORK],
       [RWORK], [LRWORK], [IWORK], [LIWORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: Z
INTEGER(8) :: N, LDZ, LWORK, LRWORK, LIWORK, INFO
INTEGER(8), DIMENSION(:) :: IWORK
REAL, DIMENSION(:) :: D, E, RWORK
```

C INTERFACE

```
#include <sunperf.h>
void cstedc(char compz, int n, float *d, float  *e,  complex
          *z, int ldz, int *info);

void cstedc_64(char compz, long n, float *d, float *e,  com-
          plex *z, long ldz, long *info);
```

PURPOSE

cstedc computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the divide and conquer method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLAED3 for details.

ARGUMENTS

```
COMPZ (input)
          = 'N':  Compute eigenvalues only.
          = 'I':  Compute eigenvectors of tridiagonal matrix
          also.
          = 'V':  Compute eigenvectors of original Hermitian
          matrix  also.   On  entry,  Z contains the unitary
```

matrix used to reduce the original matrix to tri-
diagonal form.

N (input) The dimension of the symmetric tridiagonal matrix. N >= 0.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ = 'V', Z contains the orthonormal eigenvectors of the original Hermitian matrix, and if COMPZ = 'I', Z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If COMPZ = 'N', then Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If eigenvectors are desired, then LDZ >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If COMPZ = 'N' or 'I', or N <= 1, LWORK must be at least 1. If COMPZ = 'V' and N > 1, LWORK must be at least N*N.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

RWORK (workspace)
dimension (LRWORK) On exit, if INFO = 0, RWORK(1) returns the optimal LRWORK.

LRWORK (input)
The dimension of the array RWORK. If COMPZ = 'N' or N <= 1, LRWORK must be at least 1. If COMPZ =

'V' and N > 1, LRWORK must be at least 1 + 3*N + 2*N*lg N + 3*N**2 , where lg(N) = smallest integer k such that 2**k >= N. If COMPZ = 'I' and N > 1, LRWORK must be at least 1 + 4*N + 2*N**2 .

If LRWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the RWORK array, returns this value as the first entry of the RWORK array, and no error message related to LRWORK is issued by XERBLA.

IWORK (workspace/output)
On exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. If COMPZ = 'N' or N <= 1, LIWORK must be at least 1. If COMPZ = 'V' or N > 1, LIWORK must be at least 6 + 6*N + 5*N*lg N. If COMPZ = 'I' or N > 1, LIWORK must be at least 3 + 5*N .

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The algorithm failed to compute an eigenvalue while working on the submatrix lying in rows and columns INFO/(N+1) through mod(INFO,N+1).

C INTERFACE

```
#include <sunperf.h>

void cstegr(char jobz, char range, int n,  float  *d,  float
          *e,  float  vl,  float  vu,  int il, int iu, float
          abstol, int *m, float *w, complex *z, int ldz, int
          *isuppz, int *info);

void cstegr_64(char jobz, char  range,  long  n,  float  *d,
          float  *e,  float  vl, float vu, long il, long iu,
          float abstol, long *m, float *w, complex *z,  long
          ldz, long *isuppz, long *info);
```

PURPOSE

```
cstegr b) Compute the  eigenvalues,  lambda_j,  of  L_i  D_i
L_i^T to high
       relative accuracy by the dqds algorithm,
   (c) If there is a cluster of close eigenvalues,  "choose"
sigma_i
       close to the cluster, and go to step (a),
   (d) Given the approximate eigenvalue lambda_j of L_i  D_i
L_i^T,
       compute the corresponding eigenvector by forming a
       rank-revealing twisted factorization.
The desired accuracy of the output can be specified  by  the
input parameter ABSTOL.

For more details, see "A new O(n^2) algorithm for  the  sym-
metric   tridiagonal   eigenvalue/eigenvector  problem",  by
Inderjit Dhillon, Computer Science Division Technical Report
No. UCB/CSD-97-971, UC Berkeley, May 1997.

Note 1 : Currently CSTEGR is only set up to find ALL  the  n
eigenvalues and eigenvectors of T in O(n^2) time
```

Note 2 : Currently the routine CSTEIN is called when an appropriate sigma_i cannot be chosen in step (c) above. CSTEIN invokes modified Gram-Schmidt when eigenvalues are close.

Note 3 : CSTEGR works only on machines which follow ieee-754 floating-point standard in their handling of infinities and NaNs. Normal execution of CSTEGR may create NaNs and infinities and hence may abort due to a floating point exception in environments which do not conform to the ieee standard.

ARGUMENTS

```
JOBZ (input)
          = 'N':  Compute eigenvalues only;
          = 'V':  Compute eigenvalues and eigenvectors.
RANGE (input)
          = 'A': all eigenvalues will be found.
          = 'V': all eigenvalues in the  half-open  interval
          (VL,VU]  will  be found.  = 'I': the IL-th through
          IU-th eigenvalues will be found.

N (input) The order of the matrix.  N >= 0.

D (input/output)
          On entry, the n diagonal elements of the tridiago-
          nal matrix T. On exit, D is overwritten.

E (input/output)
          On entry, the (n-1) subdiagonal  elements  of  the
          tridiagonal  matrix  T  in elements 1 to N-1 of E;
          E(N) need not be set.  On exit, E is overwritten.

VL (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

VU (input)
          If RANGE='V', the lower and upper  bounds  of  the
          interval  to be searched for eigenvalues. VL < VU.
          Not referenced if RANGE = 'A' or 'I'.

IL (input)
          If RANGE='I', the indices (in ascending order)  of
          the   smallest   and   largest   eigenvalues  to  be
          returned.  1 <= IL <= IU <= N, if N > 0;  IL  =  1
          and  IU  =  0 if N = 0.  Not referenced if RANGE =
          'A' or 'V'.
```

IU (input)
If RANGE='I', the indices (in ascending order) of the smallest and largest eigenvalues to be returned. 1 <= IL <= IU <= N, if N > 0; IL = 1 and IU = 0 if N = 0. Not referenced if RANGE = 'A' or 'V'.

ABSTOL (input)
The absolute error tolerance for the eigenvalues/eigenvectors. IF JOBZ = 'V', the eigenvalues and eigenvectors output have residual norms bounded by ABSTOL, and the dot products between different eigenvectors are bounded by ABSTOL. If ABSTOL is less than N*EPS*|T|, then N*EPS*|T| will be used in its place, where EPS is the machine precision and |T| is the 1-norm of the tridiagonal matrix. The eigenvalues are computed to an accuracy of EPS*|T| irrespective of ABSTOL. If high relative accuracy is important, set ABSTOL to DLAMCH('Safe minimum'). See Barlow and Demmel "Computing Accurate Eigensystems of Scaled Diagonally Dominant Matrices", LAPACK Working Note #7 for a discussion of which matrices define their eigenvalues to high relative accuracy.

M (output)
The total number of eigenvalues found. 0 <= M <= N. If RANGE = 'A', M = N, and if RANGE = 'I', M = IU-IL+1.

W (output)
The first M elements contain the selected eigenvalues in ascending order.

Z (input/output)
If JOBZ = 'V', then if INFO = 0, the first M columns of Z contain the orthonormal eigenvectors of the matrix T corresponding to the selected eigenvalues, with the i-th column of Z holding the eigenvector associated with W(i). If JOBZ = 'N', then Z is not referenced. Note: the user must ensure that at least max(1,M) columns are supplied in the array Z; if RANGE = 'V', the exact value of M is not known in advance and an upper bound must be used.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= max(1,N).

```
ISUPPZ (output)
          The support of the eigenvectors in  Z,  i.e.,  the
          indices  indicating the nonzero elements in Z. The
          i-th  eigenvector  is  nonzero  only  in  elements
          ISUPPZ( 2*i-1 ) through ISUPPZ( 2*i ).
WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          (and minimal) LWORK.

LWORK (input)
          The  dimension  of  the  array  WORK.   LWORK   >=
          max(1,18*N)

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace/output)
          On exit, if INFO = 0, IWORK(1) returns the optimal
          LIWORK.

LIWORK (input)
          The dimension  of  the  array  IWORK.   LIWORK  >=
          max(1,10*N)

          If LIWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the IWORK array, returns this value as  the  first
          entry  of  the  IWORK  array, and no error message
          related to LIWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = 1, internal error  in  SLARRE,  if
          INFO = 2, internal error in CLARRV.

```

C INTERFACE

```
#include <sunperf.h>

void cstein(int n, float *d, float *e, int m, float *w,  int
          *iblock,  int  *isplit,  complex  *z, int ldz, int
          *ifail, int *info);
void cstein_64(long n, float *d, float *e, long m, float *w,
          long  *iblock, long *isplit, complex *z, long ldz,
          long *ifail, long *info);
```

PURPOSE

cstein computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter MAXITS (currently set to 5).

Although the eigenvectors are real, they are stored in a complex array, which may be passed to CUNMTR or CUPMTR for back
transformation to the eigenvectors of a complex Hermitian matrix which was reduced to tridiagonal form.

ARGUMENTS

N (input) The order of the matrix. N >= 0.

D (input) The n diagonal elements of the tridiagonal matrix T.

E (input) The (n-1) subdiagonal elements of the tridiagonal matrix T, stored in elements 1 to N-1; E(N) need not be set.

M (input) The number of eigenvectors to be found. 0 <= M <= N.

W (input) The first M elements of W contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array W from SSTEBZ with ORDER = 'B' is expected here.)

IBLOCK (input)
The submatrix indices associated with the corresponding eigenvalues in W; IBLOCK(i)=1 if eigenvalue W(i) belongs to the first submatrix from the top, =2 if W(i) belongs to the second submatrix, etc. (The output array IBLOCK from SSTEBZ is expected here.)

ISPLIT (input)
The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to ISPLIT(1), the second of rows/columns ISPLIT(1)+1 through ISPLIT(2), etc. (The output array ISPLIT from SSTEBZ is expected here.)

Z (output)
The computed eigenvectors. The eigenvector associated with the eigenvalue W(i) is stored in the i-th column of Z. Any vector which fails to converge is set to its current iterate after MAXITS iterations. The imaginary parts of the eigenvectors are set to zero.

LDZ (input)
The leading dimension of the array Z. LDZ >= max(1,N).

WORK (workspace)
dimension(5*N)

IWORK (workspace)
dimension(N)

IFAIL (output)
On normal exit, all elements of IFAIL are zero. If one or more eigenvectors fail to converge after MAXITS iterations, then their indices are stored in array IFAIL.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value
> 0: if INFO = i, then i eigenvectors failed to converge in MAXITS iterations. Their indices are stored in array IFAIL.

CHARACTER(LEN=1) :: COMPZ
COMPLEX, DIMENSION(:,:) :: Z
INTEGER :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK

SUBROUTINE STEQR_64(COMPZ, [N], D, E, Z, [LDZ], [WORK], [INFO])

CHARACTER(LEN=1) :: COMPZ
COMPLEX, DIMENSION(:,:) :: Z
```

```
INTEGER(8) :: N, LDZ, INFO
REAL, DIMENSION(:) :: D, E, WORK
```

C INTERFACE

```
#include <sunperf.h>

void csteqr(char compz, int n, float *d, float  *e,  complex
          *z, int ldz, int *info);

void csteqr_64(char compz, long n, float *d, float *e,  com-
          plex *z, long ldz, long *info);
```

PURPOSE

csteqr computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. The eigenvectors of a full or band complex Hermitian matrix can also be found if CHETRD or CHPTRD or CHBTRD has been used to reduce this matrix to tridiagonal form.

ARGUMENTS

COMPZ (input)
= 'N': Compute eigenvalues only.
= 'V': Compute eigenvalues and eigenvectors of the original Hermitian matrix. On entry, Z must contain the unitary matrix used to reduce the original matrix to tridiagonal form. = 'I': Compute eigenvalues and eigenvectors of the tridiagonal matrix. Z is initialized to the identity matrix.

N (input) The order of the matrix. N >= 0.

D (input/output)
On entry, the diagonal elements of the tridiagonal matrix. On exit, if INFO = 0, the eigenvalues in ascending order.

E (input/output)
On entry, the (n-1) subdiagonal elements of the tridiagonal matrix. On exit, E has been destroyed.

Z (input) On entry, if COMPZ = 'V', then Z contains the unitary matrix used in the reduction to tridiagonal form. On exit, if INFO = 0, then if COMPZ =

```
          'V',  Z  contains  the orthonormal eigenvectors of
          the original Hermitian matrix, and if COMPZ = 'I',
          Z  contains  the  orthonormal  eigenvectors of the
          symmetric tridiagonal matrix.   If  COMPZ  =  'N',
          then Z is not referenced.

LDZ (input)
          The leading dimension of the array Z.  LDZ  >=  1,
          and  if  eigenvectors  are  desired,  then  LDZ >=
          max(1,N).

WORK (workspace)
          dimension(max(1,2*N-2)) If COMPZ = 'N', then  WORK
          is not referenced.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  the algorithm has failed  to  find  all  the
          eigenvalues in a total of 30*N iterations; if INFO
          = i, then i elements of E have  not  converged  to
          zero;  on  exit, D and E contain the elements of a
          symmetric tridiagonal matrix  which  is  unitarily
          similar to the original matrix.

          complex  *subl,  complex *b, long ldb, long *ipiv,
          long *info);
```

PURPOSE

cstsv computes the solution to a complex system of linear equations A * X = B where A is a Hermitian tridiagonal matrix.

ARGUMENTS

N (input)
The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides in B.

L (input/output)
COMPLEX array, dimension (N)
On entry, the n-1 subdiagonal elements of the tridiagonal matrix A. On exit, part of the factorization of A.

D (input/output)
REAL array, dimension (N)
On entry, the n diagonal elements of the tridiagonal matrix A. On exit, the n diagonal elements of the diagonal matrix D from the factorization of A.

SUBL (output)
COMPLEX array, dimension (N)
On exit, part of the factorization of A.

B (input/output)
The columns of B contain the right hand sides.

LDB (input)
The leading dimension of B as specified in a type or DIMENSION statement.

IPIV (output)
INTEGER array, dimension (N)
On exit, the pivot indices of the factorization.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular and division by zero will occur if it is used to solve a system of equations.

          *subl, long *ipiv, long *info);
```

PURPOSE

csttrf computes the L*D*L**H factorization of a complex Hermitian tridiagonal matrix A.

ARGUMENTS

```
N (input)  INTEGER
          The order of the matrix A.  N >= 0.

L (input/output)
           COMPLEX array, dimension (N)
          On entry, the n-1 subdiagonal elements of the tri-
          diagonal  matrix A.  On exit, part of the factori-
          zation of A.

D (input/output)
           REAL array, dimension (N)
          On entry, the n diagonal elements of the tridiago-
          nal matrix A.  On exit, the n diagonal elements of
          the diagonal matrix D from the factorization of A.

SUBL (output)
           COMPLEX array, dimension (N)
          On exit, part of the factorization of A.

IPIV (output)
           INTEGER array, dimension (N)
          On exit, the pivot indices of the factorization.

INFO (output)
           INTEGER
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, D(k,k) is  exactly  zero.   The
          factorization  has  been  completed, but the block
          diagonal matrix D is exactly singular and division
          by zero will occur if it is used to solve a system
          of equations.

#include <sunperf.h>

void csttrs(int n, int nrhs, complex *l, complex *d, complex
          *subl, complex *b, int ldb, int *ipiv, int *info);

void csttrs_64(long n, long nrhs, complex  *l,  complex  *d,
          complex  *subl,  complex *b, long ldb, long *ipiv,
          long *info);
```

PURPOSE

csttrs computes the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric tridiagonal matrix and X and B are N-by-NRHS matrices.

ARGUMENTS

N (input) INTEGER
The order of the matrix A. N >= 0.

NRHS (input)
INTEGER
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

L (input) COMPLEX array, dimension (N-1)
On entry, the subdiagonal elements of LL and DD.

D (input) COMPLEX array, dimension (N)
On entry, the diagonal elements of DD.

SUBL (input)
COMPLEX array, dimension (N-2)
On entry, the second subdiagonal elements of LL.

B (input/output)
COMPLEX array, dimension (LDB, NRHS)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
INTEGER
The leading dimension of the array B. LDB >= max(1, N)

IPIV (output)
INTEGER array, dimension (N)
Details of the interchanges and block pivot. If IPIV(K) > 0, 1 by 1 pivot, and if IPIV(K) = K + 1 an interchange done; If IPIV(K) < 0, 2 by 2 pivot, no interchange required.

INFO (output)
INTEGER
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value

NAME

```
cswap - Exchange vectors x and y.
```

SYNOPSIS

```
SUBROUTINE CSWAP(N, X, INCX, Y, INCY)

COMPLEX X(*), Y(*)
INTEGER N, INCX, INCY

SUBROUTINE CSWAP_64(N, X, INCX, Y, INCY)

COMPLEX X(*), Y(*)
INTEGER*8 N, INCX, INCY
```

F95 INTERFACE

```
SUBROUTINE SWAP([N], X, [INCX], Y, [INCY])

COMPLEX, DIMENSION(:) :: X, Y
INTEGER :: N, INCX, INCY

SUBROUTINE SWAP_64([N], X, [INCX], Y, [INCY])

COMPLEX, DIMENSION(:) :: X, Y
INTEGER(8) :: N, INCX, INCY
```

C INTERFACE

```
#include <sunperf.h>

void cswap(int n, complex *x,  int  incx,  complex  *y,  int
          incy);

void cswap_64(long n, complex *x,  long  incx,  complex  *y,
```

```
            long incy);
```

PURPOSE

cswap Exchange x and y where x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input/output)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. On exit, the y vector.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, the x vector.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

       [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL :: ANORM, RCOND
```

C INTERFACE

```
#include <sunperf.h>
void csycon(char uplo, int  n,  complex  *a,  int  lda,  int
          *ipivot, float anorm, float *rcond, int *info);

void csycon_64(char uplo, long n, complex *a, long lda, long
          *ipivot, float anorm, float *rcond, long *info);
```

PURPOSE

csycon estimates the reciprocal of the condition number (in the 1-norm) of a complex symmetric matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

A (input) The block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CSYTRF.

ANORM (input)
The 1-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)
dimension(2*N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

F95 INTERFACE

```
SUBROUTINE SYMM(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])

CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,:) :: A, B, C
INTEGER :: M, N, LDA, LDB, LDC

SUBROUTINE SYMM_64(SIDE, UPLO, [M], [N], ALPHA, A, [LDA], B, [LDB],
       BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: SIDE, UPLO
COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:,:) :: A, B, C
INTEGER(8) :: M, N, LDA, LDB, LDC
```

C INTERFACE

```
#include <sunperf.h>

void csymm(char side, char  uplo,  int  m,  int  n,  complex
          *alpha,  complex *a, int lda, complex *b, int ldb,
          complex *beta, complex *c, int ldc);

void csymm_64(char side, char uplo, long m, long n,  complex
          *alpha,  complex  *a,  long  lda, complex *b, long
          ldb, complex *beta, complex *c, long ldc);
```

PURPOSE

csymm performs one of the matrix-matrix operations C := alpha*A*B + beta*C or C := alpha*B*A + beta*C where alpha and beta are scalars, A is a symmetric matrix and B and C are m by n matrices.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether the symmetric matrix A appears on the left or right in the operation as follows:

SIDE = 'L' or 'l'   C := alpha*A*B + beta*C,

SIDE = 'R' or 'r'   C := alpha*B*A + beta*C,

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of the symmetric matrix is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of the symmetric matrix is to be referenced.

Unchanged on exit.

M (input)
On entry, M specifies the number of rows of the matrix C. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix C. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX array of DIMENSION (LDA, ka), where ka is m when SIDE = 'L' or 'l' and is n otherwise.

Before entry with SIDE = 'L' or 'l', the m by m part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading m by m upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading m by m lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Before entry with SIDE = 'R' or 'r', the n by n part of the array A must contain the symmetric matrix, such that when UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of A is not referenced, and when UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of A is not referenced.

Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When

SIDE = 'L' or 'l' then LDA >= max(1, m), otherwise LDA >= max(1, n). Unchanged on exit.

B (input)
COMPLEX array of DIMENSION (LDB, n). Before entry, the leading m by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. LDB >= max(1, m). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)
COMPLEX array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n updated matrix.

LDC (input)
On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC >= max(1, m). Unchanged on exit.

             complex *beta, complex *c, int ldc);
   void csyr2k_64(char uplo, char transa, long n, long k,  com-
             plex  *alpha,  complex  *a,  long lda, complex *b,
             long ldb, complex *beta, complex *c, long ldc);
```

PURPOSE

csyr2k performs one of the symmetric rank 2k operations C := alpha*A*B' + alpha*B*A' + beta*C or C := alpha*A'*B + alpha*B'*A + beta*C where alpha and beta are scalars, C is an n by n symmetric matrix and A and B are n by k matrices in the first case and k by n matrices in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u' Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l' Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' C := alpha*A*B' + alpha*B*A' + beta*C.

TRANSA = 'T' or 't'   C := alpha*A'*B + alpha*B'*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)

On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)

On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrices A and B, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrices A and B. K must be at least zero. Unchanged on exit.

ALPHA (input)

On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)

COMPLEX array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

B (input)

COMPLEX array of DIMENSION (LDB, kb), where kb is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array B must contain the matrix B, otherwise the leading k by n part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDB must be at least max(1, n), otherwise LDB must be at least max(1, k). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)

COMPLEX array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

          *ferr, float *berr, long *info);
```

PURPOSE

csyrfs improves the computed solution to a system of linear equations when the coefficient matrix is symmetric indefinite, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The symmetric matrix A.  If UPLO = 'U', the  lead-
          ing N-by-N upper triangular part of A contains the
```

upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factored form of the matrix A. AF contains the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSYTRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
Details of the interchanges and the block structure of D as determined by CSYTRF.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by CSYTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

```
BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).
WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

INTEGER(8) :: N, K, LDA, LDC
```

C INTERFACE

```
#include <sunperf.h>

void csyrk(char uplo, char transa, int  n,  int  k,  complex
          *alpha,  complex  *a, int lda, complex *beta, com-
          plex *c, int ldc);

void csyrk_64(char uplo, char transa, long n, long  k,  com-
          plex  *alpha, complex *a, long lda, complex *beta,
          complex *c, long ldc);
```

PURPOSE

csyrk performs one of the symmetric rank k operations C := alpha*A*A' + beta*C or C := alpha*A'*A + beta*C where alpha and beta are scalars, C is an n by n symmetric matrix and A is an n by k matrix in the first case and a k by n matrix in the second case.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the upper or lower triangular part of the array C is to be referenced as follows:

UPLO = 'U' or 'u'   Only the upper triangular part of C is to be referenced.

UPLO = 'L' or 'l'   Only the lower triangular part of C is to be referenced.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   C := alpha*A*A' + beta*C.

TRANSA = 'T' or 't'   C := alpha*A'*A + beta*C.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input)
On entry, N specifies the order of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry with TRANSA = 'N' or 'n', K specifies the number of columns of the matrix A, and on entry with TRANSA = 'T' or 't', K specifies the number of rows of the matrix A. K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
COMPLEX array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is n otherwise. Before entry with TRANSA = 'N' or 'n', the leading n by k part of the array A must contain the matrix A, otherwise the leading k by n part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA must be at least max(1, n), otherwise LDA must be at least max(1, k). Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. Unchanged on exit.

C (input/output)
COMPLEX array of DIMENSION (LDC, n).

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array C must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of C is not referenced. On exit, the upper triangular part of the array C is overwritten by the upper triangular part of the updated matrix.

Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array C must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of C is not referenced. On exit, the lower triangular part of the array C is overwritten by the lower triangular part of the updated matrix.

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC must be at least max(1, n). Unchanged on exit.

C INTERFACE

```
    #include <sunperf.h>

    void csysv(char uplo, int n, int nrhs, complex *a, int  lda,
              int *ipiv, complex *b, int ldb, int *info);
    void csysv_64(char uplo, long n, long nrhs, complex *a, long
              lda,  long  *ipiv,  complex  *b,  long  ldb,  long
              *info);
```

PURPOSE

```
    csysv computes the solution to a complex  system  of  linear
    equations
       A * X = B, where A is an N-by-N symmetric  matrix  and  X
    and B are N-by-NRHS matrices.

    The diagonal pivoting method is used to factor A as
       A = U * D * U**T,  if UPLO = 'U', or
       A = L * D * L**T,  if UPLO = 'L',
    where U (or L) is a product of permutation  and  unit  upper
    (lower)  triangular  matrices,  and D is symmetric and block
    diagonal with 1-by-1 and 2-by-2 diagonal blocks.   The  fac-
    tored  form  of  A is then used to solve the system of equa-
    tions A * X = B.
```

ARGUMENTS

```
    UPLO (input)
              = 'U':  Upper triangle of A is stored;
              = 'L':  Lower triangle of A is stored.

    N (input) The number of linear equations, i.e., the order of
              the matrix A.  N >= 0.

    NRHS (input)
              The number of right hand sides, i.e.,  the  number
              of columns of the matrix B.  NRHS >= 0.

    A (input/output)
```

On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, if INFO = 0, the block diagonal matrix D and the multipliers used to obtain the factor U or L from the factorization A = U*D*U**T or A = L*D*L**T as computed by CSYTRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)
Details of the interchanges and the block structure of D, as determined by CSYTRF. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged, and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The length of WORK. LWORK >= 1, and for best performance LWORK >= N*NB, where NB is the optimal blocksize for CSYTRF.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of

the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, so the solution could not be computed.

```
#include <sunperf.h>

void csysvx(char fact, char uplo, int n, int  nrhs,  complex
          *a,  int  lda, complex *af, int ldaf, int *ipivot,
          complex *b, int ldb, complex *x,  int  ldx,  float
          *rcond, float *ferr, float *berr, int *info);

void csysvx_64(char fact, char uplo, long n, long nrhs, com-
          plex  *a,  long  lda, complex *af, long ldaf, long
          *ipivot, complex *b, long ldb,  complex  *x,  long
          ldx,  float *rcond, float *ferr, float *berr, long
          *info);
```

PURPOSE

csysvx uses the diagonal pivoting factorization to compute the solution to a complex system of linear equations A * X = B, where A is an N-by-N symmetric matrix and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the diagonal pivoting method is used to factor A.
   The form of the factorization is
      A = U * D * U**T, if UPLO = 'U', or

```
      A = L * D * L**T,  if UPLO = 'L',
   where U (or L) is a product of permutation and unit upper
(lower)
   triangular matrices, and D is symmetric and block  diago-
nal with
   1-by-1 and 2-by-2 diagonal blocks.

2. If some D(i,i)=0, so that D is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.
3. The system of equations is solved for X  using  the  fac-
tored form
   of A.

4. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored  form  of  A
          has  been supplied on entry.  = 'F':  On entry, AF
          and IPIVOT contain the factored form of A.  A,  AF
          and  IPIVOT  will  not  be  modified.  = 'N':  The
          matrix A will be copied to AF and factored.

UPLO (input)
          = 'U':  Upper triangle of A is stored;
          = 'L':  Lower triangle of A is stored.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.
```

```
A (input) The symmetric matrix A.  If UPLO = 'U', the  lead-
          ing N-by-N upper triangular part of A contains the
          upper triangular part of the  matrix  A,  and  the
          strictly  lower triangular part of A is not refer-
          enced.  If UPLO = 'L', the  leading  N-by-N  lower
          triangular part of A contains the lower triangular
          part of the matrix A, and the strictly upper  tri-
          angular part of A is not referenced.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

AF (input/output)
          If FACT = 'F', then AF is an input argument and on
          entry contains the block diagonal matrix D and the
          multipliers used to obtain the factor U or L  from
          the  factorization A = U*D*U**T or A = L*D*L**T as
          computed by CSYTRF.

          If FACT = 'N', then AF is an output  argument  and
          on  exit  returns  the block diagonal matrix D and
          the multipliers used to obtain the factor U  or  L
          from  the  factorization  A  =  U*D*U**T  or  A  =
          L*D*L**T.

LDAF (input)
          The leading dimension of the array  AF.   LDAF  >=
          max(1,N).

IPIVOT (input or output)
          If FACT = 'F', then IPIVOT is  an  input  argument
          and  on entry contains details of the interchanges
          and the block structure of  D,  as  determined  by
          CSYTRF.  If IPIVOT(k) > 0, then rows and columns k
          and IPIVOT(k) were interchanged and  D(k,k)  is  a
          1-by-1   diagonal   block.   If  UPLO  =  'U'  and
          IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns
          k-1  and  -IPIVOT(k)  were  interchanged  and D(k-
          1:k,k-1:k) is a 2-by-2 diagonal block.  If UPLO  =
          'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and
          columns k+1 and -IPIVOT(k) were  interchanged  and
          D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

          If FACT = 'N', then IPIVOT is an  output  argument
          and  on  exit contains details of the interchanges
          and the block structure of  D,  as  determined  by
          CSYTRF.

B (input) The N-by-NRHS right hand side matrix B.
```

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >= 2*N, and for best performance LDWORK >= N*NB, where NB is the optimal blocksize for CSYTRF.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: D(i,i) is exactly zero. The factorization has been completed but the factor D is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: D is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:,:) :: A
```

```
INTEGER(8) :: N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
```

C INTERFACE

```
#include <sunperf.h>

void csytf2(char uplo, int  n,  complex  *a,  int  lda,  int
          *ipiv, int *info);

void csytf2_64(char uplo, long n, complex *a, long lda, long
          *ipiv, long *info);
```

PURPOSE

csytf2 computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method:

A = U*D*U' or A = L*D*L'

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, U' is the transpose of U, and D is symmetric and block diagonal with 1-by-1 and 2-by-2 diagonal blocks.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

UPLO (input)
Specifies whether the upper or lower triangular part of the symmetric matrix A is stored:
= 'U': Upper triangular
= 'L': Lower triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the mul-

tipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIV (output)
Details of the interchanges and the block structure of D. If IPIV(k) > 0, then rows and columns k and IPIV(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIV(k) = IPIV(k-1) < 0, then rows and columns k-1 and -IPIV(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIV(k) = IPIV(k+1) < 0, then rows and columns k+1 and -IPIV(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, D(k,k) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

1-96 - Based on modifications by J. Lewis, Boeing Computer Services
Company

If UPLO = 'U', then A = U*D*U', where
U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIV(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-

```
1,k).   If s = 2, the upper triangle of D(k) overwrites A(k-
1,k-1), A(k-1,k), and A(k,k), and  v  overwrites  A(1:k-2,k-
1:k).

If UPLO = 'L', then A = L*D*L', where
   L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where  k  increases
from  1  to  n in steps of 1 or 2, and D is a block diagonal
matrix with 1-by-1 and 2-by-2 diagonal blocks D(k).  P(k) is
a  permutation  matrix  as defined by IPIV(k), and L(k) is a
unit lower triangular matrix,  such  that  if  the  diagonal
block D(k) is of order s (s = 1 or 2), then

           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
If  s  =  1,  D(k)  overwrites  A(k,k),  and  v   overwrites
A(k+1:n,k).  If s = 2, the lower triangle of D(k) overwrites
A(k,k),  A(k+1,k),  and   A(k+1,k+1),   and   v   overwrites
A(k+2:n,k:k+1).

          *ipivot, int *info);

void csytrf_64(char uplo, long n, complex *a, long lda, long
          *ipivot, long *info);
```

PURPOSE

csytrf computes the factorization of a complex symmetric matrix A using the Bunch-Kaufman diagonal pivoting method. The form of the factorization is

A = U*D*U**T or A = L*D*L**T

where U (or L) is a product of permutation and unit upper (lower) triangular matrices, and D is symmetric and block diagonal with with 1-by-1 and 2-by-2 diagonal blocks.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A is stored;
= 'L': Lower triangle of A is stored.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the symmetric matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced.

On exit, the block diagonal matrix D and the multipliers used to obtain the factor U or L (see below for further details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
Details of the interchanges and the block structure of D. If IPIVOT(k) > 0, then rows and columns k and IPIVOT(k) were interchanged and D(k,k) is a 1-by-1 diagonal block. If UPLO = 'U' and IPIVOT(k) = IPIVOT(k-1) < 0, then rows and columns k-1 and -IPIVOT(k) were interchanged and D(k-1:k,k-1:k) is a 2-by-2 diagonal block. If UPLO = 'L' and IPIVOT(k) = IPIVOT(k+1) < 0, then rows and columns k+1 and -IPIVOT(k) were interchanged and D(k:k+1,k:k+1) is a 2-by-2 diagonal block.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The length of WORK. LDWORK >=1. For best performance LDWORK >= N*NB, where NB is the block size returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, D(i,i) is exactly zero. The factorization has been completed, but the block diagonal matrix D is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

If UPLO = 'U', then A = U*D*U', where

U = P(n)*U(n)* ... *P(k)U(k)* ...,
i.e., U is a product of terms P(k)*U(k), where k decreases from n to 1 in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and U(k) is a unit upper triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    v    0   )   k-s
   U(k) =  (   0    I    0   )   s
           (   0    0    I   )   n-k
              k-s   s   n-k
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(1:k-1,k). If s = 2, the upper triangle of D(k) overwrites A(k-1,k-1), A(k-1,k), and A(k,k), and v overwrites A(1:k-2,k-1:k).

If UPLO = 'L', then A = L*D*L', where
L = P(1)*L(1)* ... *P(k)*L(k)* ...,
i.e., L is a product of terms P(k)*L(k), where k increases from 1 to n in steps of 1 or 2, and D is a block diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks D(k). P(k) is a permutation matrix as defined by IPIVOT(k), and L(k) is a unit lower triangular matrix, such that if the diagonal block D(k) is of order s (s = 1 or 2), then

```
           (   I    0     0   )  k-1
   L(k) =  (   0    I     0   )  s
           (   0    v     I   )  n-k-s+1
              k-1   s  n-k-s+1
```

If s = 1, D(k) overwrites A(k,k), and v overwrites A(k+1:n,k). If s = 2, the lower triangle of D(k) overwrites A(k,k), A(k+1,k), and A(k+1,k+1), and v overwrites A(k+2:n,k:k+1).

          *ipivot, long *info);
```

PURPOSE

csytri computes the inverse of a complex symmetric indefinite matrix A using the factorization A = U*D*U**T or A = L*D*L**T computed by CSYTRF.

ARGUMENTS

UPLO (input)
Specifies whether the details of the factorization are stored as an upper or lower triangular matrix.
= 'U': Upper triangular, form is A = U*D*U**T;
= 'L': Lower triangular, form is A = L*D*L**T.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the block diagonal matrix D and the multipliers used to obtain the factor U or L as computed by CSYTRF.

On exit, if INFO = 0, the (symmetric) inverse of the original matrix. If UPLO = 'U', the upper triangular part of the inverse is formed and the part of A below the diagonal is not referenced; if UPLO = 'L' the lower triangular part of the inverse is formed and the part of A above the diagonal is not referenced.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

```
IPIVOT (input)
          Details of the interchanges and the  block  struc-
          ture of D as determined by CSYTRF.

WORK (workspace)
          dimension(2*N)

REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TBCON(NORM, UPLO, DIAG, [N], KD, A, [LDA], RCOND, [WORK],
       [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, KD, LDA, INFO
```

```
REAL :: RCOND
REAL, DIMENSION(:) :: WORK2

SUBROUTINE TBCON_64(NORM, UPLO, DIAG, [N], KD, A, [LDA], RCOND,
       [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, KD, LDA, INFO
REAL :: RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
void ctbcon(char norm, char uplo, char diag, int n, int  kd,
          complex *a, int lda, float *rcond, int *info);

void ctbcon_64(char norm, char uplo, char diag, long n, long
          kd,  complex  *a,  long  lda,  float  *rcond, long
          *info);
```

PURPOSE

ctbcon estimates the reciprocal of the condition number of a triangular band matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as
   RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
```

```
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals  or  subdiagonals  of
          the triangular band matrix A.  KD >= 0.

A (input) The upper  or  lower  triangular  band  matrix  A,
          stored  in  the  first kd+1 rows of the array. The
          j-th column of A is stored in the j-th  column  of
          the  array A as follows:  if UPLO = 'U', A(kd+1+i-
          j,j) = A(i,j) for  max(1,j-kd)<=i<=j;  if  UPLO  =
          'L', A(1+i-j,j)    = A(i,j) for j<=i<=min(n,j+kd).
          If DIAG = 'U', the diagonal elements of A are  not
          referenced and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          KD+1.

RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix   A,  computed  as  RCOND  =  1/(norm(A)  *
          norm(inv(A))).

WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

NAME

ctbmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

SYNOPSIS

```
SUBROUTINE CTBMV(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER N, K, LDA, INCY

SUBROUTINE CTBMV_64(UPLO, TRANSA, DIAG, N, K, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, K, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TBMV(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, K, LDA, INCY

SUBROUTINE TBMV_64(UPLO, [TRANSA], DIAG, [N], K, A, [LDA], Y,
       [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, K, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ctbmv(char uplo, char transa, char diag, int n, int  k,
          complex *a, int lda, complex *y, int incy);

void ctbmv_64(char uplo, char transa,  char  diag,  long  n,
          long  k,  complex  *a,  long lda, complex *y, long
          incy);
```

PURPOSE

ctbmv performs one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := conjg(A')*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)

On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K >= 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower

triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tran- formed vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

C INTERFACE

```
#include <sunperf.h>

void ctbrfs(char uplo, char transa, char diag,  int  n,  int
          kd, int nrhs, complex *a, int lda, complex *b, int
          ldb, complex  *x,  int  ldx,  float  *ferr,  float
          *berr, int *info);

void ctbrfs_64(char uplo, char transa, char  diag,  long  n,
          long  kd, long nrhs, complex *a, long lda, complex
          *b, long ldb, complex *x, long ldx,  float  *ferr,
          float *berr, long *info);
```

PURPOSE

ctbrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular band coefficient matrix.

The solution matrix X must be computed by CTBTRS or some other means before entering this routine. CTBRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.
```

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

KD (input)
The number of superdiagonals or subdiagonals of the triangular band matrix A. KD >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The upper or lower triangular band matrix A, stored in the first kd+1 rows of the array. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input) The solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)

```
            The componentwise relative backward error of  each
            solution  vector X(j) (i.e., the smallest relative
            change in any element of A or B that makes X(j) an
            exact solution).

WORK (workspace)
            dimension(2*N)
WORK2 (workspace)
            dimension(N)

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value
```

       [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, K, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ctbsv(char uplo, char transa, char diag, int n, int  k,
          complex *a, int lda, complex *y, int incy);

void ctbsv_64(char uplo, char transa,  char  diag,  long  n,
          long  k,  complex  *a,  long lda, complex *y, long
          incy);
```

PURPOSE

ctbsv solves one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular band matrix, with (k + 1) diagonals.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n' A*x = b.

TRANSA = 'T' or 't' A'*x = b.

TRANSA = 'C' or 'c' conjg(A')*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

K (input)
On entry with UPLO = 'U' or 'u', K specifies the number of super-diagonals of the matrix A. On entry with UPLO = 'L' or 'l', K specifies the number of sub-diagonals of the matrix A. K >= 0. Unchanged on exit.

A (input)
Before entry with UPLO = 'U' or 'u', the leading (k + 1) by n part of the array A must contain the upper triangular band part of the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (k + 1) of the array, the first super-diagonal starting at position 2 in row k, and so on. The top left k by k triangle of the array A is not referenced. The following program segment will transfer an upper triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = K + 1 - J
     DO 10, I = MAX( 1, J - K ), J
       A( M + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Before entry with UPLO = 'L' or 'l', the leading (k + 1) by n part of the array A must contain the lower triangular band part of the matrix of coefficients, supplied column by column, with the

leading diagonal of the matrix in row 1 of the array, the first sub-diagonal starting at position 1 in row 2, and so on. The bottom right k by k triangle of the array A is not referenced. The following program segment will transfer a lower triangular band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     M = 1 - J
     DO 10, I = J, MIN( N, J + K )
       A( M + I, J ) = matrix( I, J )
10  CONTINUE
20 CONTINUE
```

Note that when DIAG = 'U' or 'u' the elements of the array A corresponding to the diagonal elements of the matrix are not referenced, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (k + 1). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

          long  kd, long nrhs, complex *a, long lda, complex
          *b, long ldb, long *info);
```

PURPOSE

ctbtrs solves a triangular system of the form

where A is a triangular band matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

KD (input)
          The number of superdiagonals  or  subdiagonals  of
          the triangular band matrix A.  KD >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.
```

A (input) The upper or lower triangular band matrix A, stored in the first kd+1 rows of A. The j-th column of A is stored in the j-th column of the array A as follows: if UPLO = 'U', A(kd+1+i-j,j) = A(i,j) for max(1,j-kd)<=i<=j; if UPLO = 'L', A(1+i-j,j) = A(i,j) for j<=i<=min(n,j+kd). If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= KD+1.

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

          plex *vl, long ldvl, complex *vr, long ldvr,  long
          mm, long *m, long *info);
```

PURPOSE

ctgevc computes some or all of the right and/or left generalized eigenvectors of a pair of complex upper triangular matrices (A,B).

The right generalized eigenvector x and the left generalized eigenvector y of (A,B) corresponding to a generalized eigenvalue w are defined by:

        (A - wB) * x = 0 and y**H * (A - wB) = 0

where y**H denotes the conjugate tranpose of y.

If an eigenvalue w is determined by zero diagonal elements of both A and B, a unit vector is returned as the corresponding eigenvector.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of (A,B), or the products Z*X and/or Q*Y, where Z and Q are input unitary matrices. If (A,B) was obtained from the generalized Schur factorization of an original pair of matrices
   (A0,B0) = (Q*A*Z**H,Q*B*Z**H),

then Z*X and Q*Y are the matrices of right or left eigenvectors of A.

ARGUMENTS

SIDE (input)
= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)
= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input)
If HOWMNY='S', SELECT specifies the eigenvectors to be computed. If HOWMNY='A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrices A and B. N >= 0.

A (input) The upper triangular matrix A.

LDA (input)
The leading dimension of array A. LDA >= max(1,N).

B (input) The upper triangular matrix B. B must have real diagonal elements.

LDB (input)
The leading dimension of array B. LDB >= max(1,N).

VL (input/output)
On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of left Schur vectors returned by CHGEQZ). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of (A,B); if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of

(A,B) specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Z of right Schur vectors returned by CHGEQZ). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of (A,B); if HOWMNY = 'B', the matrix Z*X; if HOWMNY = 'S', the right eigenvectors of (A,B) specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK (workspace)
dimension(2*N)

RWORK (workspace)
dimension(2*N)

#include <sunperf.h>

void ctgexc(int wantq, int wantz, int  n,  complex  *a,  int
          lda,  complex  *b,  int  ldb, complex *q, int ldq,
          complex *z, int ldz, int  *ifst,  int  *ilst,  int
          *info);

void ctgexc_64(long wantq, long wantz, long n,  complex  *a,
          long  lda,  complex *b, long ldb, complex *q, long
          ldq, complex *z, long ldz, long *ifst, long *ilst,
          long *info);
```

PURPOSE

ctgexc reorders the generalized Schur decomposition of a complex matrix pair (A,B), using an unitary equivalence transformation (A, B) := Q * (A, B) * Z', so that the diagonal block of (A, B) with row index IFST is moved to row ILST.

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

Optionally, the matrices Q and Z of generalized Schur vectors are updated.

```
Q(in) * A(in) * Z(in)' = Q(out) * A(out) * Z(out)'
Q(in) * B(in) * Z(in)' = Q(out) * B(out) * Z(out)'
```

ARGUMENTS

WANTQ (input)

WANTZ (input)

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the upper triangular matrix A in the pair (A, B). On exit, the updated matrix A.

```
LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,N).

B (input/output)
          On entry, the upper triangular  matrix  B  in  the
          pair (A, B).  On exit, the updated matrix B.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

Q (input/output)
          On entry, if WANTQ = .TRUE., the unitary matrix Q.
          On  exit,  the  updated  matrix  Q.   If  WANTQ  =
          .FALSE., Q is not referenced.

LDQ (input)
          The leading dimension of the array Q. LDQ >= 1; If
          WANTQ = .TRUE., LDQ >= N.

Z (input/output)
          On entry, if WANTZ = .TRUE., the unitary matrix Z.
          On  exit,  the  updated  matrix  Z.   If  WANTZ  =
          .FALSE., Z is not referenced.

LDZ (input)
          The leading dimension of the array Z. LDZ >= 1; If
          WANTZ = .TRUE., LDZ >= N.

IFST (input/output)
          Specify the reordering of the diagonal  blocks  of
          (A, B).  The block with row index IFST is moved to
          row ILST, by a sequence of swapping between  adja-
          cent blocks.

ILST (input/output)
          See the description of IFST.

INFO (output)
          =0:  Successful exit.
          <0:  if INFO = -i, the i-th argument had an  ille-
          gal value.
          =1:  The transformed matrix pair (A, B)  would  be
          too  far  from generalized Schur form; the problem
          is ill- conditioned. (A, B)  may  have  been  par-
          tially reordered, and ILST points to the first row
          of the current position of the block being moved.
```

```

PURPOSE

ctgsen reorders the generalized Schur decomposition of a complex matrix pair (A, B) (in terms of an unitary equivalence trans- formation Q' * (A, B) * Z), so that a selected cluster of eigenvalues appears in the leading diag- onal blocks of the pair (A,B). The leading columns of Q and Z form unitary bases of the corresponding left and right eigenspaces (deflating subspaces). (A, B) must be in gen- eralized Schur canonical form, that is, A and B are both upper triangular.

CTGSEN also computes the generalized eigenvalues

w(j)= ALPHA(j) / BETA(j)

of the reordered matrix pair (A, B).

Optionally, the routine computes estimates of reciprocal condition numbers for eigenvalues and eigenspaces. These are Difu[(A11,B11), (A22,B22)] and Difl[(A11,B11), (A22,B22)], i.e. the separation(s) between the matrix pairs (A11, B11) and (A22,B22) that correspond to the selected cluster and the eigenvalues outside the cluster, resp., and norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster in the (1,1)-block.

ARGUMENTS

IJOB (input)
Specifies whether condition numbers are required for the cluster of eigenvalues (PL and PR) or the deflating subspaces (Difu and Difl):
=0: Only reorder w.r.t. SELECT. No extras.
=1: Reciprocal of norms of "projections" onto left and right eigenspaces w.r.t. the selected cluster (PL and PR). =2: Upper bounds on Difu and Difl. F-norm-based estimate
(DIF(1:2)).
=3: Estimate of Difu and Difl. 1-norm-based esti- mate
(DIF(1:2)). About 5 times as expensive as IJOB = 2. =4: Compute PL, PR and DIF (i.e. 0, 1 and 2 above): Economic version to get it all. =5: Com- pute PL, PR and DIF (i.e. 0, 1 and 3 above)

WANTQ (input)

WANTZ (input)

```
SELECT (input)
          SELECT specifies the eigenvalues in  the  selected
          cluster.  To  select an eigenvalue w(j), SELECT(j)
          must be set to

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
          On entry, the upper triangular matrix A,  in  gen-
          eralized  Schur  canonical  form.   On  exit, A is
          overwritten by the reordered matrix A.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,N).
B (input/output)
          On entry, the upper triangular matrix B,  in  gen-
          eralized  Schur  canonical  form.   On  exit, B is
          overwritten by the reordered matrix B.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

ALPHA (output)
          The diagonal elements of A  and  B,  respectively,
          when  the  pair (A,B) has been reduced to general-
          ized Schur form.  ALPHA(i)/BETA(i)  i=1,...,N  are
          the generalized eigenvalues.

BETA (output)
          See the description of ALPHA.

Q (input/output)
          On entry, if  WANTQ  =  .TRUE.,  Q  is  an  N-by-N
          matrix.  On exit, Q has been postmultiplied by the
          left unitary transformation matrix  which  reorder
          (A,  B); The leading M columns of Q form orthonor-
          mal bases for the specified pair  of  left  eigen-
          spaces (deflating subspaces).  If WANTQ = .FALSE.,
          Q is not referenced.

LDQ (input)
          The leading dimension of the array Q.  LDQ  >=  1.
          If WANTQ = .TRUE., LDQ >= N.

Z (input/output)
          On entry, if  WANTZ  =  .TRUE.,  Z  is  an  N-by-N
          matrix.  On exit, Z has been postmultiplied by the
          left unitary transformation matrix  which  reorder
```

(A, B); The leading M columns of Z form orthonormal bases for the specified pair of left eigenspaces (deflating subspaces). If WANTZ = .FALSE., Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1. If WANTZ = .TRUE., LDZ >= N.

M (output)
The dimension of the specified pair of left and right eigenspaces, (deflating subspaces) 0 <= M <= N.

PL (output)
IF IJOB = 1, 4, or 5, PL, PR are lower bounds on the reciprocal of the norm of "projections" onto left and right eigenspace with respect to the selected cluster.
0 < PL, PR <= 1. If M = 0 or M = N, PL = PR = 1.
If IJOB = 0, 2, or 3 PL, PR are not referenced.

PR (output)
See the description of PL.

DIF (output)
If IJOB >= 2, DIF(1:2) store the estimates of Difu and Difl.
If IJOB = 2 or 4, DIF(1:2) are F-norm-based upper bounds on
Difu and Difl. If IJOB = 3 or 5, DIF(1:2) are 1-norm-based estimates of Difu and Difl, computed using reversed communication with CLACON. If M = 0 or N, DIF(1:2) = F-norm([A, B]). If IJOB = 0 or 1, DIF is not referenced.

WORK (workspace)
If IJOB = 0, WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1 If IJOB = 1, 2 or 4, LWORK >= 2*M*(N-M) If IJOB = 3 or 5, LWORK >= 4*M*(N-M)

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace/output)
If IJOB = 0, IWORK is not referenced. Otherwise, on exit, if INFO = 0, IWORK(1) returns the optimal LIWORK.

LIWORK (input)
The dimension of the array IWORK. LIWORK >= 1. If IJOB = 1, 2 or 4, LIWORK >= N+2; If IJOB = 3 or 5, LIWORK >= MAX(N+2, 2*M*(N-M));

If LIWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the IWORK array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by XERBLA.

INFO (output)
=0: Successful exit.
<0: If INFO = -i, the i-th argument had an illegal value.
=1: Reordering of (A, B) failed because the transformed matrix pair (A, B) would be too far from generalized Schur form; the problem is very ill-conditioned. (A, B) may have been partially reordered. If requested, 0 is returned in DIF(*), PL and PR.

FURTHER DETAILS

CTGSEN first collects the selected eigenvalues by computing unitary U and W that move them to the top left corner of (A, B). In other words, the selected eigenvalues are the eigenvalues of (A11, B11) in

```
U'*(A, B)*W = (A11 A12) (B11 B12) n1
              ( 0  A22),( 0  B22) n2
                n1  n2    n1  n2
```

where N = n1+n2 and U' means the conjugate transpose of U. The first n1 columns of U and W span the specified pair of left and right eigenspaces (deflating subspaces) of (A, B).

If (A, B) has been obtained from the generalized real Schur decomposition of a matrix pair (C, D) = Q*(A, B)*Z', then the reordered generalized Schur form of (C, D) is given by

```
(C, D) = (Q*U)*(U'*(A, B)*W)*(Z*W)',
```

and the first n1 columns of Q*U and Z*W span the corresponding deflating subspaces of (C, D) (Q and Z store Q*U and Z*W, resp.).

Note that if the selected eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

The reciprocal condition numbers of the left and right eigenspaces spanned by the first n1 columns of U and W (or Q*U and Z*W) may be returned in DIF(1:2), corresponding to Difu and Difl, resp.

The Difu and Difl are defined as:
ifu[(A11, B11), (A22, B22)] = sigma-min(Zu)
and

where sigma-min(Zu) is the smallest singular value of the (2*n1*n2)-by-(2*n1*n2) matrix

```
u = [ kron(In2, A11)  -kron(A22', In1) ]
          [ kron(In2, B11)  -kron(B22', In1) ].
```

Here, Inx is the identity matrix of size nx and A22' is the transpose of A22. kron(X, Y) is the Kronecker product between the matrices X and Y.

When DIF(2) is small, small changes in (A, B) can cause large changes in the deflating subspace. An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is PS * norm((A, B)) / DIF(2),

where EPS is the machine precision.

The reciprocal norm of the projectors on the left and right eigenspaces associated with (A11, B11) may be returned in PL and PR. They are computed as follows. First we compute L and R so that P*(A, B)*Q is block diagonal, where

```
 = ( I -L ) n1           Q = ( I R ) n1
         ( 0  I ) n2    and        ( 0 I ) n2
           n1 n2                    n1 n2
```

and (L, R) is the solution to the generalized Sylvester equation 11*R - L*A22 = -A12

Then PL = (F-norm(L)**2+1)**(-1/2) and PR = (F-norm(R)**2+1)**(-1/2). An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is
EPS * norm((A, B)) / PL.

There are also global error bounds which valid for perturbations up to a certain restriction: A lower bound (x) on the smallest F-norm(E,F) for which an eigenvalue of (A11, B11) may move and coalesce with an eigenvalue of (A22, B22) under perturbation (E,F), (i.e. (A + E, B + F), is

x = min(Difu,Difl)/((1/(PL*PL)+1/(PR*PR))**(1/2)+2*max(1/PL,1/PR)).
An approximate bound on x can be computed from DIF(1:2), PL and PL.

If y = (F-norm(E,F) / x) <= 1, the angles between the perturbed (L', R') and unperturbed (L, R) left and right deflating subspaces associated with the selected cluster in the (1,1)-blocks can be bounded as

max-angle(L, L') <= arctan(y * PL / (1 - y * (1 - PL * PL)**(1/2))
max-angle(R, R') <= arctan(y * PR / (1 - y * (1 - PR * PR)**(1/2))

See LAPACK User's Guide section 4.11 or the following references for more information.

Note that if the default method for computing the Frobenius-norm- based estimate DIF is not wanted (see CLATDF), then the parameter IDIFJB (see below) should be changed from 3 to 4 (routine CLATDF (IJOB = 2 will be used)). See CTGSYL for more details.

