Preface

*Solaris Administration Guide: Naming and Directory Services (DNS, NIS and LDAP)* describes the setup and administration of the Solaris™ Operating System (Solaris OS) naming and directory services: DNS, NIS, and LDAP. This guide is part of System and Network Administration set for the current Solaris release.

**Note** – This Solaris release supports systems that use the SPARC® and x86 families of processor architectures: UltraSPARC®, SPARC64, AMD64, Pentium, and Xeon EM64T. The supported systems appear in the Solaris OS: Hardware Compatibility Lists at [http://www.sun.com/bigadmin/hcl](http://www.sun.com/bigadmin/hcl). This document cites any implementation differences between the platform types.

In this document these x86 related terms mean the following:

- "x86" refers to the larger family of 64-bit and 32-bit x86 compatible products.
- "x64" points out specific 64-bit information about AMD64 or EM64T systems.
- "32-bit x86" points out specific 32-bit information about x86 based systems.

For supported systems, see the Solaris OS: Hardware Compatibility Lists.

**Who Should Use This Book**

This guide is written for experienced system and network administrators.

Although this book introduces networking concepts relevant to Solaris naming and directory services, it explains neither the networking fundamentals nor the administration tools in the Solaris OS.
How This Book Is Organized

This guide is divided into parts according to the respective naming services.

- Part I, “About Naming and Directory Services”
- Part II, “DNS Setup and Administration”
- Part III, “NIS Setup and Administration”
- Part IV, “LDAP Naming Services Setup and Administration”
- Part V, “Active Directory Naming Service”

How the System Administration Guides Are Organized

Here is a list of the topics that are covered by the System Administration Guides.

<table>
<thead>
<tr>
<th>Book Title</th>
<th>Topics</th>
</tr>
</thead>
<tbody>
<tr>
<td>System Administration Guide: Basic Administration</td>
<td>User accounts and groups, server and client support, shutting down and booting a system, managing services, and managing software (packages and patches)</td>
</tr>
<tr>
<td>System Administration Guide: Advanced Administration</td>
<td>Terminals and modems, system resources (disk quotas, accounting, and crontabs), system processes, and troubleshooting Solaris software problems</td>
</tr>
<tr>
<td>System Administration Guide: Devices and File Systems</td>
<td>Removable media, disks and devices, file systems, and backing up and restoring data</td>
</tr>
<tr>
<td>System Administration Guide: IP Services</td>
<td>TCP/IP network administration, IPv4 and IPv6 address administration, DHCP, IPSec, IKE, Solaris IP filter, Mobile IP, and IPQoS</td>
</tr>
<tr>
<td>System Administration Guide: Naming and Directory Services (DNS, NIS, and LDAP)</td>
<td>DNS, NIS, and LDAP naming and directory services, including transitioning from NIS to LDAP</td>
</tr>
<tr>
<td>System Administration Guide: Network Interfaces and Network Virtualization</td>
<td>Networking stack, NIC driver property configuration, network interface configuration, administration of VLANS and link aggregations, IP networking multipathing (IPMP), WiFi wireless networking configuration, and virtual NICs (VNICs).</td>
</tr>

About Naming and Directory Services

This part introduces the naming and directory services for the Solaris OS. It also describes the `nsswitch.conf` file that you use to coordinate the use of the different services.
This chapter provides an overview of naming and directory services used in Solaris. This chapter also briefly describes DNS, NIS, and LDAP naming services.

What Is a Naming Service?

Naming services store information in a central place, which enables users, machines, and applications to communicate across the network. This information can include the following.

- Machine (host) names and addresses
- User names
- Passwords
- Access permissions
- Group membership, printers, and so on

Without a central naming service, each machine would have to maintain its own copy of this information. Naming service information can be stored in files, maps, or database tables. If you centralize all data, administration becomes easier.

Naming services are fundamental to any computing network. Among other features, naming service provide functionality that does the following.

- Associates (binds) names with objects
- Resolves names to objects
- Removes bindings
- Lists names
- Renames

A network information service enables machines to be identified by common names instead of numerical addresses. This makes communication simpler because users do not have to remember and try to enter cumbersome numerical addresses like 192.168.0.0.
For example, take a network of three machines that are named, pine, elm, and oak. Before pine can send a message to either elm or oak, pine must know their numerical network addresses. For this reason, pine keeps a file, /etc/hosts or /etc/inet/ipnodes, that stores the network address of every machine in the network, including itself.

Likewise, in order for elm and oak to communicate with pine or with each other, the machines must keep similar files.

In addition to storing addresses, machines store security information, mail data, network services information and so on. As networks offer more services, the list stored of information grows. As a result, each machine might need to keep an entire set of files which are similar to /etc/hosts or /etc/inet/ipnodes.

A network information service stores network information on a server, which can be queried by any machine.
The machines are known as *clients* of the server. The following figure illustrates the client-server arrangement. Whenever information about the network changes, instead of updating each client’s local file, an administrator updates only the information stored by the network information service. Doing so reduces errors, inconsistencies between clients, and the sheer size of the task.

This arrangement, of a server providing centralized services to clients across a network, is known as *client-server computing*.

Although the main purpose of a network information service is to centralize information, the network information service can also simplify network names. For example, assume your company has set up a network which is connected to the Internet. The Internet has assigned your network the network number 192.168.0.0 and the domain name doc.com. Your company has two divisions, Sales and Manufacturing (Manf), so its network is divided into a main net and one subnet for each division. Each net has its own address.
Each division could be identified by its network address, as shown above, but descriptive names made possible by naming services would be preferable.

Instead of addressing mail or other network communications to 198.168.0.0, mail could be addressed to doc. Instead of addressing mail to 192.168.2.0 or 192.168.3.0, mail could be addressed to sales.doc or manf.doc.

Names are also more flexible than physical addresses. Physical networks tend to remain stable, but company organization tends to change.

For example, assume that the doc.com network is supported by three servers, S1, S2, and S3. Assume that two of those servers, S1 and S3, support clients.
Clients C1, C2, and C3 would obtain their network information from server S1. Clients C4, C5, and C6 would obtain information from server S3. The resulting network is summarized in the following table. The table is a generalized representation of that network but does not resemble an actual network information map.

<table>
<thead>
<tr>
<th>Network Address</th>
<th>Network Name</th>
<th>Server</th>
<th>Clients</th>
</tr>
</thead>
<tbody>
<tr>
<td>192.168.1.0</td>
<td>doc</td>
<td>S1</td>
<td></td>
</tr>
<tr>
<td>192.168.2.0</td>
<td>sales.doc</td>
<td>S2</td>
<td>C1, C2, C3</td>
</tr>
<tr>
<td>192.168.3.0</td>
<td>manf.doc</td>
<td>S3</td>
<td>C4, C5, C6</td>
</tr>
</tbody>
</table>

Now, assume that you create a third division, Testing, which borrowed some resources from the other two divisions, but did not create a third subnet. The physical network would then no longer parallel the corporate structure.
Traffic for the Test Division would not have its own subnet, but would instead be split between 192.168.2.0 and 192.168.3.0. However, with a network information service, the Test Division traffic could have its own dedicated network.

Thus, when an organization changes, its network information service can change its mapping as shown here.

Now, clients C1 and C2 would obtain their information from server S2. C3, C4 and C5 would obtain information from server S3.
Subsequent changes in your organization would be accommodated by changes to the network information structure without reorganizing the network structure.

Solaris Naming Services

The Solaris platform provides the following naming services.

- DNS, the Domain Name System (see “Description of the DNS Naming Service” on page 29)
- /etc files, the original UNIX® naming system (see “Description of the /etc Files Naming Service” on page 30)
- NIS, the Network Information Service (see “Description of the NIS Naming Service” on page 30)
- LDAP, the Lightweight Directory Access Protocol (see Part IV, "LDAP Naming Services Setup and Administration"

Most modern networks use two or more of these services in combination. When more than one service is used, the services are coordinated by the nsswitch.conf file which is discussed in Chapter 2, “The Name Service Switch (Overview).”

Description of the DNS Naming Service

DNS is the naming service provided by the Internet for TCP/IP networks. DNS was developed so that machines on the network could be identified with common names instead of Internet addresses. DNS performs naming between hosts within your local administrative domain and across domain boundaries.

The collection of networked machines that use DNS are referred to as the DNS namespace. The DNS namespace can be divided into a hierarchy of domains. A DNS domain is a group of machines. Each domain is supported by two or more name servers, a principal server and one or more secondary servers. Each server implements DNS by running the /n. named daemon. On the client’s side, DNS is implemented through the “resolver.” The resolver’s function is to resolve users’ queries. The resolver queries a name server, which then returns either the requested information or a referral to another server.

Description of Multicast DNS and Service Discovery

Support for two extensions to the DNS protocol is now available. These two extensions are multicast DNS (mDNS) and DNS Service Discovery (DNS-SD). mDNS extends the Domain Name Service system to operate over link-local multicast. DNS-SD adds support for discovering network services over DNS.
Description of the /etc Files Naming Service

The original host-based UNIX naming system was developed for standalone UNIX machines and then adapted for network use. Many old UNIX operating systems and machines still use this system, but the system is not well suited for large complex networks.

Description of the NIS Naming Service

The Network Information Service (NIS) was developed independently of DNS. DNS makes communication simpler by using machine names instead of numerical IP addresses. NIS focuses on making network administration more manageable by providing centralized control over a variety of network information. NIS stores information about the network, machine names and addresses, users, and network services. This collection of network information is referred to as the NIS namespace.

NIS namespace information is stored in NIS maps. NIS maps were designed to replace UNIX /etc files, as well as other configuration files. NIS maps store much more than names and addresses. As a result, the NIS namespace has a large set of maps. See “Working With NIS Maps” on page 101 for more information.

NIS uses a client-server arrangement which is similar to DNS. Replicated NIS servers provide services to NIS clients. The principal servers are called master servers, and for reliability, the servers have backup, or slave servers. Both master and slave servers use the NIS retrieval software and both store NIS maps. For more information on NIS Architecture and NIS Administration, see Chapter 5, “Setting Up and Configuring NIS Service,” and Chapter 6, “Administering NIS (Tasks).”

Description of the LDAP Naming Services

The Solaris Operating System supports LDAP (Lightweight Directory Access Protocol) in conjunction with the Sun Java System Directory Server (formerly Sun ONE Directory Server), as well as other LDAP directory servers.

For information about LDAP naming services, see Chapter 8, “Introduction to LDAP Naming Services (Overview/Reference)”.

For information about transitioning from NIS to LDAP, see Chapter 15, “Transitioning From NIS to LDAP (Overview/Tasks).”

For information on single sign-on, as well as the setup and maintenance of Kerberos authentication services, see Part VI, “Kerberos Service,” in System Administration Guide: Security Services.

This chapter describes the name service switch. You use the name service switch to coordinate usage of different naming services.

**About the Name Service Switch**

The name service switch is a file which is named, `nsswitch.conf`. The name service switch controls how a client machine or application obtains network information. The name service switch is used by client applications that call any of the `getXbyY()` interfaces such as the following.

- `gethostbyname()`
- `getpwuid()`
- `getpwnam()`
- `getaddrinfo()`

Each machine has a switch file in its `/etc` directory. Each line of that file identifies a particular type of network information, such as host, password, and group, followed by one or more locations of that information.

A client can obtain naming information from one or more of the switch’s sources. For example, an NIS client could obtain its hosts information from an NIS map and its password information from a local `/etc` file. In addition, the client could specify the conditions under which the switch must use each source. See Table 2-1.

The Solaris system automatically loads an `nsswitch.conf` file into every machine’s `/etc` directory as part of the installation process. Four alternate (template) versions of the switch file are also loaded into `/etc` for LDAP, NIS, or files. See “The `nsswitch.conf` Template Files” on page 38.

These four files are alternate default switch files. Each file is designed for a different primary naming service: `/etc` files, NIS, or LDAP. When the Solaris software is first installed on a machine, the installer selects the machine’s default naming service: NIS, local files, or LDAP.
During installation, the corresponding template file is copied to `nsswitch.conf`. For example, for a machine client using LDAP, the installation process copies `nsswitch.ldap` to `nsswitch.conf`. Unless you have an unusual namespace, the default template file as copied to `nsswitch.conf` should be sufficient for normal operation.

No default file is provided for DNS, but you can edit any of these files to use DNS. For more information see "DNS and Internet Access" on page 43.

If you later change a machine's primary naming service, you copy the appropriate alternate switch file to `nsswitch.conf`. See "The `nsswitch.conf` Template Files" on page 38. You can also change the sources of particular types of network information used by the client by editing the appropriate lines of the `/etc/nsswitch.conf` file. The syntax is described below, and additional instructions are provided in “How to Modify the Name Service Switch” on page 42.

**Format of the `nsswitch.conf` File**

The `nsswitch.conf` file is essentially a list of 16 types of information and the sources that `getXXXbyYY()` routines search for that information. The 16 types of information, not necessarily in this order, are the following.

- aliases
- bootparams
- ethers
- group
- hosts
- ipnodes
- netgroup
- netmasks
- networks
- passwd, which includes shadow information
- protocols
- publickey
- rpc
- services
- automount
- sendmailvars

The following table provides a description of the kind of sources that can be listed in the switch file for the information types above.

### TABLE 2–1  Switch File Information Sources

<table>
<thead>
<tr>
<th>Information Sources</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>files</code></td>
<td>A file stored in the client’s <code>/etc</code> directory. For example, <code>/etc/passwd</code></td>
</tr>
<tr>
<td><code>nis</code></td>
<td>An NIS map. For example, the <code>hosts</code> map.</td>
</tr>
<tr>
<td><code>compat</code></td>
<td><code>compat</code> can be used for password and group information to support old-style <code>+</code> or <code>-</code> syntax in <code>/etc/passwd</code>, <code>/etc/shadow</code>, and <code>/etc/group</code> files.</td>
</tr>
<tr>
<td><code>dns</code></td>
<td>Can be used to specify that host information be obtained from DNS.</td>
</tr>
<tr>
<td><code>ldap</code></td>
<td>Can be used to specify entries be obtained from the LDAP directory.</td>
</tr>
</tbody>
</table>

**Search Criteria**

*Single Source.* If an information type has only one source, such as `nisplus` a routine using the switch searches for the information in that source only. If the routine finds the information, the routine returns a `success` status message. If the routine does not find the information, the routine stops searching and returns a different status message. What the routine does with the status message varies from routine to routine.