```

PURPOSE

ctgsja computes the generalized singular value decomposition (GSVD) of two complex upper triangular (or trapezoidal) matrices A and B.

On entry, it is assumed that matrices A and B have the following forms, which may be obtained by the preprocessing subroutine CGGSVP from a general M-by-N matrix A and P-by-N matrix B:

```
                 N-K-L  K    L
   A =    K ( 0    A12  A13 ) if M-K-L >= 0;
          L ( 0     0   A23 )
      M-K-L ( 0     0    0  )

               N-K-L  K    L
   A =  K ( 0    A12  A13 ) if M-K-L < 0;
      M-K ( 0     0   A23 )

               N-K-L  K    L
   B =  L ( 0     0   B13 )
      P-L ( 0     0    0  )

where the K-by-K matrix A12 and L-by-L matrix B13  are  non-
singular upper triangular; A23 is L-by-L upper triangular if
M-K-L >= 0, otherwise A23 is (M-K)-by-L upper trapezoidal.

On exit,
       U'*A*Q = D1*( 0 R ),    V'*B*Q = D2*( 0 R ),

where U, V and Q are unitary matrices, Z' denotes the conju-
gate  transpose  of  Z,  R is a nonsingular upper triangular
matrix, and D1 and D2 are ``diagonal'' matrices,  which  are
of the following structures:

If M-K-L >= 0,

                    K  L
       D1 =     K ( I  0 )
                L ( 0  C )
            M-K-L ( 0  0 )

                   K  L
       D2 = L   ( 0  S )
            P-L ( 0  0 )

                N-K-L  K    L
  ( 0 R ) = K (  0   R11  R12 ) K
            L (  0    0   R22 ) L

where

  C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
  S = diag( BETA(K+1),  ... , BETA(K+L) ),
  C**2 + S**2 = I.

  R is stored in A(1:K+L,N-K-L+1:N) on exit.

If M-K-L < 0,
```

```
               K M-K K+L-M
    D1 =   K ( I  0    0   )
         M-K ( 0  C    0   )

                 K M-K K+L-M
    D2 =   M-K ( 0  S    0   )
         K+L-M ( 0  0    I   )
           P-L ( 0  0    0   )

               N-K-L  K   M-K  K+L-M

          M-K ( 0     0   R22  R23  )
        K+L-M ( 0     0    0   R33  )
```

```
where
C = diag( ALPHA(K+1), ... , ALPHA(M) ),
S = diag( BETA(K+1),  ... , BETA(M) ),
C**2 + S**2 = I.

R = ( R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N)  and  R33
is stored
    (  0  R22 R23 )
in B(M-K+1:L,N+M-K-L+1:N) on exit.

The computation of the unitary transformation matrices U,  V
or  Q  is  optional.   These  matrices  may either be formed
explicitly,  or  they  may  be  postmultiplied  into   input
matrices U1, V1, or Q1.

CTGSJA essentially uses a variant of Kogbetliantz  algorithm
to reduce min(L,M-K)-by-L triangular (or trapezoidal) matrix
A23 and L-by-L matrix B13 to the form:
   U1'*A13*Q1 = C1*R1; V1'*B13*Q1 = S1*R1,
where U1, V1 and Q1 are unitary matrix, and Z' is the conju-
gate transpose of Z.  C1 and S1 are diagonal matrices satis-
fying
   C1**2 + S1**2 = I,
and R1 is an L-by-L nonsingular upper triangular matrix.
```

ARGUMENTS

```
JOBU (input)
          = 'U':  U must contain  a  unitary  matrix  U1  on
          entry, and the product U1*U is returned; = 'I':  U
          is initialized to the unit matrix, and the unitary
          matrix U is returned; = 'N':  U is not computed.

JOBV (input)
          = 'V':  V must contain  a  unitary  matrix  V1  on
```

entry, and the product V1*V is returned; = 'I': V is initialized to the unit matrix, and the unitary matrix V is returned; = 'N': V is not computed.

JOBQ (input)
= 'Q': Q must contain a unitary matrix Q1 on entry, and the product Q1*Q is returned; = 'I': Q is initialized to the unit matrix, and the unitary matrix Q is returned; = 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

K (input) K and L specify the subblocks in the input matrices A and B:
A23 = A(K+1:MIN(K+L,M),N-L+1:N) and B13 = B(1:L,,N-L+1:N) of A and B, whose GSVD is going to be computed by CTGSJA. See the Further Details section below.

L (input) See the description of K.

A (input/output)
On entry, the M-by-N matrix A. On exit, A(N-K+1:N,1:MIN(K+L,M)) contains the triangular matrix R or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, if necessary, B(M-K+1:L,N+M-K-L+1:N) contains a part of R. See Purpose for details.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

TOLA (input)
TOLA and TOLB are the convergence criteria for the Jacobi- Kogbetliantz iteration procedure. Generally, they are the same as used in the preprocessing step, say TOLA = MAX(M,N)*norm(A)*MACHEPS, TOLB = MAX(P,N)*norm(B)*MACHEPS.

TOLB (input)
See the description of TOLA.

ALPHA (output)
On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1, BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = diag(C),
BETA(K+1:K+L) = diag(S), or if M-K-L < 0, ALPHA(K+1:M)= C, ALPHA(M+1:K+L)= 0
BETA(K+1:M) = S, BETA(M+1:K+L) = 1. Furthermore, if K+L < N, ALPHA(K+L+1:N) = 0
BETA(K+L+1:N) = 0.

BETA (output)
See the description of ALPHA.

U (input) On entry, if JOBU = 'U', U must contain a matrix U1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBU = 'I', U contains the unitary matrix U; if JOBU = 'U', U contains the product U1*U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) On entry, if JOBV = 'V', V must contain a matrix V1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBV = 'I', V contains the unitary matrix V; if JOBV = 'V', V contains the product V1*V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) On entry, if JOBQ = 'Q', Q must contain a matrix Q1 (usually the unitary matrix returned by CGGSVP). On exit, if JOBQ = 'I', Q contains the unitary matrix Q; if JOBQ = 'Q', Q contains the product Q1*Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)
dimension(2*N)

NCYCLE (output)
The number of cycles required for convergence.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1: the procedure does not converge after MAXIT cycles.

C INTERFACE

```
#include <sunperf.h>

void ctgsna(char job, char howmnt, int *select, int n,  com-
          plex  *a,  int  lda,  complex *b, int ldb, complex
          *vl, int ldvl, complex *vr, int  ldvr,  float  *s,
          float *dif, int mm, int *m, int *info);

void ctgsna_64(char job, char howmnt, long *select, long  n,
          complex  *a,  long lda, complex *b, long ldb, com-
          plex *vl, long ldvl, complex *vr, long ldvr, float
          *s, float *dif, long mm, long *m, long *info);
```

PURPOSE

ctgsna estimates reciprocal condition numbers for specified eigenvalues and/or eigenvectors of a matrix pair (A, B).

(A, B) must be in generalized Schur canonical form, that is, A and B are both upper triangular.

ARGUMENTS

```
JOB (input)
          Specifies whether condition numbers  are  required
          for eigenvalues (S) or eigenvectors (DIF):
          = 'E': for eigenvalues only (S);
          = 'V': for eigenvectors only (DIF);
          = 'B': for both eigenvalues  and  eigenvectors  (S
```

and DIF).

HOWMNT (input)
= 'A': compute condition numbers for all eigen-pairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

SELECT (input)
If HOWMNT = 'S', SELECT specifies the eigenpairs for which condition numbers are required. To select condition numbers for the corresponding j-th eigenvalue and/or eigenvector, SELECT(j) must be set to .TRUE.. If HOWMNT = 'A', SELECT is not referenced.

N (input) The order of the square matrix pair (A, B). N >= 0.

A (input) The upper triangular matrix A in the pair (A,B).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input) The upper triangular matrix B in the pair (A, B).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

VL (input)
If JOB = 'E' or 'B', VL must contain left eigen-vectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VL, as returned by CTGEVC. If JOB = 'V', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= 1; and If JOB = 'E' or 'B', LDVL >= N.

VR (input)
If JOB = 'E' or 'B', VR must contain right eigen-vectors of (A, B), corresponding to the eigenpairs specified by HOWMNT and SELECT. The eigenvectors must be stored in consecutive columns of VR, as returned by CTGEVC. If JOB = 'V', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= 1; If JOB = 'E' or 'B', LDVR >= N.

S (output)
If JOB = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. If JOB = 'V', S is not referenced.

DIF (output)
If JOB = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. If the eigenvalues cannot be reordered to compute DIF(j), DIF(j) is set to 0; this can only occur when the true value would be very small anyway. For each eigenvalue/vector specified by SELECT, DIF stores a Frobenius norm-based estimate of Difl. If JOB = 'E', DIF is not referenced.

MM (input)
The number of elements in the arrays S and DIF. MM >= M.

M (output)
The number of elements of the arrays S and DIF used to store the specified condition numbers; for each selected eigenvalue one element is used. If HOWMNT = 'A', M is set to N.

WORK (workspace)
If JOB = 'E', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 1. If JOB = 'V' or 'B', LWORK >= 2*N*N.

IWORK (workspace)
dimension(N+2) If JOB = 'E', IWORK is not referenced.

INFO (output)
= 0: Successful exit
< 0: If INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The reciprocal of the condition number of the i-th generalized eigenvalue w = (a, b) is defined as

```
        S(I)   =   (|v'Au|**2    +    |v'Bu|**2)**(1/2)    /
(norm(u)*norm(v))
```

where u and v are the right and left eigenvectors of (A, B) corresponding to w; |z| denotes the absolute value of the complex number, and norm(u) denotes the 2-norm of the vector u. The pair (a, b) corresponds to an eigenvalue w = a/b (= v'Au/v'Bu) of the matrix pair (A, B). If both a and b equal zero, then (A,B) is singular and S(I) = -1 is returned.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue lambda is

```
        chord(w, lambda) <=   EPS * norm(A, B) / S(I),
```

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u and left eigenvector v corresponding to the generalized eigenvalue w is defined as follows. Suppose

```
                 (A, B) = ( a   *  ) ( b  *  )  1
                          ( 0  A22 ),( 0 B22 )  n-1
                            1  n-1     1 n-1
```

Then the reciprocal condition number DIF(I) is

```
        Difl[(a, b), (A22, B22)]  = sigma-min( Zl )
```

where sigma-min(Zl) denotes the smallest singular value of

```
       Zl = [ kron(a, In-1) -kron(1, A22) ]
            [ kron(b, In-1) -kron(1, B22) ].
```

Here In-1 is the identity matrix of size n-1 and X' is the conjugate transpose of X. kron(X, Y) is the Kronecker product between the matrices X and Y.

We approximate the smallest singular value of Zl with an upper bound. This is done by CLATDF.

An approximate error bound for a computed eigenvector VL(i) or VR(i) is given by

```
                    EPS * norm(A, B) / DIF(i).
```

See ref. [2-3] for more details and further references.

```

PURPOSE

ctgsyl solves the generalized Sylvester equation:

```
            A * R - L * B = scale * C            (1)
            D * R - L * E = scale * F
```

where R and L are unknown m-by-n matrices, (A, D), (B, E) and (C, F) are given matrix pairs of size m-by-m, n-by-n and m-by-n, respectively, with complex entries. A, B, D and E are upper triangular (i.e., (A,D) and (B,E) in generalized Schur form).

The solution (R, L) overwrites (C, F). 0 <= SCALE <= 1 is an output scaling factor chosen to avoid overflow.

In matrix notation (1) is equivalent to solve Zx = scale*b, where Z is defined as

```
       Z = [ kron(In, A)  -kron(B', Im) ]        (2)
           [ kron(In, D)  -kron(E', Im) ],
```

Here Ix is the identity matrix of size x and X' is the conjugate transpose of X. Kron(X, Y) is the Kronecker product between the matrices X and Y.

If TRANS = 'C', y in the conjugate transposed system Z'*y = scale*b is solved for, which is equivalent to solve for R and L in

```
            A' * R + D' * L = scale * C           (3)
            R * B' + L * E' = scale * -F
```

This case (TRANS = 'C') is used to compute an one-norm-based estimate of Dif[(A,D), (B,E)], the separation between the matrix pairs (A,D) and (B,E), using CLACON.

If IJOB >= 1, CTGSYL computes a Frobenius norm-based estimate of Dif[(A,D),(B,E)]. That is, the reciprocal of a lower bound on the reciprocal of the smallest singular value of Z.

This is a level-3 BLAS algorithm.

ARGUMENTS

TRANS (input)
= 'N': solve the generalized sylvester equation (1).
= 'C': solve the "conjugate transposed" system (3).

IJOB (input)
Specifies what kind of functionality to be performed. =0: solve (1) only.
=1: The functionality of 0 and 3.
=2: The functionality of 0 and 4.
=3: Only an estimate of Dif[(A,D), (B,E)] is computed. (look ahead strategy is used). =4: Only an estimate of Dif[(A,D), (B,E)] is computed. (CGECON on sub-systems is used). Not referenced if TRANS = 'C'.

M (input) The order of the matrices A and D, and the row

```
          dimension of the matrices C, F, R and L.

N (input) The order of the matrices B and E, and the  column
          dimension of the matrices C, F, R and L.

A (input) The upper triangular matrix A.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1, M).

B (input) The upper triangular matrix B.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1, N).

C (input/output)
          On entry, C contains the  right-hand-side  of  the
          first  matrix equation in (1) or (3).  On exit, if
          IJOB = 0, 1 or 2, C has been  overwritten  by  the
          solution  R.  If  IJOB = 3 or 4 and TRANS = 'N', C
          holds R, the solution achieved during the computa-
          tion of the Dif-estimate.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1, M).

D (input) The upper triangular matrix D.

LDD (input)
          The leading dimension  of  the  array  D.  LDD  >=
          max(1, M).

E (input) The upper triangular matrix E.

LDE (input)
          The leading dimension  of  the  array  E.  LDE  >=
          max(1, N).

F (input/output)
          On entry, F contains the  right-hand-side  of  the
          second matrix equation in (1) or (3).  On exit, if
          IJOB = 0, 1 or 2, F has been  overwritten  by  the
          solution  L.  If  IJOB = 3 or 4 and TRANS = 'N', F
          holds L, the solution achieved during the computa-
          tion of the Dif-estimate.

LDF (input)
```

```
            The leading dimension  of  the  array  F.  LDF  >=
            max(1, M).

DIF (output)
            On exit SCALE is the reciprocal of a  lower  bound
            of  the reciprocal of the Dif-function, i.e. SCALE
            is an upper bound of Dif[(A,D),  (B,E)]  =  sigma-
            min(Z), where Z as in (2).  If IJOB = 0 or TRANS =
            'C', SCALE is not referenced.

SCALE (output)
            On exit SCALE is the reciprocal of a  lower  bound
            of  the reciprocal of the Dif-function, i.e. SCALE
            is an upper bound of Dif[(A,D),  (B,E)]  =  sigma-
            min(Z), where Z as in (2).  If IJOB = 0 or TRANS =
            'C', SCALE is not referenced.

WORK (workspace)
            If IJOB = 0, WORK is not  referenced.   Otherwise,
            on  exit,  if  INFO=0  then  WORK(1)  returns  the
            optimal LWORK.

LWORK (input)
            The dimension of the array WORK. LWORK > = 1.   If
            IJOB = 1 or 2 and TRANS = 'N', LWORK >= 2*M*N.

            If LWORK = -1, then a workspace query is  assumed;
            the  routine  only  calculates the optimal size of
            the WORK array, returns this value  as  the  first
            entry  of  the  WORK  array,  and no error message
            related to LWORK is issued by XERBLA.

IWORK (workspace)
            If IJOB = 0, IWORK is not referenced.

INFO (output)
            =0: successful exit
            <0: If INFO = -i, the i-th argument had an illegal
            value.
            >0: (A, D) and (B, E) have common  or  very  close
            eigenvalues.

NAME

ctpcon - estimate the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE CTPCON(NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2, INFO)

CHARACTER * 1 NORM, UPLO, DIAG
COMPLEX A(*), WORK(*)
INTEGER N, INFO
REAL RCOND
REAL WORK2(*)

SUBROUTINE CTPCON_64(NORM, UPLO, DIAG, N, A, RCOND, WORK, WORK2,
      INFO)

CHARACTER * 1 NORM, UPLO, DIAG
COMPLEX A(*), WORK(*)
INTEGER*8 N, INFO
REAL RCOND
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TPCON(NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
       [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER :: N, INFO
REAL :: RCOND
REAL, DIMENSION(:) :: WORK2
```

```
SUBROUTINE TPCON_64(NORM, UPLO, DIAG, N, A, RCOND, [WORK], [WORK2],
       [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX, DIMENSION(:) :: A, WORK
INTEGER(8) :: N, INFO
REAL :: RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>

void ctpcon(char norm, char uplo, char diag, int n,  complex
          *a, float *rcond, int *info);
void ctpcon_64(char norm, char uplo, char diag, long n, com-
          plex *a, float *rcond, long *info);
```

PURPOSE

ctpcon estimates the reciprocal of the condition number of a packed triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

UPLO (input)
= 'U': A is upper triangular;
= 'L': A is lower triangular.

DIAG (input)
= 'N': A is non-unit triangular;
= 'U': A is unit triangular.

N (input) The order of the matrix A. N >= 0.

A (input) The upper or lower triangular matrix A, packed columnwise in a linear array. The j-th column of A is stored in the array A as follows: if UPLO = 'U', A(i + (j-1)*j/2) = A(i,j) for 1<=i<=j; if UPLO = 'L', A(i + (j-1)*(2n-j)/2) = A(i,j) for j<=i<=n. If DIAG = 'U', the diagonal elements of A are not referenced and are assumed to be 1.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

ctpmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

SYNOPSIS

```
SUBROUTINE CTPMV(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(*), Y(*)
INTEGER N, INCY

SUBROUTINE CTPMV_64(UPLO, TRANSA, DIAG, N, A, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(*), Y(*)
INTEGER*8 N, INCY
```

F95 INTERFACE

```
SUBROUTINE TPMV(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, Y
INTEGER :: N, INCY

SUBROUTINE TPMV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctpmv(char uplo, char transa, char diag, int n, complex
          *a, complex *y, int incy);

void ctpmv_64(char uplo, char transa,  char  diag,  long  n,
          complex *a, complex *y, long incy);
```

PURPOSE

ctpmv performs one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   x := A*x.

TRANSA = 'T' or 't'   x := A'*x.

TRANSA = 'C' or 'c'   x := conjg(A')*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit tri-

angular.

DIAG = 'N' or 'n'   A is not assumed to be unit
triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A.
N >= 0. Unchanged on exit.

A (input)
((n*(n + 1))/2). Before entry with UPLO =
'U' or 'u', the array A must contain the upper
triangular matrix packed sequentially, column by
column, so that A(1) contains a(1, 1), A(2)
and A(3) contain a(1, 2) and a(2, 2) respec-
tively, and so on. Before entry with UPLO = 'L'
or 'l', the array A must contain the lower tri-
angular matrix packed sequentially, column by
column, so that A(1) contains a(1, 1), A(2)
and A(3) contain a(2, 1) and a(3, 1) respec-
tively, and so on. Note that when DIAG = 'U' or
'u', the diagonal elements of A are not refer-
enced, but are assumed to be unity. Unchanged on
exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the
incremented array Y must contain the n element
vector x. On exit, Y is overwritten with the tran-
formed vector x.

INCY (input)
On entry, INCY specifies the increment for the
elements of Y. INCY <> 0. Unchanged on exit.

Contents

NAME

```
ctprfs - provide error bounds and backward  error  estimates
for the solution to a system of linear equations with a tri-
angular packed coefficient matrix
```

SYNOPSIS

```

       [LDX], FERR, BERR, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, WORK
COMPLEX, DIMENSION(:,:) :: B, X
INTEGER :: N, NRHS, LDB, LDX, INFO
REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

```
SUBROUTINE TPRFS_64(UPLO, [TRANSA], DIAG, N, [NRHS], A, B, [LDB], X,
       [LDX], FERR, BERR, [WORK], [WORK2], [INFO])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, WORK
COMPLEX, DIMENSION(:,:) :: B, X
INTEGER(8) :: N, NRHS, LDB, LDX, INFO
REAL, DIMENSION(:) :: FERR, BERR, WORK2
```

C INTERFACE

```
#include <sunperf.h>

void ctprfs(char uplo, char transa, char diag,  int  n,  int
          nrhs, complex *a, complex *b, int ldb, complex *x,
          int ldx, float *ferr, float *berr, int *info);
void ctprfs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs, complex *a, complex *b, long ldb, com-
          plex *x, long ldx, float *ferr, float *berr,  long
          *info);
```

PURPOSE

ctprfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular packed coefficient matrix.

The solution matrix X must be computed by CTPTRS or some other means before entering this routine. CTPRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
          = 'N':  A is non-unit triangular;
```

```
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The upper or lower  triangular  matrix  A,  packed
          columnwise  in a linear array.  The j-th column of
          A is stored in the array A as follows:  if UPLO  =
          'U',  A(i  +  (j-1)*j/2)  = A(i,j) for 1<=i<=j; if
          UPLO = 'L', A(i +  (j-1)*(2n-j)/2)  =  A(i,j)  for
          j<=i<=n.   If DIAG = 'U', the diagonal elements of
          A are not referenced and are assumed to be 1.

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(2*N)

WORK2 (workspace)
          dimension(N)
```

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, Y
INTEGER :: N, INCY

SUBROUTINE TPSV_64(UPLO, [TRANSA], DIAG, [N], A, Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A, Y
INTEGER(8) :: N, INCY
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctpsv(char uplo, char transa, char diag, int n, complex
          *a, complex *y, int incy);

void ctpsv_64(char uplo, char transa,  char  diag,  long  n,
          complex *a, complex *y, long incy);
```

PURPOSE

ctpsv solves one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix, supplied in packed form.

No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   conjg(A')*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

N (input)
On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)
((n*(n + 1))/2). Before entry with UPLO = 'U' or 'u', the array A must contain the upper triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(1, 2) and a(2, 2) respectively, and so on. Before entry with UPLO = 'L' or 'l', the array A must contain the lower triangular matrix packed sequentially, column by column, so that A(1) contains a(1, 1), A(2) and A(3) contain a(2, 1) and a(3, 1) respectively, and so on. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced, but are assumed to be unity. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

SUBROUTINE CTPTRI_64(UPLO, DIAG, N, A, INFO)

CHARACTER * 1 UPLO, DIAG
COMPLEX A(*)
INTEGER*8 N, INFO
```

F95 INTERFACE

```
SUBROUTINE TPTRI(UPLO, DIAG, N, A, [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX, DIMENSION(:) :: A
INTEGER :: N, INFO

SUBROUTINE TPTRI_64(UPLO, DIAG, N, A, [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX, DIMENSION(:) :: A
INTEGER(8) :: N, INFO
```

C INTERFACE

```
#include <sunperf.h>

void ctptri(char uplo, char diag, int  n,  complex  *a,  int
          *info);

void ctptri_64(char uplo, char diag,  long  n,  complex  *a,
          long *info);
```

PURPOSE

ctptri computes the inverse of a complex upper or lower triangular matrix A stored in packed format.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the upper or lower triangular matrix  A,
          stored  columnwise  in  a  linear array.  The j-th
          column of A is stored in the array A  as  follows:
          if  UPLO  =  'U',  A(i  +  (j-1)*j/2) = A(i,j) for
          1<=i<=j; if UPLO = 'L', A(i + (j-1)*((2*n-j)/2)  =
          A(i,j)   for   j<=i<=n.   See  below  for  further
          details.  On exit, the (triangular) inverse of the
          original  matrix,  in the same packed storage for-
          mat.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, A(i,i) is  exactly  zero.   The
          triangular  matrix is singular and its inverse can
          not be computed.
```

FURTHER DETAILS

A triangular matrix A can be transferred to packed storage using one of the following program segments:

UPLO = 'U':

```
      JC = 1
      DO 2 J = 1, N
         DO 1 I = 1, J
            A(JC+I-1) = A(I,J)
    1    CONTINUE
         JC = JC + J
    2 CONTINUE
```

UPLO = 'L':

```
      JC = 1
      DO 2 J = 1, N
         DO 1 I = J, N
            A(JC+I-J) = A(I,J)
    1    CONTINUE
         JC = JC + N - J + 1
    2 CONTINUE
```

SUBROUTINE TPTRS_64(UPLO, TRANSA, DIAG, N, [NRHS], A, B, [LDB], [INFO])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: A
COMPLEX, DIMENSION(:,:) :: B
INTEGER(8) :: N, NRHS, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void ctptrs(char uplo, char transa, char diag,  int  n,  int
          nrhs, complex *a, complex *b, int ldb, int *info);

void ctptrs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs, complex *a, complex *b, long ldb, long
          *info);
```

PURPOSE

ctptrs solves a triangular system of the form

where A is a triangular matrix of order N stored in packed format, and B is an N-by-NRHS matrix. A check is made to verify that A is nonsingular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input) The upper or lower  triangular  matrix  A,  packed
          columnwise  in a linear array.  The j-th column of
          A is stored in the array A as follows:  if UPLO  =
          'U',  A(i  +  (j-1)*j/2)  = A(i,j) for 1<=i<=j; if
          UPLO = 'L', A(i + (j-1)*(2*n-j)/2)  =  A(i,j)  for
          j<=i<=n.
```

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

ctrans - transpose and scale source matrix

SYNOPSIS

```
SUBROUTINE CTRANS(PLACE, SCALE, SOURCE, M, N, DEST)

CHARACTER * 1 PLACE
COMPLEX SCALE
COMPLEX SOURCE(*), DEST(*)
INTEGER M, N

SUBROUTINE CTRANS_64(PLACE, SCALE, SOURCE, M, N, DEST)

CHARACTER * 1 PLACE
COMPLEX SCALE
COMPLEX SOURCE(*), DEST(*)
INTEGER*8 M, N
```

F95 INTERFACE

```
SUBROUTINE TRANS([PLACE], SCALE, SOURCE, M, N, [DEST])

CHARACTER(LEN=1) :: PLACE
COMPLEX :: SCALE
COMPLEX, DIMENSION(:) :: SOURCE, DEST
INTEGER :: M, N

SUBROUTINE TRANS_64([PLACE], SCALE, SOURCE, M, N, [DEST])

CHARACTER(LEN=1) :: PLACE
COMPLEX :: SCALE
COMPLEX, DIMENSION(:) :: SOURCE, DEST
INTEGER(8) :: M, N
```

C INTERFACE

```
#include <sunperf.h>

void ctrans(char place, complex *scale, complex *source, int
          m, int n, complex *dest);

void ctrans_64(char place, complex *scale, complex  *source,
          long m, long n, complex *dest);
```

PURPOSE

ctrans scales and transposes the source matrix. The N2 x N1 result is written into SOURCE when PLACE = 'I' or 'i', and DEST when PLACE = 'O' or 'o'.

PLACE = 'I' or 'i': SOURCE = SCALE * SOURCE'

PLACE = 'O' or 'o': DEST = SCALE * SOURCE'

ARGUMENTS

PLACE (input)
Type of transpose. 'I' or 'i' for in-place, 'O' or 'o' for out-of-place. 'I' is default.

SCALE (input)
Scale factor on the SOURCE matrix.

SOURCE (input/output)
on input. Array of (N, M) on output if in-place transpose.

M (input)
Number of rows in the SOURCE matrix on input.

N (input)
Number of columns in the SOURCE matrix on input.

DEST (output)
Scaled and transposed SOURCE matrix if out-of-place transpose. Not referenced if in-place transpose.

NAME

ctrcon - estimate the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm

SYNOPSIS

```
SUBROUTINE CTRCON(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,
      INFO)

CHARACTER * 1 NORM, UPLO, DIAG
COMPLEX A(LDA,*), WORK(*)
INTEGER N, LDA, INFO
REAL RCOND
REAL WORK2(*)

SUBROUTINE CTRCON_64(NORM, UPLO, DIAG, N, A, LDA, RCOND, WORK, WORK2,
      INFO)

CHARACTER * 1 NORM, UPLO, DIAG
COMPLEX A(LDA,*), WORK(*)
INTEGER*8 N, LDA, INFO
REAL RCOND
REAL WORK2(*)
```

F95 INTERFACE

```
SUBROUTINE TRCON(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],
       [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, INFO
```

```
REAL :: RCOND
REAL, DIMENSION(:) :: WORK2

SUBROUTINE TRCON_64(NORM, UPLO, DIAG, [N], A, [LDA], RCOND, [WORK],
       [WORK2], [INFO])

CHARACTER(LEN=1) :: NORM, UPLO, DIAG
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
REAL :: RCOND
REAL, DIMENSION(:) :: WORK2
```

C INTERFACE

```
#include <sunperf.h>
void ctrcon(char norm, char uplo, char diag, int n,  complex
          *a, int lda, float *rcond, int *info);

void ctrcon_64(char norm, char uplo, char diag, long n, com-
          plex *a, long lda, float *rcond, long *info);
```

PURPOSE

ctrcon estimates the reciprocal of the condition number of a triangular matrix A, in either the 1-norm or the infinity-norm.

The norm of A is computed and an estimate is obtained for norm(inv(A)), then the reciprocal of the condition number is computed as

```
   RCOND = 1 / ( norm(A) * norm(inv(A)) ).
```

ARGUMENTS

```
NORM (input)
          Specifies whether the 1-norm condition  number  or
          the infinity-norm condition number is required:
          = '1' or 'O':  1-norm;
          = 'I':         Infinity-norm.

UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.
```

N (input) The order of the matrix A. N >= 0.

A (input) The triangular matrix A. If UPLO = 'U', the leading N-by-N upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```
SUBROUTINE TREVC(SIDE, HOWMNY, SELECT, [N], T, [LDT], VL, [LDVL], VR,
       [LDVR], MM, M, [WORK], [RWORK], [INFO])

CHARACTER(LEN=1) :: SIDE, HOWMNY
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: T, VL, VR
INTEGER :: N, LDT, LDVL, LDVR, MM, M, INFO
```

```
LOGICAL, DIMENSION(:) :: SELECT
REAL, DIMENSION(:) :: RWORK

SUBROUTINE TREVC_64(SIDE, HOWMNY, SELECT, [N], T, [LDT], VL, [LDVL],
       VR, [LDVR], MM, M, [WORK], [RWORK], [INFO])

CHARACTER(LEN=1) :: SIDE, HOWMNY
COMPLEX, DIMENSION(:) :: WORK
COMPLEX, DIMENSION(:,:) :: T, VL, VR
INTEGER(8) :: N, LDT, LDVL, LDVR, MM, M, INFO
LOGICAL(8), DIMENSION(:) :: SELECT
REAL, DIMENSION(:) :: RWORK
```

C INTERFACE

```
#include <sunperf.h>
void ctrevc(char side, char howmny, int *select, int n, com-
          plex  *t,  int ldt, complex *vl, int ldvl, complex
          *vr, int ldvr, int mm, int *m, int *info);

void ctrevc_64(char side, char howmny, long *select, long n,
          complex *t, long ldt, complex *vl, long ldvl, com-
          plex *vr,  long  ldvr,  long  mm,  long  *m,  long
          *info);
```

PURPOSE

ctrevc computes some or all of the right and/or left eigen-vectors of a complex upper triangular matrix T.

The right eigenvector x and the left eigenvector y of T corresponding to an eigenvalue w are defined by:

```
             T*x = w*x,     y'*T = w*y'
```

where y' denotes the conjugate transpose of the vector y.

If all eigenvectors are requested, the routine may either return the matrices X and/or Y of right or left eigenvectors of T, or the products Q*X and/or Q*Y, where Q is an input unitary
matrix. If T was obtained from the Schur factorization of an original matrix A = Q*T*Q', then Q*X and Q*Y are the matrices of right or left eigenvectors of A.

ARGUMENTS

SIDE (input)

= 'R': compute right eigenvectors only;
= 'L': compute left eigenvectors only;
= 'B': compute both right and left eigenvectors.

HOWMNY (input)
= 'A': compute all right and/or left eigenvectors;
= 'B': compute all right and/or left eigenvectors, and backtransform them using the input matrices supplied in VR and/or VL; = 'S': compute selected right and/or left eigenvectors, specified by the logical array SELECT.

SELECT (input/output)
If HOWMNY = 'S', SELECT specifies the eigenvectors to be computed. If HOWMNY = 'A' or 'B', SELECT is not referenced. To select the eigenvector corresponding to the j-th eigenvalue, SELECT(j) must be set to .TRUE..

N (input) The order of the matrix T. N >= 0.

T (input/output)
The upper triangular matrix T. T is modified, but restored on exit.

LDT (input)
The leading dimension of the array T. LDT >= max(1,N).

VL (input/output)
On entry, if SIDE = 'L' or 'B' and HOWMNY = 'B', VL must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'L' or 'B', VL contains: if HOWMNY = 'A', the matrix Y of left eigenvectors of T; VL is lower triangular. The i-th column VL(i) of VL is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q*Y; if HOWMNY = 'S', the left eigenvectors of T specified by SELECT, stored consecutively in the columns of VL, in the same order as their eigenvalues. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)

On entry, if SIDE = 'R' or 'B' and HOWMNY = 'B', VR must contain an N-by-N matrix Q (usually the unitary matrix Q of Schur vectors returned by CHSEQR). On exit, if SIDE = 'R' or 'B', VR contains: if HOWMNY = 'A', the matrix X of right eigenvectors of T; VR is upper triangular. The i-th column VR(i) of VR is the eigenvector corresponding to T(i,i). if HOWMNY = 'B', the matrix Q*X; if HOWMNY = 'S', the right eigenvectors of T specified by SELECT, stored consecutively in the columns of VR, in the same order as their eigenvalues. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR actually used to store the eigenvectors. If HOWMNY = 'A' or 'B', M is set to N. Each selected eigenvector occupies one column.

WORK (workspace)
dimension(2*N)

RWORK (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The algorithm used in this program is basically backward (forward) substitution, with scaling to make the the code robust against possible overflow.

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x| + |y|.

Contents

NAME

```
ctrexc - reorder the Schur factorization of a complex matrix
A  =  Q*T*Q**H,  so  that the diagonal element of T with row
index IFST is moved to row ILST
```

SYNOPSIS

```
SUBROUTINE CTREXC(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)

CHARACTER * 1 COMPQ
COMPLEX T(LDT,*), Q(LDQ,*)
INTEGER N, LDT, LDQ, IFST, ILST, INFO

SUBROUTINE CTREXC_64(COMPQ, N, T, LDT, Q, LDQ, IFST, ILST, INFO)

CHARACTER * 1 COMPQ
COMPLEX T(LDT,*), Q(LDQ,*)
INTEGER*8 N, LDT, LDQ, IFST, ILST, INFO
```

F95 INTERFACE

```
SUBROUTINE TREXC(COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])

CHARACTER(LEN=1) :: COMPQ
COMPLEX, DIMENSION(:,:) :: T, Q
INTEGER :: N, LDT, LDQ, IFST, ILST, INFO

SUBROUTINE TREXC_64(COMPQ, [N], T, [LDT], Q, [LDQ], IFST, ILST, [INFO])

CHARACTER(LEN=1) :: COMPQ
COMPLEX, DIMENSION(:,:) :: T, Q
INTEGER(8) :: N, LDT, LDQ, IFST, ILST, INFO
```

C INTERFACE

```
#include <sunperf.h>

void ctrexc(char compq, int n, complex *t, int ldt,  complex
          *q, int ldq, int ifst, int ilst, int *info);

void ctrexc_64(char compq, long n,  complex  *t,  long  ldt,
          complex  *q,  long ldq, long ifst, long ilst, long
          *info);
```

PURPOSE

ctrexc reorders the Schur factorization of a complex matrix A = Q*T*Q**H, so that the diagonal element of T with row index IFST is moved to row ILST.
The Schur form T is reordered by a unitary similarity transformation Z**H*T*Z, and optionally the matrix Q of Schur vectors is updated by postmultplying it with Z.

ARGUMENTS

COMPQ (input)
  = 'V': update the matrix Q of Schur vectors;
  = 'N': do not update Q.

N (input) The order of the matrix T. N >= 0.

T (input/output)
  On entry, the upper triangular matrix T. On exit, the reordered upper triangular matrix.

LDT (input)
  The leading dimension of the array T. LDT >= max(1,N).

Q (input) On entry, if COMPQ = 'V', the matrix Q of Schur vectors. On exit, if COMPQ = 'V', Q has been postmultiplied by the unitary transformation matrix Z which reorders T. If COMPQ = 'N', Q is not referenced.

LDQ (input)
  The leading dimension of the array Q. LDQ >= max(1,N).

IFST (input)
  Specify the reordering of the diagonal elements of T: The element with row index IFST is moved to

row ILST by a sequence of transpositions between adjacent elements. 1 <= IFST <= N; 1 <= ILST <= N.

ILST (input)
See the description of IFST.

CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER :: M, N, LDA, LDB
```

```
SUBROUTINE TRMM_64(SIDE, UPLO, [TRANSA], DIAG, [M], [N], ALPHA, A,
       [LDA], B, [LDB])

CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>

void ctrmm(char side, char uplo, char transa, char diag, int
          m,  int  n,  complex  *alpha, complex *a, int lda,
          complex *b, int ldb);
void ctrmm_64(char side, char uplo, char transa, char  diag,
          long  m,  long n, complex *alpha, complex *a, long
          lda, complex *b, long ldb);
```

PURPOSE

ctrmm performs one of the matrix-matrix operations B := alpha*op(A)*B, or B := alpha*B*op(A) where alpha is a scalar, B is an m by n matrix, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of op(A) = A or op(A) = A' or op(A) = conjg(A')

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether op(A) multiplies B from the left or right as follows:

SIDE = 'L' or 'l'   B := alpha*op(A)*B.

SIDE = 'R' or 'r'   B := alpha*B*op(A).

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular

```
          matrix.

          Unchanged on exit.

TRANSA (input)
          On entry, TRANSA specifies the form of op( A )  to
          be used in the matrix multiplication as follows:

          TRANSA = 'N' or 'n'   op( A ) = A.

          TRANSA = 'T' or 't'   op( A ) = A'.

          TRANSA = 'C' or 'c'   op( A ) = conjg( A' ).

          Unchanged on exit.

          TRANSA is defaulted to 'N' for F95 INTERFACE.
DIAG (input)
          On entry, DIAG specifies whether or not A is  unit
          triangular as follows:

          DIAG = 'U' or 'u'   A is assumed to be  unit  tri-
          angular.

          DIAG = 'N' or 'n'   A is not assumed  to  be  unit
          triangular.

          Unchanged on exit.

M (input)
          On entry, M specifies the number of rows of  B.  M
          >= 0.  Unchanged on exit.

N (input)
          On entry, N specifies the number of columns of  B.
          N >= 0.  Unchanged on exit.

ALPHA (input)
          On entry,  ALPHA specifies the scalar  alpha. When
          alpha  is  zero  then   A is not referenced and  B
          need not be set before entry.  Unchanged on exit.

A (input)
          COMPLEX array of DIMENSION ( LDA, k ), where k  is
          m when  SIDE = 'L' or 'l'  and is  n  when  SIDE =
          'R' or 'r'.

          Before entry  with  UPLO = 'U' or 'u',  the  lead-
          ing   k by k upper triangular part of the array  A
          must contain the upper triangular matrix  and  the
```

strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.

Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1,M), when SIDE = 'R' or 'r' then LDA >= max(1,N). Unchanged on exit.

B (input/output)

COMPLEX array of DIMENSION (LDB, n). Before entry, the leading M by N part of the array B must contain the matrix B, and on exit is overwritten by the transformed matrix.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB must be at least max(1,M). Unchanged on exit.

NAME

ctrmv - perform one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x

SYNOPSIS

```
SUBROUTINE CTRMV(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER N, LDA, INCY

SUBROUTINE CTRMV_64(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRMV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, INCY

SUBROUTINE TRMV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ctrmv(char uplo, char transa, char diag, int n, complex
          *a, int lda, complex *y, int incy);

void ctrmv_64(char uplo, char transa,  char  diag,  long  n,
          complex *a, long lda, complex *y, long incy);
```

PURPOSE

ctrmv performs one of the matrix-vector operations x := A*x, or x := A'*x, or x := conjg(A')*x where x is an n element vector and A is an n by n unit, or non-unit, upper or lower triangular matrix.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u' A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n' x := A*x.

TRANSA = 'T' or 't' x := A'*x.

TRANSA = 'C' or 'c' x := conjg(A')*x.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector x. On exit, Y is overwritten with the tranformed vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```
#include <sunperf.h>

void ctrrfs(char uplo, char transa, char diag,  int  n,  int
          nrhs,  complex  *a,  int lda, complex *b, int ldb,
          complex *x, int ldx, float *ferr, float *berr, int
          *info);

void ctrrfs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs, complex *a, long lda, complex *b, long
          ldb, complex *x,  long  ldx,  float  *ferr,  float
          *berr, long *info);
```

PURPOSE

ctrrfs provides error bounds and backward error estimates for the solution to a system of linear equations with a triangular coefficient matrix.

The solution matrix X must be computed by CTRTRS or some other means before entering this routine. CTRRFS does not do iterative refinement because doing so cannot improve the backward error.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.
```

```
DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The triangular matrix A.  If UPLO = 'U', the lead-
          ing  N-by-N  upper  triangular part of the array A
          contains the  upper  triangular  matrix,  and  the
          strictly   lower  triangular  part  of  A  is  not
          referenced.  If UPLO =  'L',  the  leading  N-by-N
          lower  triangular part of the array A contains the
          lower triangular matrix, and  the  strictly  upper
          triangular part of A is not referenced.  If DIAG =
          'U', the diagonal  elements  of  A  are  also  not
          referenced and are assumed to be 1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input) The right hand side matrix B.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

X (input) The solution matrix X.

LDX (input)
          The leading dimension of  the  array  X.   LDX  >=
          max(1,N).

FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
```

solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(2*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

LOGICAL(8), DIMENSION(:) :: SELECT
REAL :: S, SEP
```

C INTERFACE

```
#include <sunperf.h>

void ctrsen(char job, char compq, int *select, int  n,  com-
          plex *t, int ldt, complex *q, int ldq, complex *w,
          int *m, float *s, float *sep, int *info);

void ctrsen_64(char job, char compq, long *select,  long  n,
          complex  *t,  long ldt, complex *q, long ldq, com-
          plex *w, long  *m,  float  *s,  float  *sep,  long
          *info);
```

PURPOSE

ctrsen reorders the Schur factorization of a complex matrix A = Q*T*Q**H, so that a selected cluster of eigenvalues appears in the leading positions on the diagonal of the upper triangular matrix T, and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

Optionally the routine computes the reciprocal condition numbers of the cluster of eigenvalues and/or the invariant subspace.

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for the cluster of eigenvalues (S) or the invariant subspace (SEP):

```
          = 'N': none;
          = 'E': for eigenvalues only (S);
          = 'V': for invariant subspace only (SEP);
          = 'B': for both eigenvalues and invariant subspace
          (S and SEP).

COMPQ (input)
          = 'V': update the matrix Q of Schur vectors;
          = 'N': do not update Q.

SELECT (input)
          SELECT specifies the eigenvalues in  the  selected
          cluster.  To select the j-th eigenvalue, SELECT(j)
          must be set to .TRUE..

N (input) The order of the matrix T. N >= 0.
T (input/output)
          On entry, the upper triangular matrix T.  On exit,
          T  is  overwritten by the reordered matrix T, with
          the selected eigenvalues as the  leading  diagonal
          elements.

LDT (input)
          The leading dimension  of  the  array  T.  LDT  >=
          max(1,N).

Q (input) On entry, if COMPQ = 'V', the matrix  Q  of  Schur
          vectors.   On  exit,  if  COMPQ  = 'V', Q has been
          postmultiplied  by  the   unitary   transformation
          matrix  which reorders T; the leading M columns of
          Q form an  orthonormal  basis  for  the  specified
          invariant  subspace.   If  COMPQ  =  'N', Q is not
          referenced.

LDQ (input)
          The leading dimension of the array Q.  LDQ  >=  1;
          and if COMPQ = 'V', LDQ >= N.

W (output)
          The reordered eigenvalues of T, in the same  order
          as they appear on the diagonal of T.

M (output)
          The dimension of the specified invariant subspace.
          0 <= M <= N.

S (output)
          If JOB = 'E' or 'B', S is a  lower  bound  on  the
          reciprocal condition number for the selected clus-
          ter of eigenvalues.  S  cannot  underestimate  the
```

true reciprocal condition number by more than a factor of sqrt(N). If M = 0 or N, S = 1. If JOB = 'N' or 'V', S is not referenced.

SEP (output)
If JOB = 'V' or 'B', SEP is the estimated reciprocal condition number of the specified invariant subspace. If M = 0 or N, SEP = norm(T). If JOB = 'N' or 'E', SEP is not referenced.

WORK (workspace)
If JOB = 'N', WORK is not referenced. Otherwise, on exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If JOB = 'N', LWORK >= 1; if JOB = 'E', LWORK = M*(N-M); if JOB = 'V' or 'B', LWORK >= 2*M*(N-M).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

CTRSEN first collects the selected eigenvalues by computing a unitary transformation Z to move them to the top left corner of T. In other words, the selected eigenvalues are the eigenvalues of T11 in:

```
        Z'*T*Z = ( T11 T12 ) n1
                 (  0  T22 ) n2
                    n1  n2
```

where N = n1+n2 and Z' means the conjugate transpose of Z. The first n1 columns of Z span the specified invariant subspace of T.

If T has been obtained from the Schur factorization of a matrix A = Q*T*Q', then the reordered Schur factorization of A is given by A = (Q*Z)*(Z'*T*Z)*(Q*Z)', and the first n1 columns of Q*Z span the corresponding invariant subspace of A.

The reciprocal condition number of the average of the eigenvalues of T11 may be returned in S. S lies between 0 (very badly conditioned) and 1 (very well conditioned). It is computed as follows. First we compute R so that

```
P = ( I  R ) n1
    ( 0  0 ) n2
      n1 n2
```

is the projector on the invariant subspace associated with T11. R is the solution of the Sylvester equation:

```
T11*R - R*T22 = T12.
```

Let F-norm(M) denote the Frobenius-norm of M and 2-norm(M) denote the two-norm of M. Then S is computed as the lower bound

```
(1 + F-norm(R)**2)**(-1/2)
```

on the reciprocal of 2-norm(P), the true reciprocal condition number. S cannot underestimate 1 / 2-norm(P) by more than a factor of sqrt(N).

An approximate error bound for the computed average of the eigenvalues of T11 is

```
EPS * norm(T) / S
```

where EPS is the machine precision.

The reciprocal condition number of the right invariant subspace spanned by the first n1 columns of Z (or of Q*Z) is returned in SEP. SEP is defined as the separation of T11 and T22:

```
sep( T11, T22 ) = sigma-min( C )
```

where sigma-min(C) is the smallest singular value of the n1*n2-by-n1*n2 matrix

```
C  = kprod( I(n2), T11 ) - kprod( transpose(T22), I(n1) )
```

I(m) is an m by m identity matrix, and kprod denotes the Kronecker product. We estimate sigma-min(C) by the reciprocal of an estimate of the 1-norm of inverse(C). The true reciprocal 1-norm of inverse(C) cannot differ from sigma-min(C) by more than a factor of sqrt(n1*n2).

When SEP is small, small changes in T can cause large changes in the invariant subspace. An approximate bound on the maximum angular error in the computed right invariant subspace is

EPS * norm(T) / SEP

```
CHARACTER(LEN=1) :: SIDE, UPLO, TRANSA, DIAG
COMPLEX :: ALPHA
COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: M, N, LDA, LDB
```

C INTERFACE

```
#include <sunperf.h>

void ctrsm(char side, char uplo, char transa, char diag, int
          m,  int  n,  complex  *alpha, complex *a, int lda,
          complex *b, int ldb);

void ctrsm_64(char side, char uplo, char transa, char  diag,
          long  m,  long n, complex *alpha, complex *a, long
          lda, complex *b, long ldb);
```

PURPOSE

ctrsm solves one of the matrix equations op(A)*X = alpha*B, or X*op(A) = alpha*B where alpha is a scalar, X and B are m by n matrices, A is a unit, or non-unit, upper or lower triangular matrix and op(A) is one of

op(A) = A or op(A) = A' or op(A) = conjg(A').

The matrix X is overwritten on B.

ARGUMENTS

SIDE (input)
On entry, SIDE specifies whether op(A) appears on the left or right of X as follows:

SIDE = 'L' or 'l'   op(A)*X = alpha*B.

SIDE = 'R' or 'r'   X*op(A) = alpha*B.

Unchanged on exit.

UPLO (input)
On entry, UPLO specifies whether the matrix A is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l' A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n' op(A) = A.

TRANSA = 'T' or 't' op(A) = A'.

TRANSA = 'C' or 'c' op(A) = conjg(A').

Unchanged on exit.
TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u' A is assumed to be unit triangular.

DIAG = 'N' or 'n' A is not assumed to be unit triangular.

Unchanged on exit.

M (input)
On entry, M specifies the number of rows of B. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of B. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. When alpha is zero then A is not referenced and B need not be set before entry. Unchanged on exit.

A (input)
COMPLEX array of DIMENSION (LDA, k), where k is m when SIDE = 'L' or 'l' and is n when SIDE = 'R' or 'r'.

Before entry with UPLO = 'U' or 'u', the leading k by k upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced.

Before entry with UPLO = 'L' or 'l', the leading k by k lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced.

Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity.
Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When SIDE = 'L' or 'l' then LDA >= max(1,M), when SIDE = 'R' or 'r' then LDA >= max(1,N). Unchanged on exit.

B (input/output)
COMPLEX array of DIMENSION (LDB, n).
Before entry, the leading M by N part of the array B must contain the right-hand side matrix B, and on exit is overwritten by the solution matrix X.

LDB (input)
On entry, LDB specifies the first dimension of B as declared in the calling subprogram. LDB >= max(1,M). Unchanged on exit.

          plex *vr, long ldvr, float *s,  float  *sep,  long
          mm, long *m, long ldwork, long *info);
```

PURPOSE

ctrsna estimates reciprocal condition numbers for specified eigenvalues and/or right eigenvectors of a complex upper triangular matrix T (or of any matrix Q*T*Q**H with Q unitary).

ARGUMENTS

JOB (input)
Specifies whether condition numbers are required for eigenvalues (S) or eigenvectors (SEP):
= 'E': for eigenvalues only (S);
= 'V': for eigenvectors only (SEP);
= 'B': for both eigenvalues and eigenvectors (S and SEP).

HOWMNY (input)
= 'A': compute condition numbers for all eigenpairs;
= 'S': compute condition numbers for selected eigenpairs specified by the array SELECT.

```
SELECT (input)
          If HOWMNY = 'S', SELECT specifies  the  eigenpairs
          for  which  condition  numbers  are  required.  To
          select condition numbers for the  j-th  eigenpair,
          SELECT(j) must be set to .TRUE..  If HOWMNY = 'A',
          SELECT is not referenced.

N (input) The order of the matrix T. N >= 0.

T (input) The upper triangular matrix T.

LDT (input)
          The leading dimension  of  the  array  T.  LDT  >=
          max(1,N).

VL (input)
          If JOB = 'E' or 'B', VL must contain  left  eigen-
          vectors  of T (or of any Q*T*Q**H with Q unitary),
          corresponding  to  the  eigenpairs  specified   by
          HOWMNY and SELECT. The eigenvectors must be stored
          in consecutive  columns  of  VL,  as  returned  by
          CHSEIN  or CTREVC.  If JOB = 'V', VL is not refer-
          enced.

LDVL (input)
          The leading dimension of the array VL.  LDVL >= 1;
          and if JOB = 'E' or 'B', LDVL >= N.

VR (input)
          If JOB = 'E' or 'B', VR must contain right  eigen-
          vectors  of T (or of any Q*T*Q**H with Q unitary),
          corresponding  to  the  eigenpairs  specified   by
          HOWMNY and SELECT. The eigenvectors must be stored
          in consecutive  columns  of  VR,  as  returned  by
          CHSEIN  or CTREVC.  If JOB = 'V', VR is not refer-
          enced.

LDVR (input)
          The leading dimension of the array VR.  LDVR >= 1;
          and if JOB = 'E' or 'B', LDVR >= N.

S (output)
          If JOB = 'E'  or  'B',  the  reciprocal  condition
          numbers  of  the  selected  eigenvalues, stored in
          consecutive elements  of  the  array.  Thus  S(j),
          SEP(j),  and  the  j-th  columns  of VL and VR all
          correspond to the same eigenpair (but not in  gen-
          eral the j-th eigenpair, unless all eigenpairs are
          selected).  If JOB = 'V', S is not referenced.
```

```
SEP (output)
          If JOB = 'V' or 'B', the estimated reciprocal con-
          dition   numbers  of  the  selected  eigenvectors,
          stored in consecutive elements of the  array.   If
          JOB = 'E', SEP is not referenced.

MM (input)
          The number of elements in the arrays S (if  JOB  =
          'E'  or  'B') and/or SEP (if JOB = 'V' or 'B'). MM
          >= M.

M (output)
          The number of elements of the arrays S and/or  SEP
          actually  used  to  store  the estimated condition
          numbers.  If HOWMNY = 'A', M is set to N.

WORK (workspace)
          dimension(LDWORK,N+1) If JOB = 'E',  WORK  is  not
          referenced.

LDWORK (input)
          The leading dimension of the array  WORK.   LDWORK
          >= 1; and if JOB = 'V' or 'B', LDWORK >= N.

WORK1 (workspace)
          dimension(N) If JOB = 'E',  WORK1  is  not  refer-
          enced.

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
```

FURTHER DETAILS

```
The reciprocal of the  condition  number  of  an  eigenvalue
lambda is defined as

        S(lambda) = |v'*u| / (norm(u)*norm(v))

where u and v are the  right  and  left  eigenvectors  of  T
corresponding  to lambda; v' denotes the conjugate transpose
of v, and norm(u) denotes the Euclidean norm. These recipro-
cal  condition  numbers  always lie between zero (very badly
conditioned) and one (very well  conditioned).  If  n  =  1,
S(lambda) is defined to be 1.

An approximate error bound for a computed eigenvalue W(i) is
given by
```

EPS * norm(T) / S(i)

where EPS is the machine precision.