*Multiple Sources.* If a table contains multiple sources for a given information type, the switch directs the routine to search in the first listed source. If the routine finds the information, the routine returns a `success` status message. If the routine does not find the information in the first source, the routine tries the next source. The routine searches all sources until the routine has found the information, or until the routine is halted by a `return` specification. If all of the listed sources are searched without finding the information, the routine stops searching and returns a `non-success` status message.

**Switch Status Messages**

If a routine finds the information, the routine returns a `success` status message. If the routine does not find the information, the routine returns one of three error status messages. Possible status messages are listed in the following table.

### TABLE 2–2  Switch Search Status Messages

<table>
<thead>
<tr>
<th>Status Message</th>
<th>Meaning of Message</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>SUCCESS</code></td>
<td>The requested entry was found in the specified source.</td>
</tr>
<tr>
<td><code>UNAVAIL</code></td>
<td>The source is either unresponsive or unavailable. In other words, neither the NIS map, nor the <code>/etc</code> file could be found or be accessed.</td>
</tr>
<tr>
<td><code>NOTFOUND</code></td>
<td>The source responded with “No such entry.” In other words, the table, map, or file was accessed but the needed information was not found.</td>
</tr>
</tbody>
</table>
### Switch Search Status Messages (Continued)

<table>
<thead>
<tr>
<th>Status Message</th>
<th>Meaning of Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRYAGAIN</td>
<td>The source is busy. The source might respond next time. In other words, the table, map, or file was found, but could not respond to the query.</td>
</tr>
</tbody>
</table>

### Switch Action Options

You can instruct the switch to respond to status messages with either of the two actions shown in the following table.

### TABLE 2-3  Responses to Switch Status Messages

<table>
<thead>
<tr>
<th>Action</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>return</td>
<td>Stop looking for the information.</td>
</tr>
<tr>
<td>continue</td>
<td>Try the next source.</td>
</tr>
</tbody>
</table>

### Default Search Criteria

The combination of nsswitch.conf file status message and action option determines what the routine does at each step. The combination of status and action make up the search criteria.

The switch’s default search criteria are the same for every source. As described in terms of the status messages listed above, see the following.

- **SUCCESS=return**: Stop looking for the information. Proceed using the information that has been found.
- **UNAVAIL=continue**: Go to the next nsswitch.conf file source and continue searching. If this source is the last or only source, return with a NOTFOUND status.
- **NOTFOUND=continue**: Go to the next nsswitch.conf file source and continue searching. If this source is the last or only source, return with a NOTFOUND status.
- **TRYAGAIN=continue**: Go to the next nsswitch.conf file source and continue searching. If this source is the last or only source, return with a NOTFOUND status.

You can change default search criteria by explicitly specifying some other criteria by using the \texttt{STATUS=action} syntax shown above. For example, the default action for a NOTFOUND condition is to continue the search to the next source. For example, to specify for networks, the search should stop in a NOTFOUND condition, edit the networks line of the switch file. The line would read as follows.

```
networks: nis [NOTFOUND=return] files
```

The \texttt{networks: nis [NOTFOUND=return] files} line specifies a nondefault criterion for the NOTFOUND status. Nondefault criteria are delimited by square brackets.

In this example, the search routine behaves as follows:
If the networks map is available, and contains the needed information, the routine returns with a SUCCESS status message.

If the networks map is not available, the routine returns with an UNAVAIL status message. By default, the routine continues to search the appropriate /etc file.

If the networks map is available and found, but the map does not contain the needed information, the routine returns with a NOTFOUND message. But, instead of continuing on to search the appropriate /etc file, which would be the default behavior, the routine stops searching.

If the networks map is busy, the routine returns with a TRYAGAIN status message and by default continues on to search the appropriate /etc file.

Note – Lookups in the nsswitch.conf file are done in the order in which items are listed. However, password updates are done in reverse order, unless otherwise specified by using the passwd -r repository command. See “The Switch File and Password Information” on page 44 for more information.

What if the Syntax is Wrong?
Client library routines contain compiled-in default entries that are used if an entry in the nsswitch.conf file is either missing or syntactically incorrect. These entries are the same as the switch file’s defaults.

The name service switch assumes that the table and source names are spelled correctly. If you misspell a table or source name, the switch uses default values.

Auto_home and Auto_master
The switch search criteria for the auto_home and auto_master tables and maps is combined into one category, which is called automount.

Timezone and the Switch File
The timezone table does not use the switch, so the table is not included in the switch file’s list.

Comments in nsswitch.conf Files
Any nsswitch.conf file line beginning with a comment character (#) is interpreted as a comment line. A comment line is ignored by routines that search the file.

Characters preceding a comment mark are interpreted by routines that search the nsswitch.conf file. Characters to the right of the comment mark are interpreted as comments and ignored.
TABLE 2–4  Switch File Comment Examples

<table>
<thead>
<tr>
<th>Type of Line</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comment line.</td>
<td># hosts: nisplus [NOTFOUND=return] files</td>
</tr>
<tr>
<td>Interpreted line.</td>
<td>hosts: nisplus [NOTFOUND=return] file</td>
</tr>
<tr>
<td>Partially interpreted line. The files element is not interpreted.</td>
<td>hosts: nisplus [NOTFOUND=return] # files</td>
</tr>
</tbody>
</table>

Keyserver and **publickey** Entry in the Switch File

Caution – You must restart the keyserver after you make a change to `nsswitch.conf`.

The keyserver reads the `publickey` entry in the name service switch configuration file only when the keyserver is started. If you change the switch configuration file, the keyserver does not register the changes until the keyserver is restarted.

The `nsswitch.conf` Template Files

Four switch template files are provided with the Solaris system to accommodate different naming services. Each file provides a different default set of information sources.

The four template files are the following.

- **LDAP template file.** The `nsswitch.ldap` configuration file specifies the LDAP directory as the primary source of information for the machine.

  Note – In order to use LDAP naming services, you must also properly configure all LDAP client machines, in addition to modifying the `nsswitch.conf`. See Chapter 12, “Setting Up LDAP Clients (Tasks),” for more information.

- **NIS template file.** The `nsswitch.nis` configuration file specifies NIS as the primary source for all information except `passwd`, `group`, `autoumount`, and aliases. For those four files, the primary source is local `/etc` files. The secondary source is an NIS map. The `[NOTFOUND=return]` search criterion instructs the switch to stop searching the NIS maps if the switch gets a “No such entry” message. The switch searches through local files only if the NIS server is unavailable.

  Because the search order for `passwd` and `group` is `files nis`, you don’t need to place the `+` entry in the `/etc/passwd` and `/etc/group` files.
Files template file. The *nsswitch* files configuration file specifies local /etc files as the only source of information for the machine. There is no "files" source for netgroup, so the client does not use that entry in the switch file.

Copy the template file that most closely meets your requirements to the *nsswitch.conf* configuration file and then modify the file as needed.

For example, to use the LDAP template file, you would type the following command.

```
mymachine# cp /etc/nsswitch.ldap /etc/nsswitch.conf
```

### The Default Switch Template Files

The following switch files are supplied with the Solaris product.

**EXAMPLE 2-1** NIS Switch File Template

```bash
# # /etc/nsswitch.nis:
# # An example file that could be copied over to /etc/nsswitch.conf;
# # it uses NIS (YP) in conjunction with files.
# # "hosts:" and "services:" in this file are used only if the
# # /etc/netconfig file has a "-" for nametoaddr_libs of "inet"
# # transports.
# # the following two lines obviate the "+" entry in /etc/passwd
# # and /etc/group.
passwd: files nis
group: files nis
# consult /etc "files" only if nis is down.
hosts: nis [NOTFOUND=return] files
 networks: nis [NOTFOUND=return] files
 protocols: nis [NOTFOUND=return] files
 rpc: nis [NOTFOUND=return] files
 ethers: nis [NOTFOUND=return] files
 netmasks: nis [NOTFOUND=return] files
 bootparams: nis [NOTFOUND=return] files
 publickey: nis [NOTFOUND=return] files
 netgroup: nis
 automount: files nis
 aliases: files nis
 # for efficient getservbyname() avoid nis
 services: files nis
 sendmailvars: files
```
EXAMPLE 2-2  Files Switch File Template

#  
#/etc/nsswitch.files:
#  
# An example file that could be copied over to /etc/nsswitch.conf;  
# it does not use any naming service.
#  
# "hosts:" and "services:" in this file are used only if the
#/etc/netconfig file has a "." for nametoaddr_libs of "inet"
# transports.
#  
passwd:  files
#  
group:  files
hosts:  files
networks:  files
protocols:  files
rpc:  files
ethers:  files
netmasks:  files
bootparams:  files
publickey:  files
#  
# At present there isn't a 'files' back end for netgroup;
# the system will figure it out pretty quickly, and will not use
# netgroups at all.
netgroup:  files
automount:  files
aliases:  files
services:  files
sendmailvars:  files

EXAMPLE 2-3  LDAP Switch File Template

#  
#/etc/nsswitch.ldap:
#  
# An example file that could be copied over to /etc/nsswitch.conf; it
# uses LDAP in conjunction with files.
#  
# "hosts:" and "services:" in this file are used only if the
#/etc/netconfig file has a "." for nametoaddr_libs of "inet" transports.
#  
# the following two lines obviate the "*" entry in /etc/passwd
# and /etc/group.
#  
password:  files ldap
#  
group:  files ldap
#  
hosts:  ldap [NOTFOUND=return] files
EXAMPLE 2-3     LDAP Switch File Template    (Continued)

networks:     ldap [NOTFOUND=return] files
protocols:    ldap [NOTFOUND=return] files
rpc:          ldap [NOTFOUND=return] files
ethers:       ldap [NOTFOUND=return] files
netmasks:     ldap [NOTFOUND=return] files
bootparams:   ldap [NOTFOUND=return] files
publickey:    ldap [NOTFOUND=return] files

netgroup:     ldap

automount:    files ldap
aliases:      files ldap

# for efficient getservbyname() avoid ldap
services:     files ldap
sendmailvars: files

The nsswitch.conf File

The default nsswitch.conf file that is installed with the Solaris software is determined by which naming service you select during the installation process. Each line identifies a particular type of network information, such as host, password, and group, along with the information source, such as NIS maps, the DNS hosts table, or local /etc. When you chose a naming service, the switch template file for that service is copied to create the new nsswitch.conf file. For example, if you choose NIS, the nsswitch.nis file is copied to create a new nsswitch.conf file.

An nsswitch.conf file is automatically loaded into every machine’s /etc directory by the Solaris 9 release software, along with the following alternate (template) versions.

- /etc/nsswitch.nisplus
- /etc/nsswitch.nis
- /etc/nsswitch.files
- /etc/nsswitch.ldap

These alternate template files contain the default switch configurations used by the NIS services, local files, and LDAP. No default file is provided for DNS, but you can edit any of these files to use DNS. When the Solaris software is first installed on a machine, the installer selects the machine’s default naming service. During installation, the corresponding template file is copied to /etc/nsswitch.conf. For example, for a machine client using NIS, the installation process copies nsswitch.nis to nsswitch.conf.

If your network is connected to the Internet and users must access Internet hosts using DNS, you must enable DNS forwarding.
Unless you have an unusual namespace, the default template file as copied to `nsswitch.conf` should be sufficient for normal operation.

**Selecting a Different Configuration File**

When you change a machine’s naming service, you need to modify that machine’s switch file accordingly. For example, if you change a machine’s naming service from files to NIS, you need to install a switch file appropriate for NIS. You change switch files by copying the appropriate template file to `nsswitch.conf`.

Before proceeding to change switch files, make sure the sources listed in the file are properly set up. In other words, if you are going to select the NIS version, the client must eventually have access to NIS service. If you select the local files version, those files must be properly set up on the client.

**How to Modify the Name Service Switch**

To change to a switch file, follow these steps.

---

**Note** – In order to use LDAP naming services, you must also properly configure all LDAP client machines, in addition to modifying the `nsswitch.conf`. See Chapter 12, “Setting Up LDAP Clients (Tasks),” for more information.

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2. **Copy the appropriate alternate file for the machine’s naming service over the `nsswitch.conf` file.**
   **NIS Version**
   ```bash
   client1# cd /etc
   client1# cp nsswitch.nis nsswitch.conf
   ```
   **Local /etc Files Version**
   ```bash
   client1# cd /etc
   client1# cp nsswitch.files nsswitch.conf
   ```

3. **Reboot the machine.**
   The `nscd` daemon caches switch information. See the `nscd(1M)` man page for information.
Some library routines do not periodically check the nsswitch.conf file to see whether the file has been changed. You must reboot the machine to make sure that the daemon and those routines have the latest information in the file.

**DNS and Internet Access**

The nsswitch.conf file also controls DNS forwarding for clients as described in the following subsections. DNS forwarding grants Internet access to clients.

**IPv6 and Solaris Naming Services**

NIS and LDAP support storing IPv6 data, as well as using IPv6 transports for protocol traffic. Beginning with BIND version 8.3.3, DNS on the Solaris OS supports the use of IPv6 transports on the client side. As of BIND version 8.4.2, DNS provides a complete client-server solution over IPv6 networks on Solaris.

The nsswitch.conf file controls search criteria for IPv6 addresses. IPv6 increases the IP address size from 32 bits to 128 bits to support more levels of addressing hierarchy. A larger address size provides a greater number of addressable nodes. For more information about IPv6, its configuration and implementation, see *System Administration Guide: IP Services*.

Use the new ipnodes source for IPv6 addresses. The /etc/inet/ipnodes file stores both IPv4 and IPv6 addresses. The /etc/inet/ipnodes file uses the same format convention as the /etc/hosts file.

IPv6 aware naming services use the new ipnodes source for its search forwarding. For instance, if LDAP is aware of IPv6 addresses, specify the following.

```
ipnodes: ldap [NOTFOUND=return] files
```

**Caution** – Potential delay issues:

- ipnodes defaults to files. During the transition from IPv4 to IPv6, where all naming services are not aware of IPv6 addresses, accept the files default. Otherwise, unnecessary delays, such as boot timing delays, might result during the resolution of addresses.
- An application searches all ipnodes databases for IPv4 addresses before searching for IPv4 addresses in the hosts databases. Before specifying ipnodes, consider the inherent delay of searching both databases for IPv4 addresses.
Ensuring Compatibility With +/- Syntax

If +/- is used in /etc/passwd, /etc/shadow, and /etc/group files, you need to modify the nsswitch.conf file to insure compatibility.

NIS. To provide the same syntax as in the Solaris 4.x release, change the passwd and groups sources to compat.

```
passwd: compat
group: compat
```

Specifies the /etc files and NIS maps as indicated by the +/- entries in the files.

The Switch File and Password Information

It is possible to include and access password information in multiple repositories, such as files and nisplus. You can use the nsswitch.conf file to establish the lookup order for that information.

**Caution** – files must be the first source in the nsswitch.conf file for passwd information.

In an NIS environment, the passwd line of the nsswitch.conf file should list the repositories in the following order.

```
passwd: files nis
```

**Tip** – Listing files first allows root to log in, under most circumstances, even when the system encounters some network or naming services issues.

Maintaining multiple repositories for the same user is not recommended. By maintaining centralized password management in a single repository for each user, you reduce the possibilities of confusion and error. If you choose to maintain multiple repositories per user, update password information by using the passwd -r command.

```
passwd -r repository
```

If no repository is specified with the -r option, passwd updates the repositories listed in nsswitch.conf in reverse order.
PART II

DNS Setup and Administration

This part describes the configuration and administration of the BIND 9 DNS naming service in the Solaris OS.
The Solaris Operating System (Solaris OS) ships with the BIND 9.x DNS name server. This chapter provides configuration and administration information related to using BIND 9 on the Solaris operating system. General BIND and DNS information is available from many other sources, including those listed in “Related Materials” on page 47.

This chapter covers the following topics.

- “Related Materials” on page 47
- “Migrating From BIND 8 to BIND 9” on page 48
- “DNS and the Service Management Facility” on page 49
- “Implementing rndc” on page 50
- “BIND 9 Commands, Files, Tools, and Options” on page 52
- “The named.conf Options” on page 54
- “Multicast DNS and Service Discovery” on page 65

### Related Materials

For information about DNS and BIND administration, see the following documentation.

- BIND 9 Migration Notes documentation in /usr/share/doc/bind/migration.txt
- Listings of BIND features, known bugs and defects, and links to additional material on the ISC web site at http://www.isc.org
Migrating From BIND 8 to BIND 9

BIND 9 is upwards compatible with most BIND 8 features. However, there are still a number of caveats you should be aware of when upgrading an existing BIND 8 installation to use BIND 9. Be sure to read the entire Migration Notes document before installing and using BIND 9. The Migration Notes are available at /usr/share/doc/bind/migration.txt. Also, the BIND package names have changed to SUNWbind and SUNWbindr. The SUNWbindr package contains the DNS server manifest.

The following list presents a brief overview of the differences between BIND 8 and BIND 9. Details are available in the Migration Notes.

- **Configuration File Compatibility**
  - Unimplemented options warning message
  - transfer-format option changes
  - Configuration file errors
  - Logging categories have changed
  - Notify message and refresh query changes
  - Multiple classes change

- **Zone File Compatibility**
  - Stricter rules for TTLs in zone file
  - SOA serial number changes
  - Unbalanced quotes cause errors
  - Line breaks, syntax change
  - Use \$ instead of $$ in domain names

- **Interoperability Impact of New Protocol Features**
  - EDNS0 new in BIND 9
  - Zone transfers default change

- **Unrestricted Character Set**
  - No restrictions on character set
  - Security issue, improper naming

- **Server Administration Tools**
  - The rndc program replaces ndc
  - nsupdate: changes in multiple updates

- **No Information Leakage Between Zones**
  - Glue NS records handled differently

- **Umask Not Modified**
  - Possible umask permissions issues
DNS and the Service Management Facility

The DNS/BIND named service can be managed by using the Service Management Facility (SMF). For an overview of SMF, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the svcadm(1M), svcs(1), and svccfg(1M) man pages for more details. Also review the DNS server manifest, server.xml, in /var/svc/manifest/network/dns.

- Administrative actions on this service, such as enabling, disabling, or restarting, can be performed by using the svcadm command.

**Tip** – Temporarily disabling a service by using the -t option provides some protection for the service configuration. If the service is disabled with the -t option, the original settings would be restored for the service after a reboot. If the service is disabled without -t, the service will remain disabled after reboot.

- The Fault Managed Resource Identifiers (FMRIs) for the DNS service are svc:/network/dns/server:<instance> and svc:/network/dns/client:<instance>.

- You can query the status of the DNS server and client by using the svcs command.

  - Example of the svcs command and output.

    ```
    # svcs "dns*"
    STATE STIME FMRI
    online Nov_16 svc:/network/dns/server:default
    online Nov_16 svc:/network/dns/client:default
    ```

  - Example of svcs -l command and output.

    ```
    # svcs -l /network/dns/server
    fmri svc:/network/dns/server:default
    name Internet domain name server (DNS)
    enabled true
    state online
    next_state none
    restarter svc:/system/svc/restarter:default
    contract_id 25
    dependency require_all/none svc:/system/filesystem/minimal (online)
    dependency require_all/none file://localhost/etc/named.conf (online)
    dependency require_any/error svc:/network/loopback (online)
    dependency optional_all/error svc:/network/physical (online)
    ```

- If you need to start the DNS service with different options (for example with a configuration file other than /etc/named.conf), change the start method property of the DNS server manifest by using the svccfg command.
Multiple SMF service instances are only needed if you want to run multiple copies of BIND 9 name service. Each additional instance can be specified in the DNS server manifest with a different start method.

While it is recommended that you use svcadm to administer the server, you can use rndc as well. SMF is aware of the state change of the BIND 9 named service, whether administered by using svcadm or rndc.

**Note** – SMF will not be aware of the BIND 9 named service if the service is manually executed from the command line.

### Implementing rndc

The BIND 8 ndc and BIND 9 rndc name server control tools are not backward compatible. rndc can not talk to the BIND 8 name server and ndc can not talk to the BIND 9 name server. Features, options, default modes of operation, and configuration file requirements have changed. Therefore, using ndc on a BIND 9 server could result in loss of functionality or insecure operation. See the rndc(1M) man page for more information.

### The rndc.conf Configuration File

The most significant difference between ndc in BIND 8 and rndc in BIND 9 is that rndc needs its own configuration file, rndc.conf. This file can be generated by rndc-confgen commands. The rndc.conf file specifies which server controls and what algorithm the server should use.

**EXAMPLE 3-1**  Sample rndc.conf File

```
options {
    default-server localhost;
    default-key "rndc-key";
};

key "rndc-key" {
    algorithm hmac-md5;
    secret "qPWZ3NdI81aBRY9AmJhVtU==";
};
```

**EXAMPLE 3-2**  Sample named.conf File Entry for rndc

```
controls {
    inet * allow { any; } keys { "rndc-key"; }
};
```
Implementing \texttt{rndc}

\begin{example}
Sample \texttt{named.conf} File Entry for \texttt{rndc} \hspace{1cm} (Continued)

\begin{verbatim}
key "rndc-key" {
    algorithm hmac-md5;
    secret "qPwZ3Nd181aBRY9AmJhVtU==";
};
\end{verbatim}
\end{example}

\textbf{Differences in the Control Channels}

Both the \texttt{ndc} and the \texttt{rndc} utilities use a control channel to send commands to and retrieve information from a name server. However, there are differences between the utilities.

- In \texttt{BIND 8}, \texttt{ndc} can use AF\_UNIX domain sockets (UNIX control channel) or TCP/IP sockets (inet control channel). By default, \texttt{ndc} does not need any support in \texttt{/etc/named.conf}, because \texttt{BIND 8} servers use a UNIX domain socket with a path (/var/run/ndc.d/ndc) compiled into \texttt{in.named}.

For \texttt{BIND 9}, however, \texttt{rndc} only uses an authenticated TCP/IP inet control channel and so is not backward compatible with \texttt{BIND 8}. There is no UNIX domain socket support for control channels in \texttt{BIND 9} servers.

- When using \texttt{rndc}, you need to specify a 'key' clause to communicate with the name server. It is mandatory that the \texttt{BIND 9} server and the \texttt{rndc} client share the same key (defined both in \texttt{/etc/named.conf} and \texttt{/etc/rndc.conf}). Using the \texttt{BIND 8} controls entry in \texttt{BIND 9} will result in an error message.

- Some command options have changed from the \texttt{ndc} to the \texttt{rndc} implementation. This includes the -c option, which has a different syntax in \texttt{BIND 9}. Therefore, to specify the control channel in \texttt{BIND 9}, use \texttt{rndc -s <server> -p <port>}.

\textbf{Commands of \texttt{BIND 9} \texttt{rndc}}

The following list describes the \texttt{rndc} commands.

\begin{itemize}
  \item \texttt{reload} \hspace{1cm} Reload configuration file and zones
  \item \texttt{reload zone [class [view]]} \hspace{1cm} Reload a single zone
  \item \texttt{refresh zone [class [view]]} \hspace{1cm} Schedule immediate maintenance for a zone
  \item \texttt{reconfig} \hspace{1cm} Reload configuration file and new zones only
  \item \texttt{stats} \hspace{1cm} Write server statistics to the statistics file
  \item \texttt{querylog} \hspace{1cm} Toggle query logging
  \item \texttt{dumpdb} \hspace{1cm} Dump cache(s) to the dump file (named_dump.db)
  \item \texttt{stop} \hspace{1cm} Save pending updates to master files and stop the server
\end{itemize}
BIND 9 Commands, Files, Tools, and Options

Some commands, files, tools, and options have remained the same in BIND 9 as they were in BIND 8. However, some have been modified and others have been added. This section describes many of the commands, files, tools, and options in BIND 9 and the new or modified behavior associated with each item.

BIND 9 Tools and Configuration Files

The following BIND 9.x tools are available with the Solaris operating system.

- named
- nsupdate
- rndc
- dnssec-keygen
- nslookup
- dig
- dnssec-makekeyset
- dnssec-signkey
- dnssec-signzone
- named-checkconf
- named-checkzone
- rndc-confgen
- host

The following BIND 9.x configuration file is supported in Solaris 10 and Solaris Express Developer Edition releases.
Comparison of BIND 8 and BIND 9 Commands and Files

The table below compares BIND 8 and BIND 9 commands and configuration files.

<table>
<thead>
<tr>
<th>BIND 8 Command</th>
<th>BIND 9.x Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>dnskeygen(1M)</td>
<td>dnssec-keygen(1M)</td>
</tr>
<tr>
<td>ndc(1M)</td>
<td>rndc(1M)</td>
</tr>
<tr>
<td>named-bootconf(1M)</td>
<td>NONE NEEDED</td>
</tr>
<tr>
<td>nsupdate(1M)</td>
<td>nsupdate(1M)</td>
</tr>
<tr>
<td>nslookup(1M)</td>
<td>nslookup(1M)</td>
</tr>
<tr>
<td>named-xfer(1M)</td>
<td>NONE NEEDED</td>
</tr>
<tr>
<td>in.named(1M)</td>
<td>named(1M)</td>
</tr>
<tr>
<td>named.conf(4)</td>
<td>named.conf</td>
</tr>
<tr>
<td>dig(1M)</td>
<td>dig(1M)</td>
</tr>
</tbody>
</table>

1 A detailed named.conf man page is not included with BIND 9.2.4. "The named.conf Options" on page 54 includes a summary of the named.conf options that are supported in BIND 9.2.4.

Descriptions of Command and Option Changes

All incompatibles listed below are BIND 8 features and interfaces that are not supported in the equivalent BIND 9 binary. This is not intended to be an exhaustive list of the options, command line options, or features for any BIND 9.x binary.

<table>
<thead>
<tr>
<th>Command</th>
<th>Option Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>in.named(1M)</td>
<td>Some DNS name server in.named command line options are not supported. In the BIND 9.x name server, the -g group_name, -q, -r and -w directory options are not supported, and -c config_file replaces the BIND 8.x -b config_file. See the named man page for further details.</td>
</tr>
<tr>
<td>dnssec-keygen(1M)</td>
<td>dnskeygen in BIND 8.x, used to generate keys, and dnssec-keygen from BIND 9.x, have no common options. See the dnssec-keygen man page for further details.</td>
</tr>
</tbody>
</table>
RND (1M)

ndc in BIND 8.x and rndc in BIND 9.x are significantly different. They share no common options and unlike ndc, rndc needs a configuration file in /etc/rndc.conf in order to run. See man pages for rndc, rndc.conf, and rndc-confgen for further details.

NSUPDATE (1M)

In BIND 9.x, the syntax of the -k option changes in nsupdate. Instead of -k keydir: keyname, the syntax is now k keyfile. The only other difference is that whereas a blank line was used to signal sending the input to the server, an explicit send subcommand is now used to do the same. See the nsupdate man page for further details.

NSLOOKUP (1M)

The following options are unsupported in the 9.x version of BIND: help, host server, set ignoreetc, set noignoreetc, set srch[list]=N1/N2/.../N6, set ro[ot]=host, root, finger [USER], ls [opt] DOMAIN [> FILE]

NAMED.CONF (4)

A detailed named.conf man page is not included with BIND 9.2.4. Several options are unsupported, not implemented, or have changed defaults. For a list of the option changes and a summary of all named.conf options that are supported in BIND 9.2.4, see "The named.conf Options" on page 54.