The reciprocal of the condition number of the right eigenvector u corresponding to lambda is defined as follows. Suppose

```
T = ( lambda  c  )
    (   0    T22 )
```

Then the reciprocal condition number is

SEP(lambda, T22) = sigma-min(T22 - lambda*I)

where sigma-min denotes the smallest singular value. We approximate the smallest singular value by the reciprocal of an estimate of the one-norm of the inverse of T22 - lambda*I. If n = 1, SEP(1) is defined to be abs(T(1,1)).

An approximate error bound for a computed right eigenvector VR(i) is given by

EPS * norm(T) / SEP(i)

NAME

```
ctrsv - solve one of the systems of equations   A*x = b,  or
A'*x = b, or conjg( A' )*x = b
```

SYNOPSIS

```
SUBROUTINE CTRSV(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER N, LDA, INCY

SUBROUTINE CTRSV_64(UPLO, TRANSA, DIAG, N, A, LDA, Y, INCY)

CHARACTER * 1 UPLO, TRANSA, DIAG
COMPLEX A(LDA,*), Y(*)
INTEGER*8 N, LDA, INCY
```

F95 INTERFACE

```
SUBROUTINE TRSV(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, INCY

SUBROUTINE TRSV_64(UPLO, [TRANSA], DIAG, [N], A, [LDA], Y, [INCY])

CHARACTER(LEN=1) :: UPLO, TRANSA, DIAG
COMPLEX, DIMENSION(:) :: Y
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INCY
```

C INTERFACE

```
#include <sunperf.h>

void ctrsv(char uplo, char transa, char diag, int n, complex
          *a, int lda, complex *y, int incy);

void ctrsv_64(char uplo, char transa,  char  diag,  long  n,
          complex *a, long lda, complex *y, long incy);
```

PURPOSE

ctrsv solves one of the systems of equations A*x = b, or A'*x = b, or conjg(A')*x = b where b and x are n element vectors and A is an n by n unit, or non-unit, upper or lower triangular matrix.
No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

ARGUMENTS

UPLO (input)
On entry, UPLO specifies whether the matrix is an upper or lower triangular matrix as follows:

UPLO = 'U' or 'u'   A is an upper triangular matrix.

UPLO = 'L' or 'l'   A is a lower triangular matrix.

Unchanged on exit.

TRANSA (input)
On entry, TRANSA specifies the equations to be solved as follows:

TRANSA = 'N' or 'n'   A*x = b.

TRANSA = 'T' or 't'   A'*x = b.

TRANSA = 'C' or 'c'   conjg(A')*x = b.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)

On entry, DIAG specifies whether or not A is unit triangular as follows:

DIAG = 'U' or 'u'   A is assumed to be unit triangular.

DIAG = 'N' or 'n'   A is not assumed to be unit triangular.

Unchanged on exit.

N (input)

On entry, N specifies the order of the matrix A. N >= 0. Unchanged on exit.

A (input)

Before entry with UPLO = 'U' or 'u', the leading n by n upper triangular part of the array A must contain the upper triangular matrix and the strictly lower triangular part of A is not referenced. Before entry with UPLO = 'L' or 'l', the leading n by n lower triangular part of the array A must contain the lower triangular matrix and the strictly upper triangular part of A is not referenced. Note that when DIAG = 'U' or 'u', the diagonal elements of A are not referenced either, but are assumed to be unity. Unchanged on exit.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, n). Unchanged on exit.

Y (input/output)

(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element right-hand side vector b. On exit, Y is overwritten with the solution vector x.

INCY (input)

On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

```

C INTERFACE

```
#include <sunperf.h>

void ctrsyl(char trana, char tranb, int isgn, int m, int  n,
          complex  *a, int lda, complex *b, int ldb, complex
          *c, int ldc, float *scale, int *info);

void ctrsyl_64(char trana, char tranb, long  isgn,  long  m,
          long  n,  complex  *a,  long lda, complex *b, long
          ldb, complex *c,  long  ldc,  float  *scale,  long
          *info);
```

PURPOSE

ctrsyl solves the complex Sylvester matrix equation:

```
op(A)*X + X*op(B) = scale*C or
op(A)*X - X*op(B) = scale*C,
```

where op(A) = A or A**H, and A and B are both upper triangular. A is M-by-M and B is N-by-N; the right hand side C and the solution X are M-by-N; and scale is an output scale factor, set <= 1 to avoid overflow in X.

ARGUMENTS

TRANA (input)
Specifies the option op(A):
= 'N': op(A) = A   (No transpose)
= 'C': op(A) = A**H (Conjugate transpose)

TRANB (input)
Specifies the option op(B):
= 'N': op(B) = B   (No transpose)
= 'C': op(B) = B**H (Conjugate transpose)

ISGN (input)
Specifies the sign in the equation:
= +1: solve op(A)*X + X*op(B) = scale*C
= -1: solve op(A)*X - X*op(B) = scale*C

M (input) The order of the matrix A, and the number of rows

```
          in the matrices X and C. M >= 0.

N (input) The order of the  matrix  B,  and  the  number  of
          columns in the matrices X and C. N >= 0.

A (input) The upper triangular matrix A.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).

B (input) The upper triangular matrix B.
LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

C (input/output)
          On entry, the M-by-N right hand side matrix C.  On
          exit, C is overwritten by the solution matrix X.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M)

SCALE (output)
          The scale factor, scale, set <= 1 to  avoid  over-
          flow in X.

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
          = 1: A and B have  common  or  very  close  eigen-
          values;  perturbed  values  were used to solve the
          equation (but the matrices A and B are unchanged).
```

CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, INFO

SUBROUTINE TRTI2_64(UPLO, DIAG, [N], A, [LDA], [INFO])

CHARACTER(LEN=1) :: UPLO, DIAG
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctrti2(char uplo, char diag, int  n,  complex  *a,  int
          lda, int *info);

void ctrti2_64(char uplo, char diag,  long  n,  complex  *a,
          long lda, long *info);
```

PURPOSE

ctrti2 computes the inverse of a complex upper or lower triangular matrix.

This is the Level 2 BLAS version of the algorithm.

ARGUMENTS

UPLO (input)
Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular
= 'L': Lower triangular

DIAG (input)
Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular
= 'U': Unit triangular

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the triangular matrix A. If UPLO = 'U', the leading n by n upper triangular part of the array A contains the upper triangular matrix, and the strictly lower triangular part of A is not referenced. If UPLO = 'L', the leading n by n lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

On exit, the (triangular) inverse of the original matrix, in the same storage format.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

INFO (output)

= 0: successful exit

< 0: if INFO = -k, the k-th argument had an illegal value

          lda, int *info);

void ctrtri_64(char uplo, char diag,  long  n,  complex  *a,
          long lda, long *info);
```

PURPOSE

ctrtri computes the inverse of a complex upper or lower triangular matrix A.

This is the Level 3 BLAS version of the algorithm.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

A (input/output)
          On entry, the triangular matrix A.  If UPLO = 'U',
          the  leading  N-by-N  upper triangular part of the
          array A contains the upper triangular matrix,  and
          the  strictly  lower  triangular  part of A is not
          referenced.  If UPLO =  'L',  the  leading  N-by-N
          lower  triangular part of the array A contains the
          lower triangular matrix, and  the  strictly  upper
          triangular part of A is not referenced.  If DIAG =
          'U', the diagonal  elements  of  A  are  also  not
          referenced  and are assumed to be 1.  On exit, the
          (triangular) inverse of the  original  matrix,  in
          the same storage format.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

INFO (output)
          = 0: successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
```

gal value
> 0: if INFO = i, A(i,i) is exactly zero. The triangular matrix is singular and its inverse can not be computed.

COMPLEX, DIMENSION(:,:) :: A, B
INTEGER(8) :: N, NRHS, LDA, LDB, INFO
```

C INTERFACE

```
#include <sunperf.h>

void ctrtrs(char uplo, char transa, char diag,  int  n,  int
          nrhs,  complex  *a,  int lda, complex *b, int ldb,
          int *info);

void ctrtrs_64(char uplo, char transa, char  diag,  long  n,
          long  nrhs, complex *a, long lda, complex *b, long
          ldb, long *info);
```

PURPOSE

ctrtrs solves a triangular system of the form
where A is a triangular matrix of order N, and B is an N-by-NRHS matrix. A check is made to verify that A is non-singular.

ARGUMENTS

```
UPLO (input)
          = 'U':  A is upper triangular;
          = 'L':  A is lower triangular.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

DIAG (input)
          = 'N':  A is non-unit triangular;
          = 'U':  A is unit triangular.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrix B.  NRHS >= 0.

A (input) The triangular matrix A.  If UPLO = 'U', the lead-
          ing  N-by-N  upper  triangular part of the array A
          contains the  upper  triangular  matrix,  and  the
          strictly  lower triangular part of A is not refer-
```

enced. If UPLO = 'L', the leading N-by-N lower triangular part of the array A contains the lower triangular matrix, and the strictly upper triangular part of A is not referenced. If DIAG = 'U', the diagonal elements of A are also not referenced and are assumed to be 1.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the right hand side matrix B. On exit, if INFO = 0, the solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, the i-th diagonal element of A is zero, indicating that the matrix is singular and the solutions X have not been computed.

NAME

ctzrqf - routine is deprecated and has been replaced by routine CTZRZF

SYNOPSIS

```
SUBROUTINE CTZRQF(M, N, A, LDA, TAU, INFO)

COMPLEX A(LDA,*), TAU(*)
INTEGER M, N, LDA, INFO

SUBROUTINE CTZRQF_64(M, N, A, LDA, TAU, INFO)

COMPLEX A(LDA,*), TAU(*)
INTEGER*8 M, N, LDA, INFO
```

F95 INTERFACE

```
SUBROUTINE TZRQF([M], [N], A, [LDA], TAU, [INFO])

COMPLEX, DIMENSION(:) :: TAU
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, INFO

SUBROUTINE TZRQF_64([M], [N], A, [LDA], TAU, [INFO])

COMPLEX, DIMENSION(:) :: TAU
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctzrqf(int m, int n, complex *a, int lda, complex *tau,
          int *info);

void ctzrqf_64(long m, long n, complex *a, long lda, complex
          *tau, long *info);
```

PURPOSE

ctzrqf routine is deprecated and has been replaced by routine CTZRZF.

CTZRQF reduces the M-by-N (M<=N) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

```
   A = ( R  0 ) * Z,
```

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= M.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value

FURTHER DETAILS

```
The  factorization is obtained by Householder's method.  The
kth transformation matrix, Z( k ), whose conjugate transpose
is used to introduce zeros into the (m - k + 1)th row of  A,
is given in the form

   Z( k ) = ( I     0   ),
            ( 0  T( k ) )

where

   T( k ) = I - tau*u( k )*u( k )',   u( k ) = (   1    ),
                                               (   0    )
                                               ( z( k ) )

tau is a scalar and z( k ) is an ( n - m )  element  vector.
tau  and z( k ) are chosen to annihilate the elements of the
kth row of X.

The scalar tau is returned in the kth element of TAU and the
vector u( k ) in the kth row of A, such that the elements of
z( k ) are in  a( k, m + 1 ), ..., a( k, n ).  The  elements
of R are returned in the upper triangular part of A.

Z is given by

   Z =  Z( 1 ) * Z( 2 ) * ... * Z( m ).

COMPLEX, DIMENSION(:,:) :: A
INTEGER :: M, N, LDA, LWORK, INFO

SUBROUTINE TZRZF_64([M], [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void ctzrzf(int m, int n, complex *a, int lda, complex *tau,
          int *info);

void ctzrzf_64(long m, long n, complex *a, long lda, complex
          *tau, long *info);
```

PURPOSE

ctzrzf reduces the M-by-N (M<=N) complex upper trapezoidal matrix A to upper triangular form by means of unitary transformations.

The upper trapezoidal matrix A is factored as

```
   A = ( R  0 ) * Z,
```

where Z is an N-by-N unitary matrix and R is an M-by-M upper triangular matrix.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the leading M-by-N upper trapezoidal part of the array A must contain the matrix to be factorized. On exit, the leading M-by-M upper triangular part of A contains the upper triangular matrix R, and elements M+1 to N of the first M rows of A, with the array TAU, represent the unitary matrix Z as a product of M elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= max(1,M). For optimum performance LWORK >= M*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

Based on contributions by
A. Petitet, Computer Science Dept., Univ. of Tenn., Knoxville, USA

The factorization is obtained by Householder's method. The kth transformation matrix, Z(k), which is used to introduce zeros into the (m - k + 1)th row of A, is given in the form

```
   Z( k ) = ( I     0   ),
            ( 0  T( k ) )
```

where

```
   T( k ) = I - tau*u( k )*u( k )',   u( k ) = (   1    ),
                                               (   0    )
                                               ( z( k ) )
```

tau is a scalar and z(k) is an (n - m) element vector. tau and z(k) are chosen to annihilate the elements of the kth row of X.

The scalar tau is returned in the kth element of TAU and the vector u(k) in the kth row of A, such that the elements of z(k) are in a(k, m + 1), ..., a(k, n). The elements of R are returned in the upper triangular part of A.

Z is given by

```
   Z =  Z( 1 ) * Z( 2 ) * ... * Z( m ).
```

COMPLEX A(LDA,*), TAU(*), WORK(*)
INTEGER*8 M, N, K, LDA, LWORK, INFO
```

F95 INTERFACE

```
SUBROUTINE UNGBR(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: VECT
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: M, N, K, LDA, LWORK, INFO

SUBROUTINE UNGBR_64(VECT, M, [N], K, A, [LDA], TAU, [WORK], [LWORK],
       [INFO])

CHARACTER(LEN=1) :: VECT
COMPLEX, DIMENSION(:) :: TAU, WORK
```

```
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, K, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cungbr(char vect, int m, int n, int k, complex *a,  int
          lda, complex *tau, int *info);

void cungbr_64(char vect, long m, long n,  long  k,  complex
          *a, long lda, complex *tau, long *info);
```

PURPOSE

```
cungbr generates one of the complex unitary  matrices  Q  or
P**H  determined  by CGEBRD when reducing a complex matrix A
to bidiagonal form: A = Q *  B  *  P**H.   Q  and  P**H  are
defined  as  products  of elementary reflectors H(i) or G(i)
respectively.

If VECT = 'Q', A is assumed to have been an  M-by-K  matrix,
and Q is of order M:
if m >= k, Q = H(1) H(2) . . . H(k) and CUNGBR  returns  the
first n columns of Q, where m >= n >= k;
if m < k, Q = H(1) H(2) . . . H(m-1) and CUNGBR returns Q as
an M-by-M matrix.

If VECT = 'P', A is assumed to have been  a  K-by-N  matrix,
and P**H is of order N:
if k < n, P**H = G(k) . . . G(2) G(1) and CUNGBR returns the
first m rows of P**H, where n >= m >= k;
if k >= n, P**H = G(n-1) . . . G(2) G(1) and CUNGBR  returns
P**H as an N-by-N matrix.
```

ARGUMENTS

```
VECT (input)
          Specifies whether the matrix Q or the matrix  P**H
          is  required,  as  defined  in  the transformation
          applied by CGEBRD:
          = 'Q':  generate Q;
          = 'P':  generate P**H.

M (input) The number of rows of the matrix Q or P**H  to  be
          returned.  M >= 0.

N (input) The number of columns of the matrix Q or  P**H  to
```

be returned. N >= 0. If VECT = 'Q', M >= N >= min(M,K); if VECT = 'P', N >= M >= min(N,K).

K (input) If VECT = 'Q', the number of columns in the original M-by-K matrix reduced by CGEBRD. If VECT = 'P', the number of rows in the original K-by-N matrix reduced by CGEBRD. K >= 0.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by CGEBRD. On exit, the M-by-N matrix Q or P**H.

LDA (input)
The leading dimension of the array A. LDA >= M.

TAU (input)
(min(M,K)) if VECT = 'Q' (min(N,K)) if VECT = 'P' TAU(i) must contain the scalar factor of the elementary reflector H(i) or G(i), which determines Q or P**H, as returned by CGEBRD in its array argument TAUQ or TAUP.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,min(M,N)). For optimum performance LWORK >= min(M,N)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

       [INFO])

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, ILO, IHI, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cunghr(int n, int ilo, int ihi, complex  *a,  int  lda,
          complex *tau, int *info);

void cunghr_64(long n, long ilo, long ihi, complex *a,  long
          lda, complex *tau, long *info);
```

PURPOSE

cunghr generates a complex unitary matrix Q which is defined as the product of IHI-ILO elementary reflectors of order N, as returned by CGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

ARGUMENTS

N (input) The order of the matrix Q. N >= 0.

ILO (input)
ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix Q(ilo+1:ihi,ilo+1:ihi). 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description of IHI.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by CGEHRD. On exit, the N-by-N unitary matrix Q.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEHRD.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= IHI-ILO. For optimum performance LWORK >= (IHI-ILO)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

PURPOSE

cungql generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the last N columns of a product of K elementary reflectors of order M

      Q = H(k) . . . H(2) H(1)

as returned by CGEQLF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)
On entry, the (n-k+i)-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQLF in the last k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQLF.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >=

```
          max(1,N).   For optimum performance LWORK >= N*NB,
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument has an ille-
          gal value
```

COMPLEX, DIMENSION(:) :: TAU, WORKIN
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: M, N, K, LDA, LWORKIN, INFO
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cungqr(int m, int n, int k, complex *a, int  lda,  com-
          plex *tau, int *info);

void cungqr_64(long m, long n, long k, complex *a, long lda,
          complex *tau, long *info);
```

PURPOSE

cungqr generates an M-by-N complex matrix Q with orthonormal columns, which is defined as the first N columns of a product of K elementary reflectors of order M

      Q = H(1) H(2) . . . H(k)

as returned by CGEQRF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. M >= N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. N >= K >= 0.

A (input/output)
On entry, the i-th column must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGEQRF in the first k columns of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGEQRF.

WORKIN (workspace)
On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)
The dimension of the array WORKIN. LWORKIN >=

max(1,N). For optimum performance LWORKIN >= N*NB, where NB is the optimal blocksize.

If LWORKIN = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument has an illegal value

void cungr2_64(long m, long n, long k, complex *a, long lda,
          complex *tau, long *info);
```

PURPOSE

cungr2 generates an m by n complex matrix Q with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

```
      Q  =  H(1)' H(2)' . . . H(k)'
```

as returned by CGERQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)
On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGERQF in the last k rows of its array argument A. On exit, the m-by-n matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

WORK (workspace)
dimension(M)

void cungrq_64(long m, long n, long k, complex *a, long lda,
          complex *tau, long *info);
```

PURPOSE

cungrq generates an M-by-N complex matrix Q with orthonormal rows, which is defined as the last M rows of a product of K elementary reflectors of order N

      Q = H(1)' H(2)' . . . H(k)'

as returned by CGERQF.

ARGUMENTS

M (input) The number of rows of the matrix Q. M >= 0.

N (input) The number of columns of the matrix Q. N >= M.

K (input) The number of elementary reflectors whose product defines the matrix Q. M >= K >= 0.

A (input/output)
On entry, the (m-k+i)-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGERQF in the last k rows of its array argument A. On exit, the M-by-N matrix Q.

LDA (input)
The first dimension of the array A. LDA >= max(1,M).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGERQF.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,M). For optimum performance LWORK >= M*NB,

where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument has an illegal value

COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER :: N, LDA, LWORK, INFO

SUBROUTINE UNGTR_64(UPLO, [N], A, [LDA], TAU, [WORK], [LWORK], [INFO])

CHARACTER(LEN=1) :: UPLO
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A
INTEGER(8) :: N, LDA, LWORK, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cungtr(char uplo, int n, complex *a, int  lda,  complex
          *tau, int *info);

void cungtr_64(char uplo, long n, complex *a, long lda, com-
          plex *tau, long *info);
```

PURPOSE

cungtr generates a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors of order N, as returned by CHETRD:
if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

ARGUMENTS

UPLO (input)
= 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

N (input) The order of the matrix Q. N >= 0.

A (input/output)
On entry, the vectors which define the elementary reflectors, as returned by CHETRD. On exit, the N-by-N unitary matrix Q.

LDA (input)
The leading dimension of the array A. LDA >= N.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= N-1. For optimum performance LWORK >= (N-1)*NB, where

NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

C INTERFACE

```
#include <sunperf.h>

void cunmbr(char vect, char side, char trans, int m, int  n,
          int  k, complex *a, int lda, complex *tau, complex
          *c, int ldc, int *info);

void cunmbr_64(char vect, char side,  char  trans,  long  m,
          long  n,  long  k,  complex  *a, long lda, complex
          *tau, complex *c, long ldc, long *info);
```

PURPOSE

```
cunmbr VECT = 'Q', CUNMBR overwrites the general complex  M-
by-N matrix C with
                SIDE = 'L'      SIDE  =  'R'  TRANS  =  'N':
Q  *  C           C * Q TRANS = 'C':      Q**H * C       C *
Q**H

If VECT = 'P', CUNMBR overwrites the general complex  M-by-N
matrix C with
                SIDE = 'L'     SIDE = 'R'
TRANS = 'N':      P * C          C * P
TRANS = 'C':      P**H * C       C * P**H

Here Q and P**H  are  the  unitary  matrices  determined  by
CGEBRD  when reducing a complex matrix A to bidiagonal form:
A = Q * B * P**H. Q and P**H are defined as products of ele-
mentary reflectors H(i) and G(i) respectively.

Let nq = m if SIDE = 'L' and nq = n if SIDE = 'R'.  Thus  nq
is  the  order  of  the  unitary  matrix  Q  or P**H that is
applied.

If VECT = 'Q', A is assumed to have been an NQ-by-K  matrix:
if nq >= k, Q = H(1) H(2) . . . H(k);
if nq < k, Q = H(1) H(2) . . . H(nq-1).

If VECT = 'P', A is assumed to have been a  K-by-NQ  matrix:
if k < nq, P = G(1) G(2) . . . G(k);
if k >= nq, P = G(1) G(2) . . . G(nq-1).
```

ARGUMENTS

```
VECT (input)
          = 'Q': apply Q or Q**H;
          = 'P': apply P or P**H.

SIDE (input)
          = 'L': apply Q, Q**H, P or P**H from the Left;
          = 'R': apply Q, Q**H, P or P**H from the Right.

TRANS (input)
          = 'N':  No transpose, apply Q or P;
          = 'C':  Conjugate transpose, apply Q**H or P**H.

          TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.
N (input) The number of columns of the matrix C. N >= 0.

K (input) If VECT = 'Q', the number of columns in the origi-
          nal  matrix reduced by CGEBRD.  If VECT = 'P', the
          number of rows in the original matrix  reduced  by
          CGEBRD.  K >= 0.

A (input) (LDA,min(nq,K)) if VECT = 'Q'  (LDA,nq)         if
          VECT = 'P' The vectors which define the elementary
          reflectors H(i) and G(i), whose products determine
          the matrices Q and P, as returned by CGEBRD.

LDA (input)
          The leading dimension of the array A.  If  VECT  =
          'Q',  LDA  >=  max(1,nq);  if  VECT  = 'P', LDA >=
          max(1,min(nq,K)).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary  reflector H(i) or G(i) which determines Q
          or P, as returned by CGEBRD in the array  argument
          TAUQ or TAUP.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten  by  Q*C or Q**H*C or C*Q**H or C*Q or
          P*C or P**H*C or C*P or C*P**H.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
```

LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

```
#include <sunperf.h>

void cunmhr(char side, char trans, int m, int  n,  int  ilo,
          int  ihi,  complex *a, int lda, complex *tau, com-
          plex *c, int ldc, int *info);

void cunmhr_64(char side, char trans, long m, long  n,  long
          ilo, long ihi, complex *a, long lda, complex *tau,
          complex *c, long ldc, long *info);
```

PURPOSE

cunmhr overwrites the general complex M-by-N matrix C with
TRANS = 'C':   Q**H * C   C * Q**H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of IHI-ILO elementary reflectors, as returned by CGEHRD:

Q = H(ilo) H(ilo+1) . . . H(ihi-1).

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**H from the Left;
= 'R': apply Q or Q**H from the Right.

TRANS (input)
= 'N': apply Q (No transpose)
= 'C': apply Q**H (Conjugate transpose)

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

ILO (input)
ILO and IHI must have the same values as in the previous call of CGEHRD. Q is equal to the unit matrix except in the submatrix

```
          Q(ilo+1:ihi,ilo+1:ihi).   If SIDE = 'L', then 1 <=
          ILO <= IHI <= M, if M > 0, and ILO = 1 and  IHI  =
          0,  if  M = 0; if SIDE = 'R', then 1 <= ILO <= IHI
          <= N, if N > 0, and ILO = 1 and IHI = 0, if N = 0.

IHI (input)
          See the description of ILO.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE  =  'R'  The
          vectors which define the elementary reflectors, as
          returned by CGEHRD.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M)  if SIDE = 'L'; LDA >= max(1,N) if SIDE =
          'R'.

TAU (input)
          (M-1) if SIDE = 'L' (N-1) if  SIDE  =  'R'  TAU(i)
          must  contain  the scalar factor of the elementary
          reflector H(i), as returned by CGEHRD.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

SUBROUTINE UNML2_64(SIDE, TRANS, [M], [N], [K], A, [LDA], TAU, C,
       [LDC], [WORK], [INFO])
```

```
CHARACTER(LEN=1) :: SIDE, TRANS
COMPLEX, DIMENSION(:) :: TAU, WORK
COMPLEX, DIMENSION(:,:) :: A, C
INTEGER(8) :: M, N, K, LDA, LDC, INFO
```

C INTERFACE

```
#include <sunperf.h>

void cunml2(char side, char trans, int m, int n, int k, com-
          plex  *a,  int  lda, complex *tau, complex *c, int
          ldc, int *info);

void cunml2_64(char side, char trans, long m, long  n,  long
          k, complex *a, long lda, complex *tau, complex *c,
          long ldc, long *info);
```

PURPOSE

cunml2 overwrites the general complex m-by-n matrix C with

where Q is a complex unitary matrix defined as the product of k elementary reflectors

      Q = H(k)' . . . H(2)' H(1)'

as returned by CGELQF. Q is of order m if SIDE = 'L' and of order n if SIDE = 'R'.

ARGUMENTS

SIDE (input)
          = 'L': apply Q or Q' from the Left
          = 'R': apply Q or Q' from the Right

TRANS (input)
          = 'N': apply Q (No transpose)
          = 'C': apply Q' (Conjugate transpose)

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product defines the matrix Q. If SIDE = 'L', M >= K >= 0; if SIDE = 'R', N >= K >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CGELQF in the first k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)
The leading dimension of the array A. LDA >= max(1,K).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CGELQF.

C (input/output)
On entry, the m-by-n matrix C. On exit, C is overwritten by Q*C or Q'*C or C*Q' or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
(N) if SIDE = 'L', (M) if SIDE = 'R'

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

cunmlq overwrites the general complex M-by-N matrix C with
TRANS = 'C':   Q**H * C   C * Q**H

where Q is a complex unitary matrix defined as the product
of k elementary reflectors

      Q = H(k)' . . . H(2)' H(1)'

as returned by CGELQF. Q is of order M if SIDE = 'L' and of
order N if SIDE = 'R'.

ARGUMENTS

SIDE (input)
          = 'L': apply Q or Q**H from the Left;
          = 'R': apply Q or Q**H from the Right.

TRANS (input)
          = 'N': No transpose, apply Q;
          = 'C': Conjugate transpose, apply Q**H.

          TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product
          defines the matrix Q. If SIDE = 'L', M >= K >= 0;
          if SIDE = 'R', N >= K >= 0.

```
A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE =  'R'  The
          i-th row must contain the vector which defines the
          elementary reflector H(i), for i =  1,2,...,k,  as
          returned  by  CGELQF  in  the  first k rows of its
          array argument A.  A is modified  by  the  routine
          but restored on exit.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,K).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by CGELQF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  'L',  and  LWORK  >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

= 'C': Transpose, apply Q**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose product
defines the matrix Q. If SIDE = 'L', M >= K >= 0;
if SIDE = 'R', N >= K >= 0.

```
A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE =  'R'  The
          i-th row must contain the vector which defines the
          elementary reflector H(i), for i =  1,2,...,k,  as
          returned by CGERQF in the last k rows of its array
          argument A.  A is  modified  by  the  routine  but
          restored on exit.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,K).

TAU (input)
          TAU(i) must contain the scalar factor of the  ele-
          mentary reflector H(i), as returned by CGERQF.

C (input/output)
          On entry, the M-by-N matrix  C.   On  exit,  C  is
          overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
          The leading dimension  of  the  array  C.  LDC  >=
          max(1,M).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK.  If SIDE  =  'L',
          LWORK  >=  max(1,N);  if  SIDE  =  'R',  LWORK  >=
          max(1,M).  For optimum performance LWORK  >=  N*NB
          if  SIDE  =  'L', and LWORK >= M*NB if SIDE = 'R',
          where NB is the optimal blocksize.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

```

PURPOSE

```
cunmrz overwrites the general complex M-by-N matrix  C  with
TRANS = 'C':      Q**H * C       C * Q**H

where Q is a complex unitary matrix defined as  the  product
of k elementary reflectors

      Q = H(1) H(2) . . . H(k)

as returned by CTZRZF. Q is of order M if SIDE = 'L' and  of
order N if SIDE = 'R'.
```

ARGUMENTS

```
SIDE (input)
          = 'L': apply Q or Q**H from the Left;
          = 'R': apply Q or Q**H from the Right.

TRANS (input)
          = 'N':  No transpose, apply Q;
          = 'C':  Conjugate transpose, apply Q**H.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

K (input) The number of elementary reflectors whose  product
          defines the matrix Q.  If SIDE = 'L', M >= K >= 0;
          if SIDE = 'R', N >= K >= 0.
```

L (input) The number of columns of the matrix A containing the meaningful part of the Householder reflectors. If SIDE = 'L', M >= L >= 0, if SIDE = 'R', N >= L >= 0.

A (input) (LDA,M) if SIDE = 'L', (LDA,N) if SIDE = 'R' The i-th row must contain the vector which defines the elementary reflector H(i), for i = 1,2,...,k, as returned by CTZRZF in the last k rows of its array argument A. A is modified by the routine but restored on exit.

LDA (input)
The leading dimension of the array A. LDA >= max(1,K).

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CTZRZF.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >= M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

```

PURPOSE

cunmtr overwrites the general complex M-by-N matrix C with
TRANS = 'C':   Q**H * C   C * Q**H

where Q is a complex unitary matrix of order nq, with nq = m if SIDE = 'L' and nq = n if SIDE = 'R'. Q is defined as the product of nq-1 elementary reflectors, as returned by CHETRD:

if UPLO = 'U', Q = H(nq-1) . . . H(2) H(1);

if UPLO = 'L', Q = H(1) H(2) . . . H(nq-1).

ARGUMENTS

SIDE (input)
= 'L': apply Q or Q**H from the Left;
= 'R': apply Q or Q**H from the Right.

UPLO (input)
= 'U': Upper triangle of A contains elementary reflectors from CHETRD; = 'L': Lower triangle of A contains elementary reflectors from CHETRD.

TRANS (input)
= 'N': No transpose, apply Q;
= 'C': Conjugate transpose, apply Q**H.

TRANS is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix C. M >= 0.

N (input) The number of columns of the matrix C. N >= 0.

A (input) (LDA,M) if SIDE = 'L' (LDA,N) if SIDE = 'R' The vectors which define the elementary reflectors, as returned by CHETRD.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M) if SIDE = 'L'; LDA >= max(1,N) if SIDE = 'R'.

TAU (input)
(M-1) if SIDE = 'L' (N-1) if SIDE = 'R' TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHETRD.

C (input/output)
On entry, the M-by-N matrix C. On exit, C is overwritten by Q*C or Q**H*C or C*Q**H or C*Q.

LDC (input)
The leading dimension of the array C. LDC >= max(1,M).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. If SIDE = 'L', LWORK >= max(1,N); if SIDE = 'R', LWORK >= max(1,M). For optimum performance LWORK >= N*NB if SIDE = 'L', and LWORK >=M*NB if SIDE = 'R', where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

void cupgtr_64(char uplo, long n, complex *ap, complex *tau,
          complex *q, long ldq, long *info);
```

PURPOSE

cupgtr generates a complex unitary matrix Q which is defined as the product of n-1 elementary reflectors H(i) of order n, as returned by CHPTRD using packed storage:
if UPLO = 'U', Q = H(n-1) . . . H(2) H(1),

if UPLO = 'L', Q = H(1) H(2) . . . H(n-1).

ARGUMENTS

UPLO (input)
= 'U': Upper triangular packed storage used in previous call to CHPTRD; = 'L': Lower triangular packed storage used in previous call to CHPTRD.

N (input) The order of the matrix Q. N >= 0.

AP (input)
The vectors which define the elementary reflectors, as returned by CHPTRD.

TAU (input)
TAU(i) must contain the scalar factor of the elementary reflector H(i), as returned by CHPTRD.

Q (output)
The N-by-N unitary matrix Q.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N).

WORK (workspace)
dimension(N-1)

INFO (output)

```

DESCRIPTION

```
         C <- alpha op(A) B + beta C
where ALPHA and BETA are scalar, C and B are  matrices,
A is a matrix represented in variable block sparse row  format
and op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if the matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
```

```
                  DESCRA(2) upper/lower triangular indicator
                    1 : lower
                    2 : upper
                  DESCRA(3) main diagonal type
                    0 : non-unit
                    1 : unit
                  DESCRA(4) Array base  (NOT IMPLEMENTED)
                    0 : C/C++ compatible
                    1 : Fortran compatible
                  DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                    0 : unknown
                    1 : no repeated indices

VAL()             scalar array of length NNZ consisting of the block entries
                  of A where each block entry is a dense rectangular matrix
                  stored column by column.
                  NNZ is the total number of point entries in all nonzero
                  block  entries of a matrix A.
INDX()            integer array of length BNNZ+1 where BNNZ is the number of
                  block entries of a matrix A such that the I-th element of
                  INDX[] points to the location in VAL of the (1,1) element
                  of the I-th block entry.

BINDX()           integer array of length BNNZ consisting of the block
                  column indices of the block entries of A where BNNZ is
                  the number block entries of a matrix A.

RPNTR()           integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1
                  is the row index of the first point row in the I-th block
                  row.
                  RPNTR(MB+1) is set to M+RPNTR(1) where M is the number of
                  rows in matrix A.
                  Thus, the number of point rows in the I-th block row is
                  RPNTR(I+1)-RPNTR(I).

CPNTR()           integer array of length KB+1 such that CPNTR(J)-CPNTR(1)+1
                  is the column index of the first point column in the J-th
                  block column. CPNTR(KB+1) is set to K+CPNTR(1) where K is
                  the number of columns in matrix A.
                  Thus, the number of point columns in the J-th block column
                  is CPNTR(J+1)-CPNTR(J).

BPNTRB()          integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1
                  points to location in BINDX of the first block entry of
                  the I-th block row of A.

BPNTRE()          integer array of length MB such that BPNTRE(I)-BPNTRB(1)
                  points to location in BINDX of the last block entry of
                  the I-th block row of A.
```

B()   rectangular array with first dimension LDB.

LDB   leading dimension of B

BETA   Scalar parameter

C()   rectangular array with first dimension LDC.

LDC   leading dimension of C

WORK()   scratch array of length LWORK. WORK is not referenced in the current version.

LWORK   length of WORK array. LWORK is not referenced in the current version.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. For a general matrix (*DESCRA*(1)=0), array CPNTR can be different from RPNTR. For all other matrix types, RPNTR must equal CPNTR and a single array can be passed for both arguments.

2. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row format the following calling sequence should be used

```
  SUBROUTINE SVBRMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *           VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

 COMPLEX, DIMENSION(:) :: VAL, DV
 COMPLEX, DIMENSION(:, :) ::  B, C
```

```
 SUBROUTINE VBRSM_64(TRANSA, MB, [N], UNITD, DV, ALPHA, DESCRA,
*           VAL, INDX, BINDX, RPNTR, CPNTR, BPNTRB, BPNTRE,
*           B, [LDB], BETA, C,[LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, MB, UNITD
 INTEGER*8, DIMENSION(:) ::  DESCRA, INDX, BINDX
 INTEGER*8, DIMENSION(:) ::  RPNTR, CPNTR, BPNTRB, BPNTRE
 COMPLEX    ALPHA, BETA
 COMPLEX, DIMENSION(:) :: VAL, DV
 COMPLEX, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C
where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in variable block sparse row
format and  op( A )  is one  of

 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array containing the block entries of the block
              diagonal matrix D.  The size of the J-th block is
              RPNTR(J+1)-RPNTR(J) and each block contains matrix
              entries stored column-major.  The total length of
              array DV is given by the formula:

              sum over J from 1 to MB:
```

```
                  ((RPNTR(J+1)-RPNTR(J))*(RPNTR(J+1)-RPNTR(J)))

ALPHA             Scalar parameter

DESCRA()          Descriptor argument.  Five element integer array
                  DESCRA(1) matrix structure
                    0 : general
                    1 : symmetric (A=A')
                    2 : Hermitian (A= CONJG(A'))
                    3 : Triangular
                    4 : Skew(Anti)-Symmetric (A=-A')
                    5 : Diagonal
                    6 : Skew-Hermitian (A= -CONJG(A'))
                  Note: For the routine, DESCRA(1)=3 is only supported.
                  DESCRA(2) upper/lower triangular indicator
                    1 : lower
                    2 : upper
                  DESCRA(3) main diagonal type
                    0 : non-identity blocks on the main diagonal
                    1 : identity diagonal block
                    2 : diagonal blocks are dense matrices
                  DESCRA(4) Array base  (NOT IMPLEMENTED)
                    0 : C/C++ compatible
                    1 : Fortran compatible
                  DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                    0 : unknown
                    1 : no repeated indices

VAL()             scalar array of length NNZ consisting of the block entries
                  of A where each block entry is a dense rectangular matrix
                  stored column by column.
                  NNZ is the total number of point entries in all nonzero
                  block  entries of a matrix A.

INDX()            integer array of length BNNZ+1 where BNNZ is the number
                  block entries of a matrix A such that the I-th element of
                  INDX[] points to the location in VAL of the (1,1) element
                  of the I-th block entry.

BINDX()           integer array of length BNNZ consisting of the block
                  column indices of the block entries of A where BNNZ is
                  the number block entries of a matrix A.   Block column
                  indices MUST be sorted in increasing order for each block
                  row.

RPNTR()           integer array of length MB+1 such that RPNTR(I)-RPNTR(1)+1
                  is the row index of the first point row in the I-th block
                  row.
                  RPNTR(MB+1) is set to M+RPNTR(1) where M is the number
                  of rows  in square triangular matrix A.
```

Thus, the number of point rows in the I-th block row is RPNTR(I+1)-RPNTR(I).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

CPNTR() integer array of length MB+1 such that CPNTR(J)-CPNTR(1)+1 is the column index of the first point column in the J-th block column. CPNTR(MB+1) is set to M+CPNTR(1). Thus, the number of point columns in the J-th block column is CPNTR(J+1)-CPNTR(J).

NOTE: For the current version CPNTR must equal RPNTR and a single array can be passed for both arguments

BPNTRB() integer array of length MB such that BPNTRB(I)-BPNTRB(1)+1 points to location in BINDX of the first block entry of the I-th block row of A.

BPNTRE() integer array of length MB such that BPNTRE(I)-BPNTRB(1) points to location in BINDX of the last block entry of the I-th block row of A.

B() rectangular array with first dimension LDB.

LDB leading dimension of B

BETA Scalar parameter

C() rectangular array with first dimension LDC.

LDC leading dimension of C

WORK() scratch array of length LWORK. On exit, if LWORK= -1, WORK(1) returns the optimum size of LWORK.

LWORK length of WORK array. LWORK should be at least M = RPNTR(MB+1)-RPNTR(1).

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued

by XERBLA.

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the VBR representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case. *DESCRA*(2) indicates which triangle will be used.

6. It is known that there exists another representation of the variable block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of six array instead of the seven used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the array BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of variable block sparse row

format the following calling sequence should be used

```
  SUBROUTINE CVBRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, BINDX, RPNTR, CPNTR, IA, IA(2),
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

NAME

```
cvmul - compute the scaled product of complex vectors
```

SYNOPSIS

```
SUBROUTINE CVMUL(N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)

COMPLEX ALPHA, BETA
COMPLEX X(*), Y(*), Z(*)
INTEGER N, INCX, INCY, INCZ

SUBROUTINE CVMUL_64(N, ALPHA, X, INCX, Y, INCY, BETA, Z, INCZ)

COMPLEX ALPHA, BETA
COMPLEX X(*), Y(*), Z(*)
INTEGER*8 N, INCX, INCY, INCZ
```

F95 INTERFACE

```
SUBROUTINE VMUL([N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])

COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y, Z
INTEGER :: N, INCX, INCY, INCZ

SUBROUTINE VMUL_64([N], ALPHA, X, [INCX], Y, [INCY], BETA, Z, [INCZ])

COMPLEX :: ALPHA, BETA
COMPLEX, DIMENSION(:) :: X, Y, Z
INTEGER(8) :: N, INCX, INCY, INCZ
```

C INTERFACE

```
#include <sunperf.h>
```

```
void cvmul(int n, complex *alpha, complex *x, int incx, com-
          plex  *y, int incy, complex *beta, complex *z, int
          incz);

void cvmul_64(long n, complex *alpha, complex *x, long incx,
          complex  *y, long incy, complex *beta, complex *z,
          long incz);
```

PURPOSE

```
cvmul computes the scaled product of complex vectors:
  z(i) = ALPHA * x(i) * y(i) + BETA * z(i)
for 1 <= i <= N.
```

ARGUMENTS

```
N (input)
          Length of the vectors.  N >= 0.   Returns  immedi-
          ately if N = 0.

ALPHA (input)
          Scale factor on the multiplicand vectors.

X (input)  dimension(*)
          Multiplicand vector.

INCX (input)
          Stride between elements of the multiplicand vector
          X.  INCX > 0.

Y (input)  dimension(*)
          Multiplicand vector.

INCY (input)
          Stride between elements of the multiplicand vector
          Y.  INCY > 0.

BETA (input)
          Scale factor on the product vector.

Z (input/output)
           dimension(*)
          Product vector.  On exit, z(i) = ALPHA  *  x(i)  *
          y(i) + BETA * z(i).

INCZ (input)
          Stride between elements of Z.  INCZ > 0.
```

Contents

NAME

```
dasum - Return the sum of the absolute values of a vector x.
```

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DASUM(N, X, INCX)

INTEGER N, INCX
DOUBLE PRECISION X(*)

DOUBLE PRECISION FUNCTION DASUM_64(N, X, INCX)

INTEGER*8 N, INCX
DOUBLE PRECISION X(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION ASUM([N], X, [INCX])

INTEGER :: N, INCX
REAL(8), DIMENSION(:) :: X

REAL(8) FUNCTION ASUM_64([N], X, [INCX])

INTEGER(8) :: N, INCX
REAL(8), DIMENSION(:) :: X
```

C INTERFACE

```
#include <sunperf.h>

double dasum(int n, double *x, int incx);

double dasum_64(long n, double *x, long incx);
```

PURPOSE

dasum Return the sum of the absolute values of x where x is an n-vector.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Contents

NAME

```
daxpy - compute y := alpha * x + y
```

SYNOPSIS

```
SUBROUTINE DAXPY(N, ALPHA, X, INCX, Y, INCY)

INTEGER N, INCX, INCY
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*)

SUBROUTINE DAXPY_64(N, ALPHA, X, INCX, Y, INCY)

INTEGER*8 N, INCX, INCY
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE AXPY([N], ALPHA, X, [INCX], Y, [INCY])

INTEGER :: N, INCX, INCY
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y

SUBROUTINE AXPY_64([N], ALPHA, X, [INCX], Y, [INCY])

INTEGER(8) :: N, INCX, INCY
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>
```

```
void daxpy(int n, double alpha, double *x, int incx,  double
          *y, int incy);

void daxpy_64(long n, double alpha, double  *x,  long  incx,
          double *y, long incy);
```

PURPOSE

daxpy compute y := alpha * x + y where alpha is a scalar and x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input/output)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
daxpyi - Compute y := alpha * x + y
```

SYNOPSIS

```
 SUBROUTINE DAXPYI(NZ, A, X, INDX, Y)

 DOUBLE PRECISION A
 DOUBLE PRECISION X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE DAXPYI_64(NZ, A, X, INDX, Y)

 DOUBLE PRECISION A
 DOUBLE PRECISION X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE AXPYI([NZ], [A], X, INDX, Y)

 REAL(8) :: A
 REAL(8), DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE AXPYI_64([NZ], [A], X, INDX, Y)

 REAL(8) :: A
 REAL(8), DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
DAXPYI Compute y := alpha * x + y where alpha is a scalar, x
is a sparse vector, and y is a vector in full storage form

 do i = 1, n
   y(indx(i)) = alpha * x(i) + y(indx(i))
 enddo
```

ARGUMENTS

```
NZ (input) - INTEGER
        Number of elements in the compressed form.
        Unchanged on exit.

A (input)
        On entry, A(LPHA) specifies the scaling value.
        Unchanged on exit.  A is defaulted to 1.0D0 for F95
        INTERFACE.
X (input)
        Vector containing the values of the compressed form.
        Unchanged on exit.

INDX (input) - INTEGER
        Vector containing the indices of the compressed
        form.  It is assumed that the elements in INDX are
        distinct and greater than zero.  Unchanged on exit.

Y (output)
        Vector on input which contains the vector Y in full
        storage form.  On exit, only the elements
        corresponding to the indices in INDX have been
        modified.
```

                  0 : unknown
                  1 : no repeated indices

 VAL()          two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
                consisting of the NBDIAG nonzero block diagonal in
                any order. Each dense block is stored in standard
                column-major form.

 BLDA           leading block dimension of VAL().

 IBDIAG()       integer array of length NBDIAG consisting of the
                corresponding diagonal offsets of the non-zero
                block diagonals of A in VAL.  Lower triangular
                block diagonals have negative offsets, the main
                block diagonal has offset 0, and upper triangular
                block diagonals have positive offset.

 NBDIAG         the number of non-zero block diagonals in A.
 LB             dimension of dense blocks composing A.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block diagonal format
and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)

DV()          Array of length MB*LB*LB containing the elements of
              the diagonal blocks of the matrix D.  The size of each
              square block is LB-by-LB and each block
              is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))
               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-identity blocks on the main diagonal
                 1 : identity diagonal blocks
                 2 : diagonal blocks are dense matrices
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          Two-dimensional LB*LB*BLDA-by-NBDIAG scalar array
               consisting of the NBDIAG non-zero block diagonal.
               Each dense block is stored in standard column-major form.

BLDA           Leading block dimension of VAL().  Should be greater
               than or equal to MB.

IBDIAG()       integer array of length NBDIAG consisting of the
               corresponding diagonal offsets of the non-zero block
               diagonals of A in VAL.  Lower triangular block diagonals
               have negative offsets, the main block diagonal has offset
               0, and upper triangular block diagonals have positive offset.
               Elements of IBDIAG  MUST be sorted in  increasing order.

NBDIAG         The number of non-zero block diagonals in A.

LB             Dimension of dense blocks composing A.

B()            Rectangular array with first dimension LDB.

LDB            Leading dimension of B.

BETA           Scalar parameter.

C()            Rectangular array with first dimension LDC.

LDC            Leading dimension of C.
```

```
WORK()        scratch array of length LWORK.
              On exit, if LWORK= -1, WORK(1) returns the optimum  size
              of LWORK.

LWORK        length of WORK array. LWORK should be at least
             MB*LB.

             For good performance, LWORK should generally be larger.
             For optimum performance on multiple processors, LWORK
             >=MB*LB*N_CPUS where N_CPUS is the maximum number of
             processors available to the program.

             If LWORK=0, the routine is to allocate workspace needed.

             If LWORK = -1, then a workspace query is assumed; the
             routine only calculates the optimum size of the WORK array,
             returns this value as the first entry of the WORK array,
             and no error message related to LWORK is issued by XERBLA.
```

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BDI representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block

number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

          *e,  double  *u,  int  ldu,  double *vt, int ldvt,
          double *q, int *iq, int *info);

void dbdsdc_64(char uplo, char compq,  long  n,  double  *d,
          double  *e,  double *u, long ldu, double *vt, long
          ldvt, double *q, long *iq, long *info);
```

PURPOSE

dbdsdc computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = U * S * VT, using a divide and conquer method, where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and U and VT are orthogonal matrices of left and right singular vectors, respectively. SBDSDC can be used to compute all singular values, and optionally, singular vectors or singular vectors in compact form.

This code makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none. See SLASD3 for details.

The code currently call SLASDQ if singular values only are desired. However, it can be slightly modified to compute singular values using the divide and conquer method.

ARGUMENTS

```
UPLO (input)
          = 'U':  B is upper bidiagonal.
          = 'L':  B is lower bidiagonal.

COMPQ (input)
          Specifies whether singular vectors are to be  com-
          puted as follows:
          = 'N':  Compute singular values only;
          = 'P':  Compute singular values and compute singu-
          lar  vectors  in  compact  form;  =  'I':  Compute
          singular values and singular vectors.

N (input) The order of the matrix B.  N >= 0.

D (input/output)
          On entry, the n diagonal elements of the  bidiago-
          nal  matrix  B.   On exit, if INFO=0, the singular
          values of B.

E (input/output)
          On entry, the elements of E contain the  offdiago-
          nal elements of the bidiagonal matrix whose SVD is
          desired.  On exit, E has been destroyed.

U (output)
          If  COMPQ = 'I', then:  On exit, if INFO  =  0,  U
          contains the left singular vectors of the bidiago-
          nal matrix.  For other values of COMPQ, U  is  not
          referenced.

LDU (input)
          The leading dimension of the array U.  LDU  >=  1.
          If  singular vectors are desired, then LDU >= max(
          1, N ).

VT (output)
          If  COMPQ = 'I', then:  On exit, if INFO = 0,  VT'
          contains the right singular vectors of the bidiag-
          onal matrix.  For other values of COMPQ, VT is not
          referenced.

LDVT (input)
          The leading dimension of the array VT.  LDVT >= 1.
          If singular vectors are desired, then LDVT >= max(
          1, N ).

Q (input) If  COMPQ = 'P', then:  On exit, if INFO  =  0,  Q
          and IQ contain the left and right singular vectors
          in a compact form,  requiring  O(N  log  N)  space
          instead  of 2*N**2.  In particular, Q contains all
```

the REAL data in LDQ >= N*(11 + 2*SMLSIZ + 8*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, Q is not referenced.

IQ (output)
If COMPQ = 'P', then: On exit, if INFO = 0, Q and IQ contain the left and right singular vectors in a compact form, requiring O(N log N) space instead of 2*N**2. In particular, IQ contains all INTEGER data in LDIQ >= N*(3 + 3*INT(LOG_2(N/(SMLSIZ+1)))) words of memory, where SMLSIZ is returned by ILAENV and is equal to the maximum size of the subproblems at the bottom of the computation tree (usually about 25). For other values of COMPQ, IQ is not referenced.

WORK (workspace)
If COMPQ = 'N' then LWORK >= (2 * N). If COMPQ = 'P' then LWORK >= (6 * N). If COMPQ = 'I' then LWORK >= (3 * N**2 + 4 * N).

IWORK (workspace)
dimension(8*N)

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: The algorithm failed to compute an singular value. The update process of divide and conquer failed.

          double *u, long ldu, double  *c,  long  ldc,  long
          *info);
```

PURPOSE

dbdsqr computes the singular value decomposition (SVD) of a real N-by-N (upper or lower) bidiagonal matrix B: B = Q * S * P' (P' denotes the transpose of P), where S is a diagonal matrix with non-negative diagonal elements (the singular values of B), and Q and P are orthogonal matrices.

The routine computes S, and optionally computes U * Q, P' * VT, or Q' * C, for given real input matrices U, VT, and C.

See "Computing Small Singular Values of Bidiagonal Matrices With Guaranteed High Relative Accuracy," by J. Demmel and W. Kahan, LAPACK Working Note #3 (or SIAM J. Sci. Statist. Comput. vol. 11, no. 5, pp. 873-912, Sept 1990) and "Accurate singular values and differential qd algorithms," by B. Parlett and V. Fernando, Technical Report CPAM-554, Mathematics Department, University of California at Berkeley, July 1992 for a detailed description of the algorithm.

ARGUMENTS

UPLO (input)
= 'U': B is upper bidiagonal;
= 'L': B is lower bidiagonal.

N (input) The order of the matrix B. N >= 0.

NCVT (input)

```
          The number of columns of the matrix VT. NCVT >= 0.

NRU (input)
          The number of rows of the matrix U. NRU >= 0.

NCC (input)
          The number of columns of the matrix C. NCC >= 0.

D (input/output)
          On entry, the n diagonal elements of the  bidiago-
          nal  matrix  B.   On exit, if INFO=0, the singular
          values of B in decreasing order.
E (input/output)
          On entry, the elements of E contain the  offdiago-
          nal elements of the bidiagonal matrix whose SVD is
          desired. On normal exit (INFO  =  0),  E  is  des-
          troyed.   If the algorithm does not converge (INFO
          > 0), D and E will contain the diagonal and super-
          diagonal  elements of a bidiagonal matrix orthogo-
          nally equivalent to the one given as  input.  E(N)
          is used for workspace.

VT (input/output)
          On entry, an N-by-NCVT matrix VT.  On exit, VT  is
          overwritten  by  P' * VT.  VT is not referenced if
          NCVT = 0.

LDVT (input)
          The leading dimension of the array  VT.   LDVT  >=
          max(1,N) if NCVT > 0; LDVT >= 1 if NCVT = 0.

U (input/output)
          On entry, an NRU-by-N matrix U.   On  exit,  U  is
          overwritten  by U * Q.  U is not referenced if NRU
          = 0.

LDU (input)
          The leading dimension of  the  array  U.   LDU  >=
          max(1,NRU).

C (input/output)
          On entry, an N-by-NCC matrix C.   On  exit,  C  is
          overwritten by Q' * C.  C is not referenced if NCC
          = 0.

LDC (input)
          The leading dimension of  the  array  C.   LDC  >=
          max(1,N) if NCC > 0; LDC >=1 if NCC = 0.

WORK (workspace)
```

dimension(4*N)

INFO (output)
= 0: successful exit
< 0: If INFO = -i, the i-th argument had an illegal value
> 0: the algorithm did not converge; D and E contain the elements of a bidiagonal matrix which is orthogonally similar to the input matrix B; if INFO = i, i elements of E have not converged to zero.

 DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block Ellpack format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
```

```
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length LB*LB*BLDA*MAXBNZ containing
                matrix entries, stored column-major within each dense
                block.

 BINDX()        two-dimensional integer BLDA-by-MAXBNZ array such
                BINDX(i,:) consists of the block column indices of the
                nonzero blocks in block row i, padded by the integer
                value i if the number of nonzero blocks is less than
                MAXBNZ.

 BLDA           leading dimension of BINDX(:,:).

 MAXBNZ         max number of nonzeros blocks per row.
 LB             row and column dimension of the dense blocks composing
                VAL.

 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block Ellpack format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))
                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-identity blocks on the main diagonal
                  1 : identity diagonal blocks
                  2 : diagonal blocks are dense matrices
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           scalar array of length LB*LB*BLDA*MAXBNZ containing
                matrix entries, stored column-major within each dense
                block.

BINDX()         two-dimensional integer BLDA-by-MAXBNZ array such
                BINDX(i,:) consists of the block column indices of the
                nonzero blocks in block row i, padded by the integer
                value i if the number of nonzero blocks is less than
                MAXBNZ.  The block column indices MUST be sorted
                in increasing order for each block row.

BLDA            leading dimension of BINDX(:,:).

MAXBNZ          max number of nonzeros blocks per row.

LB              row and column dimension of the dense blocks composing A.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.
                On exit, if LWORK= -1, WORK(1) returns the minimum
```

size of LWORK.

LWORK length of WORK array. LWORK should be at least MB*LB.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=MB*LB*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BEL representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

 INTEGER*8, DIMENSION(:) ::    DESCRA, BINDX, BPNTRB, BPNTRE
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) :: VAL
 DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in block sparse column format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

KB            Number of block columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
```

```
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

  VAL()         scalar array of length LB*LB*BNNZ consisting of
                the block entries stored column-major within each
                dense block.

  BINDX()       integer array of length BNNZ consisting of the
                block row indices of the block entries of A.

  BPNTRB()      integer array of length KB such that
                BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                of the first block entry of the J-th block column
                of A.
  BPNTRE()      integer array of length KB such that
                BPNTRE(J)-BPNTRB(1) points to location in BINDX
                of the last block entry of the J-th block column
                of A.

  LB            dimension of dense blocks composing A.

  B()           rectangular array with first dimension LDB.

  LDB           leading dimension of B

  BETA          Scalar parameter

  C()           rectangular array with first dimension LDC.

  LDC           leading dimension of C

  WORK()        scratch array of length LWORK. WORK is not
                referenced in the current version.

  LWORK         length of WORK array. LWORK is not referenced
                in the current version.

NOTES/BUGS

It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
  CALL SBSCMM( TRANSA, MB, N, KB, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

Contents

```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block sparse column format
and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
```

```
                DESCRA(1) matrix structure
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-identity blocks on the main diagonal
                  1 : identity diagonal blocks
                  2 : diagonal blocks are dense matrices
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           scalar array of length LB*LB*BNNZ consisting of the block
                entries stored column-major within each dense block.

BINDX()         integer array of length BNNZ consisting of the
                block row indices of the block entries of A.
                The block row indices MUST be sorted
                in increasing order for each block column.

BPNTRB()        integer array of length MB such that
                BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
                of the first block entry of the J-th block column of A.

BPNTRE()        integer array of length MB such that
                BPNTRE(J)-BPNTRB(1) points to location in BINDX
                of the last block entry of the J-th block column of A.

LB              dimension of dense blocks composing A.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.
```

```
LDC           leading dimension of C

WORK()        scratch array of length LWORK.
              On exit, if LWORK= -1, WORK(1) returns the optimum
              size of LWORK.

LWORK         length of WORK array. LWORK should be at least
              MB*LB.

              For good performance, LWORK should generally be larger.
              For optimum performance on multiple processors, LWORK
              >=MB*LB*N_CPUS where N_CPUS is the maximum number of
              processors available to the program.

              If LWORK=0, the routine is to allocate workspace needed.

              If LWORK = -1, then a workspace query is assumed; the
              routine only calculates the optimum size of the WORK
              array, returns this value as the first entry of the WORK
              array, and no error message related to LWORK is issued
              by XERBLA.
```

http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BSC representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is

used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

6. It is known that there exists another representation of the block sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block column in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse column format the following calling sequence should be used

```
  CALL SBSCSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a block  diagonal matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in block sparse row format
format and  op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

MB            Number of block rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row block scaling)
                3 : Scale on right (column block scaling)

DV()          Array of the length MB*LB*LB consisting of the block
              entries of block diagonal matrix D where each
              block is stored in standard column-major form.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
```

```
               DESCRA(1) matrix structure
                 0 : general
                 1 : symmetric (A=A')
                 2 : Hermitian (A= CONJG(A'))
                 3 : Triangular
                 4 : Skew(Anti)-Symmetric (A=-A')
                 5 : Diagonal
                 6 : Skew-Hermitian (A= -CONJG(A'))

               Note: For the routine, DESCRA(1)=3 is only supported.

               DESCRA(2) upper/lower triangular indicator
                 1 : lower
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-identity blocks on the main diagonal
                 1 : identity diagonal blocks
                 2 : diagonal blocks are dense matrices
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices
VAL()          scalar array of length LB*LB*BNNZ consisting of the block
               entries stored column-major within each dense block.

BINDX()        integer array of length BNNZ consisting of the
               block column indices of the block entries of A.
               The block column indices MUST be sorted
               in increasing order for each block row.

BPNTRB()       integer array of length MB such that
               BPNTRB(J)-BPNTRB(1)+1 points to location in BINDX
               of the first block entry of the J-th block row of A.

BPNTRE()       integer array of length MB such that
               BPNTRE(J)-BPNTRB(1) points to location in BINDX
               of the last block entry of the J-th block row of A.

LB             dimension of dense blocks composing A.

B()            rectangular array with first dimension LDB.

LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.
```

```
 LDC           leading dimension of C

 WORK()        scratch array of length LWORK.
               On exit, if LWORK= -1, WORK(1) returns the optimum size
               of LWORK.

 LWORK         length of WORK array. LWORK should be at least
               MB*LB.

               For good performance, LWORK should generally be larger.
               For optimum performance on multiple processors, LWORK
               >=MB*LB*N_CPUS where N_CPUS is the maximum number of
               processors available to the program.

               If LWORK=0, the routine is to allocate workspace needed.

               If LWORK = -1, then a workspace query is assumed; the
               routine only calculates the optimum size of the WORK
               array, returns this value as the first entry of the WORK
               array, and no error message related to LWORK is issued
               by XERBLA.
```

NIST FORTRAN Sparse Blas User's Guide available at:
http://math.nist.gov/mcsd/Staff/KRemington/fspblas/

"Document for the Basic Linear Algebra Subprograms (BLAS) Standard", University of Tennessee, Knoxville, Tennessee, 1996:

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If *DESCRA*(3)=0,the lower or upper triangular part of each diagonal block is used by the routine depending on *DESCRA*(2).

3. If *DESCRA*(3)=1, the unit diagonal blocks might or might not be referenced in the BSR representation of a sparse matrix. They are not used anyway.

4. If *DESCRA*(3)=2, diagonal blocks are considered as dense matrices and the LU factorization with partial pivoting is

used by the routine. *WORK*(1)=0 on return if the factorization for all diagonal blocks has been completed successfully, otherwise *WORK*(1) = -i where i is the block number for which the LU factorization could not be computed.

5. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. Howerver *DESCRA*(1) must be equal to 3 in this case.

6. It is known that there exists another representation of the block sparse row format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each block row in the arrays VAL and BINDX is used instead of two arrays BPNTRB and BPNTRE. To use the routine with this kind of block sparse row format the following calling sequence should be used

```
  CALL DBSRSM( TRANSA, MB, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, BINDX, IA, IA(2), LB,
 *           B, LDB, BETA, C, LDC, WORK, LWORK )
```

          nz,  long k, double *z, long ifz, long inc1z, long
          inc2z, double *work, long lwork);
```

PURPOSE

dcnvcor computes the convolution or correlation of real vectors.

ARGUMENTS

CNVCOR (input)
'V' or 'v' if convolution is desired, 'R' or 'r' if correlation is desired.

FOUR (input)
'T' or 't' if the Fourier transform method is to be used, 'D' or 'd' if the computation should be done directly from the definition. The Fourier transform method is generally faster, but it may introduce noticeable errors into certain results, notably when both the filter and data vectors consist entirely of integers or vectors where elements of either the filter vector or a given data vector differ significantly in magnitude from the 1-norm of the vector.

NX (input)
Length of the filter vector. NX >= 0. DCNVCOR will return immediately if NX = 0.

X (input)
Filter vector.

IFX (input)
Index of the first element of X. NX >= IFX >= 1.

INCX (input)
Stride between elements of the filter vector in X. INCX > 0.

NY (input)
Length of the input vectors. NY >= 0. DCNVCOR will return immediately if NY = 0.

NPRE (input)
The number of implicit zeros prepended to the Y vectors. NPRE >= 0.

M (input)
Number of input vectors. M >= 0. DCNVCOR will return immediately if M = 0.

Y (input)
Input vectors.

IFY (input)
Index of the first element of Y. NY >= IFY >= 1.

INC1Y (input)
Stride between elements of the input vectors in Y. INC1Y > 0.

INC2Y (input)
Stride between the input vectors in Y. INC2Y > 0.

NZ (input)
Length of the output vectors. NZ >= 0. DCNVCOR will return immediately if NZ = 0. See the Notes section below for information about how this argument interacts with NX and NY to control circular versus end-off shifting.

K (input)
Number of Z vectors. K >= 0. If K = 0 then DCNVCOR will return immediately. If K < M then only the first K input vectors will be processed. If K > M then M input vectors will be processed.

Z (output)
Result vectors.

IFZ (input)
Index of the first element of Z. NZ >= IFZ >= 1.

INC1Z (input)
Stride between elements of the output vectors in Z. INC1Z > 0.

INC2Z (input)
Stride between the output vectors in Z. INC2Z > 0.

WORK (input/output)
Scratch space. Before the first call to DCNVCOR with particular values of the integer arguments the first element of WORK must be set to zero. If WORK is written between calls to DCNVCOR or if DCNVCOR is called with different values of the integer arguments then the first element of WORK must again be set to zero before each call. If WORK has not been written and the same values of the integer arguments are used then the first element of WORK to zero. This can avoid certain initializations that store their results into WORK, and avoiding the initialization can make DCNVCOR run faster.

LWORK (input)
Length of WORK. LWORK >= 4*MAX(NX,NY,NZ)+15.

NOTES

If any vector overlaps a writable vector, either because of argument aliasing or ill-chosen values of the various INC arguments, the results are undefined and may vary from one run to the next.

The most common form of the computation, and the case that executes fastest, is applying a filter vector X to a series of vectors stored in the columns of Y with the result placed into the columns of Z. In that case, INCX = 1, INC1Y = 1, INC2Y >= NY, INC1Z = 1, INC2Z >= NZ. Another common form is applying a filter vector X to a series of vectors stored in the rows of Y and store the result in the row of Z, in which case INCX = 1, INC1Y >= NY, INC2Y = 1, INC1Z >= NZ, and INC2Z = 1.

```

PURPOSE

dcnvcor2 computes the convolution or correlation of real matrices.

ARGUMENTS

CNVCOR (input)
'V' or 'v' to compute convolution, 'R' or 'r' to compute correlation.

METHOD (input)
'T' or 't' if the Fourier transform method is to

```
          be  used,  'D' or 'd' to compute directly from the
          definition.

TRANSX (input)
          'N' or 'n' if X is the filter matrix, 'T'  or  't'
          if transpose(X) is the filter matrix.

SCRATCHX (input)
          'N' or 'n' if X must be preserved, 'S' or 's' if X
          can  be  used as scratch space.  The contents of X
          are undefined after returning from a call in which
          X is allowed to be used for scratch.

TRANSY (input)
          'N' or 'n' if Y is the input matrix, 'T' or 't' if
          transpose(Y) is the input matrix.
SCRATCHY (input)
          'N' or 'n' if Y must be preserved, 'S' or 's' if Y
          can  be  used as scratch space.  The contents of Y
          are undefined after returning from a call in which
          Y is allowed to be used for scratch.

MX (input)
          Number of rows in the filter matrix.  MX >= 0.

NX (input)
          Number of columns in the filter matrix.  NX >= 0.

X (input)  dimension(LDX,NX)
          On entry, the filter matrix.  Unchanged on exit if
          SCRATCHX  is  'N'  or  'n',  undefined  on exit if
          SCRATCHX is 'S' or 's'.

LDX (input)
          Leading dimension of the array that  contains  the
          filter matrix.

MY (input)
          Number of rows in the input matrix.  MY >= 0.

NY (input)
          Number of columns in the input matrix.  NY >= 0.

MPRE (input)
          Number of implicit zeros to prepend to each row of
          the input matrix.  MPRE >= 0.

NPRE (input)
          Number of implicit zeros to prepend to each column
          of the input matrix.  NPRE >= 0.
```

```
Y (input)  dimension(LDY,*)
          Input matrix.  Unchanged on exit  if  SCRATCHY  is
          'N'  or  'n', undefined on exit if SCRATCHY is 'S'
          or 's'.

LDY (input)
          Leading dimension of the array that  contains  the
          input matrix.

MZ (input)
          Number of rows in the output  matrix.   MZ  >=  0.
          DCNVCOR2 will return immediately if MZ = 0.

NZ (input)
          Number of columns in the output matrix.  NZ >=  0.
          DCNVCOR2 will return immediately if NZ = 0.

Z (output)
           dimension(LDZ,*)
          Result matrix.

LDZ (input)
          Leading dimension of the array that  contains  the
          result matrix.  LDZ >= MAX(1,MZ).

WORKIN (input/output)
          (input/scratch) dimension(LWORK)
          On entry for the first call to DCNVCOR2, WORKIN(1)
          must contain 0.0.  After the first call, WORKIN(1)
          must be set to 0.0 iff  WORKIN  has  been  altered
          since  the  last call to this subroutine or if the
          sizes of the arrays have changed.

LWORK (input)
          Length of the work vector.  If the FFT  is  to  be
          used  then for best performance LWORK should be at
          least 30 words longer than the  amount  of  memory
          needed to hold the trig tables.  If the FFT is not
          used, the value of LWORK is unimportant.

       DOUBLE PRECISION, DIMENSION(:) :: VAL
       DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
              C <- alpha op(A) B + beta C

      where ALPHA and BETA are scalar, C and B are dense matrices,
      A is a matrix represented in coordinate format and
      op( A )  is one  of
      op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                           ( ' indicates matrix transpose)
```

ARGUMENTS

```
      TRANSA        Indicates how to operate with the sparse matrix
                      0 : operate with matrix
                      1 : operate with transpose matrix
                      2 : operate with the conjugate transpose of matrix.
                          2 is equivalent to 1 if matrix is real.

      M             Number of rows in matrix A

      N             Number of columns in matrix C

      K             Number of columns in matrix A

      ALPHA         Scalar parameter

      DESCRA()      Descriptor argument.  Five element integer array
                    DESCRA(1) matrix structure
                      0 : general
                      1 : symmetric (A=A')
                      2 : Hermitian (A= CONJG(A'))
                      3 : Triangular
                      4 : Skew(Anti)-Symmetric (A=-A')
                      5 : Diagonal
                      6 : Skew-Hermitian (A= -CONJG(A'))
                    DESCRA(2) upper/lower triangular indicator
                      1 : lower
                      2 : upper
```

```
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          scalar array of length NNZ consisting of the
                non-zero entries of A, in any order.

 INDX()         integer array of length NNZ consisting of the
                corresponding row indices of the entries of A.

 JNDX()         integer array of length NNZ consisting of the
                corresponding column indices of the entries of A.

 NNZ            number of non-zero elements in A.
 B()            rectangular array with first dimension LDB.

 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

NAME

```
dcopy - Copy x to y
```

SYNOPSIS

```
SUBROUTINE DCOPY(N, X, INCX, Y, INCY)

INTEGER N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)

SUBROUTINE DCOPY_64(N, X, INCX, Y, INCY)

INTEGER*8 N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE COPY([N], X, [INCX], Y, [INCY])

INTEGER :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y

SUBROUTINE COPY_64([N], X, [INCX], Y, [INCY])

INTEGER(8) :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>

void dcopy(int n, double *x, int incx, double *y, int incy);

void dcopy_64(long n, double *x, long incx, double *y,  long
          incy);
```

PURPOSE

dcopy Copy x to y where x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. N must be at least one for the subroutine to have any visible effect. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (output)
(1 + (m - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the vector x.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
dcosqb - synthesize a Fourier sequence from its  representa-
tion in terms of a cosine series with odd wave numbers.  The
COSQ operations are unnormalized inverses of themselves,  so
a  call  to  COSQF followed by a call to COSQB will multiply
the input sequence by 4 * N.
```

SYNOPSIS

```
SUBROUTINE DCOSQB(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DCOSQB_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQB([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE COSQB_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcosqb(int n, double *x, double *wsave);
```

```
void dcosqb_64(long n, double *x, double *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence   to   be   transformed.   On  exit,  the
          quarter-wave cosine synthesis of the input.
WSAVE (input)
          On entry, an array with dimension of at least (3 *
          N + 15) that has been initialized by DCOSQI.
```

Contents

NAME

```
dcosqf - compute the Fourier coefficients in a cosine series
representation  with only odd wave numbers.  The COSQ opera-
tions are unnormalized inverses of themselves, so a call  to
COSQF  followed  by  a call to COSQB will multiply the input
sequence by 4 * N.
```

SYNOPSIS

```
SUBROUTINE DCOSQF(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DCOSQF_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQF([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE COSQF_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcosqf(int n, double *x, double *wsave);
```

```
void dcosqf_64(long n, double *x, double *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence   to   be   transformed.   On  exit,  the
          quarter-wave cosine transform of the input.
WSAVE (input)
          On entry, an array with dimension of at least   (3
          * N + 15) that has been initialized by DCOSQI.
```

Contents

NAME

```
dcosqi - initialize the array WSAVE, which is used  in  both
COSQF and COSQB.
```

SYNOPSIS

```
SUBROUTINE DCOSQI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE DCOSQI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSQI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE COSQI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcosqi(int n, double *wsave);

void dcosqi_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is a product of small primes.

WSAVE (input)
On entry, an array of dimension (3 * N + 15) or greater. DCOSQI needs to be called only once to initialize WSAVE before calling DCOSQF and/or DCOSQB if N and WSAVE remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

Contents

NAME

dcost - compute the discrete Fourier cosine transform of an even sequence. The COST transforms are unnormalized inverses of themselves, so a call of COST followed by another call of COST will multiply the input sequence by 2 * (N-1).

SYNOPSIS

```
SUBROUTINE DCOST(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DCOST_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COST([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE COST_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcost(int n, double *x, double *wsave);
```

```
void dcost_64(long n, double *x, double *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines  are  most  efficient  when N - 1 is a
          product of small primes.  N >= 2.

X (input/output)
          On entry, an array  of  length  N  containing  the
          sequence  to  be transformed.  On exit, the cosine
          transform of the input.
WSAVE (input)
          On entry, an array with dimension of at least   (3
          * N + 15), initialized by DCOSTI.
```

Contents

NAME

```
dcosti - initialize the array WSAVE, which is used in COST.
```

SYNOPSIS

```
SUBROUTINE DCOSTI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE DCOSTI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE COSTI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE COSTI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dcosti(int n, double *wsave);

void dcosti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N - 1 is a product of small primes. N >= 2.

WSAVE (input)
On entry, an array of dimension (3 * N + 15) or greater. DCOSTI is called once to initialize WSAVE before calling DCOST and need not be called again between calls to DCOST if N and WSAVE remain unchanged. Thus, subsequent transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

*   PNTRB, PNTRE, B, [LDB], BETA, C, [LDC], [WORK], [LWORK] )
 INTEGER*8 TRANSA, M, K
 INTEGER*8, DIMENSION(:) ::   DESCRA, INDX, PNTRB, PNTRE
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) :: VAL
 DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in compressed sparse column format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
```

```
                 2 : upper
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

 VAL()         scalar array of length NNZ consisting of nonzero
               entries of A.

 INDX()        integer array of length NNZ consisting of the row
               indices of nonzero entries of A.

 PNTRB()       integer array of length K such that PNTRB(J)-PNTRB(1)+1
               points to location in VAL of the first nonzero element
               in column J.
 PNTRE()       integer array of length K such that PNTRE(J)-PNTRB(1)
               points to location in VAL of the last nonzero element
               in column J.

 B()           rectangular array with first dimension LDB.

 LDB           leading dimension of B

 BETA          Scalar parameter

 C()           rectangular array with first dimension LDC.

 LDC           leading dimension of C

 WORK()        scratch array of length LWORK. WORK is not
               referenced in the current version.

 LWORK         length of WORK array. LWORK is not referenced
               in the current version.

NOTES/BUGS

It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
  SUBROUTINE SCSCMM( TRANSA, M, N, K, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,
 *           C, LDC, WORK, LWORK )
```

Contents

NAME

```
dcscsm - compressed sparse column format triangular solve
```

SYNOPSIS

```
 SUBROUTINE DCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
*           VAL, INDX, PNTRB, PNTRE,
*           B, LDB, BETA, C, LDC, WORK, LWORK)
 INTEGER    TRANSA, M, N, UNITD, DESCRA(5),
*           LDB, LDC, LWORK
 INTEGER    INDX(NNZ), PNTRB(M), PNTRE(M)
 DOUBLE PRECISION ALPHA, BETA

```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in compressed sparse column
format and op( A )  is one  of
op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic column scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, DESCRA(1)=3 is only supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           scalar array of length NNZ consisting of nonzero entries
                of A.

INDX()          integer array of length NNZ consisting of the row indices
                of nonzero entries of A. (Row indices MUST be sorted in
                increasing order for each column).

PNTRB()         integer array of length M such that PNTRB(J)-PNTRB(1)+1
                points to location in VAL of the first nonzero element
                in column J.

PNTRE()         integer array of length M such that PNTRE(J)-PNTRB(1)
                points to location in VAL of the last nonzero element
                in column J.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.

                On exit,  if LWORK = -1, WORK(1) returns the optimum  LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the columns of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the columns have been scaled. UNITD=3 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the column number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the CSC representation

of a sparse matrix. They are not used anyway in these cases.
But if UNITD=4, the unit diagonal elements MUST be
referenced in the CSC representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

5. It is known that there exists another representation of the compressed sparse column format (see for example Y.Saad, "Iterative Methods for Sparse Linear Systems", WPS, 1996). Its data structure consists of three array instead of the four used in the current implementation. The main difference is that only one array, IA, containing the pointers to the beginning of each column in the arrays VAL and INDX is used instead of two arrays PNTRB and PNTRE. To use the routine with this kind of sparse column format the following calling sequence should be used

```
  SUBROUTINE SCSCSM( TRANSA, M, N, UNITD, DV, ALPHA, DESCRA,
 *           VAL, INDX, IA, IA(2), B, LDB, BETA,
 *           C, LDC, WORK, LWORK )
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in compressed sparse row format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
```

```
               DESCRA(3) main diagonal type
                 0 : non-unit
                 1 : unit
               DESCRA(4) Array base  (NOT IMPLEMENTED)
                 0 : C/C++ compatible
                 1 : Fortran compatible
               DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                 0 : unknown
                 1 : no repeated indices

 VAL()         scalar array of length NNZ consisting of nonzero
               entries of A.

 INDX()        integer array of length NNZ consisting of the
               column indices of nonzero entries of A.

 PNTRB()       integer array of length M such that PNTRB(J)-PNTRB(1)+1
               points to location in VAL of the first nonzero element
               in row J.
 PNTRE()       integer array of length M such that PNTRE(J)-PNTRB(1)
               points to location in VAL of the last nonzero element
               in row J.

 B()           rectangular array with first dimension LDB.

 LDB           leading dimension of B

 BETA          Scalar parameter

 C()           rectangular array with first dimension LDC.

 LDC           leading dimension of C

 WORK()        scratch array of length LWORK. WORK is not
               referenced in the current version.

 LWORK         length of WORK array. LWORK is not referenced
               in the current version.

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in compressed sparse row
format and op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of
              the scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, only DESCRA(1)=3 is supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           scalar array of length NNZ consisting of nonzero entries
                of A.

INDX()          integer array of length NNZ consisting of the column
                indices of nonzero entries of A (column indices MUST be
                sorted in increasing order for each row)

PNTRB()         integer array of length M such that PNTRB(J)-PNTRB(1)+1
                points to location in VAL of the first nonzero element
                in row J.

PNTRE()         integer array of length M such that PNTRE(J)-PNTRB(1)
                points to location in VAL of the last nonzero element
                in row J.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.

                On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
                0 : non-unit
                1 : unit
              DESCRA(4) Array base  (NOT IMPLEMENTED)
                0 : C/C++ compatible
                1 : Fortran compatible
              DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                0 : unknown
                1 : no repeated indices
```

```
VAL()          two-dimensional LDA-by-NDIAG array such that VAL(:,I)
               consists of non-zero elements on diagonal IDIAG(I)
               of A.  Diagonals in the lower triangular part of A
               are padded from the top, and those in the upper
               triangular part are padded from the bottom.

LDA            leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG()        integer array of length NDIAG consisting of the
               corresponding diagonal offsets of the non-zero
               diagonals of A in VAL.  Lower triangular diagonals
               have negative offsets, the main diagonal has offset
               0, and upper triangular diagonals have positive offset.

NDIAG          number of non-zero diagonals in A.

B()            rectangular array with first dimension LDB.
LDB            leading dimension of B

BETA           Scalar parameter

C()            rectangular array with first dimension LDC.

LDC            leading dimension of C

WORK()         scratch array of length LWORK. WORK is not
               referenced in the current version.

LWORK          length of WORK array. LWORK is not referenced
               in the current version.

 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) ::  DV
 DOUBLE PRECISION, DIMENSION(:, :) ::  VAL, B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in diagonal format and
op( A )  is one  of

 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
```

```
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))
                Note: For the routine, only DESCRA(1)=3 is supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           two-dimensional LDA-by-NDIAG array such that VAL(:,I)
                consists of non-zero elements on diagonal IDIAG(I)
                of A.  Diagonals in the lower triangular part of A
                are padded from the top, and those in the upper
                triangular part are padded from the bottom.

LDA             leading dimension of VAL, must be .GE. MIN(M,K)

IDIAG()         integer array of length NDIAG consisting of the
                corresponding diagonal offsets of the non-zero
                diagonals of A in VAL.  Lower triangular diagonals
                have negative offsets, the main diagonal has offset
                0, and upper triangular diagonals have positive offset.
                Elements of IDIAG of MUST be sorted in  increasing order.

NDIAG           number of non-zero diagonals in A.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.
                On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

LWORK length of WORK array. LWORK should be at least M.

For good performance, LWORK should generally be larger. For optimum performance on multiple processors, LWORK >=M*N_CPUS where N_CPUS is the maximum number of processors available to the program.

If LWORK=0, the routine is to allocate workspace needed.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimum size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

http://www.netlib.org/utk/papers/sparse.ps

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the DIA representation of a sparse matrix. They are not used anyway in these cases. But if UNITD=4, the unit diagonal elements MUST be referenced in the DIA representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

NAME

```
ddisna - compute the reciprocal condition  numbers  for  the
eigenvectors of a real symmetric or complex Hermitian matrix
or for the left or right singular vectors of  a  general  m-
by-n matrix
```

SYNOPSIS

```
SUBROUTINE DDISNA(JOB, M, N, D, SEP, INFO)

CHARACTER * 1 JOB
INTEGER M, N, INFO
DOUBLE PRECISION D(*), SEP(*)

SUBROUTINE DDISNA_64(JOB, M, N, D, SEP, INFO)

CHARACTER * 1 JOB
INTEGER*8 M, N, INFO
DOUBLE PRECISION D(*), SEP(*)
```

F95 INTERFACE

```
SUBROUTINE DISNA(JOB, M, N, D, SEP, [INFO])

CHARACTER(LEN=1) :: JOB
INTEGER :: M, N, INFO
REAL(8), DIMENSION(:) :: D, SEP

SUBROUTINE DISNA_64(JOB, M, N, D, SEP, [INFO])

CHARACTER(LEN=1) :: JOB
INTEGER(8) :: M, N, INFO
REAL(8), DIMENSION(:) :: D, SEP
```

C INTERFACE

```
#include <sunperf.h>

void ddisna(char job, int m, int n, double *d, double  *sep,
          int *info);

void ddisna_64(char job, long m, long n, double  *d,  double
          *sep, long *info);
```

PURPOSE

ddisna computes the reciprocal condition numbers for the eigenvectors of a real symmetric or complex Hermitian matrix or for the left or right singular vectors of a general m-by-n matrix. The reciprocal condition number is the 'gap' between the corresponding eigenvalue or singular value and the nearest other one.

The bound on the error, measured by angle in radians, in the I-th computed vector is given by

```
       SLAMCH( 'E' ) * ( ANORM / SEP( I ) )
```

where ANORM = 2-norm(A) = max(abs(D(j))). SEP(I) is not allowed to be smaller than SLAMCH('E')*ANORM in order to limit the size of the error bound.

SDISNA may also be used to compute error bounds for eigenvectors of the generalized symmetric definite eigenproblem.

ARGUMENTS

```
JOB (input)
          Specifies for which problem the reciprocal  condi-
          tion numbers should be computed:
          = 'E':  the eigenvectors of a  symmetric/Hermitian
          matrix;
          = 'L':  the left singular  vectors  of  a  general
          matrix;
          = 'R':  the right singular vectors  of  a  general
          matrix.

M (input) The number of rows of the matrix. M >= 0.

N (input) If JOB = 'L' or 'R', the number of columns of  the
          matrix,  in  which  case  N >= 0. Ignored if JOB =
          'E'.
```

D (input) dimension (min(M,N)) if JOB = 'L' or 'R' The eigenvalues (if JOB = 'E') or singular values (if JOB = 'L' or 'R') of the matrix, in either increasing or decreasing order. If singular values, they must be non-negative.

SEP (output)
dimension (min(M,N)) if JOB = 'L' or 'R' The reciprocal condition numbers of the vectors.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

Contents

NAME

```
ddot - compute the dot product of two vectors x and y.
```

SYNOPSIS

```
DOUBLE PRECISION FUNCTION DDOT(N, X, INCX, Y, INCY)

INTEGER N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)

DOUBLE PRECISION FUNCTION DDOT_64(N, X, INCX, Y, INCY)

INTEGER*8 N, INCX, INCY
DOUBLE PRECISION X(*), Y(*)
```

F95 INTERFACE

```
REAL(8) FUNCTION DOT([N], X, [INCX], Y, [INCY])

INTEGER :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y

REAL(8) FUNCTION DOT_64([N], X, [INCX], Y, [INCY])

INTEGER(8) :: N, INCX, INCY
REAL(8), DIMENSION(:) :: X, Y
```

C INTERFACE

```
#include <sunperf.h>

double ddot(int n, double  *x,  int  incx,  double  *y,  int
          incy);

double ddot_64(long n, double *x, long incx, double *y, long
```

```
           incy);
```

PURPOSE

ddot compute the dot product of x and y where x and y are n-vectors.

ARGUMENTS

N (input)
On entry, N specifies the number of elements in the vector. If N is not positive then the function returns the value 0.0. Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)). On entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX must not be zero. Unchanged on exit.

Y (input)
(1 + (n - 1)*abs(INCY)). On entry, the incremented array Y must contain the vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY must not be zero. Unchanged on exit.

Contents

NAME

```
ddoti - Compute the indexed dot product.
```

SYNOPSIS

```
 DOUBLE PRECISION FUNCTION DDOTI(NZ, X, INDX, Y)

 DOUBLE PRECISION X(*), Y(*)
 INTEGER NZ
 INTEGER INDX(*)

 DOUBLE PRECISION FUNCTION DDOTI_64(NZ, X, INDX, Y)

 DOUBLE PRECISION X(*), Y(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 DOUBLE PRECISION FUNCTION DOTI([NZ], X, INDX, Y)

 REAL(8), DIMENSION(:) :: X, Y
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 DOUBLE PRECISION FUNCTION DOTI_64([NZ], X, INDX, Y)

 REAL(8), DIMENSION(:) :: X, Y
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
DDOTI Compute the indexed dot product of a real sparse
vector x stored in compressed form with a real vector y in
```

full storage form.

```
dot = 0
do i = 1, n
  dot = dot + x(i) * y(indx(i))
enddo
```

ARGUMENTS

NZ (input)
Number of elements in the compressed form. Unchanged on exit.

X (input)
Vector in compressed form. Unchanged on exit.

INDX (input)
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Y (input)
Vector in full storage form. Only the elements corresponding to the indices in INDX will be accessed.

 INTEGER*8, DIMENSION(:) ::  DESCRA
 INTEGER*8, DIMENSION(:, :) ::    INDX
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:, :) ::  VAL, B, C
```

DESCRIPTION

```
where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in  Ellpack format format and
op( A )  is one  of

op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
                2 : upper
              DESCRA(3) main diagonal type
                0 : non-unit
                1 : unit
```

```
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

 VAL()          two-dimensional LDA-by-MAXNZ array such that VAL(I,:)
                consists of non-zero elements in row I of A, padded by
                zero values if the row contains less than MAXNZ.

 INDX()         two-dimensional integer LDA-by-MAXNZ array such
                INDX(I,:) consists of the column indices of the
                nonzero elements in row I, padded by the integer
                value I if the number of nonzeros is less than MAXNZ.

 LDA            leading dimension of VAL and INDX.

 MAXNZ          max number of nonzeros elements per row.

 B()            rectangular array with first dimension LDB.
 LDB            leading dimension of B

 BETA           Scalar parameter

 C()            rectangular array with first dimension LDC.

 LDC            leading dimension of C

 WORK()         scratch array of length LWORK. WORK is not
                referenced in the current version.

 LWORK          length of WORK array. LWORK is not referenced
                in the current version.

 INTEGER*8  TRANSA, M, N, UNITD, DESCRA(5), LDA, MAXNZ,
*           LDB, LDC, LWORK
 INTEGER*8  INDX(LDA,MAXNZ)
 DOUBLE PRECISION ALPHA, BETA
 DOUBLE PRECISION DV(M), VAL(LDA,MAXNZ), B(LDB,*), C(LDC,*), WORK(LWORK)
```

F95 INTERFACE

```
 SUBROUTINE ELLSM( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
*    INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER    TRANSA, M,  MAXNZ
 INTEGER, DIMENSION(:) ::  DESCRA
 INTEGER, DIMENSION(:, :) ::    INDX
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) ::  DV
 DOUBLE PRECISION, DIMENSION(:, :) ::  VAL, B, C
```

```
 SUBROUTINE ELLSM_64( TRANSA, M, [N], UNITD, DV, ALPHA, DESCRA, VAL,
*    INDX, [LDA], MAXNZ, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER*8    TRANSA, M,  MAXNZ
 INTEGER*8, DIMENSION(:) ::  DESCRA
 INTEGER*8, DIMENSION(:, :) ::    INDX
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) ::  DV
 DOUBLE PRECISION, DIMENSION(:, :) ::  VAL, B, C
```

DESCRIPTION

```
  C <- ALPHA  op(A) B + BETA C     C <- ALPHA D op(A) B + BETA C
  C <- ALPHA op(A) D B + BETA C

where ALPHA and BETA are scalar, C and B are m by n dense matrices,
D is a diagonal scaling matrix,  A is a unit, or non-unit, upper or
lower triangular matrix represented in Ellpack format and
op( A )  is one  of
 op( A ) = inv(A) or  op( A ) = inv(A')  or  op( A ) =inv(conjg( A' ))
 (inv denotes matrix inverse,  ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

UNITD         Type of scaling:
                1 : Identity matrix (argument DV[] is ignored)
                2 : Scale on left (row scaling)
                3 : Scale on right (column scaling)
                4 : Automatic row scaling (see section NOTES for
                    further details)

DV()          Array of length M containing the diagonal entries of the
              scaling diagonal matrix D.

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
```

```
                  0 : general
                  1 : symmetric (A=A')
                  2 : Hermitian (A= CONJG(A'))
                  3 : Triangular
                  4 : Skew(Anti)-Symmetric (A=-A')
                  5 : Diagonal
                  6 : Skew-Hermitian (A= -CONJG(A'))

                Note: For the routine, only DESCRA(1)=3 is supported.

                DESCRA(2) upper/lower triangular indicator
                  1 : lower
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices
VAL()           two-dimensional LDA-by-MAXNZ array such that VAL(I,:)
                consists of non-zero elements in row I of A, padded by
                zero values if the row contains less than MAXNZ.

INDX()          two-dimensional integer LDA-by-MAXNZ array such
                INDX(I,:) consists of the column indices of the
                nonzero elements in row I, padded by the integer
                value I if the number of nonzeros is less than MAXNZ.
                The column indices MUST be sorted in increasing order
                for each row.

LDA             leading dimension of VAL and INDX.

MAXNZ           max number of nonzeros elements per row.

B()             rectangular array with first dimension LDB.

LDB             leading dimension of B

BETA            Scalar parameter

C()             rectangular array with first dimension LDC.

LDC             leading dimension of C

WORK()          scratch array of length LWORK.

                On exit,  if LWORK = -1, WORK(1) returns the optimum LWORK.
```

```
LWORK         length of WORK array.  LWORK should be at least M.

              For good performance, LWORK should generally be larger.
              For optimum performance on multiple processors, LWORK
              >=M*N_CPUS where N_CPUS is the maximum number of
              processors available to the program.

              If LWORK=0, the routine is to allocate workspace needed.

              If LWORK = -1, then a workspace query is assumed; the
              routine only calculates the optimum size of the WORK
              array, returns this value as the first entry of the WORK
              array, and no error message related to LWORK is issued
              by XERBLA.
```

NOTES/BUGS

1. No test for singularity or near-singularity is included in this routine. Such tests must be performed before calling this routine.

2. If UNITD =4, the routine scales the rows of A such that their 2-norms are one. The scaling may improve the accuracy of the computed solution. Corresponding entries of VAL are changed only in the particular case. On return DV matrix stored as a vector contains the diagonal matrix by which the rows have been scaled. UNITD=2 should be used for the next calls to the routine with overwritten VAL and DV.

WORK(1)=0 on return if the scaling has been completed successfully, otherwise *WORK*(1) = -i where i is the row number which 2-norm is exactly zero.

3. If *DESCRA*(3)=1 and UNITD < 4, the unit diagonal elements might or might not be referenced in the ELL representation of a sparse matrix. They are not used anyway in these cases.

But if UNITD=4, the unit diagonal elements MUST be referenced in the ELL representation.

4. The routine can be applied for solving triangular systems when the upper or lower triangle of the general sparse matrix A is used. However *DESCRA*(1) must be equal to 3 in this case.

Contents

NAME

```
dezftb - computes a periodic sequence from its Fourier coef-
ficients.   DEZFTB  is  a  simplified  but slower version of
DFFTB.
```

SYNOPSIS

```
SUBROUTINE DEZFTB(N, R, AZERO, A, B, WSAVE)

INTEGER N
DOUBLE PRECISION AZERO
DOUBLE PRECISION R(*), A(*), B(*), WSAVE(*)

SUBROUTINE DEZFTB_64(N, R, AZERO, A, B, WSAVE)

INTEGER*8 N
DOUBLE PRECISION AZERO
DOUBLE PRECISION R(*), A(*), B(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE DEZFTB(N, R, AZERO, A, B, WSAVE)

INTEGER :: N
REAL(8) :: AZERO
REAL(8), DIMENSION(:) :: R, A, B, WSAVE

SUBROUTINE DEZFTB_64(N, R, AZERO, A, B, WSAVE)

INTEGER(8) :: N
REAL(8) :: AZERO
REAL(8), DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dezftb(int n, double *r, double azero, double *a,  dou-
          ble *b, double *wsave);

void dezftb_64(long n, double *r, double azero,  double  *a,
          double *b, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be synthesized. The method is most efficient when N is the product of small primes. N >= 0.

R (output)
On exit, the Fourier synthesis of the inputs.

AZERO (input)
On entry, the constant Fourier coefficient A0. Unchanged on exit.

A (input/output)
On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

B (input/output)
On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

WSAVE (input)
On entry, an array with dimension of at least (3 * N + 15), initialized by DEZFTI.

Contents

NAME

dezftf - computes the Fourier coefficients of a periodic sequence. DEZFTF is a simplified but slower version of DFFTF.

SYNOPSIS

```
SUBROUTINE DEZFTF(N, R, AZERO, A, B, WSAVE)

INTEGER N
DOUBLE PRECISION AZERO
DOUBLE PRECISION R(*), A(*), B(*), WSAVE(*)

SUBROUTINE DEZFTF_64(N, R, AZERO, A, B, WSAVE)

INTEGER*8 N
DOUBLE PRECISION AZERO
DOUBLE PRECISION R(*), A(*), B(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE DEZFTF(N, R, AZERO, A, B, WSAVE)

INTEGER :: N
REAL(8) :: AZERO
REAL(8), DIMENSION(:) :: R, A, B, WSAVE

SUBROUTINE DEZFTF_64(N, R, AZERO, A, B, WSAVE)

INTEGER(8) :: N
REAL(8) :: AZERO
REAL(8), DIMENSION(:) :: R, A, B, WSAVE
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dezftf(int n, double *r, double azero, double *a,  dou-
          ble *b, double *wsave);

void dezftf_64(long n, double *r, double azero,  double  *a,
          double *b, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. The method is most efficient when N is the product of small primes. N >= 0.

R (input/output)
On entry, a real array of length N containing the sequence to be transformed. On exit, R is unchanged.

AZERO (output)
On exit, the sum from i=1 to i=n of r(i)/n.

A (input/output)
On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

B (input/output)
On entry, array that contains the remaining Fourier coefficients. On exit, these arrays are unchanged.

WSAVE (input)
On entry, an array with dimension of at least (3 * N + 15), initialized by DEZFTI.

Contents

NAME

```
dezfti - initializes the array WSAVE, which is used in  both
DEZFTF and DEZFTB.
```

SYNOPSIS

```
SUBROUTINE DEZFTI(N, WSAVE)

INTEGER N
DOUBLE PRECISION WSAVE(*)

SUBROUTINE DEZFTI_64(N, WSAVE)

INTEGER*8 N
DOUBLE PRECISION WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE DEZFTI(N, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: WSAVE

SUBROUTINE DEZFTI_64(N, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dezfti(int n, double *wsave);

void dezfti_64(long n, double *wsave);
```

ARGUMENTS

N (input) Length of the sequence to be transformed. N >= 0.

WSAVE (input)
On entry, an array with a dimension of at least (3 * N + 15). The same work array can be used for both DEZFTF and DEZFTB as long as N remains unchanged. Different WSAVE arrays are required for different values of N. This initialization does not have to be repeated between calls to DEZFTF or DEZFTB as long as N and WSAVE remain unchanged, thus subsequent transforms can be obtained faster than the first.

Contents

NAME

```
dfft2b - compute a periodic sequence from its Fourier  coef-
ficients.   The  DFFT operations are unnormalized, so a call
of DFFT2F followed by a call of  DFFT2B  will  multiply  the
input sequence by M*N.
```

SYNOPSIS

```
SUBROUTINE DFFT2B(PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)

CHARACTER * 1 PLACE
INTEGER M, N, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)

SUBROUTINE DFFT2B_64(PLACE, M, N, A, LDA, B, LDB, WORK, LWORK)

CHARACTER * 1 PLACE
INTEGER*8 M, N, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2B(PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)

CHARACTER(LEN=1) :: PLACE
INTEGER :: M, N, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A, B

SUBROUTINE FFT2B_64(PLACE, [M], [N], A, [LDA], B, [LDB], WORK, LWORK)

CHARACTER(LEN=1) :: PLACE
INTEGER(8) :: M, N, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dfft2b(char place, int m, int n, double  *a,  int  lda,
          double *b, int ldb, double *work, int lwork);

void dfft2b_64(char place, long m, long n, double  *a,  long
          lda,  double  *b,  long  ldb,  double  *work, long
          lwork);
```

ARGUMENTS

PLACE (input)
Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. M >= 0; when M = 0, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. N >= 0; when N = 0, the subroutine returns immediately without changing any data.

A (input/output)
Real array of dimension (LDA,N). On entry, the two-dimensional array A(LDA,N) contains the input data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N).

LDA (input)
Integer specifying the leading dimension of A. If an out-of-place transform is desired LDA >= M. Else if an in-place transform is desired LDA >= 2*(M/2+1).

B (input/output)
Real array of dimension (2*LDB, N). On entry, if an out-of-place transform is requested B contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

LDB (input)

Integer. If an out-of-place transform is desired, 2*LDB is the leading dimension of the array B which contains the data to be transformed and 2*LDB >= 2*(M/2+1). Otherwise it is not referenced.

WORK (input/output)

One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by DFFT2I.

LWORK (input)

Integer. LWORK >= (M + 2*N + MAX(M, 2*N) + 30)

Contents

NAME

```
dfft2f - compute the  Fourier  coefficients  of  a  periodic
sequence.   The  DFFT operations are unnormalized, so a call
of DFFT2F followed by a call of  DFFT2B  will  multiply  the
input sequence by M*N.
```

SYNOPSIS

```
SUBROUTINE DFFT2F(PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)

CHARACTER * 1 PLACE, FULL
INTEGER M, N, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)

SUBROUTINE DFFT2F_64(PLACE, FULL, M, N, A, LDA, B, LDB, WORK, LWORK)

CHARACTER * 1 PLACE, FULL
INTEGER*8 M, N, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,*), B(LDB,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2F(PLACE, FULL, [M], [N], A, [LDA], B, [LDB], WORK,
       LWORK)

CHARACTER(LEN=1) :: PLACE, FULL
INTEGER :: M, N, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A, B

SUBROUTINE FFT2F_64(PLACE, FULL, [M], [N], A, [LDA], B, [LDB], WORK,
       LWORK)

CHARACTER(LEN=1) :: PLACE, FULL
INTEGER(8) :: M, N, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
```

```
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dfft2f(char place, char full, int m, int n, double  *a,
          int  lda,  double  *b,  int ldb, double *work, int
          lwork);

void dfft2f_64(char place, char full, long m, long n, double
          *a,  long  lda, double *b, long ldb, double *work,
          long lwork);
```

ARGUMENTS

PLACE (input)
Character. If PLACE = 'I' or 'i' (for in-place) , the input and output data are stored in array A. If PLACE = 'O' or 'o' (for out-of-place), the input data is stored in array B while the output is stored in A.

FULL (input)
Indicates whether or not to generate the full result matrix. 'F' or 'f' will cause DFFT2F to generate the full result matrix. Otherwise only a partial matrix that takes advantage of symmetry will be generated.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. M >= 0; when M = 0, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most most efficient when N is a product of small primes. N >= 0; when N = 0, the subroutine returns immediately without changing any data.

A (input/output)
On entry, a two-dimensional array A(LDA,N) that contains the data to be transformed. Upon exit, A is unchanged if an out-of-place transform is done. If an in-place transform with partial result is requested, A(1:(M/2+1)*2,1:N) will contain the transformed results. If an in-place transform with full result is requested, A(1:2*M,1:N) will

contain complete transformed results.

LDA (input)
Leading dimension of the array containing the data to be transformed. LDA must be even if the transformed sequences are to be stored in A.

If PLACE = ('O' or 'o') LDA >= M

If PLACE = ('I' or 'i') LDA must be even. If FULL = ('F' or 'f'), LDA >= 2*M

FULL is not ('F' or 'f'), LDA >= (M/2+1)*2

B (input/output)
Upon exit, a two-dimensional array B(2*LDB,N) that contains the transformed results if an out-of-place transform is done. Otherwise, B is not used.

If an out-of-place transform is done and FULL is not 'F' or 'f', B(1:(M/2+1)*2,1:N) will contain the partial transformed results. If FULL = 'F' or 'f', B(1:2*M,1:N) will contain the complete transformed results.

LDB (input)
2*LDB is the leading dimension of the array B. If an in-place transform is desired LDB is ignored.

If PLACE is ('O' or 'o') and

FULL is ('F' or 'f'), LDB >= M

FULL is not ('F' or 'f'), LDB >= M/2+1

Note that even though LDB is used in the argument list, 2*LDB is the actual leading dimension of B.

WORK (input/output)
One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by DFFT2I.

LWORK (input)
Integer. LWORK >= (M + 2*N + MAX(M, 2*N) + 30)

Contents

NAME

```
dfft2i - initialize the array WSAVE, which is used  in  both
the forward and backward transforms.
```

SYNOPSIS

```
SUBROUTINE DFFT2I(M, N, WORK)

INTEGER M, N
DOUBLE PRECISION WORK(*)

SUBROUTINE DFFT2I_64(M, N, WORK)

INTEGER*8 M, N
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT2I(M, N, WORK)

INTEGER :: M, N
REAL(8), DIMENSION(:) :: WORK

SUBROUTINE FFT2I_64(M, N, WORK)

INTEGER(8) :: M, N
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void dfft2i(int m, int n, double *work);

void dfft2i_64(long m, long n, double *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

WORK (input/output)
On entry, an array of dimension (M + 2*N + MAX(M, 2*N) + 30) or greater. DFFT2I needs to be called only once to initialize array WORK before calling DFFT2F and/or DFFT2B if M, N and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

#include <sunperf.h>

void dfft3b(char place, int m, int n, int k, double *a,  int
          lda, double *b, int ldb, double *work, int lwork);

void dfft3b_64(char place, long m, long n,  long  k,  double
          *a,  long  lda, double *b, long ldb, double *work,
          long lwork);
```

ARGUMENTS

PLACE (input)
Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. M >= 0; when M = 0, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. N >= 0; when N = 0, the subroutine returns immediately without changing any data.

K (input) Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. K >= 0; when K = 0, the subroutine returns immediately without changing any data.

A (input/output)
On entry, the three-dimensional array A(LDA,N,K) contains the data to be transformed if an in-place transform is requested. Otherwise, it is not referenced. Upon exit, results are stored in A(1:M,1:N,1:K).

LDA (input)
Integer specifying the leading dimension of A. If an out-of-place transform is desired LDA >= M. Else if an in-place transform is desired LDA >= 2*(M/2+1).

B (input/output)
Real array of dimension B(2*LDB,N,K). On entry, if an out-of-place transform is requested B(1:2*(M/2+1),1:N,1:K) contains the input data. Otherwise, B is not referenced. B is unchanged upon exit.

LDB (input)
If an out-of-place transform is desired, 2*LDB is the leading dimension of the array B which contains the data to be transformed and 2*LDB >= 2*(M/2+1). Otherwise it is not referenced.

WORK (input/output)
One-dimensional real array of length at least LWORK. On input, WORK must have been initialized by DFFT3I.

LWORK (input)
Integer. LWORK >= (M + 2*(N + K) + 4*K + 45).

NAME

```
dfft3f - compute the Fourier coefficients of a real periodic
sequence. The DFFT operations are unnormalized, so a call of
DFFT3F followed by a call of DFFT3B will multiply the  input
sequence by M*N*K.
```

SYNOPSIS

```
SUBROUTINE DFFT3F(PLACE, FULL, M, N, K, A, LDA, B, LDB, WORK, LWORK)

CHARACTER * 1 PLACE, FULL
INTEGER M, N, K, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,N,*), B(LDB,N,*), WORK(*)

SUBROUTINE DFFT3F_64(PLACE, FULL, M, N, K, A, LDA, B, LDB, WORK,
      LWORK)

CHARACTER * 1 PLACE, FULL
INTEGER*8 M, N, K, LDA, LDB, LWORK
DOUBLE PRECISION A(LDA,N,*), B(LDB,N,*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3F(PLACE, FULL, [M], [N], [K], A, [LDA], B, [LDB],
       WORK, LWORK)

CHARACTER(LEN=1) :: PLACE, FULL
INTEGER :: M, N, K, LDA, LDB, LWORK
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:,:) :: A, B

SUBROUTINE FFT3F_64(PLACE, FULL, [M], [N], [K], A, [LDA], B, [LDB],
       WORK, LWORK)

CHARACTER(LEN=1) :: PLACE, FULL
INTEGER(8) :: M, N, K, LDA, LDB, LWORK
```

```
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dfft3f(char place, char full, int m, int n, int k, dou-
          ble *a, int lda, double *b, int ldb, double *work,
          int lwork);

void dfft3f_64(char place, char full, long m, long  n,  long
          k,  double *a, long lda, double *b, long ldb, dou-
          ble *work, long lwork);
```

ARGUMENTS

PLACE (input)
Select an in-place ('I' or 'i') or out-of-place ('O' or 'o') transform.

FULL (input)
Select a full ('F' or 'f') or partial (' ') representation of the results. If the caller selects full representation then an MxNxK real array will transform to produce an MxNxK complex array. If the caller does not select full representation then an MxNxK real array will transform to a (M/2+1)xNxK complex array that takes advantage of the symmetry properties of a transformed real sequence.

M (input) Integer specifying the number of rows to be transformed. It is most efficient when M is a product of small primes. M >= 0; when M = 0, the subroutine returns immediately without changing any data.

N (input) Integer specifying the number of columns to be transformed. It is most efficient when N is a product of small primes. N >= 0; when N = 0, the subroutine returns immediately without changing any data.

K (input) Integer specifying the number of planes to be transformed. It is most efficient when K is a product of small primes. K >= 0; when K = 0, the subroutine returns immediately without changing any data.

A (input/output)

On entry, a three-dimensional array A(LDA,N,K) that contains input data to be transformed. On exit, if an in-place transform is done and FULL is not 'F' or 'f', A(1:2*(M/2+1),1:N,1:K) will contain the partial transformed results. If FULL = 'F' or 'f', A(1:2*M,1:N,1:K) will contain the complete transformed results.

LDA (input)

Leading dimension of the array containing the data to be transformed. LDA must be even if the transformed sequences are to be stored in A.

If PLACE = ('O' or 'o') LDA >= M

If PLACE = ('I' or 'i') LDA must be even. If

FULL = ('F' or 'f'), LDA >= 2*M

FULL is not ('F' or 'f'), LDA >= 2*(M/2+1)

B (input/output)

Upon exit, a three-dimensional array B(2*LDB,N,K) that contains the transformed results if an out-of-place transform is done. Otherwise, B is not used.

If an out-of-place transform is done and FULL is not 'F' or 'f', B(1:2*(M/2+1),1:N,1:K) will contain the partial transformed results. If FULL = 'F' or 'f', B(1:2*M,1:N,1:K) will contain the complete transformed results.

LDB (input)

2*LDB is the leading dimension of the array B. If an in-place transform is desired LDB is ignored.

If PLACE is ('O' or 'o') and

FULL is ('F' or 'f'), then LDB >= M

FULL is not ('F' or 'f'), then LDB >= M/2 + 1

Note that even though LDB is used in the argument list, 2*LDB is the actual leading dimension of B.

WORK (input/output)

One-dimensional real array of length at least LWORK. WORK must have been initialized by DFFT3I.