**The named.conf Options**

The following list compares the named.conf options between BIND 8 and BIND 9. It also provides a brief description of the changes. An OK in the Changes column denotes the option works unchanged for the BIND 9 version of named.

<table>
<thead>
<tr>
<th>Options</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ version version_string; ]</td>
<td>OK</td>
</tr>
<tr>
<td>[ directory path_name; ]</td>
<td>OK</td>
</tr>
<tr>
<td>[ named-xfer path_name; ]</td>
<td>Obsolete</td>
</tr>
<tr>
<td>[ dump-file path_name; ]</td>
<td>OK</td>
</tr>
<tr>
<td>[ memstatist-ics-file path_name; ]</td>
<td>Not Implemented</td>
</tr>
<tr>
<td>[ pid-file path_name; ]</td>
<td>OK</td>
</tr>
<tr>
<td>[ statistics-file path_name; ]</td>
<td>OK</td>
</tr>
<tr>
<td>[ auth-nxdomain yes_or_no; ]</td>
<td>OK²</td>
</tr>
<tr>
<td>[ dialup yes_or_no; ]</td>
<td>OK</td>
</tr>
</tbody>
</table>

1 Obsolete due to architectural differences.
2 Default set to yes in BIND 8, no in BIND 9.
Options {

[ fake-queries yes_or_no; ]    Obsolete
[ fetch-glue yes_or_no; ]     Obsolete
[ has-old-clients yes_or_no; ] Obsolete
[ host-statistics yes_or_no; ] Not Implemented
[ host-statistics-max-number; ] Not Implemented
[ multiple-cnames yes_or_no; ] Obsolete
[ notify yes_or_no | explicit; ] OK
[ recursion yes_or_no; ]      OK
[ rfc2308-type yes_or_no; ]    Not Implemented
[ use-id-pool yes_or_no; ]     Obsolete
[ treat-crc-as-space yes_or_no; ] Obsolete
[ also-notify yes_or_no; ]     Syntax Changed
[ forward ( only | first ); ]   OK
[ forwarders { [ in_addr; \ [ in_addr; ... ] ] }; ] OK
[ check-names ( master | slave | \ response ) ( warn | fail | ignore ); ] Not Implemented
[ allow-query { address_match_list; } ] OK
[ allow-recursion { address_match_list; } ] OK
[ allow-transfer { address_match_list; } ] OK
[ blackhole { address_match_list; } ] OK
[ listen-on [ port ip_port ] \ [ address_match_list; ] ] OK
[ query-source { address ( ip_addr | * ) \ [ port ( ip_port | * ) ]; ] OK
[ lame-_seconds; ] OK
[ max-transfer-time-in-number; ] OK

3 Needs an IP address for yes.
4 Doesn’t work if no forwarders specified; Gives an error of no matching ‘forwarders’ statement in that case.
5 See [ forward ] clause.
### The named.conf Options

<table>
<thead>
<tr>
<th>Options</th>
<th>Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>max-ncache-ttl number;</td>
<td>OK</td>
</tr>
<tr>
<td>min-roots number;</td>
<td>Not Implemented</td>
</tr>
<tr>
<td>transfer-format (one-answer</td>
<td>many-answers );</td>
</tr>
<tr>
<td>transfers-in number;</td>
<td>OK</td>
</tr>
<tr>
<td>transfers-out number;</td>
<td>OK</td>
</tr>
<tr>
<td>transfers-per-ns number;</td>
<td>OK</td>
</tr>
<tr>
<td>transfer-source ip_addr;</td>
<td>OK</td>
</tr>
<tr>
<td>maintain-ixfr-base yes_or_no;</td>
<td>Obsolete</td>
</tr>
<tr>
<td>max-ixfr-log-size number;</td>
<td>Obsolete$^7$</td>
</tr>
<tr>
<td>coresize size_spec ;</td>
<td>OK</td>
</tr>
<tr>
<td>datasize size_spec ;</td>
<td>OK</td>
</tr>
<tr>
<td>files size_spec ;</td>
<td>OK</td>
</tr>
<tr>
<td>stacksize size_spec ;</td>
<td>OK</td>
</tr>
<tr>
<td>cleaning-interval number;</td>
<td>OK</td>
</tr>
<tr>
<td>heartbeat-interval number;</td>
<td>OK</td>
</tr>
<tr>
<td>interface-interval number;</td>
<td>OK</td>
</tr>
<tr>
<td>statistics-interval number;</td>
<td>Not Implemented</td>
</tr>
<tr>
<td>topology { address_match_list };</td>
<td>Not Implemented</td>
</tr>
<tr>
<td>sortlist { address_match_list };</td>
<td>OK</td>
</tr>
<tr>
<td>rrset-order { order_spec ; \ order_spec ; ... } ];</td>
<td>Not Implemented</td>
</tr>
</tbody>
</table>

$^6$ Default set to one-answer in BIND 8 and many-answers in BIND 9.

$^7$ No need for this option as BIND 9 trims the size of its log file automatically.

## Statements in BIND 9

This section describes any differences between BIND 8 and BIND 9 statements.
The Controls Statement

`unix` is the default for `rndc` and all of the arguments are compiled in. `inet` is the only option for `rndc` and nothing is compiled in.

Syntax

```plaintext
controls {
  [ inet ip_addr
    port ip_port
    allow { address_match_list; }; ]   OK
  [ unix path_name
    perm number
    owner number
    group number; ]                    Not Implemented
};
```

Logging syntax has changed significantly. See “The named.conf Options” on page 54 for a list of named.conf options.

The Zone Statement

The syntax for the zone statement in the BIND 8 named.conf man page is mostly supported for BIND 9 except for the following:

```plaintext
[ pubkey number number number string; ]   Obsolete
[ check-names ( warn | fail | ignore ); ]   Not Implemented
```

The ACL Statement

Works unchanged in BIND 9.

Syntax

```plaintext
acl name {
  address_match_list
};
```

The Key Statement

Works unchanged in BIND 9.

Syntax

```plaintext
key key_id {
  algorithm algorithm_id;
  secret secret_string;
};
```

The Trusted-Keys Statement

Works unchanged, however the code to use this statement has been turned off in BIND 9.2.4.
Syntax
trusted-keys {
    [ domain_name flags protocol algorithm key; ]
};

The Server Statement

support-ixfr is obsolete, however all of the following options work unchanged in BIND 9. Note the default for transfer-format has changed.

Syntax
server ip_addr {
    [ bogus yes_or_no; ]
    [ transfers number; ]
    [ transfer-format ( one-answer | many-answers ); ]
    [ keys { key_id [ key_id ... ] }; ]
    [ edns yes_or_no; ]
};

The Include Statement

Works unchanged in BIND 9.

Syntax
include path_name;

Summary of the named.conf Options

A detailed named.conf man page is not included with BIND 9.2.4. Following is a summary of the named.conf options that are supported in BIND 9.2.4.

options {
    blackhole { <address_match_element>; ... };
    coresize <size>;
    datasize <size>;

Multicast DNS and Service Discovery

Two extensions to the DNS protocol are multicast DNS (mDNS) and DNS Service Discovery (DNS-SD). mDNS extends the Domain Name Service system to operate over link-local multicast. DNS-SD adds support needed to discover network services over DNS.

Multicast DNS

Multicast DNS (mDNS) provides a naming service system that is easy to set up and maintain, for computers on a local link. All participating network devices on the same local link perform standard DNS functions, using multicast DNS rather than unicast, and do not need a unicast DNS server. For administrators, the primary advantage of mDNS is that no unicast DNS server needs to be maintained on the local network. There is no need, for example, to update and maintain host names in files to resolve hostname to IP address for devices on the local link that are using mDNS.

Service Discovery

Network services include printing, file transfer, music sharing, servers for photo, document and other file sharing, and services provided by other local devices. DNS service discovery support in the Solaris OS includes open source framework and tools from Apple to enable applications to advertise and discover network services, using DNS on the Solaris OS.

For users, network service discovery makes computing easier by enabling users to browse for services on the network, rather than needing to find the service manually. Existing standards, and work done by other companies and groups, assure that cross-platform support is available.

Administering mDNS

Use the Service Management Facility (SMF) to administer the mDNS daemon. You can use SMF to start and stop the mDNS service.

For an overview of SMF, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the svcadm(1M) and svc(1) man pages for more details.

mDNS Deployment

For mDNS to function, it must be deployed on all peers that are to participate in mDNS. It is used to advertise the availability of services provided on the peer.
Multicast DNS and Service Discovery are both installed by default in the “all” cluster, when installing the Solaris OS. For other types of devices, for example, printers, music, video, and communication devices, many already have mDNS installed.

In addition to being installed, mDNS must be enabled, and must be included in the /etc/nsswitch.conf file. See nsswitch.conf(4)

Enable mDNS

For the Solaris OS, as root, or as a user with appropriate privileges, enable mDNS on each computer that will participate in mDNS.

```
# svcadm enable svc:/network/dns/multicast:default
```

Enabling mDNS this way persists through upgrades and reboots. For more information, see svcadm(1M).

Edit nsswitch.conf

To be able to resolve local hosts, edit the nsswitch.conf file and add mdns to the list of name services. For example, the file might look like the following:

```
# /etc/nsswitch.conf
hosts: files dns mdns
ipnodes: files dns mdns
```

For an example of the form such a file should take, see /etc/nsswitch.conf.dns.

Review Errors or Messages

Check the multicast DNS service log for errors or messages.

```
/var/svc/log/network-dns-multicast:default.log
```

mDNS and dns-sd Tool

Use the dns-sd command as a network diagnosis tool, to browse and discover services, similar to how you would use ping (1M) or traceroute (1M).

The dns-sd command is intended primarily for interactive use, mainly because its command line arguments and its output format can change over time, which makes invoking it from a shell script unpredictable and risky. Additionally, the asynchronous nature of DNS Service Discovery does not easily lend itself to script-oriented programming.
For complete dns-sd information, see the man page for dns-sd (1M) and to incorporate DNS service in applications, see the libdns_sd (3DNS_SD) man page.

EXAMPLES of the dns-sd command

Advertising a printing service

The following command advertises the existence of LPR printing service on port 515 on “My Test” machine, so that it will be available to DNS-SD compatible printing clients:

```
dns-sd -R "My Test"_printer._tcp. 515 pdl=application/postscript
```

For this registration to be useful, the LPR service should be available on port 515.

Advertising a web page

The following command advertises a web page being served by an HTTP server on port 80 on My Test machine. The web page will appear on the Bonjour list in Safari and other DNS-SD compatible Web clients:

```
dns-sd -R "My Test"_http._tcp. 80 path=/path-to-page.html
```
This part provides an overview of the NIS naming service, as well as the setup, administration and troubleshooting of NIS within the Solaris OS.
Network Information Service (NIS) (Overview)

This chapter provides an overview of the Network Information Service (NIS).

NIS is a distributed naming service. It is a mechanism for identifying and locating network objects and resources. It provides a uniform storage and retrieval method for network-wide information in a transport-protocol and media-independent fashion.

This chapter covers the following topics.
- “NIS Introduction” on page 71
- “NIS Machine Types” on page 73
- “NIS Elements” on page 74
- “NIS Binding” on page 81

NIS Introduction

By running NIS, the system administrator can distribute administrative databases, called maps, among a variety of servers (master and slaves). The administrator can update those databases from a centralized location in an automatic and reliable fashion to ensure that all clients share the same naming service information in a consistent manner throughout the network.

NIS was developed independently of DNS and has a slightly different focus. Whereas DNS focuses on making communication simpler by using machine names instead of numerical IP addresses, NIS focuses on making network administration more manageable by providing centralized control over a variety of network information. NIS stores information not only about machine names and addresses, but also about users, the network itself, and network services. This collection of network information is referred to as the NIS namespace.
**NIS Architecture**

NIS uses a client-server arrangement. NIS servers provide services to NIS clients. The principal servers are called *master* servers, and for reliability, they have backup, or *slave* servers. Both master and slave servers use the NIS information retrieval software and both store NIS maps.

NIS uses domains to arrange the machines, users, and networks in its namespace. However, it does not use a domain hierarchy; an NIS namespace is flat.

An NIS domain cannot be connected directly to the Internet using just NIS. However, organizations that want to use NIS and also be connected to the Internet can combine NIS with DNS. You can use NIS to manage all local information and use DNS for Internet host lookup. NIS provides a forwarding service that forwards host lookups to DNS if the information cannot be found in an NIS map. The Solaris system also allows you to set up the *nsswitch.conf* file so that hosts lookup requests go only to DNS, or to DNS and then NIS if not found by DNS, or to NIS and then DNS if not found by NIS. See Chapter 2, “The Name Service Switch (Overview),” for details.
NIS Machine Types

There are three types of NIS machines.

- Master server
- Slave servers
- Clients of NIS servers

Any machine can be an NIS client, but only machines with disks should be NIS servers, either master or slave. Servers are also clients, typically of themselves.

NIS Servers

The NIS server does not have to be the same machine as the NFS file server.

NIS servers come in two varieties, master and slave. The machine designated as master server contains the set of maps that the system administrator creates and updates as necessary. Each NIS domain must have one, and only one, master server, which can propagate NIS updates with the least performance degradation.

You can designate additional NIS servers in the domain as slave servers. A slave server has a complete copy of the master set of NIS maps. Whenever the master server maps are updated, the updates are propagated among the slave servers. Slave servers can handle any overflow of requests from the master server, minimizing “server unavailable” errors.

Normally, the system administrator designates one master server for all NIS maps. However, because each individual NIS map has the machine name of the master server encoded within it, you could designate different servers to act as master and slave servers for different maps. To minimize confusion, designate a single server as the master for all the maps you create within a single domain. The examples in this chapter assume that one server is the master for all maps in the domain.