```
LWORK (input)
          Integer.  LWORK >= (M + 2*(N + K) + 4*K + 45).
```

Contents

NAME

```
dfft3i - initialize the array WSAVE, which is used  in  both
DFFT3F and DFFT3B.
```

SYNOPSIS

```
SUBROUTINE DFFT3I(M, N, K, WORK)

INTEGER M, N, K
DOUBLE PRECISION WORK(*)

SUBROUTINE DFFT3I_64(M, N, K, WORK)

INTEGER*8 M, N, K
DOUBLE PRECISION WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT3I(M, N, K, WORK)

INTEGER :: M, N, K
REAL(8), DIMENSION(:) :: WORK

SUBROUTINE FFT3I_64(M, N, K, WORK)

INTEGER(8) :: M, N, K
REAL(8), DIMENSION(:) :: WORK
```

C INTERFACE

```
#include <sunperf.h>

void dfft3i(int m, int n, int k, double *work);

void dfft3i_64(long m, long n, long k, double *work);
```

ARGUMENTS

M (input) Number of rows to be transformed. M >= 0.

N (input) Number of columns to be transformed. N >= 0.

K (input) Number of planes to be transformed. K >= 0.

WORK (input/output)
On entry, an array of dimension (M + 2*(N + K) + 30) or greater. DFFT3I needs to be called only once to initialize array WORK before calling DFFT3F and/or DFFT3B if M, N, K and WORK remain unchanged between these calls. Thus, subsequent transforms or inverse transforms of same size can be obtained faster than the first since they do not require initialization of the workspace.

NAME

dfftb - compute a periodic sequence from its Fourier coefficients. The DFFT operations are unnormalized, so a call of DFFTF followed by a call of DFFTB will multiply the input sequence by N.

SYNOPSIS

```
SUBROUTINE DFFTB(N, X, WSAVE)

INTEGER N
DOUBLE PRECISION X(*), WSAVE(*)

SUBROUTINE DFFTB_64(N, X, WSAVE)

INTEGER*8 N
DOUBLE PRECISION X(*), WSAVE(*)
```

F95 INTERFACE

```
SUBROUTINE FFTB([N], X, WSAVE)

INTEGER :: N
REAL(8), DIMENSION(:) :: X, WSAVE

SUBROUTINE FFTB_64([N], X, WSAVE)

INTEGER(8) :: N
REAL(8), DIMENSION(:) :: X, WSAVE
```

C INTERFACE

```
#include <sunperf.h>

void dfftb(int n, double *x, double *wsave);
```

```
void dfftb_64(long n, double *x, double *wsave);
```

ARGUMENTS

```
N (input) Length of the sequence to be  transformed.   These
          subroutines are most efficient when N is a product
          of small primes.  N >= 0.

X (input) On entry, an array  of  length  N  containing  the
          sequence to be transformed.

WSAVE (input)
          On entry, WSAVE must be an array of dimension (2 *
          N  + 15) or greater and must have been initialized
          by DFFTI.
```

NAME

```
dfftopt - compute the length of the closest fast FFT
```

SYNOPSIS

```
INTEGER FUNCTION DFFTOPT(LEN)

INTEGER LEN

INTEGER*8 FUNCTION DFFTOPT_64(LEN)

INTEGER*8 LEN
```

F95 INTERFACE

```
INTEGER FUNCTION DFFTOPT(LEN)

INTEGER :: LEN

INTEGER(8) FUNCTION DFFTOPT_64(LEN)

INTEGER(8) :: LEN
```

C INTERFACE

```
#include <sunperf.h>

int dfftopt(int len);

long dfftopt_64(long len);
```

PURPOSE

```
dfftopt computes the length of the closest fast  FFT.   Fast
```

Fourier transform algorithms, including those used in Performance Library, work best with vector lengths that are products of small primes. For example, an FFT of length 32=2**5 will run faster than an FFT of prime length 31 because 32 is a product of small primes and 31 is not. If your application is such that you can taper or zero pad your vector to a larger length then this function may help you select a better length and run your FFT faster.

DFFTOPT will return an integer no smaller than the input argument N that is the closest number that is the product of small primes. DFFTOPT will return 16 for an input of N=16 and return 18=2*3*3 for an input of N=17.

Note that the length computed here is not guaranteed to be optimal, only to be a
product of small primes. Also, the value returned may change as the underlying
FFTs become capable of handling larger primes. For example, passing in N=51 to day will return 52=2*2*13 rather than 51=3*17 because the FFTs in Performance Li brary do not have fast radix 17 code. In the future, radix 17 code may be added
and then N=51 will return 51.

NAME

```
dfftz -  initialize  the  trigonometric  weight  and  factor
tables  or  compute  the forward Fast Fourier Transform of a
double precision sequence.
```

SYNOPSIS

```
SUBROUTINE DFFTZ(IOPT, N, SCALE, X, Y, TRIGS, IFAC, WORK, LWORK, IERR)

INTEGER IOPT, N, IFAC(*), LWORK, IERR
DOUBLE COMPLEX Y(*)
DOUBLE PRECISION X(*), SCALE, TRIGS(*), WORK(*)

SUBROUTINE DFFTZ_64(IOPT, N, SCALE, X, Y, TRIGS, IFAC, WORK, LWORK, IERR)

INTEGER*8 IOPT, N, IFAC(*), LWORK, IERR
DOUBLE COMPLEX Y(*)
DOUBLE PRECISION X(*), SCALE, TRIGS(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE FFT(IOPT, N, SCALE, X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)

INTEGER, INTENT(IN) :: IOPT
INTEGER, INTENT(IN), OPTIONAL :: N, LWORK
REAL(8), INTENT(IN), OPTIONAL :: SCALE
REAL(8), INTENT(IN), DIMENSION(:) :: X
COMPLEX(8), INTENT(OUT), DIMENSION(:) :: Y
REAL(8), INTENT(INOUT), DIMENSION(:) :: TRIGS
INTEGER, INTENT(INOUT), DIMENSION(:) :: IFAC
REAL(8), INTENT(OUT), DIMENSION(:) :: WORK
INTEGER, INTENT(OUT) :: IERR

SUBROUTINE FFT_64(IOPT, [N], [SCALE], X, Y, TRIGS, IFAC, WORK, [LWORK], IERR)
```

```
INTEGER(8), INTENT(IN) :: IOPT
INTEGER(8), INTENT(IN), OPTIONAL :: N, LWORK
REAL(8), INTENT(IN), OPTIONAL :: SCALE
REAL(8), INTENT(IN), DIMENSION(:) :: X
COMPLEX(8), INTENT(OUT), DIMENSION(:) :: Y
REAL(8), INTENT(INOUT), DIMENSION(:) :: TRIGS
INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
REAL(8), INTENT(OUT), DIMENSION(:) :: WORK
INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
#include <sunperf.h>

void dfftz_ (int *iopt, int *n, double  *scale,  double  *x,
          doublecomplex *y, double *trigs, int *ifac, double
          *work, int *lwork, int *ierr);

void dfftz_64_ (long *iopt, long *n, double  *scale,  double
          *x,  doublecomplex  *y, double *trigs, long *ifac,
          double *work, long *lwork, long *ierr);
```

PURPOSE

dfftz initializes the trigonometric weight and factor tables or computes the forward Fast Fourier Transform of a double precision sequence as follows:

```
               N-1
Y(k) = scale * SUM  W*X(j)
               j=0
```

where
k ranges from 0 to N-1
i = sqrt(-1)
isign = -1 for forward transform
W = exp(isign*i*j*k*2*pi/N)
In real-to-complex transform of length N, the (N/2+1) complex output data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:

IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N (input)
Integer specifying length of the input sequence X. N is most efficient when it is a product of small primes. N >= 0. Unchanged on exit.

SCALE (input)
Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) On entry, X is a real array whose first N elements contain the sequence to be transformed.

Y (output)
Double complex array whose first (N/2+1) elements contain the transform results. X and Y may be the same array starting at the same memory location, in which case the dimension of X must be at least 2*(N/2+1). Otherwise, it is assumed that there is no overlap between X and Y in memory.

TRIGS (input/output)
Double precision array of length 2*N that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 128 that contains the factors of N. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls where IOPT = -1. Unchanged on exit.

WORK (workspace)
Double precision array of dimension at least N. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following

```
values:
0 = normal return
-1 = IOPT is not 0 or -1
-2 = N < 0
-3 = (LWORK is not 0) and (LWORK is less than N)
-4 = memory allocation for workspace failed
```

     INTEGER(8), INTENT(IN) :: IOPT
     INTEGER(8), INTENT(IN), OPTIONAL :: N1, N2, LDX, LDY, LWORK
     REAL(8), INTENT(IN), OPTIONAL :: SCALE
     REAL(8), INTENT(IN), DIMENSION(:,:) :: X
     COMPLEX(8), INTENT(OUT), DIMENSION(:,:) :: Y
     REAL(8), INTENT(INOUT), DIMENSION(:) :: TRIGS
     INTEGER(8), INTENT(INOUT), DIMENSION(:) :: IFAC
     REAL(8), INTENT(OUT), DIMENSION(:) :: WORK
     INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
     #include <sunperf.h>
     void dfftz2_ (int *iopt, int *n1, int  *n2,  double  *scale,
               double  *x,  int *ldx, doublecomplex *y, int *ldy,
               double  *trigs,  int  *ifac,  double  *work,   int
               *lwork, int *ierr);

     void dfftz2_64_ (long *iopt,  long  *n1,  long  *n2,  double
               *scale,  double  *x,  long *ldx, doublecomplex *y,
               long  *ldy,  double  *trigs,  long  *ifac,  double
               *work, long *lwork, long *ierr);
```

PURPOSE

dfftz2 initializes the trigonometric weight and factor tables or computes the two-dimensional forward Fast Fourier Transform of a two-dimensional double precision array. In computing the two-dimensional FFT, one-dimensional FFTs are computed along the columns of the input array. One-dimensional FFTs are then computed along the rows of the intermediate results.

```
                   N2-1  N1-1
Y(k1,k2) = scale * SUM   SUM   W2*W1*X(j1,j2)
                   j2=0  j1=0
```

where
k1 ranges from 0 to N1-1 and k2 ranges from 0 to N2-1
i = sqrt(-1)
isign = -1 for forward transform
W1 = exp(isign*i*j1*k1*2*pi/N1)
W2 = exp(isign*i*j2*k2*2*pi/N2)
In real-to-complex transform of length N1, the (N1/2+1) com-

plex output data points stored are the positive-frequency half of the spectrum of the Discrete Fourier Transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N1 (input)
Integer specifying length of the transform in the first dimension. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying length of the transform in the second dimension. N2 is most efficient when it is a product of small primes N2 >= 0. Unchanged on exit.

SCALE (input)
Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double complex array of dimensions (LDX, N2) that contains input data to be transformed. X and Y can be the same array.

LDX (input)
Leading dimension of X. LDX >= N1 if X is not the same array as Y. Else, LDX = 2*LDY. Unchanged on exit.

Y (output)
Y is a double complex array of dimensions (LDY, N2) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. LDY >= N1/2+1 Unchanged on exit.

TRIGS (input/output)
Double precision array of length 2*(N1+N2) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 2*128 that contains the factors of N1 and N2. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)
Double precision array of dimension at least MAX(N1, 2*N2) where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1) or (LDX not equal 2*LDY when X and Y are same array)
-5 = (LDY < N1/2+1)
-6 = (LWORK not equal 0) and (LWORK < MAX(N1,2*N2))
-7 = memory allocation failed

SEE ALSO

fft

CAUTIONS

On exit, output array Y(1:LDY, 1:N2) is overwritten.

     INTEGER(8), INTENT(OUT) :: IERR
```

C INTERFACE

```
     #include <sunperf.h>

     void dfftz3_ (int *iopt, int *n1, int *n2, int  *n3,  double
               *scale,  double  *x,  int  *ldx1, int *ldx2, doub-
               lecomplex *y, int *ldy1, int *ldy2, double *trigs,
               int *ifac, double *work, int *lwork, int *ierr);

     void dfftz3_64_ (long *iopt, long *n1, long *n2,  long  *n3,
               double  *scale, double *x, long *ldx1, long *ldx2,
               doublecomplex *y, long *ldy1, long  *ldy2,  double
               *trigs,  long  *ifac,  double  *work, long *lwork,
               long *ierr);
```

PURPOSE

dfftz3 initializes the trigonometric weight and factor tables or computes the three-dimensional forward Fast Fourier Transform of a three-dimensional double complex array.

```
                          N3-1  N2-1  N1-1
     Y(k1,k2,k3) = scale * SUM   SUM   SUM   W3*W2*W1*X(j1,j2,j3)
                          j3=0  j2=0  j1=0
```

where
k1 ranges from 0 to N1-1; k2 ranges from 0 to N2-1 and k3 ranges from 0 to N3-1
i = sqrt(-1)

```
isign = -1 for forward transform
W1 = exp(isign*i*j1*k1*2*pi/N1)
W2 = exp(isign*i*j2*k2*2*pi/N2)
W3 = exp(isign*i*j3*k3*2*pi/N3)
```

ARGUMENTS

```
IOPT (input)
          Integer specifying the operation to be performed:
          IOPT = 0 computes the trigonometric  weight  table
          and factor table
          IOPT = -1 computes forward FFT

N1 (input)
          Integer specifying length of the transform in  the
          first  dimension.  N1 is most efficient when it is
          a product of small primes.  N1 >= 0.  Unchanged on
          exit.

N2 (input)
          Integer specifying length of the transform in  the
          second dimension.  N2 is most efficient when it is
          a product of small primes.  N2 >= 0.  Unchanged on
          exit.

N3 (input)
          Integer specifying length of the transform in  the
          third  dimension.  N3 is most efficient when it is
          a product of small primes.  N3 >= 0.  Unchanged on
          exit.

SCALE (input)
          Double precision scalar by which transform results
          are   scaled.   Unchanged   on  exit.   SCALE  is
          defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double precision array of dimensions (LDX1,
          LDX2,   N3)   that   contains  input  data  to  be
          transformed.  X can be same array as Y.

LDX1 (input)
          first dimension of X.  If X is not same  array  as
          Y,  LDX1  >=  N1  Else, LDX1 = 2*LDY1 Unchanged on
          exit.

LDX2 (input)
          second dimension of X.  LDX2 >=  N2  Unchanged  on
          exit.
```

Y (output)
Y is a double complex array of dimensions (LDY1, LDY2, N3) that contains the transform results. X and Y can be the same array starting at the same memory location, in which case the input data are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY1 (input)
first dimension of Y. LDY1 >= N1/2+1 Unchanged on exit.

LDY2 (input)
second dimension of Y. If X and Y are the same array, LDY2 = LDX2 Else LDY2 >= N2 Unchanged on exit.

TRIGS (input/output)
Double precision array of length 2*(N1+N2+N3) that contains the trigonometric weights. The weights are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 3*128 that contains the factors of N1, N2 and N3. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)
Double precision array of dimension at least (MAX(N,2*N2,2*N3) + 16*N3) * NCPUS where NCPUS is the number of threads used to execute the routine. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or -1
-2 = N1 < 0

-3 = N2 < 0
-4 = N3 < 0
-5 = (LDX1 < N1) or (LDX not equal 2*LDY when X and Y are same array)
-6 = (LDX2 < N2)
-7 = (LDY1 < N1/2+1)
-8 = (LDY2 < N2) or (LDY2 not equal LDX2 when X and Y are same array)
-9 = (LWORK not equal 0) and (LWORK < (MAX(N,2*N2,2*N3) + 16*N3))
-10 = memory allocation failed

SEE ALSO

fft

CAUTIONS

On exit, output subarray Y(1:LDY1, 1:N2, 1:N3) is overwritten.

C INTERFACE

```
     #include <sunperf.h>
     void dfftzm_ (int *iopt, int *m, int *n, double *scale, dou-
               ble *x, int *ldx, doublecomplex *y, int *ldy, dou-
               ble *trigs, int *ifac, double *work,  int  *lwork,
               int *ierr);

     void dfftzm_64_  (long  *iopt,  long  *m,  long  *n,  double
               *scale,  double  *x,  long *ldx, doublecomplex *y,
               long  *ldy,  double  *trigs,  long  *ifac,  double
               *work, long *lwork, long *ierr);
```

PURPOSE

dfftzm initializes the trigonometric weight and factor tables or computes the one-dimensional forward Fast Fourier Transform of a set of double precision data sequences stored in a two-dimensional array:

```
                     N1-1
     Y(k,l) = scale * SUM  W*X(j,l)
                     j=0
```

where
k ranges from 0 to N1-1 and l ranges from 0 to N2-1
i = sqrt(-1)
isign = -1 for forward transform
W = exp(isign*i*j*k*2*pi/N1)
In real-to-complex transform of length N1, the (N1/2+1) complex output data points stored are the positive-frequency half of the spectrum of the discrete Fourier transform. The other half can be obtained through complex conjugation and therefore is not stored.

ARGUMENTS

IOPT (input)
Integer specifying the operation to be performed:
IOPT = 0 computes the trigonometric weight table and factor table
IOPT = -1 computes forward FFT

N1 (input)
Integer specifying length of the input sequences. N1 is most efficient when it is a product of small primes. N1 >= 0. Unchanged on exit.

N2 (input)
Integer specifying number of input sequences. N2 >= 0. Unchanged on exit.

SCALE (input)
Double precision scalar by which transform results are scaled. Unchanged on exit. SCALE is defaulted to 1.0D0 for F95 INTERFACE.

X (input) X is a double precision array of dimensions (LDX, N2) that contains the sequences to be transformed stored in its columns.

LDX (input)
Leading dimension of X. If X and Y are the same array, LDX = 2*LDY Else LDX >= N1 Unchanged on exit.

Y (output)
Y is a double complex array of dimensions (LDY, N2) that contains the transform results of the input sequences. X and Y can be the same array starting at the same memory location, in which case the input sequences are overwritten by their transform results. Otherwise, it is assumed that there is no overlap between X and Y in memory.

LDY (input)
Leading dimension of Y. LDY >= N1/2 + 1 Unchanged on exit.

TRIGS (input/output)
Double precision array of length 2*N1 that contains the trigonometric weights. The weights are

computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

IFAC (input/output)
Integer array of dimension at least 128 that contains the factors of N1. The factors are computed when the routine is called with IOPT = 0 and they are used in subsequent calls when IOPT = -1. Unchanged on exit.

WORK (workspace)
Double precision array of dimension at least N1. The user can also choose to have the routine allocate its own workspace (see LWORK).

LWORK (input)
Integer specifying workspace size. If LWORK = 0, the routine will allocate its own workspace.

IERR (output)
On exit, integer IERR has one of the following values:
0 = normal return
-1 = IOPT is not 0 or -1
-2 = N1 < 0
-3 = N2 < 0
-4 = (LDX < N1) or (LDX not equal 2*LDY when X and Y are same array)
-4 = (LDY < N1/2 + 1)
-6 = (LWORK not equal 0) and (LWORK < N1)
-7 = memory allocation failed

void dgbbrd(char vect, int m, int n, int ncc,  int  kl,  int
          ku,  double  *ab,  int ldab, double *d, double *e,
          double *q, int ldq, double *pt, int  ldpt,  double
          *c, int ldc, int *info);
void dgbbrd_64(char vect, long m, long n, long ncc, long kl,
          long  ku, double *ab, long ldab, double *d, double
          *e, double *q, long ldq, double  *pt,  long  ldpt,
          double *c, long ldc, long *info);
```

PURPOSE

dgbbrd reduces a real general m-by-n band matrix A to upper bidiagonal form B by an orthogonal transformation: Q' * A * P = B.

The routine computes B, and optionally forms Q or P', or computes Q'*C for a given matrix C.

ARGUMENTS

VECT (input)
Specifies whether or not the matrices Q and P' are to be formed. = 'N': do not form Q or P';
= 'Q': form Q only;
= 'P': form P' only;
= 'B': form both.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NCC (input)
The number of columns of the matrix C. NCC >= 0.

KL (input)
The number of subdiagonals of the matrix A. KL >= 0.

KU (input)
The number of superdiagonals of the matrix A. KU >= 0.

AB (input/output)
DOUBLE PRECISION array, dimension(LDAB,N) On entry, the m-by-n band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array AB as follows: AB(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl). On exit, A is overwritten by values generated during the reduction.

LDAB (input)
The leading dimension of the array A. LDAB >= KL+KU+1.

D (output)
DOUBLE PRECISION array, dimension(min(M,N)) The diagonal elements of the bidiagonal matrix B.

E (output)
DOUBLE PRECISION array, dimension(min(M,N)-1) The superdiagonal elements of the bidiagonal matrix B.

Q (output)
DOUBLE PRECISION array, dimension(LDQ,M) If VECT = 'Q' or 'B', the m-by-m orthogonal matrix Q. If VECT = 'N' or 'P', the array Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,M) if VECT = 'Q' or 'B'; LDQ >= 1 otherwise.

PT (output)
DOUBLE PRECISION array, dimension(LDPT,N) If VECT = 'P' or 'B', the n-by-n orthogonal matrix P'. If VECT = 'N' or 'Q', the array PT is not referenced.

LDPT (input)
The leading dimension of the array PT. LDPT >= max(1,N) if VECT = 'P' or 'B'; LDPT >= 1 otherwise.

C (input/output)
DOUBLE PRECISION array, dimension(LDC,NCC) On entry, an m-by-ncc matrix C. On exit, C is overwritten by Q'*C. C is not referenced if NCC = 0.

```
LDC (input)
          The leading dimension of  the  array  C.   LDC  >=
          max(1,M) if NCC > 0; LDC >= 1 if NCC = 0.
WORK (workspace)
          DOUBLE PRECISION array, dimension(2*MAX(M,N))

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.

REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
void dgbcon(char norm, int n, int nsub, int  nsuper,  double
          *a,  int  lda,  int  *ipivot, double anorm, double
          *rcond, int *info);

void dgbcon_64(char norm, long n, long  nsub,  long  nsuper,
          double  *a,  long lda, long *ipivot, double anorm,
          double *rcond, long *info);
```

PURPOSE

dgbcon estimates the reciprocal of the condition number of a real general band matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGBTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as

RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I':   Infinity-norm.

N (input) The order of the matrix A. N >= 0.

NSUB (input)
The number of subdiagonals within the band of A. NSUB >= 0.

```
NSUPER (input)
          The number of superdiagonals within the band of A.
          NSUPER >= 0.

A (input) Details of the LU factorization of the band matrix
          A, as computed by SGBTRF.  U is stored as an upper
          triangular band matrix with NSUB+NSUPER superdiag-
          onals  in  rows 1 to NSUB+NSUPER+1, and the multi-
          pliers used during the factorization are stored in
          rows NSUB+NSUPER+2 to 2*NSUB+NSUPER+1.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          2*NSUB+NSUPER+1.

IPIVOT (input)
          The pivot indices; for 1 <= i <= N, row i  of  the
          matrix was interchanged with row IPIVOT(i).

ANORM (input)
          If NORM = '1' or 'O', the 1-norm of  the  original
          matrix A.  If NORM = 'I', the infinity-norm of the
          original matrix A.

RCOND (output)
          The reciprocal of  the  condition  number  of  the
          matrix   A,  computed  as  RCOND  =  1/(norm(A)  *
          norm(inv(A))).

WORK (workspace)
          dimension(3*N)

WORK2 (workspace)
          dimension (N)

INFO (output)
          = 0:  successful exit
          < 0: if INFO = -i, the i-th argument had an  ille-
          gal value
```

```

PURPOSE

dgbequ computes row and column scalings intended to equilibrate an M-by-N band matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

A (input) The band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(ku+1+i-j,j) = A(i,j)

```
          for max(1,j-ku)<=i<=min(m,j+kl).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          KL+KU+1.

R (output)
          If INFO = 0, or INFO > M, R contains the row scale
          factors for A.

C (output)
          If INFO = 0, C contains the column  scale  factors
          for A.
ROWCN (output)
          If INFO = 0 or INFO > M, ROWCN contains the  ratio
          of  the  smallest  R(i)  to  the largest R(i).  If
          ROWCN >= 0.1 and AMAX is neither too large nor too
          small, it is not worth scaling by R.

COLCN (output)
          If INFO = 0, COLCN contains the ratio of the smal-
          lest  C(i)  to the largest C(i).  If COLCN >= 0.1,
          it is not worth scaling by C.

AMAX (output)
          Absolute value of largest matrix element.  If AMAX
          is  very close to overflow or very close to under-
          flow, the matrix should be scaled.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
          > 0:  if INFO = i, and i is
          <= M:  the i-th row of A is exactly zero
          >  M:  the (i-M)-th column of A is exactly zero
```

NAME

```
dgbmv - perform one of the matrix-vector operations    y  :=
alpha*A*x + beta*y or y := alpha*A'*x + beta*y
```

SYNOPSIS

```
SUBROUTINE DGBMV(TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X, INCX,
      BETA, Y, INCY)

CHARACTER * 1 TRANSA
INTEGER M, N, NSUB, NSUPER, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)

SUBROUTINE DGBMV_64(TRANSA, M, N, NSUB, NSUPER, ALPHA, A, LDA, X,
      INCX, BETA, Y, INCY)

CHARACTER * 1 TRANSA
INTEGER*8 M, N, NSUB, NSUPER, LDA, INCX, INCY
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), X(*), Y(*)
```

F95 INTERFACE

```
SUBROUTINE GBMV([TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA], X,
       [INCX], BETA, Y, [INCY])

CHARACTER(LEN=1) :: TRANSA
INTEGER :: M, N, NSUB, NSUPER, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GBMV_64([TRANSA], [M], [N], NSUB, NSUPER, ALPHA, A, [LDA],
```

```
          X, [INCX], BETA, Y, [INCY])

   CHARACTER(LEN=1) :: TRANSA
   INTEGER(8) :: M, N, NSUB, NSUPER, LDA, INCX, INCY
   REAL(8) :: ALPHA, BETA
   REAL(8), DIMENSION(:) :: X, Y
   REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgbmv(char transa, int m, int n, int nsub, int  nsuper,
          double  alpha,  double *a, int lda, double *x, int
          incx, double beta, double *y, int incy);
void dgbmv_64(char transa, long m, long n, long  nsub,  long
          nsuper,  double alpha, double *a, long lda, double
          *x, long incx, double beta, double *y, long incy);
```

PURPOSE

dgbmv performs one of the matrix-vector operations y := alpha*A*x + beta*y or y := alpha*A'*x + beta*y, where alpha and beta are scalars, x and y are vectors and A is an m by n band matrix, with nsub sub-diagonals and nsuper super-diagonals.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   y := alpha*A*x + beta*y.

TRANSA = 'T' or 't'   y := alpha*A'*x + beta*y.

TRANSA = 'C' or 'c'   y := alpha*A'*x + beta*y.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)

On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

NSUB (input)
On entry, NSUB specifies the number of sub-diagonals of the matrix A. NSUB >= 0. Unchanged on exit.

NSUPER (input)
On entry, NSUPER specifies the number of super-diagonals of the matrix A. NSUPER >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry, the leading (nsub + nsuper + 1) by n part of the array A must contain the matrix of coefficients, supplied column by column, with the leading diagonal of the matrix in row (nsuper + 1) of the array, the first super-diagonal starting at position 2 in row nsuper, the first sub-diagonal starting at position 1 in row (nsuper + 2), and so on. Elements in the array A that do not correspond to elements in the band matrix (such as the top left nsuper by nsuper triangle) are not referenced. The following program segment will transfer a band matrix from conventional full matrix storage to band storage:

```
   DO 20, J = 1, N
     K = NSUPER + 1 - J
     DO 10, I = MAX( 1, J - NSUPER ), MIN( M, J  +
NSUB )
       A( K + I, J ) = matrix( I, J )
10   CONTINUE
20 CONTINUE
```

Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= (nsub + nsuper + 1). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X

must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (m - 1)*abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

          long *ipivot, double *b, long ldb, double *x, long
          ldx, double *ferr, double *berr, long *info);
```

PURPOSE

dgbrfs improves the computed solution to a system of linear equations when the coefficient matrix is banded, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

KL (input)
```

The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input) The original band matrix A, stored in rows 1 to KL+KU+1. The j-th column of A is stored in the j-th column of the array A as follows: A(ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(n,j+kl).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input)
Details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1.

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL*KU+1.

IPIVOT (input)
The pivot indices from SGBTRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SGBTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

```
FERR (output)
          The estimated forward error bound for  each  solu-
          tion  vector X(j) (the j-th column of the solution
          matrix  X).   If  XTRUE  is  the   true   solution
          corresponding  to  X(j),  FERR(j)  is an estimated
          upper bound for the magnitude of the largest  ele-
          ment in (X(j) - XTRUE) divided by the magnitude of
          the largest element in X(j).  The estimate  is  as
          reliable  as the estimate for RCOND, and is almost
          always a slight overestimate of the true error.

BERR (output)
          The componentwise relative backward error of  each
          solution  vector X(j) (i.e., the smallest relative
          change in any element of A or B that makes X(j) an
          exact solution).

WORK (workspace)
          dimension(3*N)

WORK2 (workspace)
          dimension(N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

```

C INTERFACE

```
#include <sunperf.h>

void dgbsv(int n, int kl, int ku, int nrhs, double  *a,  int
          lda, int *ipivot, double *b, int ldb, int *info);

void dgbsv_64(long n, long kl, long ku,  long  nrhs,  double
          *a,  long  lda, long *ipivot, double *b, long ldb,
          long *info);
```

PURPOSE

dgbsv computes the solution to a real system of linear equations A * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as A = L * U, where L is a product of permutation and unit lower triangular matrices with KL subdiagonals, and U is upper triangular with KL+KU superdiagonals. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the matrix A in band storage, in rows

KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: A(KL+KU+1+i-j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+KL) On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDA (input)
The leading dimension of the array A. LDA >= 2*KL+KU+1.

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the N-by-NRHS right hand side matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and the solution has not been computed.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

```
On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
```

```
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U because of fill-in resulting from the row interchanges.

void dgbsvx_64(char fact, char transa, long n, long kl, long
          ku,  long  nrhs,  double *a, long lda, double *af,
          long ldaf, long *ipivot, char  equed,  double  *r,
          double  *c,  double  *b, long ldb, double *x, long
          ldx, double *rcond, double  *ferr,  double  *berr,
          long *info);
```

PURPOSE

dgbsvx uses the LU factorization to compute the solution to a real system of linear equations A * X = B, A**T * X = B, or A**H * X = B, where A is a band matrix of order N with KL subdiagonals and KU superdiagonals, and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed by this subroutine:

1. If FACT = 'E', real scaling factors are computed to

equilibrate
   the system:
      TRANS = 'N': diag(R)*A*diag(C)   *inv(diag(C))*X =
diag(R)*B
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X =
diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X =
diag(C)*B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used, A
is
   overwritten by diag(R)*A*diag(C) and B by diag(R)*B (if
TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to
factor the
   matrix A (after equilibration if FACT = 'E') as
      A = L * U,
   where L is a product of permutation and unit lower tri-
angular
   matrices with KL subdiagonals, and U is upper triangular
with
   KL+KU superdiagonals.

3. If some U(i,i)=0, so that U is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of A
is used
   to estimate the condition number of the matrix A. If the
   reciprocal of the condition number is less than machine
precision,
   INFO = N+1 is returned as a warning, but the routine
still goes on
   to solve for X and compute error bounds as described
below.

4. The system of equations is solved for X using the fac-
tored form
   of A.

5. Iterative refinement is applied to improve the computed
solution
   matrix and calculate error bounds and backward error
estimates
   for it.

6. If equilibration was used, the matrix X is premultiplied
by

```
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS  =  'T'  or
'C') so
   that it solves the original system before equilibration.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored form of  the
          matrix A is supplied on entry, and if not, whether
          the matrix A should be equilibrated before  it  is
          factored.  = 'F':  On entry, AF and IPIVOT contain
          the factored form of A.  If EQUED is not 'N',  the
          matrix  A  has been equilibrated with scaling fac-
          tors given by R and C.  A, AF, and IPIVOT are  not
          modified.   = 'N':  The matrix A will be copied to
          AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.
TRANSA (input)
          Specifies the form of the system of equations.   =
          'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

KL (input)
          The number of subdiagonals within the band  of  A.
          KL >= 0.

KU (input)
          The number of superdiagonals within the band of A.
          KU >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the matrix A in band storage, in rows  1
          to KL+KU+1.  The j-th column of A is stored in the
          j-th column of the array A as follows:   A(KU+1+i-
          j,j) = A(i,j) for max(1,j-KU)<=i<=min(N,j+kl)

          If FACT = 'F' and EQUED is not 'N',  then  A  must
          have been equilibrated by the scaling factors in R
```

and/or C. A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

On exit, if EQUED .ne. 'N', A is scaled as follows: EQUED = 'R': A := diag(R) * A
EQUED = 'C': A := A * diag(C)
EQUED = 'B': A := diag(R) * A * diag(C).

LDA (input)
The leading dimension of the array A. LDA >= KL+KU+1.

AF (input/output)
If FACT = 'F', then AF is an input argument and on entry contains details of the LU factorization of the band matrix A, as computed by SGBTRF. U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. If EQUED .ne. 'N', then AF is the factored form of the equilibrated matrix A.

If FACT = 'N', then AF is an output argument and on exit returns details of the LU factorization of A.

If FACT = 'E', then AF is an output argument and on exit returns details of the LU factorization of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)
The leading dimension of the array AF. LDAF >= 2*KL+KU+1.

IPIVOT (input)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = L*U as computed by SGBTRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = L*U of the equilibrated matrix A.

EQUED (input)
Specifies the form of equilibration that was done. = 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input/output)
The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input/output)
The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)
On entry, the right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))*X if TRANSA = 'N' and EQUED = 'C' or 'B', or inv(diag(R))*X if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)
The leading dimension of the array X. LDX >=

max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N) On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly

singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

NAME

```
dgbtf2 - compute an LU factorization of a real  m-by-n  band
matrix A using partial pivoting with row interchanges
```

SYNOPSIS

```
SUBROUTINE DGBTF2(M, N, KL, KU, AB, LDAB, IPIV, INFO)

INTEGER M, N, KL, KU, LDAB, INFO
INTEGER IPIV(*)
DOUBLE PRECISION AB(LDAB,*)

SUBROUTINE DGBTF2_64(M, N, KL, KU, AB, LDAB, IPIV, INFO)

INTEGER*8 M, N, KL, KU, LDAB, INFO
INTEGER*8 IPIV(*)
DOUBLE PRECISION AB(LDAB,*)
```

F95 INTERFACE

```
SUBROUTINE GBTF2([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])

INTEGER :: M, N, KL, KU, LDAB, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:,:) :: AB

SUBROUTINE GBTF2_64([M], [N], KL, KU, AB, [LDAB], IPIV, [INFO])

INTEGER(8) :: M, N, KL, KU, LDAB, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:,:) :: AB
```

C INTERFACE

```
#include <sunperf.h>

void dgbtf2(int m, int n, int kl, int ku,  double  *ab,  int
          ldab, int *ipiv, int *info);

void dgbtf2_64(long m, long n, long kl, long ku, double *ab,
          long ldab, long *ipiv, long *info);
```

PURPOSE

dgbtf2 computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the unblocked version of the algorithm, calling Level 2 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

KL (input)
The number of subdiagonals within the band of A. KL >= 0.

KU (input)
The number of superdiagonals within the band of A. KU >= 0.

AB (input/output)
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array AB as follows: AB(kl+ku+1+i-j,j) = A(i,j) for max(1,j-ku)<=i<=min(m,j+kl)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

LDAB (input)
The leading dimension of the array AB. LDAB >=

2*KL+KU+1.

IPIV (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = +i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

FURTHER DETAILS

The band storage scheme is illustrated by the following example, when M = N = 6, KL = 2, KU = 1:

```
On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*
```

Array elements marked * are not used by the routine; elements marked + need not be set on entry, but are required by the routine to store elements of U, because of fill-in resulting from the row interchanges.

          long ldab, long *ipivot, long *info);
```

PURPOSE

dgbtrf computes an LU factorization of a real m-by-n band matrix A using partial pivoting with row interchanges.

This is the blocked version of the algorithm, calling Level 3 BLAS.

ARGUMENTS

M (input) Integer
The number of rows of the matrix A. M >= 0.

N (input) Integer
The number of columns of the matrix A. N >= 0.

KL (input) Integer
The number of subdiagonals within the band of A. KL >= 0.

KU (input) Integer
The number of superdiagonals within the band of A. KU >= 0.

AB (input/output) Double precision array of dimension (LDAB,N).
On entry, the matrix A in band storage, in rows KL+1 to 2*KL+KU+1; rows 1 to KL of the array need not be set. The j-th column of A is stored in the j-th column of the array A as follows: AB(KL+KU+1+I-J,J) = A(I,J) for MAX(1,J-KU)<=I<=MIN(M,J+KL)

On exit, details of the factorization: U is stored as an upper triangular band matrix with KL+KU superdiagonals in rows 1 to KL+KU+1, and the multipliers used during the factorization are stored in rows KL+KU+2 to 2*KL+KU+1. See below for further details.

```
LDAB (input) Integer array of dimension MIN(M,N)
          The leading dimension of the array  AB.   LDAB  >=
          2*KL+KU+1.

IPIVOT (output) Integer array of dimension MIN(M,N)
          The pivot indices; for 1 <= I <= MIN(M,N),  row  I
          of the matrix was interchanged with row IPIVOT(I).

INFO (output) Integer
          = 0: successful exit
          < 0: if INFO = -I, the I-th argument had an  ille-
          gal value
          > 0: if INFO = +I, U(I,I)  is  exactly  zero.  The
          factorization has been completed, but the factor U
          is exactly singular, and  division  by  zero  will
          occur  if  it  is  used to solve a system of equa-
          tions.
```

FURTHER DETAILS

```
The band storage scheme  is  illustrated  by  the  following
example, when M = N = 6, KL = 2, KU = 1:

On entry:                       On exit:

    *    *    *    +    +    +       *    *    *   u14   u25
u36
    *    *    +    +    +    +       *    *   u13  u24   u35
u46
    *   a12  a23  a34  a45  a56      *   u12  u23  u34   u45
u56
   a11  a22  a33  a44  a55  a66     u11  u22  u33  u44   u55
u66
   a21  a32  a43  a54  a65   *      m21  m32  m43  m54   m65
*
   a31  a42  a53  a64   *    *      m31  m42  m53   m64    *
*

Array elements marked * are not used by  the  routine;  ele-
ments marked + need not be set on entry, but are required by
the routine to  store  elements  of  U  because  of  fill-in
resulting from the row interchanges.
```

void dgebak(char job, char side, int n, int  ilo,  int  ihi,
          double  *scale,  int  m,  double  *v, int ldv, int
          *info);

void dgebak_64(char job, char side, long n, long  ilo,  long
          ihi,  double  *scale, long m, double *v, long ldv,
          long *info);
```

PURPOSE

dgebak forms the right or left eigenvectors of a real general matrix by backward transformation on the computed eigenvectors of the balanced matrix output by SGEBAL.

ARGUMENTS

JOB (input)
Specifies the type of backward transformation required: = 'N', do nothing, return immediately; = 'P', do backward transformation for permutation only; = 'S', do backward transformation for scaling only; = 'B', do backward transformations for both permutation and scaling. JOB must be the same as the argument JOB supplied to SGEBAL.

SIDE (input)
= 'R': V contains right eigenvectors;
= 'L': V contains left eigenvectors.

N (input) The number of rows of the matrix V. N >= 0.

ILO (input)
The integers ILO and IHI determined by SGEBAL. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description for ILO.

SCALE (input)
Details of the permutation and scaling factors, as

returned by SGEBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)
On entry, the matrix of right or left eigenvectors to be transformed, as returned by SHSEIN or STREVC. On exit, V is overwritten by the transformed eigenvectors.

LDV (input)
The leading dimension of the array V. LDV >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

SUBROUTINE GEBAL_64(JOB, [N], A, [LDA], ILO, IHI, SCALE, [INFO])

CHARACTER(LEN=1) :: JOB
INTEGER(8) :: N, LDA, ILO, IHI, INFO
REAL(8), DIMENSION(:) :: SCALE
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgebal(char job, int n, double *a, int lda,  int  *ilo,
          int *ihi, double *scale, int *info);

void dgebal_64(char job, long n, double *a, long  lda,  long
          *ilo, long *ihi, double *scale, long *info);
```

PURPOSE

dgebal balances a general real matrix A. This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to ILO-1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

ARGUMENTS

JOB (input)
Specifies the operations to be performed on A:
= 'N': none: simply set ILO = 1, IHI = N, SCALE(I) = 1.0 for i = 1,...,N; = 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N', A is not referenced. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ILO (output)
ILO and IHI are set to integers such that on exit A(i,j) = 0 if i > j and j = 1,...,ILO-1 or I =

IHI+1,...,N. If JOB = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
See the description for ILO.

SCALE (output)
Details of the permutations and scaling factors applied to A. If P(j) is the index of the row and column interchanged with row and column j and D(j) is the scaling factor applied to row and column j, then SCALE(j) = P(j) for j = 1,...,ILO-1 = D(j) for j = ILO,...,IHI = P(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The permutations consist of row and column interchanges which put the matrix in the form

```
           ( T1   X   Y  )
   P A P = (  0   B   Z  )
           (  0   0   T2 )
```

where T1 and T2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ILO and IHI mark the starting and ending columns of the submatrix B. Balancing consists of applying a diagonal similarity transformation inv(D) * B * D to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

```
   ( T1     X*D          Y    )
   (  0  inv(D)*B*D  inv(D)*Z ).
   (  0      0           T2   )
```

Information about the permutations P and the diagonal matrix D is returned in the vector SCALE.

This subroutine is based on the EISPACK routine BALANC.

NAME

```
dgebrd - reduce a general real M-by-N matrix A to  upper  or
lower bidiagonal form B by an orthogonal transformation
```

SYNOPSIS

```
SUBROUTINE DGEBRD(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK, INFO)

INTEGER M, N, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*),  D(*),  E(*),  TAUQ(*),  TAUP(*),
WORK(*)

SUBROUTINE DGEBRD_64(M, N, A, LDA, D, E, TAUQ, TAUP, WORK, LWORK,
      INFO)

INTEGER*8 M, N, LDA, LWORK, INFO
DOUBLE PRECISION A(LDA,*),  D(*),  E(*),  TAUQ(*),  TAUP(*),
WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEBRD([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK], [LWORK],
       [INFO])

INTEGER :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: D, E, TAUQ, TAUP, WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GEBRD_64([M], [N], A, [LDA], D, E, TAUQ, TAUP, [WORK],
       [LWORK], [INFO])

INTEGER(8) :: M, N, LDA, LWORK, INFO
REAL(8), DIMENSION(:) :: D, E, TAUQ, TAUP, WORK
```

```
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgebrd(int m, int n, double *a,  int  lda,  double  *d,
          double *e, double *tauq, double *taup, int *info);

void dgebrd_64(long m, long n, double *a, long  lda,  double
          *d,  double  *e,  double *tauq, double *taup, long
          *info);
```

PURPOSE

dgebrd reduces a general real M-by-N matrix A to upper or lower bidiagonal form B by an orthogonal transformation: Q**T * A * P = B.

If m >= n, B is upper bidiagonal; if m < n, B is lower bidiagonal.

ARGUMENTS

M (input) The number of rows in the matrix A. M >= 0.

N (input) The number of columns in the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N general matrix to be reduced. On exit, if m >= n, the diagonal and the first superdiagonal are overwritten with the upper bidiagonal matrix B; the elements below the diagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors; if m < n, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B; the elements below the first subdiagonal, with the array TAUQ, represent the orthogonal matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array TAUP, represent the orthogonal matrix P as a product of elementary reflectors. See Further Details.

LDA (input)

```
            The leading dimension of  the  array  A.   LDA  >=
            max(1,M).

D (output)
            The diagonal elements of the bidiagonal matrix  B:
            D(i) = A(i,i).

E (output)
            The off-diagonal elements of the bidiagonal matrix
            B:   if m >= n, E(i) = A(i,i+1) for i = 1,2,...,n-
            1; if m < n, E(i) = A(i+1,i) for i = 1,2,...,m-1.

TAUQ (output)
            The scalar factors of  the  elementary  reflectors
            which  represent  the  orthogonal  matrix  Q.  See
            Further Details.

TAUP (output)
            The scalar factors of  the  elementary  reflectors
            which  represent  the  orthogonal  matrix  P.  See
            Further Details.

WORK (workspace)
            On exit, if INFO = 0, WORK(1) returns the  optimal
            LWORK.

LWORK (input)
            The  length  of  the   array   WORK.    LWORK   >=
            max(1,M,N).   For  optimum  performance  LWORK  >=
            (M+N)*NB, where NB is the optimal blocksize.

            If LWORK = -1, then a workspace query is  assumed;
            the  routine  only  calculates the optimal size of
            the WORK array, returns this value  as  the  first
            entry  of  the  WORK  array,  and no error message
            related to LWORK is issued by XERBLA.

INFO (output)
            = 0:  successful exit
            < 0:  if INFO = -i, the i-th argument had an ille-
            gal value.
```

FURTHER DETAILS

```
The matrices Q and P are represented as products of  elemen-
tary reflectors:

If m >= n,

   Q = H(1) H(2) . . . H(n)  and  P = G(1) G(2) . . . G(n-1)
```

Each H(i) and G(i) has the form:

```
   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'
```

where tauq and taup are real scalars, and v and u are real vectors; v(1:i-1) = 0, v(i) = 1, and v(i+1:m) is stored on exit in A(i+1:m,i); u(1:i) = 0, u(i+1) = 1, and u(i+2:n) is stored on exit in A(i,i+2:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

If m < n,

```
   Q = H(1) H(2) . . . H(m-1)  and  P = G(1) G(2) . . . G(m)
```

Each H(i) and G(i) has the form:

```
   H(i) = I - tauq * v * v'  and G(i) = I - taup * u * u'
```

where tauq and taup are real scalars, and v and u are real vectors; v(1:i) = 0, v(i+1) = 1, and v(i+2:m) is stored on exit in A(i+2:m,i); u(1:i-1) = 0, u(i) = 1, and u(i+1:n) is stored on exit in A(i,i+1:n); tauq is stored in TAUQ(i) and taup in TAUP(i).

The contents of A on exit are illustrated by the following examples:

```
m = 6 and n = 5 (m > n):          m = 5 and n = 6 (m < n):

  (  d   e   u1  u1  u1 )           (  d   u1   u1   u1   u1
u1 )
  (  v1  d   e   u2  u2 )           (  e   d    u2   u2   u2
u2 )
  (  v1  v2  d   e   u3 )           (  v1  e    d    u3   u3
u3 )
  (  v1  v2  v3  d   e  )           (  v1  v2   e    d    u4
u4 )
  (  v1  v2  v3  v4  d  )           (  v1   v2   v3   e    d
u5 )
  (  v1  v2  v3  v4  v5 )
```

where d and e denote diagonal and off-diagonal elements of B, vi denotes an element of the vector defining H(i), and ui an element of the vector defining G(i).

C INTERFACE

```
#include <sunperf.h>
void dgecon(char norm, int n, double  *a,  int  lda,  double
          anorm, double *rcond, int *info);

void dgecon_64(char norm, long n, double *a, long lda,  dou-
          ble anorm, double *rcond, long *info);
```

PURPOSE

dgecon estimates the reciprocal of the condition number of a general real matrix A, in either the 1-norm or the infinity-norm, using the LU factorization computed by SGETRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as
   RCOND = 1 / (norm(A) * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I':   Infinity-norm.

N (input) The order of the matrix A. N >= 0.

A (input) The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

ANORM (input)
If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)
The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(norm(A) * norm(inv(A))).

WORK (workspace)
dimension(4*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

NAME

dgeequ - compute row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number

SYNOPSIS

```
SUBROUTINE DGEEQU(M, N, A, LDA, R, C, ROWCN, COLCN, AMAX,
      INFO)

INTEGER M, N, LDA, INFO
DOUBLE PRECISION ROWCN, COLCN, AMAX
DOUBLE PRECISION A(LDA,*), R(*), C(*)

SUBROUTINE DGEEQU_64(M, N, A, LDA, R, C, ROWCN, COLCN, AMAX,
      INFO)

INTEGER*8 M, N, LDA, INFO
DOUBLE PRECISION ROWCN, COLCN, AMAX
DOUBLE PRECISION A(LDA,*), R(*), C(*)
```

F95 INTERFACE

```
SUBROUTINE GEEQU([M], [N], A, [LDA], R, C, ROWCN, COLCN,
       AMAX, [INFO])

INTEGER :: M, N, LDA, INFO
REAL(8) :: ROWCN, COLCN, AMAX
REAL(8), DIMENSION(:) :: R, C
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GEEQU_64([M], [N], A, [LDA], R, C, ROWCN, COLCN,
       AMAX, [INFO])

INTEGER(8) :: M, N, LDA, INFO
```

```
REAL(8) :: ROWCN, COLCN, AMAX
REAL(8), DIMENSION(:) :: R, C
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgeequ(int m, int n, double *a,  int  lda,  double  *r,
          double  *c,  double  *rowcn, double *colcn, double
          *amax, int *info);

void dgeequ_64(long m, long n, double *a, long  lda,  double
          *r,  double *c, double *rowcn, double *colcn, dou-
          ble *amax, long *info);
```

PURPOSE

dgeequ computes row and column scalings intended to equilibrate an M-by-N matrix A and reduce its condition number. R returns the row scale factors and C the column scale factors, chosen to try to make the largest element in each row and column of the matrix B with elements B(i,j)=R(i)*A(i,j)*C(j) have absolute value 1.

R(i) and C(j) are restricted to be between SMLNUM = smallest safe number and BIGNUM = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of A but works well in practice.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input) The M-by-N matrix whose equilibration factors are to be computed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

R (output)
If INFO = 0 or INFO > M, R contains the row scale factors for A.

C (output)

If INFO = 0, C contains the column scale factors for A.

ROWCN (output)
If INFO = 0 or INFO > M, ROWCN contains the ratio of the smallest R(i) to the largest R(i). If ROWCN >= 0.1 and AMAX is neither too large nor too small, it is not worth scaling by R.

COLCN (output)
If INFO = 0, COLCN contains the ratio of the smallest C(i) to the largest C(i). If COLCN >= 0.1, it is not worth scaling by C.

AMAX (output)
Absolute value of largest matrix element. If AMAX is very close to overflow or very close to underflow, the matrix should be scaled.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= M: the i-th row of A is exactly zero
> M: the (i-M)-th column of A is exactly zero

C INTERFACE

```
#include <sunperf.h>
void       dgees(char       jobz,        char        sortev,
          int(*select)(double,double), int n, double *a, int
          lda, int *nout, double *wr, double *wi, double *z,
          int ldz, int *info);

void      dgees_64(char       jobz,       char       sortev,
          long(*select)(double,double),  long  n, double *a,
          long lda, long *nout, double *wr, double *wi, dou-
          ble *z, long ldz, long *info);
```

PURPOSE

dgees computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z**T).

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left. The leading columns of Z then form an orthonormal basis for the invariant subspace corresponding to the selected eigenvalues.

A matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

```
        [  a  b  ]
        [  c  a  ]
```

where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

ARGUMENTS

```
JOBZ (input)
          = 'N': Schur vectors are not computed;
          = 'V': Schur vectors are computed.

SORTEV (input)
          Specifies whether or not to order the  eigenvalues
          on  the diagonal of the Schur form.  = 'N': Eigen-
          values are not ordered;
          = 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
          SELECT must be declared EXTERNAL  in  the  calling
          subroutine.   If  SORTEV  = 'S', SELECT is used to
          select eigenvalues to sort to the top left of  the
          Schur  form.   If  SORTEV  =  'N',  SELECT  is not
          referenced.  An eigenvalue WR(j)+sqrt(-1)*WI(j) is
          selected  if SELECT(WR(j),WI(j)) is true; i.e., if
          either one of a complex conjugate pair  of  eigen-
          values  is selected, then both complex eigenvalues
          are selected.  Note that a selected complex eigen-
          value  may no longer satisfy SELECT(WR(j),WI(j)) =
          .TRUE. after ordering, since ordering  may  change
          the  value  of  complex eigenvalues (especially if
          the eigenvalue is ill-conditioned); in  this  case
          INFO is set to N+2 (see INFO below).

N (input) The order of the matrix A. N >= 0.

A (input/output)
          On entry, the N-by-N matrix A.   On  exit,  A  has
          been overwritten by its real Schur form T.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

NOUT (output)
          If SORTEV = 'N', NOUT = 0.  If SORTEV = 'S',  NOUT
          =  number of eigenvalues (after sorting) for which
          SELECT is true. (Complex conjugate pairs for which
          SELECT is true for either eigenvalue count as 2.)

WR (output)
          WR and WI contain the real  and  imaginary  parts,
          respectively,  of  the computed eigenvalues in the
          same order that they appear on the diagonal of the
          output  Schur  form T.  Complex conjugate pairs of
          eigenvalues will  appear  consecutively  with  the
```

eigenvalue having the positive imaginary part first.

WI (output)
See the description for WR.

Z (output)
If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1; if JOBZ = 'V', LDZ >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) contains the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,3*N). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

WORK3 (workspace)
dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is
<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the matrix which reduces A to its partially converged Schur form. = N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

          ble *wi, double *z, long ldz, double *srcone, dou-
          ble *rconv, long *info);
```

PURPOSE

dgeesx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues, the real Schur form T, and, optionally, the matrix of Schur vectors Z. This gives the Schur factorization A = Z*T*(Z**T).

Optionally, it also orders the eigenvalues on the diagonal of the real Schur form so that selected eigenvalues are at the top left; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right invariant subspace corresponding to the selected eigenvalues (RCONDV). The leading columns of Z form an orthonormal basis for this invariant subspace.

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.10 of the LAPACK Users' Guide (where these quantities are called s and sep respectively).

A real matrix is in real Schur form if it is upper quasi-triangular with 1-by-1 and 2-by-2 blocks. 2-by-2 blocks will be standardized in the form

```
          [  a  b  ]
          [  c  a  ]
```

where b*c < 0. The eigenvalues of such a block are a +- sqrt(bc).

ARGUMENTS

JOBZ (input)
= 'N': Schur vectors are not computed;
= 'V': Schur vectors are computed.

SORTEV (input)
Specifies whether or not to order the eigenvalues on the diagonal of the Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see SELECT).

SELECT (input)
SELECT must be declared EXTERNAL in the calling subroutine. If SORTEV = 'S', SELECT is used to select eigenvalues to sort to the top left of the Schur form. If SORTEV = 'N', SELECT is not referenced. An eigenvalue WR(j)+sqrt(-1)*WI(j) is selected if SELECT(WR(j),WI(j)) is true; i.e., if either one of a complex conjugate pair of eigenvalues is selected, then both are. Note that a selected complex eigenvalue may no longer satisfy SELECT(WR(j),WI(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case INFO may be set to N+3 (see INFO below).

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for average of selected eigenvalues only;
= 'V': Computed for selected right invariant subspace only;
= 'B': Computed for both. If SENSE = 'E', 'V' or 'B', SORTEV must equal 'S'.

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the N-by-N matrix A. On exit, A is overwritten by its real Schur form T.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

NOUT (output)
If SORTEV = 'N', NOUT = 0. If SORTEV = 'S', NOUT = number of eigenvalues (after sorting) for which SELECT is true. (Complex conjugate pairs for which SELECT is true for either eigenvalue count as 2.)

WR (output)
WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues, in the same order that they appear on the diagonal of the output Schur form T. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)
See the description for WR.

Z (output)
If JOBZ = 'V', Z contains the orthogonal matrix Z of Schur vectors. If JOBZ = 'N', Z is not referenced.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1, and if JOBZ = 'V', LDZ >= N.

SRCONE (output)
If SENSE = 'E' or 'B', SRCONE contains the reciprocal condition number for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONV (output)
If SENSE = 'V' or 'B', RCONV contains the reciprocal condition number for the selected right invariant subspace. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,3*N). Also, if SENSE = 'E' or 'V' or 'B', LDWORK >= N+2*NOUT*(N-NOUT), where NOUT is the number of selected eigenvalues computed by this routine. Note that N+2*NOUT*(N-NOUT) <= N+N*N/2. For good performance, LDWORK must generally be larger.

IWORK2 (workspace/output)
Not referenced if SENSE = 'N' or 'E'. On exit, if INFO = 0, IWORK2(1) returns the optimal LDWRK2.

LDWRK2 (input)
The dimension of the array IWORK2. LDWRK2 >= 1; if SENSE = 'V' or 'B', LDWRK2 >= NOUT*(N-NOUT).

BWORK3 (workspace)
dimension(N) Not referenced if SORTEV = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, and i is
<= N: the QR algorithm failed to compute all the eigenvalues; elements 1:ILO-1 and i+1:N of WR and WI contain those eigenvalues which have converged; if JOBZ = 'V', Z contains the transformation which reduces A to its partially converged Schur form.
= N+1: the eigenvalues could not be reordered because some eigenvalues were too close to separate (the problem is very ill-conditioned); = N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Schur form no longer satisfy SELECT=.TRUE. This could also be caused by underflow due to scaling.

             long lda, double *wr, double *wi, double *vl, long
             ldvl, double *vr, long ldvr, long *info);
```

PURPOSE

```
   dgeev computes for an N-by-N real nonsymmetric matrix A, the
   eigenvalues and, optionally, the left and/or right eigenvec-
   tors.

   The right eigenvector v(j) of A satisfies
                    A * v(j) = lambda(j) * v(j)
   where lambda(j) is its eigenvalue.
   The left eigenvector u(j) of A satisfies
                 u(j)**H * A = lambda(j) * u(j)**H
   where u(j)**H denotes the conjugate transpose of u(j).

   The computed eigenvectors are normalized to  have  Euclidean
   norm equal to 1 and largest component real.
```

ARGUMENTS

```
   JOBVL (input)
             = 'N': left eigenvectors of A are not computed;
             = 'V': left eigenvectors of A are computed.

   JOBVR (input)
             = 'N': right eigenvectors of A are not computed;
             = 'V': right eigenvectors of A are computed.

   N (input) The order of the matrix A. N >= 0.

   A (input/output)
             On entry, the N-by-N matrix A.   On  exit,  A  has
```

been overwritten.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

WR (output)
WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)
See the description for WR.

VL (output)
If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL (input)
The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR (input)
If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR (input)
The leading dimension of the array VR. LDVR >= 1; if JOBVR = 'V', LDVR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK >= max(1,3*N), and if JOBVL = 'V' or JOBVR = 'V', LDWORK >= 4*N. For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors have been computed; elements i+1:N of WR and WI contain eigenvalues which have converged.

          double *abnrm, double *rcone, double *rconv,  long
          *info);
```

PURPOSE

dgeevx computes for an N-by-N real nonsymmetric matrix A, the eigenvalues and, optionally, the left and/or right eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, SCALE, and ABNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right
eigenvectors (RCONDV).

The right eigenvector v(j) of A satisfies

```
                 A * v(j) = lambda(j) * v(j)
where lambda(j) is its eigenvalue.
The left eigenvector u(j) of A satisfies
              u(j)**H * A = lambda(j) * u(j)**H
where u(j)**H denotes the conjugate transpose of u(j).
```

The computed eigenvectors are normalized to have Euclidean norm equal to 1 and largest component real.

Balancing a matrix means permuting the rows and columns to make it more nearly upper triangular, and applying a diagonal similarity transformation D * A * D**(-1), where D is a diagonal matrix, to make its rows and columns closer in norm and the condition numbers of its eigenvalues and eigenvectors smaller. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.10.2 of the LAPACK Users' Guide.

ARGUMENTS

BALANC (input)
Indicates how the input matrix should be diagonally scaled and/or permuted to improve the conditioning of its eigenvalues. = 'N': Do not diagonally scale or permute;
= 'P': Perform permutations to make the matrix more nearly upper triangular. Do not diagonally scale; = 'S': Diagonally scale the matrix, i.e. replace A by D*A*D**(-1), where D is a diagonal matrix chosen to make the rows and columns of A more equal in norm. Do not permute; = 'B': Both diagonally scale and permute A.

Computed reciprocal condition numbers will be for the matrix after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)
= 'N': left eigenvectors of A are not computed;
= 'V': left eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVL must = 'V'.

JOBVR (input)
= 'N': right eigenvectors of A are not computed;

= 'V': right eigenvectors of A are computed. If SENSE = 'E' or 'B', JOBVR must = 'V'.

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N': None are computed;
= 'E': Computed for eigenvalues only;
= 'V': Computed for right eigenvectors only;
= 'B': Computed for eigenvalues and right eigenvectors.

If SENSE = 'E' or 'B', both left and right eigenvectors must also be computed (JOBVL = 'V' and JOBVR = 'V').

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the N-by-N matrix A. On exit, A has been overwritten. If JOBVL = 'V' or JOBVR = 'V', A contains the real Schur form of the balanced version of the input matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

WR (output)
WR and WI contain the real and imaginary parts, respectively, of the computed eigenvalues. Complex conjugate pairs of eigenvalues will appear consecutively with the eigenvalue having the positive imaginary part first.

WI (output)
See the description for WR.

VL (output)
If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If JOBVL = 'N', VL is not referenced. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then u(j) = VL(:,j) + i*VL(:,j+1) and
u(j+1) = VL(:,j) - i*VL(:,j+1).

LDVL (input)
The leading dimension of the array VL. LDVL >= 1; if JOBVL = 'V', LDVL >= N.

VR (output)
If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If JOBVR = 'N', VR is not referenced. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-st eigenvalues form a complex conjugate pair, then v(j) = VR(:,j) + i*VR(:,j+1) and
v(j+1) = VR(:,j) - i*VR(:,j+1).

LDVR (input)
The leading dimension of the array VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO (output)
ILO and IHI are integer values determined when A was balanced. The balanced A(i,j) = 0 if I > J and J = 1,...,ILO-1 or I = IHI+1,...,N.

IHI (output)
See the description of ILO.

SCALE (output)
Details of the permutations and scaling factors applied when balancing A. If P(j) is the index of the row and column interchanged with row and column j, and D(j) is the scaling factor applied to row and column j, then SCALE(J) = P(J), for J = 1,...,ILO-1 = D(J), for J = ILO,...,IHI = P(J) for J = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)
The one-norm of the balanced matrix (the maximum of the sum of absolute values of elements of any column).

RCONE (output)
RCONE(j) is the reciprocal condition number of the j-th eigenvalue.

RCONV (output)
RCONV(j) is the reciprocal condition number of the j-th right eigenvector.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. If SENSE = 'N' or 'E', LDWORK >= max(1,2*N), and if JOBVL = 'V' or JOBVR = 'V', LDWORK >= 3*N. If SENSE = 'V' or 'B', LDWORK >= N*(N+6). For good performance, LDWORK must generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

IWORK2 (workspace)
dimension(2*N-2) If SENSE = 'N' or 'E', not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = i, the QR algorithm failed to compute all the eigenvalues, and no eigenvectors or condition numbers have been computed; elements 1:ILO-1 and i+1:N of WR and WI contain eigenvalues which have converged.

PURPOSE

dgegs routine is deprecated and has been replaced by routine SGGES.

SGEGS computes for a pair of N-by-N real nonsymmetric matrices A, B: the generalized eigenvalues (alphar +/- alphai*i, beta), the real Schur form (A, B), and optionally left and/or right Schur vectors (VSL and VSR).

(If only the generalized eigenvalues are needed, use the driver SGEGV instead.)

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

The (generalized) Schur form of a pair of matrices is the result of multiplying both matrices on the left by one orthogonal matrix and both on the right by another orthogonal matrix, these two orthogonal matrices being chosen so as to bring the pair of matrices into (real) Schur form.

A pair of matrices A, B is in generalized real Schur form if B is upper triangular with non-negative diagonal and A is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues,

```
while 2-by-2 blocks of A will be  "standardized"  by  making
the corresponding elements of B have the form:
        [  a  0  ]
        [  0  b  ]

and the pair of corresponding 2-by-2 blocks in A and B  will
have a complex conjugate pair of generalized eigenvalues.

The left and right Schur vectors are the columns of VSL  and
VSR,  respectively,  where  VSL  and  VSR are the orthogonal
matrices which reduce A and B to Schur form:

Schur form of (A,B) = ( (VSL)**T A (VSR), (VSL)**T B (VSR) )
```

ARGUMENTS

```
JOBVSL (input)
          = 'N':  do not compute the left Schur vectors;
          = 'V':  compute the left Schur vectors.

JOBVSR (input)
          = 'N':  do not compute the right Schur vectors;
          = 'V':  compute the right Schur vectors.

N (input) The order of the matrices A, B, VSL, and  VSR.   N
          >= 0.

A (input/output)
          On entry, the first of the pair of matrices  whose
          generalized  eigenvalues  and  (optionally)  Schur
          vectors are to be computed.  On exit, the general-
          ized  Schur  form  of A.  Note: to avoid overflow,
          the Frobenius norm of the matrix A should be  less
          than the overflow threshold.

LDA (input)
          The leading dimension of A.  LDA >= max(1,N).

B (input/output)
          On entry, the second of the pair of matrices whose
          generalized  eigenvalues  and  (optionally)  Schur
          vectors are to be computed.  On exit, the general-
          ized  Schur  form  of B.  Note: to avoid overflow,
          the Frobenius norm of the matrix B should be  less
          than the overflow threshold.

LDB (input)
          The leading dimension of B.  LDB >= max(1,N).
```

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, j=1,...,N and BETA(j),j=1,...,N are the diagonals of the complex Schur form (A,B) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. (See "Purpose", above.) Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
If JOBVSR = 'V', VSR will contain the right Schur vectors. (See "Purpose", above.) Not referenced if JOBVSR = 'N'.

LDVSR (input)
The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal

LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,4*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: NB -- MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR The optimal LDWORK is 2*N + N*(NB+1).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from SGGBAL
=N+2: error return from SGEQRF
=N+3: error return from SORMQR
=N+4: error return from SORGQR
=N+5: error return from SGGHRD
=N+6: error return from SHGEQZ (other than failed iteration) =N+7: error return from SGGBAK (computing VSL)
=N+8: error return from SGGBAK (computing VSR)
=N+9: error return from SLASCL (various places)

          ldvl, double *vr, long ldvr, long *info);
```

PURPOSE

dgegv routine is deprecated and has been replaced by routine SGGEV.

SGEGV computes for a pair of n-by-n real nonsymmetric matrices A and B, the generalized eigenvalues (alphar +/- alphai*i, beta), and optionally, the left and/or right generalized eigenvectors (VL and VR).

A generalized eigenvalue for a pair of matrices (A,B) is, roughly speaking, a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero. A good beginning reference is the book, "Matrix Computations", by G. Golub & C. van Loan (Johns Hopkins U. Press)

A right generalized eigenvector corresponding to a generalized eigenvalue w for a pair of matrices (A,B) is a vector r such that (A - w B) r = 0 . A left generalized eigenvector is a vector l such that l**H * (A - w B) = 0, where l**H is the
conjugate-transpose of l.

Note: this routine performs "full balancing" on A and B -- see "Further Details", below.

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of A on exit, see "Further Details", below.)

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices whose generalized eigenvalues and (optionally) generalized eigenvectors are to be computed. On exit, the contents will have been destroyed. (For a description of the contents of B on exit, see "Further Details", below.)

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description of ALPHAR.

BETA (output)
See the description of ALPHAR.

VL (output)
If JOBVL = 'V', the left generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVL = 'N'.

LDVL (input)
The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (output)
If JOBVR = 'V', the right generalized eigenvectors. (See "Purpose", above.) Real eigenvectors take one column, complex take two columns, the first for the real part and the second for the imaginary part. Complex eigenvectors correspond to an eigenvalue with positive imaginary part. Each eigenvector will be scaled so the largest component will have abs(real part) + abs(imag. part) = 1, *except* that for eigenvalues with alpha=beta=0, a zero vector will be returned as the corresponding eigenvector. Not referenced if JOBVR = 'N'.

LDVR (input)
The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)

The dimension of the array WORK. LDWORK >= max(1,8*N). For good performance, LDWORK must generally be larger. To compute the optimal value of LDWORK, call ILAENV to get blocksizes (for SGEQRF, SORMQR, and SORGQR.) Then compute: NB -- MAX of the blocksizes for SGEQRF, SORMQR, and SORGQR; The optimal LDWORK is: 2*N + MAX(6*N, N*(NB+1)).

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: errors that usually indicate LAPACK problems:
=N+1: error return from SGGBAL
=N+2: error return from SGEQRF
=N+3: error return from SORMQR
=N+4: error return from SORGQR
=N+5: error return from SGGHRD
=N+6: error return from SHGEQZ (other than failed iteration) =N+7: error return from STGEVC
=N+8: error return from SGGBAK (computing VL)
=N+9: error return from SGGBAK (computing VR)
=N+10: error return from SLASCL (various calls)

FURTHER DETAILS

Balancing

This driver calls SGGBAL to both permute and scale rows and columns of A and B. The permutations PL and PR are chosen so that PL*A*PR and PL*B*R will be upper triangular except for the diagonal blocks A(i:j,i:j) and B(i:j,i:j), with i and j as close together as possible. The diagonal scaling matrices DL and DR are chosen so that the pair DL*PL*A*PR*DR, DL*PL*B*PR*DR have elements close to one (except for the elements that start out zero.)

After the eigenvalues and eigenvectors of the balanced matrices have been computed, SGGBAK transforms the eigenvectors back to what they would have been (in perfect arithmetic) if they had not been balanced.

Contents of A and B on Exit
-------- -- - --- - -- ----

If any eigenvectors are computed (either JOBVL='V' or JOBVR='V' or both), then on exit the arrays A and B will contain the real Schur form[*] of the "balanced" versions of A and B. If no eigenvectors are computed, then only the diagonal blocks will be correct.

[*] See SHGEQZ, SGEGS, or read the book "Matrix Computations",
by Golub & van Loan, pub. by Johns Hopkins U. Press.

NAME

```
dgehrd - reduce a real general matrix A to upper  Hessenberg
form H by an orthogonal similarity transformation
```

SYNOPSIS

```
SUBROUTINE DGEHRD(N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)

INTEGER N, ILO, IHI, LDA, LWORKIN, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORKIN(*)

SUBROUTINE DGEHRD_64(N, ILO, IHI, A, LDA, TAU, WORKIN, LWORKIN, INFO)

INTEGER*8 N, ILO, IHI, LDA, LWORKIN, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORKIN(*)
```

F95 INTERFACE

```
SUBROUTINE GEHRD([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
       [INFO])

INTEGER :: N, ILO, IHI, LDA, LWORKIN, INFO
REAL(8), DIMENSION(:) :: TAU, WORKIN
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GEHRD_64([N], ILO, IHI, A, [LDA], TAU, [WORKIN], [LWORKIN],
       [INFO])

INTEGER(8) :: N, ILO, IHI, LDA, LWORKIN, INFO
REAL(8), DIMENSION(:) :: TAU, WORKIN
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgehrd(int n, int ilo, int ihi,  double  *a,  int  lda,
          double *tau, int *info);

void dgehrd_64(long n, long ilo, long ihi, double  *a,  long
          lda, double *tau, long *info);
```

PURPOSE

dgehrd reduces a real general matrix A to upper Hessenberg form H by an orthogonal similarity transformation: Q' * A * Q = H .

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. ILO and IHI are normally set by a previous call to SGEBAL; otherwise they should be set to 1 and N respectively. See Further Details.

IHI (input)
See the description of ILO.

A (input/output)
On entry, the N-by-N general matrix to be reduced. On exit, the upper triangle and the first subdiagonal of A are overwritten with the upper Hessenberg matrix H, and the elements below the first subdiagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors. See Further Details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details). Elements 1:ILO-1 and IHI:N-1 of TAU are set to zero.

WORKIN (workspace)

On exit, if INFO = 0, WORKIN(1) returns the optimal LWORKIN.

LWORKIN (input)
The length of the array WORKIN. LWORKIN >= max(1,N). For optimum performance LWORKIN >= N*NB, where NB is the optimal blocksize.

If LWORKIN = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORKIN array, returns this value as the first entry of the WORKIN array, and no error message related to LWORKIN is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of (ihi-ilo) elementary reflectors

```
   Q = H(ilo) H(ilo+1) . . . H(ihi-1).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(1:i) = 0, v(i+1) = 1 and v(ihi+1:n) = 0; v(i+2:ihi) is stored on exit in A(i+2:ihi,i), and tau in TAU(i).

The contents of A are illustrated by the following example, with n = 7, ilo = 2 and ihi = 6:

```
on entry,                        on exit,

( a   a   a   a   a   a   a )    (  a   a   h    h    h    h
a  )  (      a   a   a   a   a   a )    (      a   h   h   h
h   a ) (     a   a   a   a   a   a )    (       h    h    h
h    h    h  ) (     a   a   a   a   a   a )    (      v2  h
h   h   h   h ) (     a   a   a   a   a   a )     (       v2
v3   h    h    h    h  )  (     a   a   a   a   a   a )    (
v2  v3  v4  h   h   h ) (                         a  )     (
a )
```

where a denotes an element of the original matrix A, h denotes a modified element of the upper Hessenberg matrix H, and vi denotes an element of the vector defining H(i).

          *tau, long *info);
```

PURPOSE

dgelqf computes an LQ factorization of a real M-by-N matrix A: A = L * Q.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the elements on and below the diagonal of the array contain the m-by-min(m,n) lower trapezoidal matrix L (L is lower triangular if m <= n); the elements above the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(k) . . . H(2) H(1), where k = min(m,n).

Each H(i) has the form
   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is  stored  on  exit  in
A(i,i+1:n), and tau in TAU(i).

```

C INTERFACE

```
#include <sunperf.h>

void dgels (char, int, int, int, double*, int, double*, int,
          int*);

void dgels_64 (char, long, long, long, double*,  long,  dou-
          ble*, long, long*);
```

PURPOSE

dgels solves overdetermined or underdetermined real linear systems involving an M-by-N matrix A, or its transpose, using a QR or LQ factorization of A. It is assumed that A has full rank.

The following options are provided:

```
1. If TRANS = 'N' and m >= n:  find the least squares  solu-
tion of
   an overdetermined system, i.e., solve the  least  squares
problem
                minimize || B - A*X ||.

2. If TRANS = 'N' and m < n:  find the minimum norm solution
of
   an underdetermined system A * X = B.

3. If TRANS = 'T' and m >= n:  find the minimum  norm  solu-
tion of
   an undetermined system A**T * X = B.

4. If TRANS = 'T' and m < n:  find the least  squares  solu-
tion of
   an overdetermined system, i.e., solve the  least  squares
problem
                minimize || B - A**T * X ||.
```

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

ARGUMENTS

```
TRANSA (input)
          = 'N': the linear system involves A;
          = 'T': the linear system involves A**T.

          TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X. NRHS >=0.
A (input/output)
          On entry, the M-by-N matrix A.  On exit, if  M  >=
          N,  A is overwritten by details of its QR factori-
          zation as returned by SGEQRF; if  M  <   N,  A  is
          overwritten  by details of its LQ factorization as
          returned by SGELQF.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

B (input/output)
          On entry, the matrix B of right hand side vectors,
          stored columnwise; B is M-by-NRHS if TRANSA = 'N',
          or N-by-NRHS if TRANSA  =  'T'.   On  exit,  B  is
          overwritten   by   the  solution  vectors,  stored
          columnwise:  if TRANSA = 'N' and m >= n, rows 1 to
          n of B contain the least squares solution vectors;
          the residual sum of squares for  the  solution  in
          each column is given by the sum of squares of ele-
          ments N+1 to M in that column; if TRANSA = 'N' and
          m  <  n, rows 1 to N of B contain the minimum norm
          solution vectors; if TRANSA = 'T' and m >= n, rows
          1 to M of B contain the minimum norm solution vec-
          tors; if TRANSA = 'T' and m < n, rows 1 to M of  B
          contain  the  least  squares solution vectors; the
          residual sum of squares for the solution  in  each
          column  is given by the sum of squares of elements
          M+1 to N in that column.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          MAX(1,M,N).
```

```
WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LDWORK.

LDWORK (output)
          The dimension of the array WORK.  LDWORK  >=  max(
          1,  MN  +  max( MN, NRHS ) ).  For optimal perfor-
          mance, LDWORK >= max( 1, MN + max( MN,  NRHS  )*NB
          ).   where  MN  =  min(M,N)  and NB is the optimum
          block size.

          If LDWORK = -1, then a workspace query is assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LDWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value

REAL(8), DIMENSION(:) :: S, WORK
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dgelsd(int m, int n, int nrhs, double *a, int lda, dou-
          ble  *b,  int  ldb,  double  *s, double rcond, int
          *rank, int *info);
void dgelsd_64(long m, long n, long nrhs,  double  *a,  long
          lda, double *b, long ldb, double *s, double rcond,
          long *rank, long *info);
```

PURPOSE

```
dgelsd computes the minimum-norm solution to a  real  linear
least squares problem:
    minimize 2-norm(| b - A*x |)
using the singular value decomposition (SVD) of A. A  is  an
M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can
be  handled in a single call; they are stored as the columns
of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
solution matrix X.

The problem is solved in three steps:
(1) Reduce the coefficient matrix A to bidiagonal form with
    Householder transformations, reducing the original prob-
lem
    into a "bidiagonal least squares problem" (BLS)
(2) Solve the BLS using a divide and conquer approach.
(3) Apply back all the Householder tranformations to solve
    the original least squares problem.

The effective rank of A is determined by  treating  as  zero
those  singular  values  which are less than RCOND times the
largest singular value.

The divide and conquer algorithm makes very mild assumptions
about  floating  point  arithmetic. It will work on machines
with a guard digit  in  add/subtract,  or  on  those  binary
machines  without  guard digits which subtract like the Cray
```

X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

M (input) The number of rows of A. M >= 0.

N (input) The number of columns of A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A has been destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and RANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)
The leading dimension of the array B. LDB >= max(1,max(M,N)).

S (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm = S(1)/S(min(m,n)).

RCOND (input)
RCOND is used to determine the effective rank of A. Singular values S(i) <= RCOND*S(1) are treated as zero. If RCOND < 0, machine precision is used instead.

RANK (output)
The effective rank of A, i.e., the number of singular values which are greater than RCOND*S(1).

```
WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.

LWORK (input)
          The dimension of the array WORK. LWORK >= 1.   The
          exact  minimum  amount of workspace needed depends
          on M, N and NRHS.  As long as LWORK  is  at  least
          12*N   +   2*N*SMLSIZ   +   8*N*NLVL  +  N*NRHS  *
          (SMLSIZ+1)**2, if M is greater than or equal to  N
          or  12*M  +  2*M*SMLSIZ  +  8*M*NLVL  +  M*NRHS  +
          (SMLSIZ+1)**2, if M is less than N, the code  will
          execute  correctly.   SMLSIZ is returned by ILAENV
          and is equal to the maximum size of  the  subprob-
          lems  at  the bottom of the computation tree (usu-
          ally about 25), and NLVL = INT(  LOG_2(  MIN(  M,N
          )/(SMLSIZ+1)  )  ) + 1 For good performance, LWORK
          should generally be larger.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

IWORK (workspace)
          LIWORK >= 3 * MINMN * NLVL +  11  *  MINMN,  where
          MINMN = MIN( M,N ).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  the algorithm for computing the  SVD  failed
          to  converge; if INFO = i, i off-diagonal elements
          of an intermediate bidiagonal form  did  not  con-
          verge to zero.

```

PURPOSE

dgelss computes the minimum norm solution to a real linear least squares problem:

Minimize 2-norm(| b - A*x |).

using the singular value decomposition (SVD) of A. A is an M-by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the M-by-NRHS right hand side matrix B and the N-by-NRHS solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrices B and X. NRHS >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the first min(m,n) rows of A are overwritten with its right

singular vectors, stored rowwise.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the M-by-NRHS right hand side matrix B. On exit, B is overwritten by the N-by-NRHS solution matrix X. If m >= n and IRANK = n, the residual sum-of-squares for the solution in the i-th column is given by the sum of squares of elements n+1:m in that column.

LDB (input)
The leading dimension of the array B. LDB >= max(1,max(M,N)).

SING (output)
The singular values of A in decreasing order. The condition number of A in the 2-norm = SING(1)/SING(min(m,n)).

RCOND (input)
RCOND is used to determine the effective rank of A. Singular values SING(i) <= RCOND*SING(1) are treated as zero. If RCOND < 0, machine precision is used instead.

IRANK (output)
The effective rank of A, i.e., the number of singular values which are greater than RCOND*SING(1).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= 1, and also: LDWORK >= 3*min(M,N) + max(2*min(M,N), max(M,N), NRHS) For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: the algorithm for computing the SVD failed to converge; if INFO = i, i off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

          lda,  double  *b,  long  ldb, long *jpivot, double
          rcond, long *irank, long *info);
```

PURPOSE

```
dgelsx routine is deprecated and has been replaced  by  rou-
tine SGELSY.

SGELSX computes the minimum-norm solution to a  real  linear
least squares problem:
    minimize || A * X - B ||
using a complete orthogonal factorization of A.  A is an  M-
by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can
be  handled in a single call; they are stored as the columns
of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
solution matrix X.

The routine first computes a QR  factorization  with  column
pivoting:
    A * P = Q * [ R11 R12 ]
                [  0  R22 ]
with R11 defined as  the  largest  leading  submatrix  whose
estimated  condition number is less than 1/RCOND.  The order
of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihi-
lated by orthogonal transformations from the right, arriving
at the complete orthogonal factorization:
   A * P = Q * [ T11 0 ] * Z
               [  0  0 ]
The minimum-norm solution is then
   X = P * Z' [ inv(T11)*Q1'*B ]
```

```
                [        0       ]
     where Q1 consists of the first RANK columns of Q.
```

ARGUMENTS

```
     M (input) The number of rows of the matrix A.  M >= 0.

     N (input) The number of columns of the matrix A.  N >= 0.

     NRHS (input)
               The number of right hand sides, i.e.,  the  number
               of columns of matrices B and X. NRHS >= 0.
     A (input/output)
               On entry, the M-by-N matrix A.   On  exit,  A  has
               been   overwritten  by  details  of  its  complete
               orthogonal factorization.

     LDA (input)
               The leading dimension of  the  array  A.   LDA  >=
               max(1,M).

     B (input/output)
               On entry, the M-by-NRHS right hand side matrix  B.
               On exit, the N-by-NRHS solution matrix X.  If m >=
               n and IRANK = n, the residual  sum-of-squares  for
               the  solution  in  the i-th column is given by the
               sum of squares of elements N+1:M in that column.

     LDB (input)
               The leading dimension  of  the  array  B.  LDB  >=
               max(1,M,N).

     JPIVOT (input/output)
               On entry, if JPIVOT(i) .ne. 0, the i-th column  of
               A  is  an  initial  column, otherwise it is a free
               column.  Before the QR  factorization  of  A,  all
               initial  columns are permuted to the leading posi-
               tions; only the remaining free columns  are  moved
               as a result of column pivoting during the factori-
               zation.  On exit, if JPIVOT(i) = k, then the  i-th
               column of A*P was the k-th column of A.

     RCOND (input)
               RCOND is used to determine the effective  rank  of
               A,  which  is  defined as the order of the largest
               leading triangular submatrix R11 in the QR factor-
               ization with pivoting of A, whose estimated condi-
               tion number < 1/RCOND.
```

IRANK (output)
The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)
(max(min(M,N)+3*N, 2*min(M,N)+NRHS)),

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

```

PURPOSE

```
dgelsy computes the minimum-norm solution to a  real  linear
least squares problem:
    minimize || A * X - B ||
using a complete orthogonal factorization of A.  A is an  M-
by-N matrix which may be rank-deficient.

Several right hand side vectors b and solution vectors x can
be  handled in a single call; they are stored as the columns
of the M-by-NRHS right hand side matrix B and the  N-by-NRHS
solution matrix X.

The routine first computes a QR  factorization  with  column
pivoting:
    A * P = Q * [ R11 R12 ]
                [  0  R22 ]
with R11 defined as  the  largest  leading  submatrix  whose
estimated  condition number is less than 1/RCOND.  The order
of R11, RANK, is the effective rank of A.

Then, R22 is considered to be negligible, and R12 is annihi-
lated by orthogonal transformations from the right, arriving
at the complete orthogonal factorization:
   A * P = Q * [ T11 0 ] * Z
               [  0  0 ]
The minimum-norm solution is then
   X = P * Z' [ inv(T11)*Q1'*B ]
              [        0       ]
where Q1 consists of the first RANK columns of Q.
```

```
This routine is basically identical to the  original  xGELSX
except three differences:
  o The call to the subroutine xGEQPF has  been  substituted
by the
    the call to the subroutine xGEQP3. This subroutine is  a
Blas-3
    version of the QR factorization with column pivoting.
  o Matrix B (the right hand side) is updated with Blas-3.
  o The permutation of matrix B (the  right  hand  side)  is
faster and
    more simple.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.
N (input) The number of columns of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of matrices B and X. NRHS >= 0.

A (input/output)
          On entry, the M-by-N matrix A.   On  exit,  A  has
          been   overwritten  by  details  of  its  complete
          orthogonal factorization.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

B (input/output)
          On entry, the M-by-NRHS right hand side matrix  B.
          On exit, the N-by-NRHS solution matrix X.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,M,N).

JPVT (input/output)
          On entry, if JPVT(i) .ne. 0, the i-th column of  A
          is permuted to the front of AP, otherwise column i
          is a free column.  On exit, if JPVT(i) =  k,  then
          the i-th column of AP was the k-th column of A.

RCOND (input)
          RCOND is used to determine the effective  rank  of
          A,  which  is  defined as the order of the largest
```

leading triangular submatrix R11 in the QR factorization with pivoting of A, whose estimated condition number < 1/RCOND.

RANK (output)
The effective rank of A, i.e., the order of the submatrix R11. This is the same as the order of the submatrix T11 in the complete orthogonal factorization of A.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. The unblocked strategy requires that: LWORK >= MAX(MN+3*N+1, 2*MN+NRHS), where MN = min(M, N). The block algorithm requires that: LWORK >= MAX(MN+2*N+NB*(N+1), 2*MN+NB*NRHS), where NB is an upper bound on the blocksize returned by ILAENV for the routines SGEQP3, STZRZF, STZRQF, SORMQR, and SORMRZ.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: If INFO = -i, the i-th argument had an illegal value.

NAME

dgemm - perform one of the matrix-matrix operations C := alpha*op(A)*op(B) + beta*C

SYNOPSIS

```
SUBROUTINE DGEMM(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
      BETA, C, LDC)

CHARACTER * 1 TRANSA, TRANSB
INTEGER M, N, K, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)

SUBROUTINE DGEMM_64(TRANSA, TRANSB, M, N, K, ALPHA, A, LDA, B, LDB,
      BETA, C, LDC)

CHARACTER * 1 TRANSA, TRANSB
INTEGER*8 M, N, K, LDA, LDB, LDC
DOUBLE PRECISION ALPHA, BETA
DOUBLE PRECISION A(LDA,*), B(LDB,*), C(LDC,*)
```

F95 INTERFACE

```
SUBROUTINE GEMM([TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],
       B, [LDB], BETA, C, [LDC])

CHARACTER(LEN=1) :: TRANSA, TRANSB
INTEGER :: M, N, K, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,:) :: A, B, C

SUBROUTINE GEMM_64([TRANSA], [TRANSB], [M], [N], [K], ALPHA, A, [LDA],
       B, [LDB], BETA, C, [LDC])
```

```
CHARACTER(LEN=1) :: TRANSA, TRANSB
INTEGER(8) :: M, N, K, LDA, LDB, LDC
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:,:) :: A, B, C
```

C INTERFACE

```
#include <sunperf.h>

void dgemm(char transa, char transb, int m, int  n,  int  k,
          double  alpha,  double *a, int lda, double *b, int
          ldb, double beta, double *c, int ldc);

void dgemm_64(char transa, char transb, long m, long n, long
          k,  double  alpha, double *a, long lda, double *b,
          long ldb, double beta, double *c, long ldc);
```

PURPOSE

dgemm performs one of the matrix-matrix operations C := alpha*op(A)*op(B) + beta*C where op(X) is one of

op(X) = X   or   op(X) = X',

alpha and beta are scalars, and A, B and C are matrices, with op(A) an m by k matrix, op(B) a k by n matrix and C an m by n matrix.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the form of op(A) to be used in the matrix multiplication as follows:

TRANSA = 'N' or 'n', op(A) = A.

TRANSA = 'T' or 't', op(A) = A'.

TRANSA = 'C' or 'c', op(A) = A'.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

TRANSB (input)
On entry, TRANSB specifies the form of op(B) to be used in the matrix multiplication as follows:

TRANSB = 'N' or 'n', op(B) = B.

TRANSB = 'T' or 't', op(B) = B'.

TRANSB = 'C' or 'c', op(B) = B'.

Unchanged on exit.

TRANSB is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix op(A) and of the matrix C. M must be at least zero. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix op(B) and the number of columns of the matrix C. N must be at least zero. Unchanged on exit.

K (input)
On entry, K specifies the number of columns of the matrix op(A) and the number of rows of the matrix op(B). K must be at least zero. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
DOUBLE PRECISION array of DIMENSION (LDA, ka), where ka is k when TRANSA = 'N' or 'n', and is m otherwise. Before entry with TRANSA = 'N' or 'n', the leading m by k part of the array A must contain the matrix A, otherwise the leading k by m part of the array A must contain the matrix A. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. When TRANSA = 'N' or 'n' then LDA >= max(1, m), otherwise LDA >= max(1, k). Unchanged on exit.

B (input)
DOUBLE PRECISION array of DIMENSION (LDB, kb), where kb is n when TRANSB = 'N' or 'n', and is k otherwise. Before entry with TRANSB = 'N' or

'n', the leading k by n part of the array B must contain the matrix B, otherwise the leading n by k part of the array B must contain the matrix B. Unchanged on exit.

LDB (input)

On entry, LDB specifies the first dimension of B as declared in the calling (sub) program. When TRANSB = 'N' or 'n' then LDB >= max(1, k), otherwise LDB >= max(1, n). Unchanged on exit.

BETA (input)

On entry, BETA specifies the scalar beta. When BETA is supplied as zero then C need not be set on input. Unchanged on exit.

C (input/output)

DOUBLE PRECISION array of DIMENSION (LDC, n). Before entry, the leading m by n part of the array C must contain the matrix C, except when beta is zero, in which case C need not be set on entry. On exit, the array C is overwritten by the m by n matrix (alpha*op(A)*op(B) + beta*C).

LDC (input)

On entry, LDC specifies the first dimension of C as declared in the calling (sub) program. LDC >= max(1, m). Unchanged on exit.

SUBROUTINE GEMV_64([TRANSA], [M], [N], ALPHA, A, [LDA], X, [INCX],
       BETA, Y, [INCY])
```

```
CHARACTER(LEN=1) :: TRANSA
INTEGER(8) :: M, N, LDA, INCX, INCY
REAL(8) :: ALPHA, BETA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgemv(char transa, int m, int n, double  alpha,  double
          *a,  int  lda,  double  *x, int incx, double beta,
          double *y, int incy);
void dgemv_64(char transa, long m,  long  n,  double  alpha,
          double  *a, long lda, double *x, long incx, double
          beta, double *y, long incy);
```

PURPOSE

dgemv performs one of the matrix-vector operations y := alpha*A*x + beta*y, or y := alpha*A'*x + beta*y, where alpha and beta are scalars, x and y are vectors and A is an m by n matrix.

ARGUMENTS

TRANSA (input)
On entry, TRANSA specifies the operation to be performed as follows:

TRANSA = 'N' or 'n'   y := alpha*A*x + beta*y.

TRANSA = 'T' or 't'   y := alpha*A'*x + beta*y.

TRANSA = 'C' or 'c'   y := alpha*A'*x + beta*y.

Unchanged on exit.

TRANSA is defaulted to 'N' for F95 INTERFACE.

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

A (input)
Before entry, the leading m by n part of the array A must contain the matrix of coefficients. Unchanged on exit.

LDA (input)
On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

X (input)
(1 + (n - 1)*abs(INCX)) when TRANSA = 'N' or 'n' and at least (1 + (m - 1)*abs(INCX)) otherwise. Before entry, the incremented array X must contain the vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

BETA (input)
On entry, BETA specifies the scalar beta. When BETA is supplied as zero then Y need not be set on input. Unchanged on exit.

Y (input/output)
(1 + (m - 1)*abs(INCY)) when TRANSA = 'N' or 'n' and at least (1 + (n - 1)*abs(INCY)) otherwise. Before entry with BETA non-zero, the incremented array Y must contain the vector y. On exit, Y is overwritten by the updated vector y.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

NAME

```
dgeqlf - compute a QL factorization of a real M-by-N  matrix
A
```

SYNOPSIS

```
SUBROUTINE DGEQLF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

INTEGER M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)

SUBROUTINE DGEQLF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

INTEGER*8 M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQLF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

INTEGER :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GEQLF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgeqlf(int m, int n, double *a, int lda,  double  *tau,
          int *info);

void dgeqlf_64(long m, long n, double *a, long  lda,  double
          *tau, long *info);
```

PURPOSE

dgeqlf computes a QL factorization of a real M-by-N matrix A: A = Q * L.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if m >= n,   the lower triangle of the subarray A(m-n+1:m,1:n) contains the N-by-N lower triangular matrix L; if m <= n, the elements on and below the (n-m)-th superdiagonal contain the M-by-N lower trapezoidal matrix L; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK.   LDWORK >= max(1,N). For optimum performance LDWORK >= N*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(k) . . . H(2) H(1), where k = min(m,n).
```

Each H(i) has the form

```
   H(i) = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(m-k+i+1:m) = 0 and v(m-k+i) = 1; v(1:m-k+i-1) is stored on exit in A(1:m-k+i-1,n-k+i), and tau in TAU(i).

Contents

NAME

```
dgeqp3 - compute a QR factorization with column pivoting  of
a matrix A
```

SYNOPSIS

```
SUBROUTINE DGEQP3(M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)

INTEGER M, N, LDA, LWORK, INFO
INTEGER JPVT(*)
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)

SUBROUTINE DGEQP3_64(M, N, A, LDA, JPVT, TAU, WORK, LWORK, INFO)

INTEGER*8 M, N, LDA, LWORK, INFO
INTEGER*8 JPVT(*)
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GEQP3([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
       [INFO])

INTEGER :: M, N, LDA, LWORK, INFO
INTEGER, DIMENSION(:) :: JPVT
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GEQP3_64([M], [N], A, [LDA], JPVT, TAU, [WORK], [LWORK],
       [INFO])

INTEGER(8) :: M, N, LDA, LWORK, INFO
INTEGER(8), DIMENSION(:) :: JPVT
```

```
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgeqp3(int m, int n, double *a,  int  lda,  int  *jpvt,
          double *tau, int *info);

void dgeqp3_64(long m, long n, double  *a,  long  lda,  long
          *jpvt, double *tau, long *info);
```

PURPOSE

dgeqp3 computes a QR factorization with column pivoting of a matrix A: A*P = Q*R using Level 3 BLAS.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M,N)-by-N upper trapezoidal matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of min(M,N) elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

JPVT (input/output)
On entry, if JPVT(J).ne.0, the J-th column of A is permuted to the front of A*P (a leading column); if JPVT(J)=0, the J-th column of A is a free column. On exit, if JPVT(J)=K, then the J-th column of A*P was the the K-th column of A.

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)
On exit, if INFO=0, WORK(1) returns the optimal

LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 3*N+1. For optimal performance LWORK >= 2*N+(N+1)*NB, where NB is the optimal blocksize.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form

H(i) = I - tau * v * v'

where tau is a real/complex scalar, and v is a real/complex vector with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i), and tau in TAU(i).

          double *tau, int *info);

void dgeqpf_64(long m, long n, double  *a,  long  lda,  long
          *jpivot, double *tau, long *info);
```

PURPOSE

dgeqpf routine is deprecated and has been replaced by routine SGEQP3.

SGEQPF computes a QR factorization with column pivoting of a real M-by-N matrix A: A*P = Q*R.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0

A (input/output)
On entry, the M-by-N matrix A. On exit, the upper triangle of the array contains the min(M,N)-by-N upper triangular matrix R; the elements below the diagonal, together with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

JPIVOT (input/output)
On entry, if JPIVOT(i) .ne. 0, the i-th column of A is permuted to the front of A*P (a leading column); if JPIVOT(i) = 0, the i-th column of A is a free column. On exit, if JPIVOT(i) = k, then the i-th column of A*P was the k-th column of A.

TAU (output)
The scalar factors of the elementary reflectors.

WORK (workspace)

dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
Q = H(1) H(2) . . . H(n)
```

Each H(i) has the form

```
H = I - tau * v * v'
```

where tau is a real scalar, and v is a real vector with v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is stored on exit in A(i+1:m,i).

The matrix P is represented in jpvt as follows: If

```
jpvt(j) = i
```

then the jth column of P is the ith canonical unit vector.

          *tau, long *info);
```

PURPOSE

dgeqrf computes a QR factorization of a real M-by-N matrix A: A = Q * R.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.
N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, the elements on and above the diagonal of the array contain the min(M,N)-by-N upper trapezoidal matrix R (R is upper triangular if m >= n); the elements below the diagonal, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK.   LDWORK >= max(1,N). For optimum performance LDWORK >= N*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

```
INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form
   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:m) is  stored  on  exit  in
A(i+1:m,i), and tau in TAU(i).

SUBROUTINE DGER(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)

INTEGER M, N, INCX, INCY, LDA
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*), A(LDA,*)

SUBROUTINE DGER_64(M, N, ALPHA, X, INCX, Y, INCY, A, LDA)

INTEGER*8 M, N, INCX, INCY, LDA
DOUBLE PRECISION ALPHA
DOUBLE PRECISION X(*), Y(*), A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GER([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

INTEGER :: M, N, INCX, INCY, LDA
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GER_64([M], [N], ALPHA, X, [INCX], Y, [INCY], A, [LDA])

INTEGER(8) :: M, N, INCX, INCY, LDA
REAL(8) :: ALPHA
REAL(8), DIMENSION(:) :: X, Y
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dger(int m, int n, double alpha, double *x,  int  incx,
          double *y, int incy, double *a, int lda);

void dger_64(long m, long n, double alpha, double  *x,  long
          incx, double *y, long incy, double *a, long lda);
```

PURPOSE

dger performs the rank 1 operation A := alpha*x*y' + A, where alpha is a scalar, x is an m element vector, y is an n element vector and A is an m by n matrix.

ARGUMENTS

M (input)
On entry, M specifies the number of rows of the matrix A. M >= 0. Unchanged on exit.

N (input)
On entry, N specifies the number of columns of the matrix A. N >= 0. Unchanged on exit.

ALPHA (input)
On entry, ALPHA specifies the scalar alpha. Unchanged on exit.

X (input)
(1 + (m - 1)*abs(INCX)). Before entry, the incremented array X must contain the m element vector x. Unchanged on exit.

INCX (input)
On entry, INCX specifies the increment for the elements of X. INCX <> 0. Unchanged on exit.

Y (input)
(1 + (n - 1)*abs(INCY)). Before entry, the incremented array Y must contain the n element vector y. Unchanged on exit.

INCY (input)
On entry, INCY specifies the increment for the elements of Y. INCY <> 0. Unchanged on exit.

A (input/output)

Before entry, the leading m by n part of the array A must contain the matrix of coefficients. On exit, A is overwritten by the updated matrix.

LDA (input)

On entry, LDA specifies the first dimension of A as declared in the calling (sub) program. LDA >= max(1, m). Unchanged on exit.

          double *b, long ldb, double *x, long  ldx,  double
          *ferr, double *berr, long *info);
```

PURPOSE

dgerfs improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Conjugate transpose = Tran-
          spose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input) The original N-by-N matrix A.
```

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

AF (input)
The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDAF (input)
The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input)
The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SGETRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-
gal value

NAME

```
dgerqf - compute an RQ factorization of a real M-by-N matrix
A
```

SYNOPSIS

```
SUBROUTINE DGERQF(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

INTEGER M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)

SUBROUTINE DGERQF_64(M, N, A, LDA, TAU, WORK, LDWORK, INFO)

INTEGER*8 M, N, LDA, LDWORK, INFO
DOUBLE PRECISION A(LDA,*), TAU(*), WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GERQF([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

INTEGER :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GERQF_64([M], [N], A, [LDA], TAU, [WORK], [LDWORK], [INFO])

INTEGER(8) :: M, N, LDA, LDWORK, INFO
REAL(8), DIMENSION(:) :: TAU, WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgerqf(int m, int n, double *a, int lda,  double  *tau,
          int *info);

void dgerqf_64(long m, long n, double *a, long  lda,  double
          *tau, long *info);
```

PURPOSE

dgerqf computes an RQ factorization of a real M-by-N matrix A: A = R * Q.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if m <= n, the upper triangle of the subarray A(1:m,n-m+1:n) contains the M-by-M upper triangular matrix R; if m >= n, the elements on and above the (m-n)-th subdiagonal contain the M-by-N upper trapezoidal matrix R; the remaining elements, with the array TAU, represent the orthogonal matrix Q as a product of min(m,n) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

TAU (output)
The scalar factors of the elementary reflectors (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M). For optimum performance LDWORK >= M*NB, where NB is the optimal blocksize.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

FURTHER DETAILS

The matrix Q is represented as a product of elementary reflectors

```
   Q = H(1) H(2) . . . H(k), where k = min(m,n).
Each H(i) has the form

   H(i) = I - tau * v * v'

where tau is a real scalar, and v is a real vector with
v(n-k+i+1:n) = 0 and v(n-k+i) = 1; v(1:n-k+i-1) is stored on
exit in A(m-k+i,1:n-k+i-1), and tau in TAU(i).

C INTERFACE

```
#include <sunperf.h>
void dgesdd(char jobz, int m, int n,  double  *a,  int  lda,
          double  *s,  double  *u,  int ldu, double *vt, int
          ldvt, int *info);

void dgesdd_64(char jobz, long m, long n,  double  *a,  long
          lda,  double  *s, double *u, long ldu, double *vt,
          long ldvt, long *info);
```

PURPOSE

dgesdd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and right singular vectors. If singular vectors are desired, it uses a divide-and-conquer algorithm.

The SVD is written
 = U * SIGMA * transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns VT = V**T, not V.

The divide and conquer algorithm makes very mild assumptions about floating point arithmetic. It will work on machines with a guard digit in add/subtract, or on those binary machines without guard digits which subtract like the Cray X-MP, Cray Y-MP, Cray C-90, or Cray-2. It could conceivably fail on hexadecimal or decimal machines without guard digits, but we know of none.

ARGUMENTS

```
JOBZ (input)
          Specifies options for computing all or part of the
          matrix U:
          = 'A':  all M columns of U and all N rows of  V**T
          are  returned  in the arrays U and VT; = 'S':  the
          first min(M,N) columns of U and the first min(M,N)
          rows  of V**T are returned in the arrays U and VT;
          = 'O':  If M >= N, the first N columns  of  U  are
          overwritten  on  the  array A and all rows of V**T
          are returned  in  the  array  VT;  otherwise,  all
          columns  of  U are returned in the array U and the
          first M rows of V**T are overwritten in the  array
          VT;  =  'N':   no columns of U or rows of V**T are
          computed.

M (input) The number of rows of the input matrix A.  M >= 0.

N (input) The number of columns of the input matrix A.  N >=
          0.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, if JOBZ =
          'O',  A is overwritten with the first N columns of
          U (the left singular vectors,  stored  columnwise)
          if  M >= N; A is overwritten with the first M rows
          of V**T (the right singular vectors,  stored  row-
          wise)  otherwise.   if JOBZ .ne. 'O', the contents
          of A are destroyed.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,M).

S (output)
          The singular values of A, sorted so that  S(i)  >=
          S(i+1).

U (output)
          UCOL = M if JOBZ = 'A' or JOBZ = 'O' and  M  <  N;
          UCOL  =  min(M,N) if JOBZ = 'S'.  If JOBZ = 'A' or
          JOBZ = 'O' and  M  <  N,  U  contains  the  M-by-M
          orthogonal matrix U; if JOBZ = 'S', U contains the
          first min(M,N) columns of  U  (the  left  singular
          vectors,  stored  columnwise); if JOBZ = 'O' and M
          >= N, or JOBZ = 'N', U is not referenced.
```

```
LDU (input)
          The leading dimension of the array U.  LDU  >=  1;
          if  JOBZ = 'S' or 'A' or JOBZ = 'O' and M < N, LDU
          >= M.

VT (output)
          If JOBZ = 'A' or JOBZ = 'O' and M >=  N,  VT  con-
          tains the N-by-N orthogonal matrix V**T; if JOBZ =
          'S', VT contains the first min(M,N) rows  of  V**T
          (the  right  singular vectors, stored rowwise); if
          JOBZ = 'O' and M < N, or JOBZ =  'N',  VT  is  not
          referenced.

LDVT (input)
          The leading dimension of the array VT.  LDVT >= 1;
          if JOBZ = 'A' or JOBZ = 'O' and M >= N, LDVT >= N;
          if JOBZ = 'S', LDVT >= min(M,N).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK;

LWORK (input)
          The dimension of the array WORK. LWORK >=  1.   If
          JOBZ    =    'N',    LWORK    >=    3*min(M,N)   +
          max(max(M,N),6*min(M,N)).  If JOBZ = 'O', LWORK >=
          3*min(M,N)*min(M,N)   +   max(max(M,N),5*min(M,N)*
          min(M,N)+4*min(M,N)).  If JOBZ = 'S' or 'A'  LWORK
          >=  3*min(M,N)*min(M,N) + max(max(M,N),4*min(M,N)*
          min(M,N)+4*min(M,N)).  For good performance, LWORK
          should  generally  be  larger.   If  LWORK < 0 but
          other input arguments are legal,  WORK(1)  returns
          optimal LWORK.

IWORK (workspace)
          dimension(8*MIN(M,N))

INFO (output)
          = 0:  successful exit.
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
          > 0:  SBDSDC did not  converge,  updating  process
          failed.

INTEGER(8) :: N, NRHS, LDA, LDB, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgesv(int n, int nrhs, double *a, int lda, int *ipivot,
          double *b, int ldb, int *info);

void dgesv_64(long n, long nrhs, double *a, long  lda,  long
          *ipivot, double *b, long ldb, long *info);
```

PURPOSE

dgesv computes the solution to a real system of linear equations
   A * X = B, where A is an N-by-N matrix and X and B are N-by-NRHS matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor A as
   A = P * L * U,
where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. The factored form of A is then used to solve the system of equations A * X = B.