NIS Clients

NIS clients run processes that request data from maps on the servers. Clients do not make a distinction between master and slave servers, since all NIS servers should have the same information.

Note – The Solaris operating system does not support a configuration in which a NIS client and a Native LDAP client co-exist on the same client machine.
NIS Elements

The NIS naming service is composed of the following elements:

- Domains (see “The NIS Domain” on page 74)
- Daemons (see “NIS Daemons” on page 74)
- Utilities (see “NIS Utilities” on page 75)
- Maps (see “NIS Maps” on page 75)
- NIS Command Set (see “NIS-Related Commands” on page 79)

The NIS Domain

An NIS domain is a collection of machines which share a common set of NIS maps. Each domain has a domain name and each machine sharing the common set of maps belongs to that domain.

Any machine can belong to a given domain, as long as there is a server for that domain’s maps in the same network. An NIS client machine obtains its domain name and binds to an NIS server as part of its boot process.

NIS Daemons

NIS service is provided by five daemons as shown in Table 4–1. The NIS service is managed by the Service Management Facility. Administrative actions on this service, such as enabling, disabling, or restarting, can be performed by using the svcadm command. For an overview of SMF, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the svcadm(1M) and svc(1) man pages for more details.

**TABLE 4–1  NIS Daemons**

<table>

</tr>
<tr>
<td><strong>See NOTE below</strong></td>
<td></td>
</tr>
<tr>
<td>rpc.ypupdated</td>
<td>Modifies other maps such as pubkey</td>
</tr>
</tbody>
</table>

**NOTE:**

The rpc.yppasswdd daemon is used to update the NIS password maps. It is not used to update the public key maps, which are updated by the rpc.ypupdated daemon. For more information about the rpc.yppasswdd daemon, see the System Administration Guide: Basic Administration.
Note – rpc.yppasswd considers all shells that begin with an r to be restricted. For example, if you are in /bin/rksh, you are not allowed to change from that shell to another one. If you have a shell that begins with r but is not intended to be restricted as such, refer to Chapter 7, "NIS Troubleshooting," for the workaround.

NIS Utilities

NIS service is supported by nine utilities as shown in Table 4–2.

<table>
<thead>
<tr>
<th>Utility</th>

<td>ypwhich</td>
<td>Transfers data from master to slave NIS server</td>
</tr>
</tbody>
</table>

NIS Maps

The information in NIS maps is stored in ndbm format. ypfiles(4) and ndbm(3C) explain the format of the map file.

NIS maps were designed to replace UNIX /etc files, as well as other configuration files, so they store much more than names and addresses. On a network running NIS, the NIS master server for each NIS domain maintains a set of NIS maps for other machines in the domain to query. NIS slave servers also maintain duplicates of the master server’s maps. NIS client machines can obtain namespace information from either master or slave servers.

NIS maps are essentially two-column tables. One column is the key and the other column is information related to the key. NIS finds information for a client by searching through the keys. Some information is stored in several maps because each map uses a different key. For example, the names and addresses of machines are stored in two maps: hosts.bname and
hosts.byaddr. When a server has a machine’s name and needs to find its address, it looks in the hosts.byname map. When it has the address and needs to find the name, it looks in the hosts.byaddr map.

An NIS Makefile is stored in the /var/yp directory of machines designated as an NIS server at installation time. Running make in that directory causes makedbm to create or modify the default NIS maps from the input files.

**Note** – Always create maps on the master server, as maps created on a slave will not automatically be pushed to the master server.

### Default NIS Maps

A default set of NIS maps are provided in the Solaris system. You might want to use all these maps or only some of them. NIS can also use whatever maps you create or add when you install other software products.

Default maps for an NIS domain are located in each server’s /var/yp/domainname directory. For example, the maps that belong to the domain test.com are located in each server’s /var/yp/test.com directory.

**Table 4-3** describes the default NIS maps, information they contain, and whether the software consults the corresponding administrative files when NIS is running.

**TABLE 4-3**  NIS Map Descriptions

</tbody>
</table>

New ipnodes maps (ipnodes.byaddr and ipnodes.byname) are added to NIS. The maps store both IPv4 and IPv6 addresses.

**Note** – Starting with Solaris Express 10/06, the Solaris OS does not have two separate hosts files. The /etc/inet/hosts file is the single hosts file that contains both IPv4 and IPv6 entries. You do not need to maintain IPv4 entries in two hosts files that always require synchronization. For backward compatibility, the /etc/inet/ipnodes file is replaced with a symbolic link of the same name to the /etc/inet/hosts file.

For more information, see the hosts(4) man page.

NIS clients and servers can communicate using either IPv4 or IPv6 RPC transports.

The ageing.byname mapping contains information used by yppasswdd to read and write password aging information to the DIT when the NIS-to-LDAP transition is implemented. If password aging is not being used, then it can be commented out of the mapping file. For more information about the NIS-to-LDAP transition, see Chapter 15, “Transitioning From NIS to LDAP (Overview/ Tasks).”

**Using NIS Maps**

NIS makes updating network databases much simpler than with the /etc files system. You no longer have to change the administrative /etc files on every machine each time you modify the network environment.

For example, when you add a new machine to a network running NIS, you only have to update the input file in the master server and run make. This automatically updates the hosts.byname and hosts.byaddr maps. These maps are then transferred to any slave servers and are made...
available to all of the domain’s client machines and their programs. When a client machine or application requests a machine name or address, the NIS server refers to the `hosts.byname` or `hosts.byaddr` map as appropriate and sends the requested information to the client.

You can use the `ypcat` command to display the values in a map. The `ypcat` basic format is the following.

\[ %\texttt{ypcat mapname} \]

where `mapname` is the name of the map you want to examine or its `nickname`. If a map is composed only of keys, as in the case of `ypservers`, use `ypcat -k`. Otherwise, `ypcat` prints blank lines. The `ypcat`(1) man page describes more options for `ypcat`.

You can use the `ypwhich` command to determine which server is the master of a particular map. Type the following.

\[ %\texttt{ypwhich -m mapname} \]

where `mapname` is the name or the nickname of the map whose master you want to find. `ypwhich` responds by displaying the name of the master server. For complete information, refer to the `ypwhich`(1) man page.

**NIS Map Nicknames**

Nicknames are aliases for full map names. To obtain a list of available map nicknames, such as `passwd` for `passwd.byname`, type `ypcat -x` or `ypwhich -x`.

Nicknames are stored in the `/var/yp/nicknames` file, which contains a map nickname followed by the fully specified name for the map, separated by a space. This list might be added to or modified. Currently, there is a limit of 500 nicknames.

**NIS-Related Commands**

The NIS service includes specialized daemons, system programs, and commands, which are summarized in the following table.

<table>
<thead>
<tr>
<th>Command</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>ypserv</code></td>
<td>Services NIS clients' requests for information from an NIS map. <code>ypserv</code> is a daemon that runs on NIS servers with a complete set of maps. At least one <code>ypserv</code> daemon must be present on the network for NIS service to function.</td>
</tr>
<tr>
<td>Command</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>ypbind</td>
<td>Provides NIS server binding information to clients. It provides binding by finding a ypserv process that serves maps within the domain of the requesting client. ypbind must run on all servers and clients.</td>
</tr>
<tr>
<td>ypinit</td>
<td>Automatically creates maps for an NIS server from the input files. It is also used to construct the initial /var/yp/binding/domain/ypservers file on the clients. Use ypinit to set up the master NIS server and the slave NIS servers for the first time.</td>
</tr>
<tr>
<td>make</td>
<td>Updates NIS maps by reading the Makefile (when run in the /var/yp directory). You can use make to update all maps based on the input files or to update individual maps. The ypmake(1M) man page describes the functionality of make for NIS.</td>
</tr>
<tr>
<td>makedbm</td>
<td>makedbm takes an input file and converts it into dbm.dir and dbm.pag files – valid dbm files that NIS can use as maps. You can also use makedbm -u to disassemble a map, so that you can see the key-value pairs that comprise it.</td>
</tr>
<tr>
<td>ypxfr</td>
<td>Pulls an NIS map from a remote server to the local /var/yp/domain directory, using NIS itself as the transport medium. You can run ypxfr interactively, or periodically from a crontab file. It is also called ypserv to initiate a transfer.</td>
</tr>
<tr>
<td>ypxfrd</td>
<td>Provides map transfers service for ypxfr requests (generally slave servers). It is run only on the master server.</td>
</tr>
<tr>
<td>yppush</td>
<td>Copies a new version of an NIS map from the NIS master server to its slaves. You run it on the master NIS server.</td>
</tr>
<tr>
<td>ypset</td>
<td>Tells a ypbind process to bind to a named NIS server. This is not for casual use and its use is discouraged because of security implications. See the ypset(1M) and ypbind(1M) man pages for information about the ypset and ypsetme options to the ypbind process.</td>
</tr>
<tr>
<td>yppoll</td>
<td>Tells which version of an NIS map is running on a server that you specify. It also lists the master server for the map.</td>
</tr>
<tr>
<td>ypcat</td>
<td>Displays the contents of an NIS map.</td>
</tr>
<tr>
<td>ypmatch</td>
<td>Prints the value for one or more specified keys in an NIS map. You cannot specify which version of the NIS server map you are seeing.</td>
</tr>
<tr>
<td>ypwhich</td>
<td>Shows which NIS server a client is using at the moment for NIS services, or, if invoked with the -n mapname option, which NIS server is master of each of the maps. If only -n is used, it displays the names of all the maps available and their respective master servers.</td>
</tr>
</tbody>
</table>
NIS Binding

NIS clients get information from an NIS server through the binding process, which can work in one of two modes: server-list or broadcast.

- Server-list. In the server-list mode, the `ypbind` process queries the `/var/yp/binding/domain/ypservers` list for the names of all of the NIS servers in the domain. The `ypbind` process binds only to servers in this file. The file is created by running `ypinit -c`.

- Broadcast. The `ypbind` process can also use an RPC broadcast to initiate a binding. Since broadcasts are only local subnet events that are not routed further, there must be at least one server (master or slave) on the same subnet as the client. The servers themselves might exist throughout different subnets since map propagation works across subnet boundaries. In a subnet environment, one common method is to make the subnet router an NIS server. This allows the domain server to serve clients on either subnet interface.

Server-List Mode

The binding process in server-list mode works as follows:

1. Any program, running on the NIS client machine that needs information provided by an NIS map, asks `ypbind` for the name of a server.
2. `ypbind` looks in the `/var/yp/binding/domainname/ypservers` file for a list of NIS servers for the domain.
3. `ypbind` initiates binding to the first server in the list. If the server does not respond, `ypbind` tries the second, and so on, until it finds a server or exhausts the list.
4. `ypbind` tells the client process which server to talk to. The client then sends the request directly to the server.
5. The `ypserv` daemon on the NIS server handles the request by consulting the appropriate map.
6. `ypserv` sends the requested information back to the client.

Broadcast Mode

The broadcast mode binding process works as follows:

1. `ypbind` must be started with the broadcast option set (`broadcast`).
2. `ypbind` issues an RPC broadcast in search of an NIS server.
Note – In order to support such clients, it is necessary to have an NIS server on each subnet requiring NIS service.

3. ypbind initiates binding to the first server that responds to the broadcast.
4. ypbind tells the client process which server to talk to. The client then sends the request directly to the server.
5. The ypserv daemon on the NIS server handles the request by consulting the appropriate map.
6. ypserv sends the requested information back to the client.

Normally, once a client is bound to a server it stays bound to that server until something causes it to change. For example, if a server goes out of service, the clients it served will then bind to new servers.

To find out which NIS server is currently providing service to a specific client, use the following command.

%ypwhich machinename

Where machinename is the name of the client. If no machine name is mentioned, ypwhich defaults to the local machine (that is, the machine on which the command is run).
Setting Up and Configuring NIS Service

This chapter describes initial setup and configuration of the Network Information Service (NIS).

Note – In some contexts, *machine* names are referred to as *host* names or *machine* names. This discussion uses “machine,” but some screen messages or NIS map names might use *host* or *machine*.

This chapter covers the following topics.

- “Configuring NIS Task Map” on page 83
- “Before You Begin Configuring NIS” on page 84
- “Planning Your NIS Domain” on page 85
- “Preparing the Master Server” on page 86
- “Starting and Stopping NIS Service on the Master Server” on page 92
- “Setting Up NIS Slave Servers” on page 93
- “Setting Up NIS Clients” on page 95

### Configuring NIS Task Map

<table>
<thead>
<tr>
<th>Task</th>
<th>For Instructions, Go To</th>
</tr>
</thead>
<tbody>
<tr>
<td>Prepare source files for conversion.</td>
<td>“Preparing Source Files for Conversion to NIS Maps” on page 87</td>
</tr>
<tr>
<td>Set up master server using <em>ypinit</em></td>
<td>“Setting Up the Master Server With <em>ypinit</em>” on page 90</td>
</tr>
<tr>
<td>Start NIS on master server.</td>
<td>“Starting and Stopping NIS Service on the Master Server” on page 92</td>
</tr>
</tbody>
</table>
Before You Begin Configuring NIS

Before configuring your NIS namespace, you must do the following.

- Install properly configured `nsswitch.conf` files on all the machines that will be using NIS. See Chapter 2, “The Name Service Switch (Overview),” for details.
- Plan your NIS domain.

NIS and the Service Management Facility

The NIS service is managed by the Service Management Facility. For an overview of SMF, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the `svcadm(1M)` and `svcs(1)` man pages for more details.

- Administrative actions on this service, such as enabling, disabling, or restarting, can be performed by using the `svcadm` command. However, `ypstart` and `ypstop` can also be used from the command line to start or stop NIS. See the `ypstart(1M)` and `ypstop(1M)` man pages for more information.

  **Tip** – Temporarily disabling a service by using the `-t` option provides some protection for the service configuration. If the service is disabled with the `-t` option, the original settings would be restored for the service after a reboot. If the service is disabled without `-t`, the service will remain disabled after reboot.

- The NIS Fault Managed Resource Identifiers (FMRIs) are
  `svc:/network/nis/server:<instance>` for the NIS server and
  `svc:/network/nis/client:<instance>` for the NIS client.
- You can query the status of NIS by using the `svcs` command.
- Examples of `svcs` command and output.

```
# svcs network/nis/server
STATE    STIME        FMRI
online   Jan_10  svc:/network/nis/server:default

# svcs \"nis\"
STATE    STIME        FMRI
disabled 12:39:18  svc:/network/rpc/nisplus:default
```
Planning Your NIS Domain

Before you configure machines as NIS servers or clients, you must plan the NIS domain.

Decide which machines will be in your NIS domain. An NIS domain does not have to be congruent with your network. A network can have more than one NIS domain, and there can be machines on your network that are outside of your NIS domain.

Choose an NIS domain name, which can be 256 characters long. A good practice is to limit domain names to no more than 32 characters. Domain names are case-sensitive. For convenience, you can use your Internet domain name as the basis for your NIS domain name. For example, if your Internet domain name is doc.com, you can name your NIS domain doc.com. If you wanted to divide doc.com into two NIS domains, one for the sales department and the other for the manufacturing department, you could name one sales.doc.com and the other manf.doc.com.

Note – Do not use the -f option with ps because this option attempts to translate user IDs to names, which causes more naming service lookups that might not succeed.
Before a machine can use NIS services, the correct NIS domain name and machine name must be set. A machine’s name is set by the machine’s /etc/nodename file and the machine’s domain name is set by the machine’s /etc/defaultdomain file. These files are read at boot time and the contents are used by the `uname -S` and `domainname` commands, respectively. Diskless machines read these files from their boot server.

**Identify Your NIS Servers and Clients**

Select one machine to be the master server. Decide which machines, if any, will be slave servers.

Decide which machines will be NIS clients. Typically all machines in your domain are set to be NIS clients, although this is not necessary.

**Preparing the Master Server**

The following sections describe how to prepare the source files and the `passwd` files for the master server.

**Source Files Directory**

The source files should be located in the /etc directory, on the master server or in some other directory. Having them in /etc is undesirable because the contents of the maps are then the same as the contents of the local files on the master server. This is a special problem for `passwd` and `shadow` files because all users have access to the master server maps and the root password would be passed to all NIS clients through the `passwd` map. See “**Passwd Files and Namespace Security**” on page 86 for additional information.

However, if you put the source files in some other directory, you must modify the `Makefile` in /var/yp by changing the `DIR=/etc` line to `DIR=/your-choice`, where `your-choice` is the name of the directory you will be using to store the source files. This allows you to treat the local files on the server as if they were those of a client. (It is good practice to first save a copy of the original `Makefile`.)

In addition, if `audit_user`, `auth_attr`, `exec_attr` and `prof_attr` are to be taken from a directory other than the default, you must amend the `RBACDIR=/etc/security` to `RBACDIR=/your-choice`.

**Passwd Files and Namespace Security**

The `passwd` map is a special case. In addition to the old Solaris 1 `passwd` file format, this implementation of NIS accepts the `/etc/passwd` and `/etc/shadow` file formats as input for building the NIS password maps.
For security reasons, the files used to build the NIS password maps should not contain an entry for root, to prevent unauthorized root access. Therefore, the password maps should not be built from the files located in the master server’s /etc directory. The password files used to build the password maps should have the root entry removed from them and be located in a directory that can be protected from unauthorized access.

For example, the master server password input files should be stored in a directory such as /var/yp, or any directory of your choice, as long as the file itself is not a link to another file and its location is specified in the Makefile. The correct directory option is set automatically according to the configuration specified in your Makefile.

**Caution** – Be sure that the passwd file in the directory specified by PWDIR does not contain an entry for root.

If your source files are in a directory other than /etc, you must alter the PWDIR password macro in the Makefile to refer to the directory where the passwd and shadow files reside, changing the line PWDIR=/etc to PWDIR=your-choice, where your-choice is the name of the directory you will be using to store the passwd map source files.

## Preparing Source Files for Conversion to NIS Maps

Prepare the source files for conversion to NIS maps.

### How to Prepare Source Files for Conversion

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in *System Administration Guide: Security Services*.

2. **Check the source files on the master server to make sure they reflect an up-to-date picture of your system.**
   Check the following files:
   - auto.home or auto_home
   - auto.master or auto_master
   - audit_user
   - auth_attr
   - bootparams
   - ethers
   - exec_attr
   - group
Preparing the Master Server

- hosts
- ipnodes
- netgroup
- netmasks
- networks
- passwd
- protocols
- rpc
- service
- shadow
- user_attr

3 Copy all of these source files, except passwd, to the DIR directory that you have selected.

4 Copy the passwd file to the PWDIR directory that you have selected.

5 Copy audit_user, auth_attr, exec_attr, and prof_attr to the selected RBACDIR directory.

6 Check the /etc/mail/aliases file.

   Unlike other source files, the /etc/mail/aliases file cannot be moved to another directory. This file must reside in the /etc/mail directory. Refer to aliases(4) for more information.

   Note – You can add a nis-specific mail aliases file by pointing the ALIASES = /etc/mail/aliases entry in /var/yp/Makefile to another location. When you then run a make, the ALIASES entry creates a mail.aliases map. The sendmail service uses this map in addition to the /etc/mail/aliases file when the /etc/nsswitch.conf file properly targets nis in addition to files. Refer to “Modifying and Using the Makefile” on page 105.

7 Clean all comments and other extraneous lines and information from the source files.

   These operations can be done through a sed or awk script or with a text editor. The Makefile performs some file cleaning automatically for you, but it is good practice to examine and clean these files by hand before running.

8 Make sure that the data in all the source files is correctly formatted.

   Source file data needs to be in the correct format for that particular file. Check the man pages for the different files to make sure that each file is in the correct format.
Preparing the Makefile

After checking the source files and copying them into the source file directory, you now need to convert those source files into the ndbm format maps that the NIS service uses. This is done automatically for you by ypinit when called on the master server, as explained in “Setting Up the Master Server With ypinit” on page 90.

The ypinit script calls the program make, which uses the Makefile located in the /var/yp directory. A default Makefile is provided for you in the /var/yp directory and contains the commands needed to transform the source files into the desired ndbm format maps.

You can use the default Makefile as it is, or modify it if you want. (If you do modify the default Makefile, be sure to first copy and store the original default Makefile in case you need it for future use.) You might need to make one or more of the following modifications to the Makefile:

- **Nondefault maps**
  If you have created your own non-default source files and want to convert them to NIS maps, you must add those source files to the Makefile.

- **DIR value**
  If you want the Makefile to use source files stored in some directory other than /etc, as explained in “Source Files Directory” on page 86, you must change the value of DIR in the Makefile to the directory that you want to use. When changing this value in the Makefile, do not indent the line.

- **PWDIR value**
  If you want the Makefile to use passwd, shadow, and/or adjunct source files stored in some directory other than /etc, you must change the value of PWDIR in the Makefile to the directory that you want to use. When changing this value in the Makefile, do not indent the line.

- **Domain name resolver**
  If you want the NIS server to use the domain name resolver for machines not in the current domain, comment out the Makefile line B=, and uncomment (activate) the line B=-b.

The function of the Makefile is to create the appropriate NIS maps for each of the databases listed under all. After passing through makedbm the data is collected in two files, mapname.dir and mapname.pag. Both files are in the /var/yp/domainname directory on the master server.

The Makefile builds passwd maps from the /PWDIR/passwd, /PWDIR/shadow, and /PWDIR/security/passwd.adjunct files, as appropriate.
Setting Up the Master Server With ypinit

The ypinit script sets up master and slave servers and clients to use NIS. It also initially runs make to create the maps on the master server.

To use ypinit to build a fresh set of NIS maps on the master server, do the following.

How to set up the master server using ypinit

1. **On the master server, become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2. **Copy the contents of the nsswitch.files file to the nsswitch.conf file.**
   
   ```
   # cp /etc/nsswitch.files /etc/nsswitch.conf
   ```

3. **Edit the /etc/hosts or /etc/inet/ipnodes file to add the name and IP address of each of the NIS servers.**

4. **Build new maps on the master server.**
   
   ```
   # /usr/sbin/ypinit -m
   ```

5. **When ypinit prompts for a list of other machines to become NIS slave servers, type the name of the server you are working on, along with the names of your NIS slave servers.**

6. **When ypinit asks whether you want the procedure to terminate at the first nonfatal error or continue despite nonfatal errors, type y.**
   When you choose y, ypinit exits upon encountering the first problem; you can then fix it and restart ypinit. This is recommended if you are running ypinit for the first time. If you prefer to continue, you can try to manually fix all problems that occur, and then restart ypinit.

   **Note** – A nonfatal error can appear when some of the map files are not present. This is not an error that affects the functionality of NIS. You might need to add maps manually if they were not created automatically. Refer to “Default NIS Maps” on page 76 for a description of all default NIS maps.

7. **ypinit asks whether the existing files in the /var/yp/domainname directory can be destroyed.**
   This message is displayed only if NIS has been previously installed.
After ypinit has constructed the list of servers, it invokes make. This program uses the instructions contained in the Makefile (either the default one or the one you modified) located in /var/yp. The make command cleans any remaining comment lines from the files you designated. It also runs makedbm on the files, creating the appropriate maps and establishing the name of the master server for each map.

If the map or maps being pushed by the Makefile correspond to a domain other than the one returned by the command domainname on the master, you can make sure that they are pushed to the correct domain by starting make in the ypinit shell script with a proper identification of the variable DOM, as follows:

```
# make DOM=domainname password
```

This pushes the password map to the intended domain, instead of the domain to which the master belongs.

To enable NIS as the naming service, type the following.

```
# cp /etc/nsswitch.nis /etc/nsswitch.conf
```

This replaces the current switch file with the default NIS-oriented switch file. You can edit this file as necessary.

### Master Supporting Multiple NIS Domains

Normally, an NIS master server supports only one NIS domain. However, if you are using a master server to support multiple domains, you must slightly modify the steps, as described in “Setting Up the Master Server With ypinit” on page 90, when setting up the server to serve the additional domains.

Run the domainname command on the server. The domain name returned by the command is the server's default domain. The steps described in “Setting Up the Master Server With ypinit” on page 90 will work properly for setting up service for that domain. To configure service for any other domain, you must modify the ypinit shell script as follows.

```
# make DOM=correct-domain passwd
```

`correct-domain` is the name of the other domain that you are setting up service for, and passwd is the make target. This command pushes the passwd map to the intended domain, instead of the domain to which the master belongs.
Starting and Stopping NIS Service on the Master Server

Now that the master maps are created, you can start the NIS daemons on the master server and begin service. When you enable the NIS service, ypserv and ypbind start on the server. When a client requests information from the server, ypserv is the daemon that answers information requests from clients after looking them up in the NIS maps. The ypserv and ypbind daemons are administered as a unit.

There are three ways that NIS service can be started or stopped on a server:

- By automatically invoking the /usr/lib/netsvc/yp/ypstart script during the boot process
- By using the Service Management Facility svcadm enable <fmri> and svcadm disable <fmri> commands from the command line
  See svcadm(1M) for more information about SMF.
- By using the ypstart(1M) and ypstop(1M) commands from the command line

Starting NIS Service Automatically

After the NIS master server has been configured by running ypinit, ypstart is automatically invoked to start up ypserv when the machine is booted. See “Setting Up the Master Server With ypinit” on page 90.

Starting and Stopping NIS From the Command Line

Use the Service Management Facility svcadm commands or the ypstart/ypstop commands to start and stop NIS from the command line. When using svcadm, the instance name is needed only if you are running more than one instance of the service. For more information, see “NIS and the Service Management Facility” on page 84, or see the svcadm(1M), ypstart(1M), and ypstop(1M) man pages.

To begin NIS service from the command line, run the svcadm enable command or the ypstart command.

```
# svcadm enable network/nis/server:<instance>
# svcadm enable network/nis/client:<instance>
```
or
```
# ypstart
```
Note – Because there is a slight delay before ypserv is ready to respond to calls after startup, you should issue a three to five second sleep after svcadm when calling it from inside a program or script.

To stop NIS service, run the svcadm disable command or the ypstop.

```
# svcadm disable network/nis/server:<instance>
# svcadm disable network/nis/client:<instance>
```

or

```
# ypstop
```

To stop and immediately restart an NIS service, use the svcadm restart command.

```
# svcadm restart network/nis/server:<instance>
# svcadm restart network/nis/client:<instance>
```

Setting Up NIS Slave Servers

Your network can have one or more slave servers. Having slave servers ensures the continuity of NIS services when the master server is not available.

Preparing a Slave Server

Before actually running ypinit to create the slave servers, you should run the domainname command on each NIS slave to make sure the domain name is consistent with the master server.

Note – Domain names are case-sensitive.

Make sure that the network is working properly before you configure an NIS slave server. In particular, check to be sure you can use rcp to send files from the master NIS server to NIS slaves.

Setting Up a Slave Server

The following procedure shows how to set up a slave server.
How to Set Up a Slave Server

1. Become superuser or assume an equivalent role.
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2. Edit the /etc/hosts or /etc/inet/ipnodes file on the slave server to add the name and IP addresses of all the other NIS servers.

3. Change directory to /var/yp on the slave server.
   
   **Note** – You must first configure the new slave server as an NIS client so that it can get the NIS maps from the master for the first time. See “Setting Up NIS Clients” on page 95 for details.

4. Initialize the slave server as a client.
   
   ```
   # /usr/sbin/ypinit -c
   ```
   The ypinit command prompts you for a list of NIS servers. Enter the name of the local slave you are working on first, then the master server, followed by the other NIS slave servers in your domain in order from the physically closest to the furthest in network terms.