ARGUMENTS

N (input) The number of linear equations, i.e., the order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input/output)
On entry, the N-by-N coefficient matrix A. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (output)
The pivot indices that define the permutation matrix P; row i of the matrix was interchanged with row IPIVOT(i).

B (input/output)
On entry, the N-by-NRHS matrix of right hand side

matrix B. On exit, if INFO = 0, the N-by-NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution could not be computed.

```

PURPOSE

dgesvd computes the singular value decomposition (SVD) of a real M-by-N matrix A, optionally computing the left and/or right singular vectors. The SVD is written
= U * SIGMA * transpose(V)

where SIGMA is an M-by-N matrix which is zero except for its min(m,n) diagonal elements, U is an M-by-M orthogonal matrix, and V is an N-by-N orthogonal matrix. The diagonal elements of SIGMA are the singular values of A; they are real and non-negative, and are returned in descending order. The first min(m,n) columns of U and V are the left and right singular vectors of A.

Note that the routine returns V**T, not V.

ARGUMENTS

JOBU (input)
Specifies options for computing all or part of the matrix U:
= 'A': all M columns of U are returned in array U:
= 'S': the first min(m,n) columns of U (the left singular vectors) are returned in the array U; = 'O': the first min(m,n) columns of U (the left singular vectors) are overwritten on the array A;
= 'N': no columns of U (no left singular vectors) are computed.

JOBVT (input)
Specifies options for computing all or part of the matrix V**T:
= 'A': all N rows of V**T are returned in the array VT;
= 'S': the first min(m,n) rows of V**T (the right singular vectors) are returned in the array VT; = 'O': the first min(m,n) rows of V**T (the right singular vectors) are overwritten on the array A;
= 'N': no rows of V**T (no right singular vectors) are computed.

JOBVT and JOBU cannot both be 'O'.

M (input) The number of rows of the input matrix A. M >= 0.

N (input) The number of columns of the input matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, if JOBU = 'O', A is overwritten with the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBVT = 'O', A is overwritten with the first min(m,n) rows of V**T (the right singular vectors, stored rowwise); if JOBU .ne. 'O' and JOBVT .ne. 'O', the contents of A are destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

SING (output)
The singular values of A, sorted so that SING(i) >= SING(i+1).

U (input) (LDU,M) if JOBU = 'A' or (LDU,min(M,N)) if JOBU = 'S'. If JOBU = 'A', U contains the M-by-M orthogonal matrix U; if JOBU = 'S', U contains the first min(m,n) columns of U (the left singular vectors, stored columnwise); if JOBU = 'N' or 'O', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= 1; if JOBU = 'S' or 'A', LDU >= M.

VT (input)
If JOBVT = 'A', VT contains the N-by-N orthogonal matrix V**T; if JOBVT = 'S', VT contains the first

min(m,n) rows of V**T (the right singular vectors, stored rowwise); if JOBVT = 'N' or 'O', VT is not referenced.

LDVT (input)
The leading dimension of the array VT. LDVT >= 1; if JOBVT = 'A', LDVT >= N; if JOBVT = 'S', LDVT >= min(M,N).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK; if INFO > 0, WORK(2:MIN(M,N)) contains the unconverged superdiagonal elements of an upper bidiagonal matrix B whose diagonal is in SING (not necessarily sorted). B satisfies A = U * B * VT, so it has the same singular values as A, and singular vectors related by U and VT.

LDWORK (input)
The dimension of the array WORK. LDWORK >= 1. LDWORK >= MAX(3*MIN(M,N)+MAX(M,N),5*MIN(M,N)). For good performance, LDWORK should generally be larger.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if SBDSQR did not converge, INFO specifies how many superdiagonals of an intermediate bidiagonal form B did not converge to zero. See the description of WORK above for details.

void dgesvx_64(char fact, char transa, long  n,  long  nrhs,
          double  *a,  long lda, double *af, long ldaf, long
          *ipivot, char equed, double *r, double *c,  double
          *b,  long ldb, double *x, long ldx, double *rcond,
          double *ferr, double *berr, long *info);
```

PURPOSE

```
dgesvx uses the LU factorization to compute the solution  to
a real system of linear equations
   A * X = B, where A is an N-by-N matrix and X  and  B  are
N-by-NRHS matrices.

Error bounds on the solution and a  condition  estimate  are
also provided.

The following steps are performed:

1. If FACT = 'E',  real  scaling  factors  are  computed  to
equilibrate
   the system:
      TRANS = 'N':  diag(R)*A*diag(C)     *inv(diag(C))*X  =
diag(R)*B
```

```
      TRANS = 'T': (diag(R)*A*diag(C))**T *inv(diag(R))*X  =
diag(C)*B
      TRANS = 'C': (diag(R)*A*diag(C))**H *inv(diag(R))*X  =
diag(C)*B
   Whether or not the system will be equilibrated depends on
the
   scaling of the matrix A, but if equilibration is used,  A
is
   overwritten by diag(R)*A*diag(C) and B by  diag(R)*B  (if
TRANS='N')
   or diag(C)*B (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU  decomposition  is  used  to
factor the
   matrix A (after equilibration if FACT = 'E') as
      A = P * L * U,
   where P is a permutation matrix, L is a unit  lower  tri-
angular
   matrix, and U is upper triangular.
3. If some U(i,i)=0, so that U is exactly singular, then the
routine
   returns with INFO = i. Otherwise, the factored form of  A
is used
   to estimate the condition number of the matrix A.  If the
   reciprocal of the condition number is less  than  machine
precision,
   INFO = N+1 is returned as  a  warning,  but  the  routine
still goes on
   to solve for X and  compute  error  bounds  as  described
below.

4. The system of equations is solved for X  using  the  fac-
tored form
   of A.

5. Iterative refinement is applied to improve  the  computed
solution
   matrix and calculate  error  bounds  and  backward  error
estimates
   for it.

6. If equilibration was used, the matrix X is  premultiplied
by
   diag(C) (if TRANS = 'N') or diag(R) (if TRANS  =  'T'  or
'C') so
   that it solves the original system before equilibration.
```

ARGUMENTS

```
FACT (input)
          Specifies whether or not the factored form of  the
          matrix A is supplied on entry, and if not, whether
          the matrix A should be equilibrated before  it  is
          factored.  = 'F':  On entry, AF and IPIVOT contain
          the factored form of A.  If EQUED is not 'N',  the
          matrix  A  has been equilibrated with scaling fac-
          tors given by R and C.  A, AF, and IPIVOT are  not
          modified.   = 'N':  The matrix A will be copied to
          AF and factored.
          = 'E':  The  matrix  A  will  be  equilibrated  if
          necessary, then copied to AF and factored.

TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
          = 'C':  A**H * X = B  (Transpose)

          TRANSA is defaulted to 'N' for F95 INTERFACE.
N (input) The number of linear equations, i.e., the order of
          the matrix A.  N >= 0.

NRHS (input)
          The number of right hand sides, i.e.,  the  number
          of columns of the matrices B and X.  NRHS >= 0.

A (input/output)
          On entry, the N-by-N matrix A.  If FACT = 'F'  and
          EQUED  is  not  'N', then A must have been equili-
          brated by the scaling factors in R and/or C.  A is
          not  modified  if  FACT = 'F' or 'N', or if FACT =
          'E' and EQUED = 'N' on exit.

          On exit, if EQUED .ne. 'N', A is  scaled  as  fol-
          lows:  EQUED = 'R':  A := diag(R) * A
          EQUED = 'C':  A := A * diag(C)
          EQUED = 'B':  A := diag(R) * A * diag(C).

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

AF (input/output)
          If FACT = 'F', then AF is an input argument and on
          entry  contains  the factors L and U from the fac-
          torization A = P*L*U as computed  by  SGETRF.   If
          EQUED  .ne.  'N',  then AF is the factored form of
          the equilibrated matrix A.
```

If FACT = 'N', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then AF is an output argument and on exit returns the factors L and U from the factorization A = P*L*U of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

LDAF (input)

The leading dimension of the array AF. LDAF >= max(1,N).

IPIVOT (input or output)

If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the factorization A = P*L*U as computed by SGETRF; row i of the matrix was interchanged with row IPIVOT(i).

If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the original matrix A.

If FACT = 'E', then IPIVOT is an output argument and on exit contains the pivot indices from the factorization A = P*L*U of the equilibrated matrix A.

EQUED (input/output)

Specifies the form of equilibration that was done.
= 'N': No equilibration (always true if FACT = 'N').
= 'R': Row equilibration, i.e., A has been premultiplied by diag(R). = 'C': Column equilibration, i.e., A has been postmultiplied by diag(C). = 'B': Both row and column equilibration, i.e., A has been replaced by diag(R) * A * diag(C). EQUED is an input argument if FACT = 'F'; otherwise, it is an output argument.

R (input/output)

The row scale factors for A. If EQUED = 'R' or 'B', A is multiplied on the left by diag(R); if EQUED = 'N' or 'C', R is not accessed. R is an input argument if FACT = 'F'; otherwise, R is an output argument. If FACT = 'F' and EQUED = 'R' or 'B', each element of R must be positive.

C (input/output)

The column scale factors for A. If EQUED = 'C' or 'B', A is multiplied on the right by diag(C); if EQUED = 'N' or 'R', C is not accessed. C is an input argument if FACT = 'F'; otherwise, C is an output argument. If FACT = 'F' and EQUED = 'C' or 'B', each element of C must be positive.

B (input/output)

On entry, the N-by-NRHS right hand side matrix B. On exit, if EQUED = 'N', B is not modified; if TRANSA = 'N' and EQUED = 'R' or 'B', B is overwritten by diag(R)*B; if TRANSA = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by diag(C)*B.

LDB (input)

The leading dimension of the array B. LDB >= max(1,N).

X (output)

If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X to the original system of equations. Note that A and B are modified on exit if EQUED .ne. 'N', and the solution to the equilibrated system is inv(diag(C))*X if TRANSA = 'N' and EQUED = 'C' or 'B', or inv(diag(R))*X if TRANSA = 'T' or 'C' and EQUED = 'R' or 'B'.

LDX (input)

The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)

The estimate of the reciprocal condition number of the matrix A after equilibration (if done). If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)

The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(4*N) On exit, WORK(1) contains the reciprocal pivot growth factor norm(A)/norm(U). The "max absolute element" norm is used. If WORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with 0<INFO<=N, then WORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

NAME

dgetf2 - compute an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges

SYNOPSIS

```
SUBROUTINE DGETF2(M, N, A, LDA, IPIV, INFO)

INTEGER M, N, LDA, INFO
INTEGER IPIV(*)
DOUBLE PRECISION A(LDA,*)

SUBROUTINE DGETF2_64(M, N, A, LDA, IPIV, INFO)

INTEGER*8 M, N, LDA, INFO
INTEGER*8 IPIV(*)
DOUBLE PRECISION A(LDA,*)
```

F95 INTERFACE

```
SUBROUTINE GETF2([M], [N], A, [LDA], IPIV, [INFO])

INTEGER :: M, N, LDA, INFO
INTEGER, DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GETF2_64([M], [N], A, [LDA], IPIV, [INFO])

INTEGER(8) :: M, N, LDA, INFO
INTEGER(8), DIMENSION(:) :: IPIV
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>
```

```
void dgetf2(int m, int n, double *a, int lda, int *ipiv, int
          *info);

void dgetf2_64(long m, long n, double  *a,  long  lda,  long
          *ipiv, long *info);
```

PURPOSE

dgetf2 computes an LU factorization of a general m-by-n matrix A using partial pivoting with row interchanges.

The factorization has the form
   A = P * L * U
where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 2 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the m by n matrix to be factored. On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

IPIV (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIV(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is

exactly singular, and division by zero will occur if it is used to solve a system of equations.

          int *info);

void dgetrf_64(long m, long n, double  *a,  long  lda,  long
          *ipivot, long *info);
```

PURPOSE

dgetrf computes an LU factorization of a general M-by-N matrix A using partial pivoting with row interchanges.

The factorization has the form

```
   A = P * L * U
```

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if m > n), and U is upper triangular (upper trapezoidal if m < n).

This is the right-looking Level 3 BLAS version of the algorithm.

ARGUMENTS

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrix A. N >= 0.

A (input/output)
On entry, the M-by-N matrix to be factored.   On exit, the factors L and U from the factorization A = P*L*U; the unit diagonal elements of L are not stored.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,M).

IPIVOT (output)
The pivot indices; for 1 <= i <= min(M,N), row i of the matrix was interchanged with row IPIVOT(i).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero. The factorization has been completed, but the factor U

is exactly singular, and division by zero will occur if it is used to solve a system of equations.

REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A

SUBROUTINE GETRI_64([N], A, [LDA], IPIVOT, [WORK], [LDWORK], [INFO])

INTEGER(8) :: N, LDA, LDWORK, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT
REAL(8), DIMENSION(:) :: WORK
REAL(8), DIMENSION(:,:) :: A
```

C INTERFACE

```
#include <sunperf.h>

void dgetri(int n, double *a,  int  lda,  int  *ipivot,  int
          *info);

void dgetri_64(long n, double *a, long  lda,  long  *ipivot,
          long *info);
```

PURPOSE

dgetri computes the inverse of a matrix using the LU factorization computed by SGETRF.

This method inverts U and then computes inv(A) by solving the system inv(A)*L = inv(U) for inv(A).

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

A (input/output)
On entry, the factors L and U from the factorization A = P*L*U as computed by SGETRF. On exit, if INFO = 0, the inverse of the original matrix A.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

IPIVOT (input)
The pivot indices from SGETRF; for 1<=i<=N, row i of the matrix was interchanged with row IPIVOT(i).

WORK (workspace)
On exit, if INFO=0, then WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N). For optimal performance LDWORK >= N*NB, where NB is the optimal blocksize returned by ILAENV.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first

entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, U(i,i) is exactly zero; the matrix is singular and its inverse could not be computed.

```

C INTERFACE

```
#include <sunperf.h>

void dgetrs(char transa, int n, int  nrhs,  double  *a,  int
          lda, int *ipivot, double *b, int ldb, int *info);

void dgetrs_64(char transa, long n, long  nrhs,  double  *a,
          long  lda, long *ipivot, double *b, long ldb, long
          *info);
```

PURPOSE

dgetrs solves a system of linear equations
   A * X = B or A' * X = B with a general N-by-N matrix A
using the LU factorization computed by SGETRF.

ARGUMENTS

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A'* X = B (Transpose)
= 'C': A'* X = B (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

A (input) The factors L and U from the factorization A = P*L*U as computed by SGETRF.

LDA (input)
The leading dimension of the array A.   LDA >= max(1,N).

IPIVOT (input)
The pivot indices from SGETRF; for 1<=i<=N, row i

```
          of the matrix was interchanged with row IPIVOT(i).

B (input/output)
          On entry, the right hand side matrix B.  On  exit,
          the solution matrix X.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value
```

   CHARACTER(LEN=1) :: JOB, SIDE
   INTEGER(8) :: N, ILO, IHI, M, LDV, INFO
   REAL(8), DIMENSION(:) :: LSCALE, RSCALE
   REAL(8), DIMENSION(:,:) :: V
```

C INTERFACE

```
#include <sunperf.h>

void dggbak(char job, char side, int n, int  ilo,  int  ihi,
          double  *lscale, double *rscale, int m, double *v,
          int ldv, int *info);

void dggbak_64(char job, char side, long n, long  ilo,  long
          ihi,  double  *lscale,  double  *rscale,  long  m,
          double *v, long ldv, long *info);
```

PURPOSE

dggbak forms the right or left eigenvectors of a real generalized eigenvalue problem A*x = lambda*B*x, by backward transformation on the computed eigenvectors of the balanced pair of matrices output by SGGBAL.

ARGUMENTS

```
JOB (input)
          Specifies  the  type  of  backward  transformation
          required:
          = 'N':  do nothing, return immediately;
          = 'P':  do backward transformation for permutation
          only;
          = 'S':  do  backward  transformation  for  scaling
          only;
          = 'B':  do backward transformations for both  per-
          mutation and scaling.  JOB must be the same as the
          argument JOB supplied to SGGBAL.

SIDE (input)
          = 'R':  V contains right eigenvectors;
          = 'L':  V contains left eigenvectors.

N (input) The number of rows of the matrix V.  N >= 0.

ILO (input)
          The integers ILO and IHI determined by SGGBAL.   1
```

<= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description for ILO.

LSCALE (input)
Details of the permutations and/or scaling factors applied to the left side of A and B, as returned by SGGBAL.

RSCALE (input)
Details of the permutations and/or scaling factors applied to the right side of A and B, as returned by SGGBAL.

M (input) The number of columns of the matrix V. M >= 0.

V (input/output)
On entry, the matrix of right or left eigenvectors to be transformed, as returned by STGEVC. On exit, V is overwritten by the transformed eigen- vectors.

LDV (input)
The leading dimension of the matrix V. LDV >= max(1,N).

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an ille- gal value.

FURTHER DETAILS

```

C INTERFACE

```
#include <sunperf.h>

void dggbal(char job, int n, double *a, int lda, double  *b,
          int  ldb, int *ilo, int *ihi, double *lscale, dou-
          ble *rscale, int *info);

void dggbal_64(char job, long n, double *a, long lda, double
          *b,   long  ldb,  long  *ilo,  long  *ihi,  double
          *lscale, double *rscale, long *info);
```

PURPOSE

dggbal balances a pair of general real matrices (A,B). This involves, first, permuting A and B by similarity transformations to isolate eigenvalues in the first 1 to ILO$-$1 and last IHI+1 to N elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ILO to IHI to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrices, and improve the accuracy of the computed eigenvalues and/or eigenvectors in the generalized eigenvalue problem A*x = lambda*B*x.

ARGUMENTS

JOB (input)
Specifies the operations to be performed on A and B:
= 'N': none: simply set ILO = 1, IHI = N, LSCALE(I) = 1.0 and RSCALE(I) = 1.0 for i = 1,...,N. = 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale.

N (input) The order of the matrices A and B. N >= 0.

A (input/output)
On entry, the input matrix A. On exit, A is overwritten by the balanced matrix. If JOB = 'N',

```
          A is not referenced.

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,N).

B (input) On entry, the input matrix  B.   On  exit,   B  is
          overwritten by the balanced matrix.  If JOB = 'N',
          B is not referenced.

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,N).

ILO (output)
          ILO and IHI are set to integers such that on  exit
          A(i,j)  =  0  and  B(i,j)  =  0  if  i > j and j =
          1,...,ILO-1 or i = IHI+1,...,N.  If JOB =  'N'  or
          'S', ILO = 1 and IHI = N.

IHI (output)
          See the description for ILO.

LSCALE (input)
          Details of the permutations  and  scaling  factors
          applied  to  the left side of A and B.  If P(j) is
          the index of the row interchanged with row j,  and
          D(j)  is the scaling factor applied to row j, then
          LSCALE(j) = P(j)    for J  =  1,...,ILO-1  =  D(j)
          for J = ILO,...,IHI = P(j)    for J = IHI+1,...,N.
          The order in which the interchanges are made is  N
          to IHI+1, then 1 to ILO-1.

RSCALE (input)
          Details of the permutations  and  scaling  factors
          applied  to the right side of A and B.  If P(j) is
          the index of the column interchanged  with  column
          j,  and  D(j)  is  the  scaling  factor applied to
          column  j,  then  LSCALE(j)  =  P(j)     for  J  =
          1,...,ILO-1  =  D(j)    for J = ILO,...,IHI = P(j)
          for J =  IHI+1,...,N.   The  order  in  which  the
          interchanges  are  made  is  N to IHI+1, then 1 to
          ILO-1.

WORK (workspace)
          dimension(6*N)

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
```

gal value.

          ble *vsl, long ldvsl, double *vsr, long ldvsr,
          long *info);
```

PURPOSE

dgges computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the generalized real Schur form (S,T), optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization

(A,B) = ((VSL)*S*(VSR)**T, (VSL)*T*(VSR)**T)

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T.The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

(If only the generalized eigenvalues are needed, use the driver SGGEV instead, which is faster.)

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
        [  a  0  ]
        [  0  b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)
- = 'N': do not compute the left Schur vectors;
- = 'V': compute the left Schur vectors.

JOBVSR (input)
- = 'N': do not compute the right Schur vectors;
- = 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see DELCTG);

DELCTG (input)
DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if DELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy DELCTG(ALPHAR(j),ALPHAI(j), BETA(j)) = .TRUE. after ordering. INFO is to be set to N+2 in this case.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true. (Complex conjugate pairs for which DELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i, and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)
The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= 8*N+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

BWORK (workspace)
dimension(N) Not referenced if SORT = 'N'.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ.

=N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigen- values in the Generalized Schur form no longer satisfy DELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

          ldvsr,   double   *rconde,  double  *rcondv,  long
          *info);
```

PURPOSE

dggesx computes for a pair of N-by-N real nonsymmetric matrices (A,B), the generalized eigenvalues, the real Schur form (S,T), and, optionally, the left and/or right matrices of Schur vectors (VSL and VSR). This gives the generalized Schur factorization
A,B) = ((VSL) S (VSR)**T, (VSL) T (VSR)**T)

Optionally, it also orders the eigenvalues so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix S and the upper triangular matrix T; computes a reciprocal condition number for the average of the selected eigenvalues (RCONDE); and computes a reciprocal condition number for the right and left deflating subspaces corresponding to the selected eigenvalues (RCONDV). The leading columns of VSL and VSR then form an orthonormal basis for the corresponding left and right eigenspaces (deflating subspaces).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar w or a ratio alpha/beta = w, such that A - w*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0 or for both being zero.

A pair of matrices (S,T) is in generalized real Schur form if T is upper triangular with non-negative diagonal and S is block upper triangular with 1-by-1 and 2-by-2 blocks. 1-by-1 blocks correspond to real generalized eigenvalues, while 2-by-2 blocks of S will be "standardized" by making the corresponding elements of T have the form:

```
        [  a  0  ]
        [  0  b  ]
```

and the pair of corresponding 2-by-2 blocks in S and T will have a complex conjugate pair of generalized eigenvalues.

ARGUMENTS

JOBVSL (input)
= 'N': do not compute the left Schur vectors;
= 'V': compute the left Schur vectors.

JOBVSR (input)
= 'N': do not compute the right Schur vectors;
= 'V': compute the right Schur vectors.

SORT (input)
Specifies whether or not to order the eigenvalues on the diagonal of the generalized Schur form. = 'N': Eigenvalues are not ordered;
= 'S': Eigenvalues are ordered (see DELCTG).

DELCTG (input)
DELCTG must be declared EXTERNAL in the calling subroutine. If SORT = 'N', DELCTG is not referenced. If SORT = 'S', DELCTG is used to select eigenvalues to sort to the top left of the Schur form. An eigenvalue (ALPHAR(j)+ALPHAI(j))/BETA(j) is selected if DELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) is true; i.e. if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected. Note that a selected complex eigenvalue may no longer satisfy DELCTG(ALPHAR(j),ALPHAI(j),BETA(j)) = .TRUE. after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned), in this case INFO is set to N+3.

SENSE (input)
Determines which reciprocal condition numbers are computed. = 'N' : None are computed;
= 'E' : Computed for average of selected eigenvalues only;
= 'V' : Computed for selected deflating subspaces only;
= 'B' : Computed for both. If SENSE = 'E', 'V', or 'B', SORT must equal 'S'.

N (input) The order of the matrices A, B, VSL, and VSR. N >= 0.

A (input/output)
On entry, the first of the pair of matrices. On exit, A has been overwritten by its generalized Schur form S.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the second of the pair of matrices. On exit, B has been overwritten by its generalized Schur form T.

LDB (input)

The leading dimension of B. LDB >= max(1,N).

SDIM (output)
If SORT = 'N', SDIM = 0. If SORT = 'S', SDIM = number of eigenvalues (after sorting) for which DELCTG is true. (Complex conjugate pairs for which DELCTG is true for either eigenvalue count as 2.)

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. ALPHAR(j) + ALPHAI(j)*i and BETA(j),j=1,...,N are the diagonals of the complex Schur form (S,T) that would result if the 2-by-2 diagonal blocks of the real Schur form of (A,B) were further reduced to triangular form using 2-by-2 complex unitary transformations. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VSL (input)
If JOBVSL = 'V', VSL will contain the left Schur vectors. Not referenced if JOBVSL = 'N'.

LDVSL (input)
The leading dimension of the matrix VSL. LDVSL >=1, and if JOBVSL = 'V', LDVSL >= N.

VSR (input)
If JOBVSR = 'V', VSR will contain the right Schur vectors. Not referenced if JOBVSR = 'N'.

LDVSR (input)

The leading dimension of the matrix VSR. LDVSR >= 1, and if JOBVSR = 'V', LDVSR >= N.

RCONDE (output)

If SENSE = 'E' or 'B', RCONDE(1) and RCONDE(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if SENSE = 'N' or 'V'.

RCONDV (output)

If SENSE = 'V' or 'B', RCONDV(1) and RCONDV(2) contain the reciprocal condition numbers for the selected deflating subspaces. Not referenced if SENSE = 'N' or 'E'.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)

The dimension of the array WORK. LWORK >= 8*(N+1)+16. If SENSE = 'E', 'V', or 'B', LWORK >= MAX(8*(N+1)+16, 2*SDIM*(N-SDIM)).

IWORK (workspace)

Not referenced if SENSE = 'N'.

LIWORK (input)

The dimension of the array WORK. LIWORK >= N+6.

BWORK (workspace)

dimension(N) Not referenced if SORT = 'N'.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value.

= 1,...,N: The QZ iteration failed. (A,B) are not in Schur form, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ =N+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the Generalized Schur form no longer satisfy DELCTG=.TRUE. This could also be caused due to scaling. =N+3: reordering failed in STGSEN.

Further details ===============

An approximate (asymptotic) bound on the average absolute error of the selected eigenvalues is

EPS * norm((A, B)) / RCONDE(1).

An approximate (asymptotic) bound on the maximum angular error in the computed deflating subspaces is

EPS * norm((A, B)) / RCONDV(2).

See LAPACK User's Guide, section 4.11 for more information.

```

PURPOSE

dggev computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.

The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

A * v(j) = lambda(j) * B * v(j).

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

u(j)**H * A = lambda(j) * u(j)**H * B .

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;

= 'V': compute the left generalized eigenvectors.

JOBVR (input)
= 'N': do not compute the right generalized eigenvectors;
= 'V': compute the right generalized eigenvectors.

N (input) The order of the matrices A, B, VL, and VR. N >= 0.

A (input/output)
On entry, the matrix A in the pair (A,B). On exit, A has been overwritten.

LDA (input)
The leading dimension of A. LDA >= max(1,N).

B (input/output)
On entry, the matrix B in the pair (A,B). On exit, B has been overwritten.

LDB (input)
The leading dimension of B. LDB >= max(1,N).

ALPHAR (output)
On exit, (ALPHAR(j) + ALPHAI(j)*i)/BETA(j), j=1,...,N, will be the generalized eigenvalues. If ALPHAI(j) is zero, then the j-th eigenvalue is real; if positive, then the j-th and (j+1)-st eigenvalues are a complex conjugate pair, with ALPHAI(j+1) negative.

Note: the quotients ALPHAR(j)/BETA(j) and ALPHAI(j)/BETA(j) may easily over- or underflow, and BETA(j) may even be zero. Thus, the user should avoid naively computing the ratio alpha/beta. However, ALPHAR and ALPHAI will be always less than and usually comparable with norm(A) in magnitude, and BETA always less than and usually comparable with norm(B).

ALPHAI (output)
See the description for ALPHAR.

BETA (output)
See the description for ALPHAR.

VL (input)
If JOBVL = 'V', the left eigenvectors u(j) are

stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part)+abs(imag. part)=1. Not referenced if JOBVL = 'N'.

LDVL (input)
The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (input)
If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part)+abs(imag. part)=1. Not referenced if JOBVR = 'N'.

LDVR (input)
The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,8*N). For good performance, LWORK must generally be larger.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an ille-

gal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ.
=N+2: error return from STGEVC.

```

PURPOSE

dggevx computes for a pair of N-by-N real nonsymmetric matrices (A,B) the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ILO, IHI, LSCALE, RSCALE, ABNRM, and BBNRM), reciprocal condition numbers for the eigenvalues (RCONDE), and reciprocal condition numbers for the right eigenvectors (RCONDV).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar lambda or a ratio alpha/beta = lambda, such that A - lambda*B is singular. It is usually represented as the pair (alpha,beta), as there is a reasonable interpretation for beta=0, and even for both being zero.
The right eigenvector v(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
A * v(j) = lambda(j) * B * v(j) .
```

The left eigenvector u(j) corresponding to the eigenvalue lambda(j) of (A,B) satisfies

```
u(j)**H * A  = lambda(j) * u(j)**H * B.
```

where u(j)**H is the conjugate-transpose of u(j).

ARGUMENTS

BALANC (input)
Specifies the balance option to be performed. = 'N': do not diagonally scale or permute;
= 'P': permute only;
= 'S': scale only;
= 'B': both permute and scale. Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does.

JOBVL (input)
= 'N': do not compute the left generalized eigenvectors;
= 'V': compute the left generalized eigenvectors.

JOBVR (input)

```
          = 'N':   do  not  compute  the  right  generalized
          eigenvectors;
          = 'V':  compute the  right  generalized  eigenvec-
          tors.

SENSE (input)
          Determines which reciprocal condition numbers  are
          computed.  = 'N': none are computed;
          = 'E': computed for eigenvalues only;
          = 'V': computed for eigenvectors only;
          = 'B': computed for eigenvalues and eigenvectors.

N (input) The order of the matrices A, B, VL, and VR.  N  >=
          0.
A (input/output)
          On entry, the matrix A  in  the  pair  (A,B).   On
          exit,  A  has  been  overwritten.  If JOBVL='V' or
          JOBVR='V' or both, then A contains the first  part
          of  the real Schur form of the "balanced" versions
          of the input A and B.

LDA (input)
          The leading dimension of A.  LDA >= max(1,N).

B (input/output)
          On entry, the matrix B  in  the  pair  (A,B).   On
          exit,  B  has  been  overwritten.  If JOBVL='V' or
          JOBVR='V' or both, then B contains the second part
          of  the real Schur form of the "balanced" versions
          of the input A and B.

LDB (input)
          The leading dimension of B.  LDB >= max(1,N).

ALPHAR (output)
          On  exit,   (ALPHAR(j)   +   ALPHAI(j)*i)/BETA(j),
          j=1,...,N,  will  be  the generalized eigenvalues.
          If ALPHAI(j) is zero, then the j-th eigenvalue  is
          real;  if  positive,  then  the  j-th and (j+1)-st
          eigenvalues are a  complex  conjugate  pair,  with
          ALPHAI(j+1) negative.

          Note:   the   quotients   ALPHAR(j)/BETA(j)    and
          ALPHAI(j)/BETA(j)  may  easily over- or underflow,
          and BETA(j) may even  be  zero.   Thus,  the  user
          should   avoid   naively   computing   the   ratio
          ALPHA/BETA. However, ALPHAR  and  ALPHAI  will  be
          always  less  than  and  usually  comparable  with
          norm(A) in magnitude, and BETA  always  less  than
          and usually comparable with norm(B).
```

ALPHAI (output)
See the description of ALPHAR.

BETA (output)
See the description of ALPHAR.

VL (output)
If JOBVL = 'V', the left eigenvectors u(j) are stored one after another in the columns of VL, in the same order as their eigenvalues. If the j-th eigenvalue is real, then u(j) = VL(:,j), the j-th column of VL. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then u(j) = VL(:,j)+i*VL(:,j+1) and u(j+1) = VL(:,j)-i*VL(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVL = 'N'.

LDVL (input)
The leading dimension of the matrix VL. LDVL >= 1, and if JOBVL = 'V', LDVL >= N.

VR (output)
If JOBVR = 'V', the right eigenvectors v(j) are stored one after another in the columns of VR, in the same order as their eigenvalues. If the j-th eigenvalue is real, then v(j) = VR(:,j), the j-th column of VR. If the j-th and (j+1)-th eigenvalues form a complex conjugate pair, then v(j) = VR(:,j)+i*VR(:,j+1) and v(j+1) = VR(:,j)-i*VR(:,j+1). Each eigenvector will be scaled so the largest component have abs(real part) + abs(imag. part) = 1. Not referenced if JOBVR = 'N'.

LDVR (input)
The leading dimension of the matrix VR. LDVR >= 1, and if JOBVR = 'V', LDVR >= N.

ILO (output)
ILO and IHI are integer values such that on exit A(i,j) = 0 and B(i,j) = 0 if i > j and j = 1,...,ILO-1 or i = IHI+1,...,N. If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

IHI (output)
See the description of ILO.

LSCALE (output)
Details of the permutations and scaling factors applied to the left side of A and B. If PL(j) is the index of the row interchanged with row j, and DL(j) is the scaling factor applied to row j, then LSCALE(j) = PL(j) for j = 1,...,ILO-1 = DL(j) for j = ILO,...,IHI = PL(j) for j = IHI+1,...,N. The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

RSCALE (output)
Details of the permutations and scaling factors applied to the right side of A and B. If PR(j) is the index of the column interchanged with column j, and DR(j) is the scaling factor applied to column j, then RSCALE(j) = PR(j) for j = 1,...,ILO-1 = DR(j) for j = ILO,...,IHI = PR(j) for j = IHI+1,...,N The order in which the interchanges are made is N to IHI+1, then 1 to ILO-1.

ABNRM (output)
The one-norm of the balanced matrix A.

BBNRM (output)
The one-norm of the balanced matrix B.

RCONDE (output)
If SENSE = 'E' or 'B', the reciprocal condition numbers of the selected eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of RCONDE are set to the same value. Thus RCONDE(j), RCONDV(j), and the j-th columns of VL and VR all correspond to the same eigenpair (but not in general the j-th eigenpair, unless all eigenpairs are selected). If SENSE = 'V', RCONDE is not referenced.

RCONDV (output)
If SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of RCONDV are set to the same value. If the eigenvalues cannot be reordered to compute RCONDV(j), RCONDV(j) is set to 0; this can only occur when the true value would be very small anyway. If SENSE = 'E', RCONDV is not referenced.

WORK (workspace)

On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,6*N). If SENSE = 'E', LWORK >= 12*N. If SENSE = 'V' or 'B', LWORK >= 2*N*N+12*N+16.

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

IWORK (workspace)
dimension(N+6) If SENSE = 'E', IWORK is not referenced.

BWORK (workspace)
dimension(N) If SENSE = 'N', BWORK is not referenced.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
= 1,...,N: The QZ iteration failed. No eigenvectors have been calculated, but ALPHAR(j), ALPHAI(j), and BETA(j) should be correct for j=INFO+1,...,N. > N: =N+1: other than QZ iteration failed in SHGEQZ.
=N+2: error return from STGEVC.

FURTHER DETAILS

Balancing a matrix pair (A,B) includes, first, permuting rows and columns to isolate eigenvalues, second, applying diagonal similarity transformation to the rows and columns to make the rows and columns as close in norm as possible. The computed reciprocal condition numbers correspond to the balanced matrix. Permuting rows and columns will not change the condition numbers (in exact arithmetic) but diagonal scaling will. For further explanation of balancing, see section 4.11.1.2 of LAPACK Users' Guide.

An approximate error bound on the chordal distance between the i-th computed generalized eigenvalue w and the corresponding exact eigenvalue lambda is
hord(w, lambda) <= EPS * norm(ABNRM, BBNRM) / RCONDE(I)
An approximate error bound for the angle between the i-th

computed eigenvector VL(i) or VR(i) is given by
PS * norm(ABNRM, BBNRM) / DIF(i).

For further explanation of the reciprocal condition numbers
RCONDE and RCONDV, see section 4.11 of LAPACK User's Guide.

```

```
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dggglm(int n, int m, int p, double *a, int lda,  double
          *b,  int ldb, double *d, double *x, double *y, int
          *info);

void dggglm_64(long n, long m, long p, double *a, long  lda,
          double  *b, long ldb, double *d, double *x, double
          *y, long *info);
```

PURPOSE

```
dggglm solves a  general  Gauss-Markov  linear  model  (GLM)
problem:

        minimize || y ||_2   subject to   d = A*x + B*y
            x

where A is an N-by-M matrix, B is an N-by-P matrix, and d is
a given N-vector. It is assumed that M <= N <= M+P, and

           rank(A) = M    and    rank( A B ) = N.

Under these assumptions, the constrained equation is  always
consistent,  and  there is a unique solution x and a minimal
2-norm solution y, which is obtained using a generalized  QR
factorization of A and B.

In particular, if matrix B is square nonsingular,  then  the
problem  GLM  is equivalent to the following weighted linear
least squares problem

             minimize || inv(B)*(d-A*x) ||_2
                 x

where inv(B) denotes the inverse of B.
```

ARGUMENTS

```
N (input) The number of rows of the matrices A and B.  N  >=
          0.

M (input) The number of columns of the matrix A.  0 <= M  <=
          N.
```

P (input) The number of columns of the matrix B. P >= N-M.

A (input/output)
On entry, the N-by-M matrix A. On exit, A is destroyed.

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

B (input/output)
On entry, the N-by-P matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

D (input/output)
On entry, D is the left hand side of the GLM equation. On exit, D is destroyed.

X (output)
On exit, X and Y are the solutions of the GLM problem.

Y (output)
See the description of X.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,N+M+P). For optimum performance, LDWORK >= M+min(N,P)+max(N,P)*NB, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an ille-

gal value.

NAME

dgghrd - reduce a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular

SYNOPSIS

```
SUBROUTINE DGGHRD(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q, LDQ,
      Z, LDZ, INFO)

CHARACTER * 1 COMPQ, COMPZ
INTEGER N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*), Q(LDQ,*), Z(LDZ,*)

SUBROUTINE DGGHRD_64(COMPQ, COMPZ, N, ILO, IHI, A, LDA, B, LDB, Q,
      LDQ, Z, LDZ, INFO)

CHARACTER * 1 COMPQ, COMPZ
INTEGER*8 N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
DOUBLE PRECISION A(LDA,*), B(LDB,*), Q(LDQ,*), Z(LDZ,*)
```

F95 INTERFACE

```
SUBROUTINE GGHRD(COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB], Q,
       [LDQ], Z, [LDZ], [INFO])

CHARACTER(LEN=1) :: COMPQ, COMPZ
INTEGER :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
REAL(8), DIMENSION(:,:) :: A, B, Q, Z

SUBROUTINE GGHRD_64(COMPQ, COMPZ, [N], ILO, IHI, A, [LDA], B, [LDB],
       Q, [LDQ], Z, [LDZ], [INFO])
```

```
CHARACTER(LEN=1) :: COMPQ, COMPZ
INTEGER(8) :: N, ILO, IHI, LDA, LDB, LDQ, LDZ, INFO
REAL(8), DIMENSION(:,:) :: A, B, Q, Z
```

C INTERFACE

```
#include <sunperf.h>

void dgghrd(char compq, char compz, int n, int ilo, int ihi,
          double *a, int lda, double *b, int ldb, double *q,
          int ldq, double *z, int ldz, int *info);

void dgghrd_64(char compq, char compz,  long  n,  long  ilo,
          long  ihi,  double  *a,  long lda, double *b, long
          ldb, double *q, long ldq,  double  *z,  long  ldz,
          long *info);
```

PURPOSE

dgghrd reduces a pair of real matrices (A,B) to generalized upper Hessenberg form using orthogonal transformations, where A is a general matrix and B is upper triangular: Q' * A * Z = H and Q' * B * Z = T, where H is upper Hessenberg, T is upper triangular, and Q and Z are orthogonal, and ' means transpose.

The orthogonal matrices Q and Z are determined as products of Givens rotations. They may either be formed explicitly, or they may be postmultiplied into input matrices Q1 and Z1, so that
1 * A * Z1' = (Q1*Q) * H * (Z1*Z)'

ARGUMENTS

COMPQ (input)
= 'N': do not compute Q;
= 'I': Q is initialized to the unit matrix, and the orthogonal matrix Q is returned; = 'V': Q must contain an orthogonal matrix Q1 on entry, and the product Q1*Q is returned.

COMPZ (input)
= 'N': do not compute Z;
= 'I': Z is initialized to the unit matrix, and the orthogonal matrix Z is returned; = 'V': Z must contain an orthogonal matrix Z1 on entry, and the product Z1*Z is returned.

```
N (input) The order of the matrices A and B.  N >= 0.

ILO (input)
          It is assumed that A is already  upper  triangular
          in  rows and columns 1:ILO-1 and IHI+1:N.  ILO and
          IHI are normally set by a previous call to SGGBAL;
          otherwise  they  should  be set to 1 and N respec-
          tively.  1 <= ILO <= IHI <= N, if N > 0; ILO=1 and
          IHI=0, if N=0.

IHI (input)
          See the description of ILO.

A (input/output)
          On entry, the N-by-N general matrix to be reduced.
          On   exit,   the  upper  triangle  and  the  first
          subdiagonal of A are overwritten  with  the  upper
          Hessenberg matrix H, and the rest is set to zero.

LDA (input)
          The leading dimension of  the  array  A.   LDA  >=
          max(1,N).

B (input/output)
          On entry, the N-by-N upper  triangular  matrix  B.
          On  exit,  the upper triangular matrix T = Q' B Z.
          The elements below the diagonal are set to zero.

LDB (input)
          The leading dimension of  the  array  B.   LDB  >=
          max(1,N).

Q (input/output)
          If COMPQ='N':  Q is not referenced.
          If COMPQ='I':  on entry, Q need not be set, and on
          exit it contains the orthogonal matrix Q, where Q'
          is the product of the Givens transformations which
          are applied to A and B on the left.  If COMPQ='V':
          on entry, Q must contain an orthogonal matrix  Q1,
          and on exit this is overwritten by Q1*Q.

LDQ (input)
          The leading dimension of the array Q.  LDQ >= N if
          COMPQ='V' or 'I'; LDQ >= 1 otherwise.

Z (input/output)
          If COMPZ='N':  Z is not referenced.
          If COMPZ='I':  on entry, Z need not be set, and on
          exit it contains the orthogonal matrix Z, which is
          the product of the  Givens  transformations  which
```

are applied to A and B on the right. If COMPZ='V': on entry, Z must contain an orthogonal matrix Z1, and on exit this is overwritten by Z1*Z.

LDZ (input)
The leading dimension of the array Z. LDZ >= N if COMPZ='V' or 'I'; LDZ >= 1 otherwise.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

This routine reduces A to Hessenberg and B to triangular form by an unblocked reduction, as described in _Matrix_Computations_, by Golub and Van Loan (Johns Hopkins Press.)

SUBROUTINE DGGLSE_64(M, N, P, A, LDA, B, LDB, C, D, X, WORK, LDWORK,
      INFO)

INTEGER*8 M, N, P, LDA, LDB, LDWORK, INFO
DOUBLE  PRECISION  A(LDA,*),  B(LDB,*),  C(*),  D(*),  X(*),
WORK(*)
```

F95 INTERFACE

```
SUBROUTINE GGLSE([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],
       [LDWORK], [INFO])

INTEGER :: M, N, P, LDA, LDB, LDWORK, INFO
REAL(8), DIMENSION(:) :: C, D, X, WORK
REAL(8), DIMENSION(:,:) :: A, B

SUBROUTINE GGLSE_64([M], [N], [P], A, [LDA], B, [LDB], C, D, X, [WORK],
       [LDWORK], [INFO])

INTEGER(8) :: M, N, P, LDA, LDB, LDWORK, INFO
REAL(8), DIMENSION(:) :: C, D, X, WORK
```

```
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dgglse(int m, int n, int p, double *a, int lda,  double
          *b,  int ldb, double *c, double *d, double *x, int
          *info);

void dgglse_64(long m, long n, long p, double *a, long  lda,
          double  *b, long ldb, double *c, double *d, double
          *x, long *info);
```

PURPOSE

```
dgglse solves the linear equality-constrained least  squares
(LSE) problem:

        minimize || c - A*x ||_2   subject to   B*x = d

where A is an M-by-N matrix, B is a P-by-N matrix,  c  is  a
given  M-vector,  and  d  is a given P-vector. It is assumed
that
P <= N <= M+P, and

         rank(B) = P and  rank( ( A ) ) = N.
                                ( ( B ) )

These conditions ensure that the LSE problem  has  a  unique
solution, which is obtained using a GRQ factorization of the
matrices B and A.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.

N (input) The number of columns of the matrices A and  B.  N
          >= 0.

P (input) The number of rows of the matrix B. 0 <= P <= N <=
          M+P.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, A is des-
          troyed.

LDA (input)
```

The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B is destroyed.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

C (input/output)
On entry, C contains the right hand side vector for the least squares part of the LSE problem. On exit, the residual sum of squares for the solution is given by the sum of squares of elements N-P+1 to M of vector C.

D (input/output)
On entry, D contains the right hand side vector for the constrained equation. On exit, D is destroyed.

X (output)
On exit, X is the solution of the LSE problem.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LDWORK.

LDWORK (input)
The dimension of the array WORK. LDWORK >= max(1,M+N+P). For optimum performance LDWORK >= P+min(M,N)+max(M,N)*NB, where NB is an upper bound for the optimal blocksizes for SGEQRF, SGERQF, SORMQR and SORMRQ.

If LDWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LDWORK is issued by XERBLA.

INFO (output)
= 0: successful exit.
< 0: if INFO = -i, the i-th argument had an illegal value.

```

```
REAL(8), DIMENSION(:) :: TAUA, TAUB, WORK
REAL(8), DIMENSION(:,:) :: A, B
```

C INTERFACE

```
#include <sunperf.h>

void dggqrf(int n, int m, int p, double *a, int lda,  double
          *taua,  double  *b,  int  ldb,  double  *taub, int
          *info);

void dggqrf_64(long n, long m, long p, double *a, long  lda,
          double  *taua,  double *b, long ldb, double *taub,
          long *info);
```

PURPOSE

```
dggqrf computes a generalized QR factorization of an  N-by-M
matrix A and an N-by-P matrix B:

            A = Q*R,        B = Q*T*Z,

where Q is an  N-by-N  orthogonal  matrix,  Z  is  a  P-by-P
orthogonal matrix, and R and T assume one of the forms:

if N >= M,  R = ( R11 ) M  ,   or if N < M,  R = ( R11   R12
) N,
                (  0  ) N-M                         N   M-N
                   M

where R11 is upper triangular, and

if N <= P,  T = ( 0  T12 ) N,   or if N > P,  T =  (  T11  )
N-P,
                 P-N  N                           ( T21 ) P
                                                     P

where T12 or T21 is upper triangular.

In particular, if B is square and nonsingular, the GQR  fac-
torization  of A and B implicitly gives the QR factorization
of inv(B)*A:

             inv(B)*A = Z'*(inv(T)*R)

where inv(B) denotes the inverse of the  matrix  B,  and  Z'
denotes the transpose of the matrix Z.
```

ARGUMENTS

N (input) The number of rows of the matrices A and B. N >= 0.

M (input) The number of columns of the matrix A. M >= 0.

P (input) The number of columns of the matrix B. P >= 0.

A (input/output)
On entry, the N-by-M matrix A. On exit, the elements on and above the diagonal of the array contain the min(N,M)-by-M upper trapezoidal matrix R (R is upper triangular if N >= M); the elements below the diagonal, with the array TAUA, represent the orthogonal matrix Q as a product of min(N,M) elementary reflectors (see Further Details).

LDA (input)
The leading dimension of the array A. LDA >= max(1,N).

TAUA (output)
The scalar factors of the elementary reflectors which represent the orthogonal matrix Q (see Further Details).

B (input/output)
On entry, the N-by-P matrix B. On exit, if N <= P, the upper triangle of the subarray B(1:N,P-N+1:P) contains the N-by-N upper triangular matrix T; if N > P, the elements on and above the (N-P)-th subdiagonal contain the N-by-P upper trapezoidal matrix T; the remaining elements, with the array TAUB, represent the orthogonal matrix Z as a product of elementary reflectors (see Further Details).

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

TAUB (output)
The scalar factors of the elementary reflectors which represent the orthogonal matrix Z (see Further Details).

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

```
LWORK (input)
          The  dimension  of  the  array  WORK.   LWORK   >=
          max(1,N,M,P).   For  optimum  performance LWORK >=
          max(N,M,P)*max(NB1,NB2,NB3),  where  NB1  is   the
          optimal  blocksize  for the QR factorization of an
          N-by-M matrix, NB2 is the  optimal  blocksize  for
          the  RQ factorization of an N-by-P matrix, and NB3
          is the optimal blocksize for a call of SORMQR.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INFO = -i, the i-th argument had an ille-
          gal value.
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(n,m).

Each H(i) has the form

   H(i) = I - taua * v * v'

where taua is a real scalar, and v is a real vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:n) is  stored  on  exit  in
A(i+1:n,i), and taua in TAUA(i).
To form Q explicitly, use LAPACK subroutine SORGQR.
To use Q to update another  matrix,  use  LAPACK  subroutine
SORMQR.

The matrix Z is  represented  as  a  product  of  elementary
reflectors

   Z = H(1) H(2) . . . H(k), where k = min(n,p).