5. Determine if the NIS client is running, then start the client service as needed.
   
   ```
   # svcs network/nis/client
   ```
   
   **STATE** | **STIME** | **FMRI**
   --- | --- | ---
   online | 20:32:56 | svc:/network/nis/client:default
   
   If svc:/network/nis/client is displayed with an online state, then NIS is running. If the service state is disabled, then NIS is not running.

   a. If the NIS client is running, restart the client service.
      
      ```
      # svcadm restart network/nis/client
      ```

   b. If the NIS client is not running, start the client service.
      
      ```
      # svcadm enable network/nis/client
      ```

6. If NIS is running, stop and restart the service.
   
   ```
   # /usr/lib/netsvc/yp/ypstop
   ```

7. Type the following to restart ypbind.
   
   ```
   # /usr/lib/netsvc/yp/ypstart
   ```
Initialize this machine as a slave.
# /usr/sbin/ypinit -s master

Where master is the machine name of the existing NIS master server.
Repeat the procedures described in this section for each machine you want configured as an NIS slave server.

How to Start NIS on a Slave Server
The following procedure shows how to start NIS on a slave server.

1 Become superuser or assume an equivalent role.
Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2 Stop the client service and start all NIS server processes.
   # svcadm disable network/nis/client
   # svcadm enable network/nis/server

Setting Up NIS Clients
The two methods for configuring a client machine to use NIS as its naming service are explained below.

Note – The Solaris operating system does not support a configuration in which a NIS client and a Native LDAP client co-exist on the same client machine.

- **ypinit.** The recommended method for configuring a client machine to use NIS is to login to the machine as root and run ypinit -c.

  # ypinit -c

  You will be asked to name NIS servers from which the client obtains naming service information. You can list as many master or slave servers as you want. The servers that you list can be located anywhere in the domain. It is a better practice to first list the servers closest (in network terms) to the machine, than those that are on more distant parts of the net.

- **Broadcast method.** An older method of configuring a client machine to use NIS to log in to the machine as root, set the domain name with the domainname command, then run ypbind.

  ypstart will automatically invoke the NIS client in broadcast mode (ypbind -broadcast), if the /var/yp/binding/domenname/ypservers file does not exist.
When you run `ypbind`, it searches the local subnet for an NIS server. If it finds a subnet, `ypbind` binds to it. This search is referred to as "broadcasting." If there is no NIS server on the client's local subnet, `ypbind` fails to bind and the client machine is not able to obtain namespace data from the NIS service.

**Note** – For reasons of security and administrative control it is preferable to specify the servers a client is to bind to in the client's `ypservers` file rather than have the client search for servers through broadcasting. Broadcasting slows down the network, slows the client, and prevents you from balancing server load by listing different servers for different clients.
Administering NIS (Tasks)

This chapter describes how to administer NIS. The following topics are covered.

- “Password Files and Namespace Security” on page 97
- “Administering NIS Users” on page 98
- “Working With NIS Maps” on page 101
- “Updating and Modifying Existing Maps” on page 107
- “Adding a Slave Server” on page 113
- “Using NIS With C2 Security” on page 114
- “Changing a Machine’s NIS Domain” on page 115
- “Using NIS in Conjunction With DNS” on page 116
- “Turning Off NIS Services” on page 117

Note – The NIS service is managed by the Service Management Facility. Administrative actions on this service, such as enabling, disabling, or restarting, can be performed by using the svcadm command. See “NIS and the Service Management Facility” on page 84 for more information about using SMF with NIS. For an overview of SMF, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the svcadm(1M) and svcs(1) man pages for more details.

NIS services can also be started and stopped by using the ypstart and ypstop commands. See the ypstart(1M) and ypstop(1M) man pages for more information.

Password Files and Namespace Security

For security reasons, follow these guidelines.

- It is best to limit access to the NIS maps on the master server.
The files used to build the NIS password maps should not contain an entry for root to protect against unauthorized access. To accomplish this, the password files used to build the password maps should have the root entry removed from them and be located in a directory other than the master server's /etc directory. This directory should be secured against unauthorized access.

For example, the master server password input files could be stored in a directory such as /var/yp, or any directory of your choice, as long as the file itself is not a link to another file and is specified in the Makefile. When you use either the Service Management Facility or the ypstart script to start the NIS service, the correct directory option is set according to the configuration specified in your Makefile.

Note – In addition to the older Solaris 1 version passwd file format, this implementation of NIS accepts the Solaris 2 passwd and shadow file formats as input for building the NIS password maps.

Administering NIS Users

This section includes information about setting user passwords, adding new users to an NIS domain, and assigning users to netgroups.

How to Add a New NIS User to an NIS Domain

1. On the master NIS server, become superuser or assume an equivalent role.

Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2. Create the new user’s login ID with the useradd command.

   # useradd userID

   userID is the login ID of the new user. This command creates entries in the /etc/passwd and /etc/shadow files on the master NIS server.

3. Create the new user’s initial password.

   To create an initial password that the new user can use to log in, run the passwd command.

   # passwd userID

   Where userID is the login ID of the new user. You will be prompted for the password to assign to this user.
This step is necessary because the password entry created by the useradd command is locked, which means that the new user cannot log in. By specifying an initial password, you unlock the entry.

4 If necessary, copy the new entry into the server's passwd map input files.

   The map source files on your master server should be in a directory other than /etc. Copy and paste the new lines from the /etc/passwd and /etc/shadow files into the passwd map input files on the server. See "Password Files and Namespace Security" on page 97 for additional information.

   For example, if you added the new user brown, the line from /etc/passwd that you would copy to your passwd input file would look like the following.

   brown:x:123:10:User brown:/home/brown:/bin/csh:

   The line for brown that you would copy from /etc/shadow would look like:

   brown:W12345GhHic:6445::::::

5 Make sure that the Makefile correctly specifies the directory where the password input file resides.

6 If appropriate, delete the new user's entries from /etc/passwd and /etc/shadow input files.

   For security reasons, do not keep user entries in the NIS master server /etc/passwd and /etc/shadow files. After copying the entries for the new user to the NIS map source files that are stored in some other directory, use the userdel command on the master server to delete the new user.

   For example, to delete the new user brown from the master server's /etc files, you would enter the following.

   # userdel brown

   For more information about userdel, see the userdel man page.

7 Update the NIS passwd maps.

   After you have updated the passwd input file on the master server, update the passwd maps by running make in the directory containing the source file.

   # userdel brown
   # cd /var/yp
   # /usr/ccs/bin/make passwd

8 Tell the new user the initial password you have assigned to his or her login ID.

   After logging in, the new user can run passwd at any time to establish a different password.
Setting User Passwords

Users run `passwd` to change their passwords.

```
% passwd username
```

Before users can change their passwords, you must start the `rpc.yppasswd` daemon on the master server to update the password file.

The `rpc.yppasswd` daemon starts automatically on the master server. Notice that when the `-m` option is given to `rpc.yppasswd`, a `make` is forced in `/var/yp` immediately following a modification of the file. If you want to avoid having this `make` take place each time the `passwd` file is changed, remove the `-m` option from the `rpc.yppasswd` command in the `ypstart` script and control the pushing of the `passwd` maps through the `crontab` file.

**Note** – No arguments should follow the `rpc.yppasswd -m` command. Although you can edit the `ypstart` script file to achieve a different action, it is not recommended that you modify this file other than optionally removing the `-m` option. All commands and daemons invoked by this file with the proper set of command line parameters. If you choose to edit this file, be especially careful when editing the `rpc.yppasswd` command. If you add an explicit call to the `passwd.adjunct` file, the exact `$SPWDIR/security/passwd.adjunct` path must be used; otherwise, incorrect processing results.

NIS Netgroups

NIS netgroups are groups (sets) of users or machines that you define for your administrative purposes. For example, you can create netgroups that do the following.

- Define a set of users who can access a specific machine
- Define a set of NFS client machines to be given some specific file system access
- Define a set of users who are to have administrator privileges on all the machines in a particular NIS domain

Each netgroup is given a netgroup name. Netgroups do not directly set permissions or access rights. Instead, the netgroup names are used by other NIS maps in places where a user name or machine name would normally be used. For example, suppose you created a netgroup of network administrators called `netadmins`. To grant all members of the `netadmins` group access to a given machine, you need only add a `netadmin` entry to that machine’s `/etc/passwd` file. Netgroup names can also be added to the `/etc/netgroup` file and propagated to the NIS netgroup map. See `netgroup(4)` for more detailed information on using netgroups.

On a network using NIS, the `netgroup input file` on the master NIS server is used for generating three maps: `netgroup`, `netgroup.byuser`, and `netgroup.byhost`. The `netgroup` map contains the basic information in the `netgroup` input file. The two other NIS maps contain information in a format that speeds lookups of netgroup information, given the machine or user.
Entries in the netgroup input file are in the format: name ID, where name is the name you give to a netgroup, and ID identifies a machine or user who belongs to the netgroup. You can specify as many IDs (members) to a netgroup as you want, separated by commas. For example, to create a netgroup with three members, the netgroup input file entry would be in the format: name ID, ID, ID. The member IDs in a netgroup input file entry are in the following format.

([-|machine], [-|user], [domain])

Where machine is a machine name, user is a user ID, and domain is the machine or user’s NIS domain. The domain element is optional and should only be used to identify machines or users in some other NIS domain. The machine and user element of each member’s entry are required, but a dash (-) is used to denote a null. There is no necessary relationship between the machine and user elements in an entry.

The following are two sample netgroup input file entries, each of which create a netgroup named admins composed of the users hauri and juanita who is in the remote domain sales and the machines altair and sirius.

admins (altair, hauri), (sirius, juanita, sales)
admins (altair,-), (sirius,-), (-,hauri), (-,juanita, sales)

Various programs use the netgroup NIS maps for permission checking during login, remote mount, remote login, and remote shell creation. These programs include mountd, login, rlogin, and rsh. The login command consults the netgroup maps for user classifications if it encounters netgroup names in the passwd database. The mountd daemon consults the netgroup maps for machine classifications if it encounters netgroup names in the /etc/dfs/dfstab file. rlogin and rsh in fact, any program that uses the ruserok interface consults the netgroup maps for both machine and user classifications if they encounter netgroup names in the /etc/hosts.equiv or .rhosts files.

If you add a new NIS user or machine to your network, be sure to add them to appropriate netgroups in the netgroup input file. Then use the make and yppush commands to create the netgroup maps and push them to all of your NIS servers. See netgroup(4) for detailed information on using netgroups and netgroup input file syntax.

Working With NIS Maps

This section contains the following information:
- “Obtaining Map Information” on page 102
- “Changing a Map’s Master Server” on page 103
- “Modifying Configuration Files” on page 104
- “Modifying and Using the Makefile” on page 105
Obtaining Map Information

Users can obtain information from and about the maps at any time by using the `ypcat`, `ypwhich`, and `ypmatch` commands. In the examples that follow, `mapname` refers both to the official name of a map and to its nickname, if any.

To list all the values in a map, type the following.

```
% ypcat mapname
```

To list both the keys and the values (if any) in a map, type the following.

```
% ypcat -k mapname
```

To list all the map nicknames, type any of the following commands.

```
% ypcat -x
% ypmatch -x
% ypwhich -x
```

To list all the available maps and their master(s), type the following.

```
% ypwhich -m
```

To list the master server for a particular map, type the following.

```
% ypwhich -m mapname
```

To match a key with an entry in a map, type the following.

```
% ypmatch key mapname
```

If the item you are looking for is not a key in a map, type the following.

```
% ypcat mapname | grep item
```

where `item` is the information for which you are searching. To obtain information about other domains, use the `-d domainname` options of these commands.

If the machine requesting information for a domain other than its default does not have a binding for the requested domain, `ypbind` consults the `/var/yp/binding/domainname/ypservers` file for a list of servers for that domain. If this file does not exist it issues an RPC broadcast for a server. In this case, there must be a server for the requested domain on the same subnet as the requesting machine.
Changing a Map's Master Server

To change the master server for a selected map, you first have to build the map on the new NIS master. Since the old master server name occurs as a key-value pair in the existing map (this pair is inserted automatically by makedbm), copying the map to the new master or transferring a copy to the new master with ypxfr is insufficient. You have to reassociate the key with the new master server name. If the map has an ASCII source file, you should copy this file to the new master.

▼ How to Change a Map's Master Server

1. **On the new master, become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, "Using Role-Based Access Control (Tasks)," in System Administration Guide: Security Services.

   ```
   newmaster# cd /var/yp
   ```

2. **Change directories.**

   ```
   newmaster# cd /var/yp
   ```

3. **The Makefile must have an entry for the new map before you specify the map to make. If this is not the case, edit the Makefile now, using a map called sites.bynam.**

4. **To update or remake the map, type the following.**

   ```
   newmaster# make sites.bynam
   ```

5. **If the old master remains an NIS server, remote log in (rlogin) to the old master and edit Makefile. Make sure you comment out the section of the Makefile that made sites.bynam so that it is no longer made there.**

6. **If sites.bynam only exists as an ndbm file, remake it on the new master by disassembling a copy from any NIS server, then running the disassembled version through makedbm.**

   ```
   newmaster# cd /var/yp
   newmaster# ypcat sites.bynam | makedbm -domain-/sites.bynam
   ```

   After making the map on the new master, you must send a copy of the new map to the other slave servers. Do not use yppush, because the other slaves will try to get new copies from the old master, rather than the new one. A typical method for circumventing this is to transfer a copy of the map from the new master back to the old master. To do this, become superuser, or assume an equivalent role, on the old master server and type the following.

   ```
   oldmaster# /usr/lib/netsvc/yp/ypxfr -h newmaster sites.bynam
   ```
Now it is safe to run yppush. Any remaining slave servers still believe that the old master is the current master and will attempt to get the current version of the map from the old master. When clients do so, they will get the new map, which names the new master as the current master.

If this method fails, you can log in as root on each NIS server and execute the `ypxfr` command shown above.

## Modifying Configuration Files

NIS intelligently parses the setup files. Although this makes NIS administration easier, it does make the behavior of NIS more sensitive to changes in the setup and configuration files.