Each H(i) has the form

   H(i) = I - taub * v * v'

where taub is a real scalar, and v is a real vector with
v(p-k+i+1:p) = 0 and v(p-k+i) = 1; v(1:p-k+i-1) is stored on
```

exit in B(n-k+i,1:p-k+i-1), and taub in TAUB(i).
To form Z explicitly, use LAPACK subroutine SORGRQ.
To use Z to update another matrix, use LAPACK subroutine SORMRQ.

Contents

NAME

dggrqf - compute a generalized RQ factorization of an M-by-N matrix A and a P-by-N matrix B

SYNOPSIS

```
SUBROUTINE DGGRQF(M, P, N, A, LDA, TAUA, B, LDB, TAUB, WORK, LWORK,

C INTERFACE

```
#include <sunperf.h>

void dggrqf(int m, int p, int n, double *a, int lda,  double
          *taua,  double  *b,  int  ldb,  double  *taub, int
          *info);

void dggrqf_64(long m, long p, long n, double *a, long  lda,
          double  *taua,  double *b, long ldb, double *taub,
          long *info);
```

PURPOSE

```
dggrqf computes a generalized RQ factorization of an  M-by-N
matrix A and a P-by-N matrix B:

            A = R*Q,        B = Z*T*Q,

where Q is an  N-by-N  orthogonal  matrix,  Z  is  a  P-by-P
orthogonal matrix, and R and T assume one of the forms:

if M <= N,  R = ( 0  R12 ) M,   or if M > N,  R =  (  R11  )
M-N,
                 N-M  M                           ( R21 ) N
                                                     N

where R12 or R21 is upper triangular, and

if P >= N,  T = ( T11 ) N  ,   or if P < N,  T = ( T11   T12
) P,
                (  0  ) P-N                         P   N-P
                   N

where T11 is upper triangular.

In particular, if B is square and nonsingular, the GRQ  fac-
torization  of A and B implicitly gives the RQ factorization
of A*inv(B):

             A*inv(B) = (R*inv(T))*Z'

where inv(B) denotes the inverse of the  matrix  B,  and  Z'
denotes the transpose of the matrix Z.
```

ARGUMENTS

```
M (input) The number of rows of the matrix A.  M >= 0.

P (input) The number of rows of the matrix B.  P >= 0.

N (input) The number of columns of the matrices A and  B.  N
          >= 0.

A (input/output)
          On entry, the M-by-N matrix A.  On exit, if  M  <=
          N,  the  upper  triangle  of the subarray A(1:M,N-
          M+1:N) contains the M-by-M upper triangular matrix
          R;  if M > N, the elements on and above the (M-N)-
          th  subdiagonal  contain  the  M-by-N  upper  tra-
          pezoidal  matrix  R;  the remaining elements, with
          the array TAUA, represent the orthogonal matrix  Q
          as a product of elementary reflectors (see Further
          Details).

LDA (input)
          The leading dimension  of  the  array  A.  LDA  >=
          max(1,M).

TAUA (output)
          The scalar factors of  the  elementary  reflectors
          which  represent  the  orthogonal  matrix  Q  (see
          Further Details).

B (input/output)
          On entry, the P-by-N matrix B.  On exit, the  ele-
          ments  on and above the diagonal of the array con-
          tain the min(P,N)-by-N upper trapezoidal matrix  T
          (T  is  upper  triangular if P >= N); the elements
          below the diagonal, with the array TAUB, represent
          the orthogonal matrix Z as a product of elementary
          reflectors (see Further Details).

LDB (input)
          The leading dimension  of  the  array  B.  LDB  >=
          max(1,P).

TAUB (output)
          The scalar factors of  the  elementary  reflectors
          which  represent  the  orthogonal  matrix  Z  (see
          Further Details).

WORK (workspace)
          On exit, if INFO = 0, WORK(1) returns the  optimal
          LWORK.
```

```
LWORK (input)
          The  dimension  of  the  array  WORK.   LWORK   >=
          max(1,N,M,P).   For  optimum  performance LWORK >=
          max(N,M,P)*max(NB1,NB2,NB3),  where  NB1  is   the
          optimal  blocksize  for the RQ factorization of an
          M-by-N matrix, NB2 is the  optimal  blocksize  for
          the  QR  factorization of a P-by-N matrix, and NB3
          is the optimal blocksize for a call of SORMRQ.

          If LWORK = -1, then a workspace query is  assumed;
          the  routine  only  calculates the optimal size of
          the WORK array, returns this value  as  the  first
          entry  of  the  WORK  array,  and no error message
          related to LWORK is issued by XERBLA.

INFO (output)
          = 0:  successful exit
          < 0:  if INF0= -i, the i-th argument had an  ille-
          gal value.
```

FURTHER DETAILS

```
The matrix Q is  represented  as  a  product  of  elementary
reflectors

   Q = H(1) H(2) . . . H(k), where k = min(m,n).

Each H(i) has the form

   H(i) = I - taua * v * v'

where taua is a real scalar, and v is a real vector with
v(n-k+i+1:n) = 0 and v(n-k+i) = 1; v(1:n-k+i-1) is stored on
exit in A(m-k+i,1:n-k+i-1), and taua in TAUA(i).
To form Q explicitly, use LAPACK subroutine SORGRQ.
To use Q to update another  matrix,  use  LAPACK  subroutine
SORMRQ.

The matrix Z is  represented  as  a  product  of  elementary
reflectors

   Z = H(1) H(2) . . . H(k), where k = min(p,n).

Each H(i) has the form

   H(i) = I - taub * v * v'

where taub is a real scalar, and v is a real vector with
v(1:i-1) = 0 and v(i) = 1; v(i+1:p) is  stored  on  exit  in
```

```
B(i+1:p,i), and taub in TAUB(i).
To form Z explicitly, use LAPACK subroutine SORGQR.
To use Z to update another  matrix,  use  LAPACK  subroutine
SORMQR.

          double  *u,  long ldu, double *v, long ldv, double
          *q, long ldq, long *iwork3, long *info);
```

PURPOSE

```
dggsvd computes the generalized singular value decomposition
(GSVD) of an M-by-N real matrix A and P-by-N real matrix B:

    U'*A*Q = D1*( 0 R ),    V'*B*Q = D2*( 0 R )

where U, V and Q are orthogonal  matrices,  and  Z'  is  the
transpose  of  Z.  Let K+L = the effective numerical rank of
the matrix (A',B')', then  R  is  a  K+L-by-K+L  nonsingular
upper  triangular matrix, D1 and D2 are M-by-(K+L) and P-by-
(K+L) "diagonal" matrices and of the  following  structures,
respectively:

If M-K-L >= 0,

                    K  L
       D1 =     K ( I  0 )
                L ( 0  C )
            M-K-L ( 0  0 )

                  K  L
```

```
       D2 =   L ( 0  S )
            P-L ( 0  0 )

                N-K-L  K    L
  ( 0 R ) = K (  0   R11  R12 )
            L (  0    0   R22 )

where

  C = diag( ALPHA(K+1), ... , ALPHA(K+L) ),
  S = diag( BETA(K+1),  ... , BETA(K+L) ),
  C**2 + S**2 = I.

  R is stored in A(1:K+L,N-K-L+1:N) on exit.

If M-K-L < 0,

                  K M-K K+L-M
       D1 =   K ( I  0    0   )
            M-K ( 0  C    0   )

                    K M-K K+L-M
       D2 =   M-K ( 0  S    0  )
            K+L-M ( 0  0    I  )
              P-L ( 0  0    0  )

                   N-K-L  K   M-K  K+L-M
  ( 0 R ) =     K ( 0    R11  R12  R13  )
              M-K ( 0     0   R22  R23  )
            K+L-M ( 0     0    0   R33  )

where

  C = diag( ALPHA(K+1), ... , ALPHA(M) ),
  S = diag( BETA(K+1),  ... , BETA(M) ),
  C**2 + S**2 = I.

  (R11 R12 R13 ) is stored in A(1:M, N-K-L+1:N), and R33  is
stored
  ( 0  R22 R23 )
  in B(M-K+1:L,N+M-K-L+1:N) on exit.

The routine computes C, S, R, and optionally the  orthogonal
transformation matrices U, V and Q.

In particular, if B is an N-by-N  nonsingular  matrix,  then
the GSVD of A and B implicitly gives the SVD of A*inv(B):
                     A*inv(B) = U*(D1*inv(D2))*V'.
If ( A',B')' has orthonormal columns, then the GSVD of A and
B is also equal to the CS decomposition of A and B. Further-
```

more, the GSVD can be used to derive the solution of the eigenvalue problem:

```
A'*A x = lambda* B'*B x.
```

In some literature, the GSVD of A and B is presented in the form

```
U'*A*X = ( 0 D1 ),   V'*B*X = ( 0 D2 )
```

where U and V are orthogonal and X is nonsingular, D1 and D2 are ``diagonal''. The former GSVD form can be converted to the latter form by taking the nonsingular matrix X as

```
X = Q*( I   0    )
      ( 0 inv(R) ).
```

ARGUMENTS

JOBU (input)
= 'U': Orthogonal matrix U is computed;
= 'N': U is not computed.

JOBV (input)
= 'V': Orthogonal matrix V is computed;
= 'N': V is not computed.

JOBQ (input)
= 'Q': Orthogonal matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

P (input) The number of rows of the matrix B. P >= 0.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in the Purpose section. K + L = effective numerical rank of (A',B')'.

L (output)
See the description of K.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular matrix R, or part of R. See Purpose for details.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix R if M-K-L < 0. See Purpose for details.

LDB (input)
The leading dimension of the array B. LDA >= max(1,P).

ALPHA (output)
On exit, ALPHA and BETA contain the generalized singular value pairs of A and B; ALPHA(1:K) = 1,
BETA(1:K) = 0, and if M-K-L >= 0, ALPHA(K+1:K+L) = C,
BETA(K+1:K+L) = S, or if M-K-L < 0,
ALPHA(K+1:M)=C, ALPHA(M+1:K+L)=0
BETA(K+1:M) =S, BETA(M+1:K+L) =1 and
ALPHA(K+L+1:N) = 0
BETA(K+L+1:N) = 0

BETA (output)
See the description of ALPHA.

U (output)
If JOBU = 'U', U contains the M-by-M orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (output)
If JOBV = 'V', V contains the P-by-P orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (output)
If JOBQ = 'Q', Q contains the N-by-N orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

WORK (workspace)
dimension (max(3*N,M,P)+N)

IWORK3 (output)
dimension(N) On exit, IWORK3 stores the sorting information. More precisely, the following loop will sort ALPHA for I = K+1, min(M,K+L) swap ALPHA(I) and ALPHA(IWORK3(I)) endfor such that ALPHA(1) >= ALPHA(2) >= ... >= ALPHA(N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.
> 0: if INFO = 1, the Jacobi-type procedure failed to converge. For further details, see subroutine STGSJA.

PURPOSE

```
dggsvp computes orthogonal matrices U, V and Q such that
              L ( 0     0   A23 )
          M-K-L ( 0     0    0  )

                 N-K-L  K    L
        =     K ( 0    A12  A13 )  if M-K-L < 0;
            M-K ( 0     0   A23 )

               N-K-L  K    L
 V'*B*Q =   L ( 0     0   B13 )
          P-L ( 0     0    0  )

where the K-by-K matrix A12 and L-by-L matrix B13  are  non-
singular upper triangular; A23 is L-by-L upper triangular if
M-K-L >= 0, otherwise A23 is (M-K)-by-L  upper  trapezoidal.
K+L  = the effective numerical rank of the (M+P)-by-N matrix
```

(A',B')'. Z' denotes the transpose of Z.

This decomposition is the preprocessing step for computing the Generalized Singular Value Decomposition (GSVD), see subroutine SGGSVD.

ARGUMENTS

JOBU (input)
= 'U': Orthogonal matrix U is computed;
= 'N': U is not computed.

JOBV (input)
= 'V': Orthogonal matrix V is computed;
= 'N': V is not computed.

JOBQ (input)
= 'Q': Orthogonal matrix Q is computed;
= 'N': Q is not computed.

M (input) The number of rows of the matrix A. M >= 0.

P (input) The number of rows of the matrix B. P >= 0.

N (input) The number of columns of the matrices A and B. N >= 0.

A (input/output)
On entry, the M-by-N matrix A. On exit, A contains the triangular (or trapezoidal) matrix described in the Purpose section.

LDA (input)
The leading dimension of the array A. LDA >= max(1,M).

B (input/output)
On entry, the P-by-N matrix B. On exit, B contains the triangular matrix described in the Purpose section.

LDB (input)
The leading dimension of the array B. LDB >= max(1,P).

TOLA (input)
TOLA and TOLB are the thresholds to determine the effective numerical rank of matrix B and a subblock of A. Generally, they are set to TOLA =

MAX(M,N)*norm(A)*MACHEPS, TOLB = MAX(P,N)*norm(B)*MACHEPS. The size of TOLA and TOLB may affect the size of backward errors of the decomposition.

TOLB (input)
See the description of TOLA.

K (output)
On exit, K and L specify the dimension of the sub-blocks described in Purpose. K + L = effective numerical rank of (A',B')'.

L (output)
See the description of K.

U (input) If JOBU = 'U', U contains the orthogonal matrix U. If JOBU = 'N', U is not referenced.

LDU (input)
The leading dimension of the array U. LDU >= max(1,M) if JOBU = 'U'; LDU >= 1 otherwise.

V (input) If JOBV = 'V', V contains the orthogonal matrix V. If JOBV = 'N', V is not referenced.

LDV (input)
The leading dimension of the array V. LDV >= max(1,P) if JOBV = 'V'; LDV >= 1 otherwise.

Q (input) If JOBQ = 'Q', Q contains the orthogonal matrix Q. If JOBQ = 'N', Q is not referenced.

LDQ (input)
The leading dimension of the array Q. LDQ >= max(1,N) if JOBQ = 'Q'; LDQ >= 1 otherwise.

IWORK (workspace)
dimension(N)

TAU (workspace)
dimension(N)

WORK (workspace)
dimension(MAX(3*N,M,P))

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value.

FURTHER DETAILS

The subroutine uses LAPACK subroutine SGEQPF for the QR factorization with column pivoting to detect the effective numerical rank of the a matrix. It may be replaced by a better rank determination strategy.

NAME

```
dgssco - General sparse solver condition number estimate.
```

SYNOPSIS

```
 SUBROUTINE DGSSCO ( COND, HANDLE, IER )

 INTEGER            IER
 DOUBLE PRECISION   COND
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

DGSSCO - Condition number estimate.

PARAMETERS

```
COND      - DOUBLE PRECISION
        On exit, an estimate of the condition number of the
        factored matrix.  Must be called after the numerical
        factorization subroutine, DGSSFA().

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -700 : Invalid calling sequence - need to call DGSSFA first.
```

```
-710 : Condition number estimate not available (not implemented
       for this HANDLE's matix type).
```

Contents

NAME

```
dgssda - Deallocate working storage for the general sparse
solver.
```

SYNOPSIS

```
 SUBROUTINE ZGSSDA ( HANDLE, IER )

 INTEGER           IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

ZGSSDA - Deallocate dynamically allocated working storage.

PARAMETERS

```
HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         none
```

Contents

NAME

dgssfa - General sparse solver numeric factorization.

SYNOPSIS

```
SUBROUTINE DGSSFA ( NEQNS, COLSTR, ROWIND, VALUES, HANDLE, IER )

INTEGER            NEQNS, COLSTR(*), ROWIND(*), IER
DOUBLE PRECISION   VALUES(*)
DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

DGSSFA - Numeric factorization of a sparse matrix.

PARAMETERS

```
NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        coefficient matrix.  Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.

ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

VALUES(*) - DOUBLE PRECISION array
        On entry, VALUES(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the numeric values of
```

```
        the sparse matrix to be factored.  Unchanged on
        exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER        - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -300 : Invalid calling sequence - need to call DGSSOR first.
         -301 : Failure to dynamically allocate memory.
         -666 : Internal error.
```

NAME

dgssfs - General sparse solver one call interface.

SYNOPSIS

```
SUBROUTINE DGSSFS ( MTXTYP, PIVOT , NEQNS, COLSTR, ROWIND,
                    VALUES, NRHS  , RHS   , LDRHS , ORDMTHD,
                    OUTUNT, MSGLVL, HANDLE, IER )

CHARACTER*2       MTXTYP
CHARACTER*1       PIVOT
INTEGER           NEQNS, COLSTR(*), ROWIND(*), NRHS, LDRHS,
                  OUTUNT, MSGLVL, IER
CHARACTER*3       ORDMTHD
DOUBLE PRECISION  VALUES(*), RHS(*)
DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

DGSSFS - General sparse solver one call interface.

PARAMETERS

```
MTXTYP    - CHARACTER*2
        On entry, MTXTYP specifies the coefficient matrix
        type.  Specifically, the valid options are:

         'sp' or 'SP' - symmetric structure, positive-definite values
         'ss' or 'SS' - symmetric structure, symmetric values
         'su' or 'SU' - symmetric structure, unsymmetric values
         'uu' or 'UU' - unsymmetric structure, unsymmetric values

        Unchanged on exit.
```

```
PIVOT     - CHARACTER*1
        On entry, pivot specifies whether or not pivoting is
        used in the course of the numeric factorization.
        The valid options are:

         'n' or 'N' - no pivoting is used
         (Pivoting is not supported for this release).

        Unchanged on exit.

NEQNS     - INTEGER
        On entry, NEQNS specifies the number of equations in
        the coefficient matrix.  NEQNS must be at least one.
        Unchanged on exit.

COLSTR(*) - INTEGER array
        On entry, COLSTR(*) is an array of size (NEQNS+1),
        containing the pointers of the matrix structure.
        Unchanged on exit.
ROWIND(*) - INTEGER array
        On entry, ROWIND(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the indices of the
        matrix structure.  Unchanged on exit.

VALUES(*) - DOUBLE PRECISION array
        On entry, VALUES(*) is an array of size
        COLSTR(NEQNS+1)-1, containing the non-zero numeric
        values of the sparse matrix to be factored.
        Unchanged on exit.

NRHS      - INTEGER
        On entry, NRHS specifies the number of right hand
        sides to solve for.  Unchanged on exit.

RHS(*)    - DOUBLE PRECISION array
        On entry, RHS(LDRHS,NRHS) contains the NRHS right
        hand sides.  On exit, it contains the solutions.

LDRHS     - INTEGER
        On entry, LDRHS specifies the leading dimension of
        the RHS array. Unchanged on exit.

ORDMTHD   - CHARACTER*3
        On entry, ORDMTHD specifies the fill-reducing
        ordering to be used by the sparse solver.
        Specifically, the valid options are:

         'nat' or 'NAT' - natural ordering (no ordering)
         'mmd' or 'MMD' - multiple minimum degree
         'gnd' or 'GND' - general nested dissection
```

```
          'uso' or 'USO' - user specified ordering (see DGSSUO)

         Unchanged on exit.

 OUTUNT    - INTEGER
         Output unit.  Unchanged on exit.

 MSGLVL    - INTEGER
         Message level.

          0 - no output from solver.
          (No messages supported for this release.)

         Unchanged on exit.

 HANDLE(150)  - DOUBLE PRECISION array
         On entry, HANDLE(*) is an array of containing
         information needed by the solver, and must be passed
         unchanged to each sparse solver subroutine.
         Modified on exit.
 IER       - INTEGER
         Error number.  If no error encountered, unchanged on
         exit.  If error encountered, it is set to a non-zero
         integer.  Error numbers set by this subroutine:

          -101 : Failure to dynamically allocate memory.
          -102 : Invalid matrix type.
          -103 : Invalid pivot option.
          -104 : Number of nonzeros is less than NEQNS.
          -105 : NEQNS < 1
          -201 : Failure to dynamically allocate memory.
          -301 : Failure to dynamically allocate memory.
          -401 : Failure to dynamically allocate memory.
          -402 : NRHS < 1
          -403 : NEQNS > LDRHS
          -666 : Internal error.
```

Contents

NAME

dgssin - Initialize the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSIN ( MTXTYP, PIVOT, NEQNS, COLSTR, ROWIND, OUTUNT,
                    MSGLVL, HANDLE, IER )

CHARACTER*2       MTXTYP
CHARACTER*1       PIVOT
INTEGER           NEQNS, COLSTR(*), ROWIND(*), OUTUNT, MSGLVL, IER
DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

DGSSIN - Initialize the sparse solver and input the matrix structure.

PARAMETERS

```
MTXTYP    - CHARACTER*2
        On entry, MTXTYP specifies the coefficient matrix
        type.  Specifically, the valid options are:

         'sp' or 'SP' - symmetric structure, positive-definite values
         'ss' or 'SS' - symmetric structure, symmetric values
         'su' or 'SU' - symmetric structure, unsymmetric values
         'uu' or 'UU' - unsymmetric structure, unsymmetric values

        Unchanged on exit.

PIVOT     - CHARACTER*1
        On entry, PIVOT specifies whether or not pivoting is
        used in the course of the numeric factorization.
```

The valid options are:

'n' or 'N' - no pivoting is used
(Pivoting is not supported for this release).

Unchanged on exit.

NEQNS - INTEGER
On entry, NEQNS specifies the number of equations in the coefficient matrix. NEQNS must be at least one. Unchanged on exit.

COLSTR(*) - INTEGER array
On entry, *COLSTR*(*) is an array of size (NEQNS+1), containing the pointers of the matrix structure. Unchanged on exit.

ROWIND(*) - INTEGER array
On entry, *ROWIND*(*) is an array of size COLSTR(NEQNS+1)-1, containing the indices of the matrix structure. Unchanged on exit.

HANDLE(150) - DOUBLE PRECISION array
On entry, *HANDLE*(*) is an array containing information needed by the solver, and must be passed unchanged to each sparse solver subroutine. Modified on exit.

OUTUNT - INTEGER
Output unit. Unchanged on exit.

MSGLVL - INTEGER
Message level.

0 - no output from solver.
(No messages supported for this release.)

Unchanged on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

-101 : Failure to dynamically allocate memory.
-102 : Invalid matrix type.
-103 : Invalid pivot option.
-104 : Number of nonzeros less than NEQNS.
-105 : NEQNS < 1

NAME

dgssor - General sparse solver ordering and symbolic factorization.

SYNOPSIS

```
 SUBROUTINE DGSSOR ( ORDMTHD, HANDLE, IER )

 CHARACTER*3       ORDMTHD
 INTEGER           IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

DGSSOR - Orders and symbolically factors a sparse matrix.

PARAMETERS

```
ORDMTHD   - CHARACTER*3
        On entry, ORDMTHD specifies the fill-reducing
        ordering to be used by the sparse solver.
        Specifically, the valid options are:

         'nat' or 'NAT' - natural ordering (no ordering)
         'mmd' or 'MMD' - multiple minimum degree
         'gnd' or 'GND' - general nested dissection
         'uso' or 'USO' - user specified ordering (see DGSSUO)

        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
```

Modified on exit.

IER - INTEGER
Error number. If no error encountered, unchanged on exit. If error encountered, it is set to a non-zero integer. Error numbers set by this subroutine:

- -200 : Invalid calling sequence - need to call DGSSIN first.
- -201 : Failure to dynamically allocate memory.
- -666 : Internal error.

Contents

NAME

```
dgssps - Print general sparse solver statics.
```

SYNOPSIS

```
 SUBROUTINE DGSSPS ( HANDLE, IER )

 INTEGER           IER
 DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

DGSSPS - Print solver statistics.

PARAMETERS

```
HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER        - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -800 : Invalid calling sequence - need to call DGSSSL first.
         -899 : Printed solver statistics not supported this release.
```

Contents

NAME

dgssrp - Return permutation used by the general sparse solver.

SYNOPSIS

```
SUBROUTINE DGSSRP ( PERM, HANDLE, IER )

INTEGER           PERM(*), IER
DOUBLE PRECISION  HANDLE(150)
```

PURPOSE

DGSSRP - Returns the permutation used by the solver for the fill-reducing ordering.

PARAMETERS

```
PERM(NEQNS)  - INTEGER array
        Undefined on entry.  PERM(NEQNS) is the permutation
        array used by the sparse solver for the fill-
        reducing ordering.  Modified on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER        - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:
```

-600 : Invalid calling sequence - need to call DGSSOR first.

Contents

NAME

```
dgsssl - Solve routine for the general sparse solver.
```

SYNOPSIS

```
 SUBROUTINE DGSSSL ( NRHS, RHS, LDRHS, HANDLE, IER )

 INTEGER            NRHS, LDRHS, IER
 DOUBLE PRECISION   RHS(LDRHS,NRHS)
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

DGSSSL - Triangular solve of a factored sparse matrix.

PARAMETERS

```
NRHS      - INTEGER
        On entry, NRHS specifies the number of right hand
        sides to solve for.  Unchanged on exit.

RHS(LDRHS,*) - DOUBLE PRECISION array
        On entry, RHS(LDRHS,NRHS) contains the NRHS right
        hand sides.  On exit, it contains the solutions.

LDRHS     - INTEGER
        On entry, LDRHS specifies the leading dimension of
        the RHS array. Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.
```

```
IER       - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:

         -400 : Invalid calling sequence - need to call DGSSFA first.
         -401 : Failure to dynamically allocate memory.
         -402 : NRHS < 1
         -403 : NEQNS > LDRHS
```

Contents

NAME

```
dgssuo - User supplied permutation for ordering used in the
general sparse solver.
```

SYNOPSIS

```
 SUBROUTINE DGSSUO ( PERM, HANDLE, IER )

 INTEGER            PERM(*), IER
 DOUBLE PRECISION   HANDLE(150)
```

PURPOSE

DGSSUO - User supplied permutation for ordering. Must be
called after *DGSSIN*() (sparse solver initialization) and
before *DGSSOR*() (sparse solver ordering).

PARAMETERS

```
PERM(NEQNS)  - INTEGER array
        On entry, PERM(NEQNS) is a permutation array
        supplied by the user for the fill-reducing ordering.
        Unchanged on exit.

HANDLE(150)  - DOUBLE PRECISION array
        On entry, HANDLE(*) is an array containing
        information needed by the solver, and must be passed
        unchanged to each sparse solver subroutine.
        Modified on exit.

IER          - INTEGER
        Error number.  If no error encountered, unchanged on
        exit.  If error encountered, it is set to a non-zero
        integer.  Error numbers set by this subroutine:
```

-500 : Invalid calling sequence - need to call DGSSIN first.

Contents

NAME

```

```
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK

SUBROUTINE GTCON_64(NORM, [N], LOW, DIAG, UP1, UP2, IPIVOT, ANORM,
       RCOND, [WORK], [IWORK2], [INFO])

CHARACTER(LEN=1) :: NORM
INTEGER(8) :: N, INFO
INTEGER(8), DIMENSION(:) :: IPIVOT, IWORK2
REAL(8) :: ANORM, RCOND
REAL(8), DIMENSION(:) :: LOW, DIAG, UP1, UP2, WORK
```

C INTERFACE

```
#include <sunperf.h>
void dgtcon(char norm, int n,  double  *low,  double  *diag,
          double  *up1,  double  *up2,  int  *ipivot, double
          anorm, double *rcond, int *info);

void dgtcon_64(char norm, long n, double *low, double *diag,
          double  *up1,  double  *up2,  long *ipivot, double
          anorm, double *rcond, long *info);
```

PURPOSE

dgtcon estimates the reciprocal of the condition number of a real tridiagonal matrix A using the LU factorization as computed by SGTTRF.

An estimate is obtained for norm(inv(A)), and the reciprocal of the condition number is computed as RCOND = 1 / (ANORM * norm(inv(A))).

ARGUMENTS

NORM (input)
Specifies whether the 1-norm condition number or the infinity-norm condition number is required:
= '1' or 'O': 1-norm;
= 'I': Infinity-norm.

N (input) The order of the matrix A. N >= 0.

LOW (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

DIAG (input)

The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input)

The (n-1) elements of the first superdiagonal of U.

UP2 (input)

The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)

The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

ANORM (input)

If NORM = '1' or 'O', the 1-norm of the original matrix A. If NORM = 'I', the infinity-norm of the original matrix A.

RCOND (output)

The reciprocal of the condition number of the matrix A, computed as RCOND = 1/(ANORM * AINVNM), where AINVNM is an estimate of the 1-norm of inv(A) computed in this routine.

WORK (workspace)

dimension(2*N)

IWORK2 (workspace)

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

NAME

```
dgthr - Gathers specified elements from y into x.
```

SYNOPSIS

```
 SUBROUTINE DGTHR(NZ, Y, X, INDX)

 DOUBLE PRECISION Y(*), X(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE DGTHR_64(NZ, Y, X, INDX)

 DOUBLE PRECISION Y(*), X(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE GTHR([NZ], Y, X, INDX)

 REAL(8), DIMENSION(:) :: Y, X
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE GTHR_64([NZ], Y, X, INDX)

 REAL(8), DIMENSION(:) :: Y, X
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
DGTHR - Gathers the specified elements from a vector y in
full storage form into a vector x in compressed form.  Only
```

the elements of y whose indices are listed in indx are referenced.

```
do i = 1, n
  x(i) = y(indx(i))
enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form. Unchanged on exit.

Y (input)
Vector in full storage form. Unchanged on exit.

X (output)
Vector in compressed form. Contains elements of y whose indices are listed in indx on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed form. It is assumed that the elements in INDX are distinct and greater than zero. Unchanged on exit.

Contents

NAME

```
dgthrz - Gather and zero.
```

SYNOPSIS

```
 SUBROUTINE DGTHRZ(NZ, Y, X, INDX)

 DOUBLE PRECISION Y(*), X(*)
 INTEGER NZ
 INTEGER INDX(*)

 SUBROUTINE DGTHRZ_64(NZ, Y, X, INDX)

 DOUBLE PRECISION Y(*), X(*)
 INTEGER*8 NZ
 INTEGER*8 INDX(*)

F95 INTERFACE
 SUBROUTINE GTHRZ([NZ], Y, X, INDX)

 REAL(8), DIMENSION(:) :: Y, X
 INTEGER :: NZ
 INTEGER, DIMENSION(:) :: INDX

 SUBROUTINE GTHRZ_64([NZ], Y, X, INDX)

 REAL(8), DIMENSION(:) :: Y, X
 INTEGER(8) :: NZ
 INTEGER(8), DIMENSION(:) :: INDX
```

PURPOSE

```
DGTHRZ - Gathers the specified elements from a vector y in
full storage form into a vector x in compressed form.  The
```

gathered elements of y are set to zero. Only the elements
of y whose indices are listed in indx are referenced.

```
 do i = 1, n
   x(i) = y(indx(i))
   y(indx(i)) = 0
 enddo
```

ARGUMENTS

NZ (input) - INTEGER
Number of elements in the compressed form.
Unchanged on exit.

Y (input/output)
Vector in full storage form. Gathered elements are
set to zero.

X (output)
Vector in compressed form. Contains elements of y
whose indices are listed in indx on exit.

INDX (input) - INTEGER
Vector containing the indices of the compressed
form. It is assumed that the elements in INDX are
distinct and greater than zero. Unchanged on exit.

          double  *b,  long ldb, double *x, long ldx, double
          *ferr, double *berr, long *info);
```

PURPOSE

dgtrfs improves the computed solution to a system of linear equations when the coefficient matrix is tridiagonal, and provides error bounds and backward error estimates for the solution.

ARGUMENTS

```
TRANSA (input)
          Specifies the form of the system of equations:
          = 'N':  A * X = B     (No transpose)
          = 'T':  A**T * X = B  (Transpose)
```

= 'C': A**H * X = B (Conjugate transpose = Transpose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input)
The (n-1) subdiagonal elements of A.

DIAG (input)
The diagonal elements of A.

UP (input)
The (n-1) superdiagonal elements of A.

LOWF (input)
The (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

DIAGF (input)
The n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input)
The (n-1) elements of the first superdiagonal of U.

UPF2 (input)
The (n-2) elements of the second superdiagonal of U.

IPIVOT (input)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (input/output)
On entry, the solution matrix X, as computed by SGTTRS. On exit, the improved solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value

          ble *up, double *b, int ldb, int *info);
```

```
void dgtsv_64(long n, long nrhs, double *low, double  *diag,
          double *up, double *b, long ldb, long *info);
```

PURPOSE

dgtsv solves the equation

where A is an n by n tridiagonal matrix, by Gaussian elimination with partial pivoting.

Note that the equation A'*X = B may be solved by interchanging the order of the arguments DU and DL.

ARGUMENTS

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input/output)
On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-2) elements of the second super-diagonal of the upper triangular matrix U from the LU factorization of A, in LOW(1), ..., LOW(n-2).

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of U.

UP (input/output)
On entry, UP must contain the (n-1) super-diagonal elements of A.

On exit, UP is overwritten by the (n-1) elements of the first super-diagonal of U.

B (input/output)
On entry, the N by NRHS matrix of right hand side

matrix B. On exit, if INFO = 0, the N by NRHS solution matrix X.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, U(i,i) is exactly zero, and the solution has not been computed. The factorization has not been completed unless i = N.

```

PURPOSE

dgtsvx uses the LU factorization to compute the solution to a real system of linear equations A * X = B or A**T * X = B, where A is a tridiagonal matrix of order N and X and B are N-by-NRHS matrices.

Error bounds on the solution and a condition estimate are also provided.

The following steps are performed:

1. If FACT = 'N', the LU decomposition is used to factor the matrix A
   as A = L * U, where L is a product of permutation and unit lower
   bidiagonal matrices and U is upper triangular with nonzeros in
   only the main diagonal and first two superdiagonals.

2. If some U(i,i)=0, so that U is exactly singular, then the routine
   returns with INFO = i. Otherwise, the factored form of A is used
   to estimate the condition number of the matrix A. If the
   reciprocal of the condition number is less than machine precision,
   INFO = N+1 is returned as a warning, but the routine still goes on
   to solve for X and compute error bounds as described below.

3. The system of equations is solved for X using the factored form
   of A.

4. Iterative refinement is applied to improve the computed solution
   matrix and calculate error bounds and backward error estimates
   for it.

ARGUMENTS

FACT (input)
Specifies whether or not the factored form of A has been supplied on entry. = 'F': LOWF, DIAGF, UPF1, UPF2, and IPIVOT contain the factored form of A; LOW, DIAG, UP, LOWF, DIAGF, UPF1, UPF2 and IPIVOT will not be modified. = 'N': The matrix will be copied to LOWF, DIAGF, and UPF1 and factored.

TRANSA (input)
Specifies the form of the system of equations:
= 'N': A * X = B (No transpose)
= 'T': A**T * X = B (Transpose)
= 'C': A**H * X = B (Conjugate transpose = Tran-

spose)

TRANSA is defaulted to 'N' for F95 INTERFACE.

N (input) The order of the matrix A. N >= 0.

NRHS (input)
The number of right hand sides, i.e., the number of columns of the matrix B. NRHS >= 0.

LOW (input)
The (n-1) subdiagonal elements of A.

DIAG (input)
The n diagonal elements of A.

UP (input/output)
The (n-1) superdiagonal elements of A.

LOWF (input/output)
If FACT = 'F', then LOWF is an input argument and on entry contains the (n-1) multipliers that define the matrix L from the LU factorization of A as computed by SGTTRF.

If FACT = 'N', then LOWF is an output argument and on exit contains the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAGF (input/output)
If FACT = 'F', then DIAGF is an input argument and on entry contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

If FACT = 'N', then DIAGF is an output argument and on exit contains the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UPF1 (input/output)
If FACT = 'F', then UPF1 is an input argument and on entry contains the (n-1) elements of the first superdiagonal of U.

If FACT = 'N', then UPF1 is an output argument and on exit contains the (n-1) elements of the first superdiagonal of U.

UPF2 (input/output)
If FACT = 'F', then UPF2 is an input argument and

on entry contains the (n-2) elements of the second superdiagonal of U.

If FACT = 'N', then UPF2 is an output argument and on exit contains the (n-2) elements of the second superdiagonal of U.

IPIVOT (input/output)
If FACT = 'F', then IPIVOT is an input argument and on entry contains the pivot indices from the LU factorization of A as computed by SGTTRF.
If FACT = 'N', then IPIVOT is an output argument and on exit contains the pivot indices from the LU factorization of A; row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

B (input) The N-by-NRHS right hand side matrix B.

LDB (input)
The leading dimension of the array B. LDB >= max(1,N).

X (output)
If INFO = 0 or INFO = N+1, the N-by-NRHS solution matrix X.

LDX (input)
The leading dimension of the array X. LDX >= max(1,N).

RCOND (output)
The estimate of the reciprocal condition number of the matrix A. If RCOND is less than the machine precision (in particular, if RCOND = 0), the matrix is singular to working precision. This condition is indicated by a return code of INFO > 0.

FERR (output)
The estimated forward error bound for each solution vector X(j) (the j-th column of the solution matrix X). If XTRUE is the true solution corresponding to X(j), FERR(j) is an estimated upper bound for the magnitude of the largest element in (X(j) - XTRUE) divided by the magnitude of the largest element in X(j). The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

BERR (output)
The componentwise relative backward error of each solution vector X(j) (i.e., the smallest relative change in any element of A or B that makes X(j) an exact solution).

WORK (workspace)
dimension(3*N)

WORK2 (workspace)
dimension(N)

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, and i is
<= N: U(i,i) is exactly zero. The factorization has not been completed unless i = N, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned. = N+1: U is nonsingular, but RCOND is less than machine precision, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

```
#include <sunperf.h>

void dgttrf(int n, double *low, double *diag,  double  *up1,
          double *up2, int *ipivot, int *info);

void dgttrf_64(long n, double  *low,  double  *diag,  double
          *up1, double *up2, long *ipivot, long *info);
```

PURPOSE

dgttrf computes an LU factorization of a real tridiagonal matrix A using elimination with partial pivoting and row interchanges.

The factorization has the form

   A = L * U

where L is a product of permutation and unit lower bidiagonal matrices and U is upper triangular with nonzeros in only the main diagonal and first two superdiagonals.

ARGUMENTS

N (input) The order of the matrix A.

LOW (input/output)
On entry, LOW must contain the (n-1) sub-diagonal elements of A.

On exit, LOW is overwritten by the (n-1) multipliers that define the matrix L from the LU factorization of A.

DIAG (input/output)
On entry, DIAG must contain the diagonal elements of A.

On exit, DIAG is overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A.

UP1 (input/output)
On entry, UP1 must contain the (n-1) super-diagonal elements of A.

On exit, UP1 is overwritten by the (n-1) elements of the first super-diagonal of U.

UP2 (output)
On exit, UP2 is overwritten by the (n-2) elements of the second super-diagonal of U.

IPIVOT (output)
The pivot indices; for 1 <= i <= n, row i of the matrix was interchanged with row IPIVOT(i). IPIVOT(i) will always be either i or i+1; IPIVOT(i) = i indicates a row interchange was not required.

INFO (output)
= 0: successful exit
< 0: if INFO = -k, the k-th argument had an illegal value
> 0: if INFO = k, U(k,k) is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

```

PURPOSE

dhgeqz implements a single-/double-shift version of the QZ method for finding the generalized eigenvalues B is upper triangular, and A is block upper triangular, where the diagonal blocks are either 1-by-1 or 2-by-2, the 2-by-2 blocks having complex generalized eigenvalues (see the description of the argument JOB.)

If JOB='S', then the pair (A,B) is simultaneously reduced to Schur form by applying one orthogonal tranformation (usually called Q) on the left and another (usually called Z) on the right. The 2-by-2 upper-triangular diagonal blocks of B corresponding to 2-by-2 blocks of A will be reduced to positive diagonal matrices. (I.e., if A(j+1,j) is non-zero, then B(j+1,j)=B(j,j+1)=0 and B(j,j) and B(j+1,j+1) will be positive.)

If JOB='E', then at each iteration, the same transformations are computed, but they are only applied to those parts of A and B which are needed to compute ALPHAR, ALPHAI, and BETAR.

If JOB='S' and COMPQ and COMPZ are 'V' or 'I', then the

orthogonal transformations used to reduce (A,B) are accumulated into the arrays Q and Z s.t.:
(in) A(in) Z(in)* = Q(out) A(out) Z(out)*

Ref: C.B. Moler & G.W. Stewart, "An Algorithm for Generalized Matrixigenvalue Problems", SIAM J. Numer. Anal., 10(1973),p. 241--256.

ARGUMENTS

JOB (input)
= 'E': compute only ALPHAR, ALPHAI, and BETA. A and B will not necessarily be put into generalized Schur form. = 'S': put A and B into generalized Schur form, as well as computing ALPHAR, ALPHAI, and BETA.

COMPQ (input)
= 'N': do not modify Q.
= 'V': multiply the array Q on the right by the transpose of the orthogonal tranformation that is applied to the left side of A and B to reduce them to Schur form. = 'I': like COMPQ='V', except that Q will be initialized to the identity first.

COMPZ (input)
= 'N': do not modify Z.
= 'V': multiply the array Z on the right by the orthogonal tranformation that is applied to the right side of A and B to reduce them to Schur form. = 'I': like COMPZ='V', except that Z will be initialized to the identity first.

N (input) The order of the matrices A, B, Q, and Z. N >= 0.

ILO (input)
It is assumed that A is already upper triangular in rows and columns 1:ILO-1 and IHI+1:N. 1 <= ILO <= IHI <= N, if N > 0; ILO=1 and IHI=0, if N=0.

IHI (input)
See the description of ILO.

A (input) On entry, the N-by-N upper Hessenberg matrix A. Elements below the subdiagonal must be zero. If JOB='S', then on exit A and B will have been simultaneously reduced to generalized Schur form. If JOB='E', then on exit A will have been destroyed. The diagonal blocks will be correct, but the off-diagonal portion will be meaningless.

LDA (input)
The leading dimension of the array A. LDA >= max(1, N).

B (input) On entry, the N-by-N upper triangular matrix B. Elements below the diagonal must be zero. 2-by-2 blocks in B corresponding to 2-by-2 blocks in A will be reduced to positive diagonal form. (I.e., if A(j+1,j) is non-zero, then B(j+1,j)=B(j,j+1)=0 and B(j,j) and B(j+1,j+1) will be positive.) If JOB='S', then on exit A and B will have been simultaneously reduced to Schur form. If JOB='E', then on exit B will have been destroyed. Elements corresponding to diagonal blocks of A will be correct, but the off-diagonal portion will be meaningless.

LDB (input)
The leading dimension of the array B. LDB >= max(1, N).

ALPHAR (output)
ALPHAR(1:N) will be set to real parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then ALPHAR(j)=A(j,j). Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB.

ALPHAI (output)
ALPHAI(1:N) will be set to imaginary parts of the diagonal elements of A that would result from reducing A and B to Schur form and then further reducing them both to triangular form using unitary transformations s.t. the diagonal of B was non-negative real. Thus, if A(j,j) is in a 1-by-1 block (i.e., A(j+1,j)=A(j,j+1)=0), then ALPHAR(j)=0. Note that the (real or complex) values (ALPHAR(j) + i*ALPHAI(j))/BETA(j), j=1,...,N, are the generalized eigenvalues of the matrix pencil A - wB.

BETA (output)

BETA(1:N) will be set to the (real) diagonal ele-
ments of B that would result from reducing A and B
to Schur form and then further reducing them both
to triangular form using unitary transformations
s.t. the diagonal of B was non-negative real.
Thus, if A(j,j) is in a 1-by-1 block (i.e.,
A(j+1,j)=A(j,j+1)=0), then BETA(j)=B(j,j). Note
that the (real or complex) values (ALPHAR(j) +
i*ALPHAI(j))/BETA(j), j=1,...,N, are the general-
ized eigenvalues of the matrix pencil A - wB.
(Note that BETA(1:N) will always be non-negative,
and no BETAI is necessary.)

Q (input/output)
If COMPQ='N', then Q will not be referenced. If
COMPQ='V' or 'I', then the transpose of the
orthogonal transformations which are applied to A
and B on the left will be applied to the array Q
on the right.

LDQ (input)
The leading dimension of the array Q. LDQ >= 1.
If COMPQ='V' or 'I', then LDQ >= N.

Z (input/output)
If COMPZ='N', then Z will not be referenced. If
COMPZ='V' or 'I', then the orthogonal transforma-
tions which are applied to A and B on the right
will be applied to the array Z on the right.

LDZ (input)
The leading dimension of the array Z. LDZ >= 1.
If COMPZ='V' or 'I', then LDZ >= N.

WORK (workspace)
On exit, if INFO >= 0, WORK(1) returns the optimal
LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >=
max(1,N).

If LWORK = -1, then a workspace query is assumed;
the routine only calculates the optimal size of
the WORK array, returns this value as the first
entry of the WORK array, and no error message
related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value
= 1,...,N: the QZ iteration did not converge. (A,B) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO+1,...,N should be correct. = N+1,...,2*N: the shift calculation failed. (A,B) is not in Schur form, but ALPHAR(i), ALPHAI(i), and BETA(i), i=INFO-N+1,...,N should be correct. > 2*N: various "impossible" errors.

FURTHER DETAILS

```
Iteration counters:

JITER  -- counts iterations.
IITER  -- counts iterations run since ILAST was last
          changed.  This is therefore reset only when  a  1-
by-1 or
          2-by-2 block deflates off the bottom.

          *select,  long n, double *h, long ldh, double *wr,
          double *wi, double *vl,  long  ldvl,  double  *vr,
          long  ldvr,  long  mm, long *m, long *ifaill, long
          *ifailr, long *info);
```

PURPOSE

dhsein uses inverse iteration to find specified right and/or left eigenvectors of a real upper Hessenberg matrix H.

The right eigenvector x and the left eigenvector y of the matrix H corresponding to an eigenvalue w are defined by:

```
H * x = w * x,     y**h * H = w * y**h
```

where y**h denotes the conjugate transpose of the vector y.

ARGUMENTS

```
SIDE (input)
          = 'R': compute right eigenvectors only;
          = 'L': compute left eigenvectors only;
          = 'B': compute both right and left eigenvectors.
```

EIGSRC (input)
Specifies the source of eigenvalues supplied in (WR,WI):
= 'Q': the eigenvalues were found using SHSEQR; thus, if H has zero subdiagonal elements, and so is block-triangular, then the j-th eigenvalue can be assumed to be an eigenvalue of the block containing the j-th row/column. This property allows SHSEIN to perform inverse iteration on just one diagonal block. = 'N': no assumptions are made on the correspondence between eigenvalues and diagonal blocks. In this case, SHSEIN must always perform inverse iteration using the whole matrix H.

INITV (input)
= 'N': no initial vectors are supplied;
= 'U': user-supplied initial vectors are stored in the arrays VL and/or VR.

SELECT (input/output)
Specifies the eigenvectors to be computed. To select the real eigenvector corresponding to a real eigenvalue WR(j), SELECT(j) must be set to .TRUE.. To select the complex eigenvector corresponding to a complex eigenvalue (WR(j),WI(j)), with complex conjugate (WR(j+1),WI(j+1)), either SELECT(j) or SELECT(j+1) or both must be set to

N (input) The order of the matrix H. N >= 0.

H (input) The upper Hessenberg matrix H.

LDH (input)
The leading dimension of the array H. LDH >= max(1,N).

WR (input/output)
On entry, the real and imaginary parts of the eigenvalues of H; a complex conjugate pair of eigenvalues must be stored in consecutive elements of WR and WI. On exit, WR may have been altered since close eigenvalues are perturbed slightly in searching for independent eigenvectors.

WI (input)
See the description of WR.

VL (input/output)
On entry, if INITV = 'U' and SIDE = 'L' or 'B', VL

must contain starting vectors for the inverse iteration for the left eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'L' or 'B', the left eigenvectors specified by SELECT will be stored consecutively in the columns of VL, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'R', VL is not referenced.

LDVL (input)
The leading dimension of the array VL. LDVL >= max(1,N) if SIDE = 'L' or 'B'; LDVL >= 1 otherwise.

VR (input/output)
On entry, if INITV = 'U' and SIDE = 'R' or 'B', VR must contain starting vectors for the inverse iteration for the right eigenvectors; the starting vector for each eigenvector must be in the same column(s) in which the eigenvector will be stored. On exit, if SIDE = 'R' or 'B', the right eigenvectors specified by SELECT will be stored consecutively in the columns of VR, in the same order as their eigenvalues. A complex eigenvector corresponding to a complex eigenvalue is stored in two consecutive columns, the first holding the real part and the second the imaginary part. If SIDE = 'L', VR is not referenced.

LDVR (input)
The leading dimension of the array VR. LDVR >= max(1,N) if SIDE = 'R' or 'B'; LDVR >= 1 otherwise.

MM (input)
The number of columns in the arrays VL and/or VR. MM >= M.

M (output)
The number of columns in the arrays VL and/or VR required to store the eigenvectors; each selected real eigenvector occupies one column and each selected complex eigenvector occupies two columns.

WORK (workspace)
dimension((N+2)*N)

IFAILL (output)

If SIDE = 'L' or 'B', IFAILL(i) = j > 0 if the left eigenvector in the i-th column of VL (corresponding to the eigenvalue w(j)) failed to converge; IFAILL(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VL hold a complex eigenvector, then IFAILL(i) and IFAILL(i+1) are set to the same value. If SIDE = 'R', IFAILL is not referenced.

IFAILR (output)

If SIDE = 'R' or 'B', IFAILR(i) = j > 0 if the right eigenvector in the i-th column of VR (corresponding to the eigenvalue w(j)) failed to converge; IFAILR(i) = 0 if the eigenvector converged satisfactorily. If the i-th and (i+1)th columns of VR hold a complex eigenvector, then IFAILR(i) and IFAILR(i+1) are set to the same value. If SIDE = 'L', IFAILR is not referenced.

INFO (output)

= 0: successful exit

< 0: if INFO = -i, the i-th argument had an illegal value

> 0: if INFO = i, i is the number of eigenvectors which failed to converge; see IFAILL and IFAILR for further details.

FURTHER DETAILS

Each eigenvector is normalized so that the element of largest magnitude has magnitude 1; here the magnitude of a complex number (x,y) is taken to be |x|+|y|.

C INTERFACE

```
     #include <sunperf.h>

     void dhseqr(char job, char compz, int n, int ilo,  int  ihi,
               double *h, int ldh, double *wr, double *wi, double
               *z, int ldz, int *info);
     void dhseqr_64(char job, char compz, long n, long ilo,  long
               ihi,  double *h, long ldh, double *wr, double *wi,
               double *z, long ldz, long *info);
```

PURPOSE

dhseqr computes the eigenvalues of a real upper Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition H = Z T Z**T, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q, so that this routine can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q: A = Q*H*Q**T = (QZ)*T*(QZ)**T.

ARGUMENTS

JOB (input)
= 'E': compute eigenvalues only;
= 'S': compute eigenvalues and the Schur form T.

COMPZ (input)
= 'N': no Schur vectors are computed;
= 'I': Z is initialized to the unit matrix and the matrix Z of Schur vectors of H is returned; = 'V': Z must contain an orthogonal matrix Q on entry, and the product Q*Z is returned.

N (input) The order of the matrix H. N >= 0.

ILO (input)

```
            It is assumed that H is already  upper  triangular
            in  rows  and columns 1:ILO-1 and IHI+1:N. ILO and
            IHI are normally set by a previous call to SGEBAL,
            and  then  passed to SGEHRD when the matrix output
            by SGEBAL is reduced to Hessenberg form. Otherwise
            ILO and IHI should be set to 1 and N respectively.
            1 <= ILO <= IHI <= N, if N > 0; ILO=1  and  IHI=0,
            if N=0.

IHI (input)
            See the description of ILO.
H (input/output)
            On entry, the upper Hessenberg matrix H.  On exit,
            if   JOB  =  'S',  H  contains  the  upper  quasi-
            triangular matrix T from the  Schur  decomposition
            (the   Schur   form);   2-by-2   diagonal   blocks
            (corresponding  to  complex  conjugate  pairs   of
            eigenvalues)  are  returned in standard form, with
            H(i,i) = H(i+1,i+1) and H(i+1,i)*H(i,i+1) < 0.  If
            JOB  =  'E',  the contents of H are unspecified on
            exit.

LDH (input)
            The leading dimension  of  the  array  H.  LDH  >=
            max(1,N).

WR (output)
            The real and imaginary parts, respectively, of the
            computed  eigenvalues. If two eigenvalues are com-
            puted as a complex conjugate pair, they are stored
            in consecutive elements of WR and WI, say the i-th
            and (i+1)th, with WI(i) > 0 and WI(i+1)  <  0.  If
            JOB  = 'S', the eigenvalues are stored in the same
            order  as  on  the  diagonal  of  the  Schur  form
            returned  in  H,  with  WR(i)  =  H(i,i)  and,  if
            H(i:i+1,i:i+1) is a 2-by-2 diagonal block, WI(i) =
            sqrt(H(i+1,i)*H(i,i+1)) and WI(i+1) = -WI(i).

WI (output)
            See the description of WR.

Z (input)   If COMPZ = 'N': Z is not referenced.
            If COMPZ = 'I': on entry, Z need not be  set,  and
            on exit, Z contains the orthogonal matrix Z of the
            Schur vectors of H.  If COMPZ = 'V':  on  entry  Z
            must  contain an N-by-N matrix Q, which is assumed
            to be equal to the unit matrix except for the sub-
            matrix Z(ILO:IHI,ILO:IHI); on exit Z contains Q*Z.
            Normally Q is the orthogonal matrix  generated  by
            SORGHR  after  the call to SGEHRD which formed the
```

Hessenberg matrix H.

LDZ (input)
The leading dimension of the array Z. LDZ >= max(1,N) if COMPZ = 'I' or 'V'; LDZ >= 1 otherwise.

WORK (workspace)
On exit, if INFO = 0, WORK(1) returns the optimal LWORK.

LWORK (input)
The dimension of the array WORK. LWORK >= max(1,N).

If LWORK = -1, then a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued by XERBLA.

INFO (output)
= 0: successful exit
< 0: if INFO = -i, the i-th argument had an illegal value
> 0: if INFO = i, SHSEQR failed to compute all of the eigenvalues in a total of 30*(IHI-ILO+1) iterations; elements 1:ilo-1 and i+1:n of WR and WI contain those eigenvalues which have been successfully computed.

*            LDB, LDC, LWORK
 INTEGER*8  INDX(NNZ), PNTR(MAXNZ+1), IPERM(M)
 DOUBLE PRECISION ALPHA, BETA
 DOUBLE PRECISION VAL(NNZ), B(LDB,*), C(LDC,*), WORK(LWORK)

where NNZ=PNTR(MAXNZ+1)-PNTR(1)+1 is the number of non-zero elements
```

F95 INTERFACE

```
 SUBROUTINE JADMM( TRANSA, M, [N], K, ALPHA, DESCRA, VAL, INDX,
*    PNTR, MAXNZ, IPERM, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER    TRANSA, M, K, MAXNZ
 INTEGER, DIMENSION(:) ::  DESCRA, INDX, PNTR, IPERM
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) ::  VAL
```

```
 DOUBLE PRECISION, DIMENSION(:, :) ::  B, C

 SUBROUTINE JADMM_64( TRANSA, M, [N], K, ALPHA, DESCRA, VAL, INDX,
*    PNTR, MAXNZ, IPERM, B, [LDB], BETA, C, [LDC], [WORK], [LWORK])
 INTEGER*8     TRANSA, M, K, MAXNZ
 INTEGER*8, DIMENSION(:) ::  DESCRA, INDX, PNTR, IPERM
 DOUBLE PRECISION    ALPHA, BETA
 DOUBLE PRECISION, DIMENSION(:) ::  VAL
 DOUBLE PRECISION, DIMENSION(:, :) ::  B, C
```

DESCRIPTION

```
        C <- alpha op(A) B + beta C

where ALPHA and BETA are scalar, C and B are dense matrices,
A is a matrix represented in jagged-diagonal format and
op( A )  is one  of
op( A ) = A   or   op( A ) = A'   or   op( A ) = conjg( A' ).
                                   ( ' indicates matrix transpose)
```

ARGUMENTS

```
TRANSA        Indicates how to operate with the sparse matrix
                0 : operate with matrix
                1 : operate with transpose matrix
                2 : operate with the conjugate transpose of matrix.
                    2 is equivalent to 1 if matrix is real.

M             Number of rows in matrix A

N             Number of columns in matrix C

K             Number of columns in matrix A

ALPHA         Scalar parameter

DESCRA()      Descriptor argument.  Five element integer array
              DESCRA(1) matrix structure
                0 : general
                1 : symmetric (A=A')
                2 : Hermitian (A= CONJG(A'))
                3 : Triangular
                4 : Skew(Anti)-Symmetric (A=-A')
                5 : Diagonal
                6 : Skew-Hermitian (A= -CONJG(A'))
              DESCRA(2) upper/lower triangular indicator
                1 : lower
```

```
                  2 : upper
                DESCRA(3) main diagonal type
                  0 : non-unit
                  1 : unit
                DESCRA(4) Array base  (NOT IMPLEMENTED)
                  0 : C/C++ compatible
                  1 : Fortran compatible
                DESCRA(5) repeated indices? (NOT IMPLEMENTED)
                  0 : unknown
                  1 : no repeated indices

  VAL()         array of length NNZ consisting of entries of A.
                VAL can be viewed as a column major ordering of a
                row permutation of the Ellpack representation of A,
                where the Ellpack representation is permuted so that
                the rows are non-increasing in the number of nonzero