Use the procedures in this section when modifying any of the following.

- `/var/yp/Makefile` to add or delete supported maps
- Adding or deleting `/etc/resolv.conf` to allow or deny DNS forwarding
- Adding or deleting `$PWDIR/security/passwd.adjunct` to allow or deny C2 security ($PWDIR is defined in `/var/yp/Makefile`

### How to Modify Configuration Files

You do not have to stop and start NIS when changing NIS maps or the map source files.

Keep the following in mind.

- Deleting a map or source file from an NIS master server does not automatically result in corresponding deletions from slave servers. You must delete maps and source files from slave servers by hand.
- New maps do not automatically get pushed to existing slave servers. You must run `ypxfr` from the slaves.

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, "Using Role-Based Access Control (Tasks)," in System Administration Guide: Security Services.

2. **Stop the NIS server.**
   ```sh
   # svcadm disable network/nis/server
   ```

3. **Make the necessary changes to your files.**

4. **Start the NIS server.**
   ```sh
   # svcadm enable network/nis/server
   ```
Modifying and Using the Makefile

You can modify the Makefile provided by default in /var/yp to suit your needs. You can add or delete maps, and you can change the names of some of the directories.

**Tip** – Keep an unmodified copy of the original Makefile for future reference.

Working With the Makefile

To add a new NIS map, you must get copies of the ndbm files for the map into the /var/yp/domainname directory on each of the NIS servers in the domain. This is normally done for you by the Makefile. After deciding which NIS server is the master of the map, modify the Makefile on the master server so that you can conveniently rebuild the map. Different servers can be masters of different maps, but in most cases this leads to administrative confusion. Try to set only one server as the master of all maps.

Typically a human-readable text file is filtered through awk, sed, or grep to make it suitable for input to makendb. Refer to the default Makefile for examples. See the make(1S) for general information about the make command.

Use the mechanisms already in place in the Makefile when deciding how to create dependencies that make will recognize. Be aware that make is very sensitive to the presence or absence of tabs at the beginning of lines within the dependency rules. A missing tab can invalidate an entry that is otherwise well formed.

Adding an entry to the Makefile involves the following.

- Adding the name of the database to the all rule
- Writing the time rule
- Adding the rule for the database

For example, in order for the Makefile to work on automounter input files, you would have to add the auto_direct.time and auto_home.time maps to the NIS database.

To add these maps to the NIS database you need to modify the Makefile.

Changing Makefile Macros/Variables

You can change the settings of the variables defined at the top of the Makefile by changing the value to the right of the equal sign (=). For instance, if you do not want to use the files located in /etc as input for the maps, but you would rather use files located in another directory, such as /var/etc/domainname, you should change DIR from DIR=/etc to DIR=/var/etc/domainname. You should also change PWDIR from PWDIR=/etc to PWDIR=/var/etc/domainname.

The variables are the following.
- **DIR**: The directory containing all of the NIS input files except passwd and shadow. The default value is /etc. Since it is not good practice to use the files in the master server's /etc directory as NIS input files, you should change this value.

- **PWDIR**: The directory containing the passwd and shadow NIS input files. Since it is not good practice to use the files in the master server's /etc directory as NIS input files, you should change this value.

- **DOM**: The NIS domain name. The default value of DOM is set using the domainname command. However, most NIS commands use the current machine's domain which is set in the machine's /etc/defaultdomain file.

### Modifying Makefile Entries

The following procedure describes how to add and delete databases from the Makefile.

#### How to Modify the Makefile to Use Specific Databases

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in *System Administration Guide: Security Services*.

2. **Modify the line that starts with the word all** by adding the name(s) of the database you want to add:

   ```
   all: passwd group hosts ethers networks rpc services protocols 
   netgroup bootparams aliases netid netmasks 
   audit user auth attr exec attr prof attr 
   auto_direct auto_home auto_direct.time auto_home.time
   ```

   The order of the entries is not relevant, but the blank space at the beginning of the continuation lines must be a Tab, not spaces.

3. **Add the following lines at the end of the Makefile**:

   ```
   auto_direct: auto_direct.time
   auto_home: auto_home.time
   ```

4. **Add an entry for auto_direct.time in the middle of the file**.

   ```
   auto_direct.time: $(DIR)/auto_direct
   ```

   Example (partial):

   ```
   @while read L; do echo $$L; done < $(DIR)/auto_direct
   $(CHKPIPE)) | \ (sed -e "/^#/d" -e "s/#.*$$//" -e "^ *$$/d"
   $(CHKPIPE)) | \ $(MAKEDBM) - $(YPDBDIR)/$(DOM)/auto_direct;
   @touch auto_direct.time;
   @echo "updated auto_direct";
   @if [ ! $(NOPUSH) ]; then $(YPPUSH) auto_direct; fi
   ```
Pipes allow the combining of processes for pipelining. If the operation to the left of the pipe (!) are successfully completed before piping the results to next commands, the process is terminated with a NIS make terminated message. If the operations to the left of the pipe do not successfully complete, the process is terminated with a NIS make terminated message.

The while loop at the beginning is designed to eliminate any backslash-extended lines in the input file. The sed script eliminates comment and empty lines. The same procedure should be followed for all other automounter maps, such as auto_home, or any other nondefault maps.

5 Run make.

# make mapname

Where mapname is the name of the map you want to make.

How to Modify the Makefile to Delete Databases

If you do not want the Makefile to produce maps for a specific database, edit the Makefile as follows.

1 Delete the name of the database from the all rule.

2 Delete or comment out the database rule for the database you want to delete.
   For example, to delete the hosts database, the hosts.time entry should be removed.

3 Remove the time rule.
   For example, to delete the hosts database, the hosts: hosts.time entry should be removed.

4 Remove the map from the master and slave servers.

Updating and Modifying Existing Maps

After you have installed NIS, you might discover that some maps require frequent updating while others never need to change. For example, the passwd.byname map can change frequently on a large company’s network, while the auto_master map changes little, if at all.

As mentioned in “Default NIS Maps” on page 76, the default location of the default NIS maps is on the master server in /var/yp/domainname, where domainname is the name of the NIS.
domain. When you need to update a map, you can use one of two updating procedures, depending on whether or not it is a default map.

- A default map is a map in the default set created by `ypinit` from the network databases.
- Nondefault maps can be any of the following.
  - Maps included with an application purchased from a vendor
  - Maps created specifically for your site
  - Maps created from a nontext file

The following sections explain how to use various updating tools. In practice, you might decide to only use them if you add nondefault maps or change the set of NIS servers after the system is already up and running.

▼ How to Update Maps Supplied With the Default Set

Use the following procedure for updating maps supplied with the default set.

1. **Become a superuser on the master server.**
   Always modify NIS maps only on the master server.

2. **Edit the source file for the map you want to change, whether that file resides in `/etc` or in some other directory of your choice.**

3. **Type the following.**
   ```
   # cd /var/yp
   # make mapname
   ```
   The `make` command then updates your map according to the changes you made in its corresponding file. It also propagates the changes among the other servers.

Maintaining Updated Maps

The following sections describe additional procedures after you have completed updating maps that are supplied with the default set.

Propagating an NIS Map

After a map is changed, the `Makefile` uses `yppush` to propagate a new map to the slave servers (unless `NOPUSH` is set in the `Makefile`). It does this by informing the `ypserv` daemon and sending a map transfer request. The `ypserv` daemon on the slave then starts a `ypxfr` process, which in turn contacts the `ypxfrd` daemon on the master server. Some basic checks are made (for example did the map really change?) and then the map is transferred. `ypxfr` on the slave then sends a response to the `yppush` process indicating whether the transfer succeeded.
The above procedure will not work for newly created maps that do not yet exist on the slave servers. New maps must be sent to the slave servers by running ypxfr on the slaves.

Occasionally, maps fail to propagate and you must to use ypxfr manually to send new map information. You can choose to use ypxfr in two different ways: periodically through the root crontab file, or interactively on the command line. These approaches are discussed in the following sections.

**Using cron for Map Transfers**

Maps have different rates of change. For instance, some might not change for months at a time, such as protocols.byname among the default maps and auto_master among the nondefault maps; but passwd.byname can change several times a day. Scheduling map transfer using the crontab command allows you to set specific propagation times for individual maps.

To periodically run ypxfr at a rate appropriate for the map, the root crontab file on each slave server should contain the appropriate ypxfr entries. ypxfr contacts the master server and transfers the map only if the copy on the master server is more recent than the local copy.

If your master server runs rpc.yppasswd with the default -m option, then each time someone changes their yp password, the passwd daemon runs make, which rebuilds the passwd maps.

**Using Shell Scripts With cron and ypxfr**

As an alternative to creating separate crontab entries for each map, you might prefer to have the root crontab command run a shell script that periodically updates all maps. Sample map-updating shell scripts are in the /usr/lib/netsvc/yp directory. The script names are ypxfr_1perday, ypxfr_1perhour, and ypxfr_2perday. You can modify or replace these shell scripts to fit your site requirements. Example 6–1 shows the default ypxfr_1perday shell script.

```
EXAMPLE 6–1  ypxfr_1perday Shell Script

#!/bin/sh
#
# ypxfr_1perday.sh - Do daily yp map check/updates
PATH=/bin:/usr/bin:/usr/lib/netsvc/yp:$PATH
export PATH
# set -xv
ypxfr group.byname
ypxfr group.bygid
ypxfr protocols.byname
ypxfr protocols.bynumber
```

Chapter 6 • Administering NIS (Tasks) 109
### EXAMPLE 6-1 ypxfr 1perday Shell Script (Continued)

```bash
ypxfr networksbyname
ypxfr networksbyaddr
ypxfr servicesbyname
ypxfr ypservers
```

This shell script updates the maps once per day, if the root crontab is executed daily. You can also have scripts that update maps once a week, once a month, once every hour, and so forth, but be aware of the performance degradation implied in frequently propagating the maps.

Run the same shell scripts as root on each slave server configured for the NIS domain. Alter the exact time of execution from one server to another to avoid bogging down the master.

If you want to transfer the map from a particular slave server, use the `-h machine` option of `ypxfr` within the shell script. Here is the syntax of the commands you put in the script.

```bash
# /usr/lib/netsvc/yp/ypxfr -h machine [ -c ] mapname
```

Where `machine` is the name of the server with the maps you want to transfer, and `mapname` is the name of the requested map. If you use the `-h` option without specifying a machine, `ypxfr` tries to get the map from the master server. If `ypserv` is not running locally at the time `ypxfr` is executed, you must use the `-c` flag so that `ypxfr` does not send a clear current map request to the local `ypserver`.

You can use the `-s domain` option to transfer maps from another domain to your local domain. These maps should be the same across domains. For example, two domains might share the same `servicesbyname` and `servicesbyaddr` maps. Alternatively, you can use `rcp`, or `rdist` for more control, to transfer files across domains.

### Directly Invoking `ypxfr`

The second method of invoking `ypxfr` is to run it as a command. Typically, you do this only in exceptional situations – for example, when setting up a temporary NIS server to create a test environment or when trying to quickly get an NIS server that has been out of service consistent with the other servers.

### Logging `ypxfr` Activity

The transfer attempts and results of `ypxfr` can be captured in a log file. If a file called `/var/yp/ypxfr.log` exists, results are appended to it. No attempt to limit the size of the log file is made. To prevent it from growing indefinitely, empty it from time to time by typing the following.

```bash
# cd /var/yp
# cp ypxfr.log ypxfr.log.old
# cat /dev/null > /var/yp/ypxfr.log
```
You can have `crontab` execute these commands once a week. To turn off logging, remove the log file.

**Modifying Default Maps**

To update a nondefault map, you must do the following.

1. Create or edit its corresponding text file.

2. Build (or rebuild) the new or updated map. There are two ways to build a map.
   - Use the Makefile. Using the Makefile is the preferred method of building a non-default map. If the map has an entry in the Makefile, run `make name` where `name` is the name of the map you want to build. If the map does not have a Makefile entry, try to create one following the instructions in "Modifying and Using the Makefile" on page 105.
   - Use the `/usr/sbin/makedbm` program. `makedbm(1M)` fully describes this command.

**Using `makedbm` to Modify a Non-Default Map**

There are two different methods for using `makedbm` to modify maps if you do not have an input file:

- Redirect the `makedbm -u` output to a temporary file, modify the file, then use the modified file as input to `makedbm`.
- Have the output of `makedbm -u` operated on within a pipeline that feeds into `makedbm`. This is appropriate if you can update the disassembled map with either `awk`, `sed`, or `cat append`.

**Creating New Maps from Text Files**

Assume that a text file `/var/yp/mymap.asc` was created with an editor or a shell script on the master. You want to create an NIS map from this file and locate it in the `homedomain` subdirectory. To do this, type the following on the master server.

```
# cd /var/yp
# makedbm mymap.asc homedomain/mymap
```

The `mymap` map now exists on the master server in the directory `homedomain`. To distribute the new map to slave servers run `ypxfr`.

**Adding Entries to a File-Based Map**

Adding entries to `mymap` is simple. First, you must modify the text file `/var/yp/mymap.asc`. If you modify the actual `dbm` files without modifying the corresponding text file, the modifications are lost. Then run `makedbm` as shown above.
Creating Maps From Standard Input

When no original text file exists, create the NIS map from the keyboard by typing input to `makedbm`, as shown below (end with Control-D).

```
ypmaster# cd /var/yp
ypmaster# makedbm -homedomain-/mymap key1 value1 key2 value2 key3 value3
```

Modifying Maps Made From Standard Input

If you later need to modify the map, you can use `makedbm` to disassemble the map and create a temporary text intermediate file. To disassemble the map and create a temporary file, type the following.

```
% cd /var/yp
% makedbm -u homedomain/mymap > mymap.temp
```

The resulting temporary file `mymap.temp` has one entry per line. You can edit this file as needed, using any text editor.

To update the map, give the name of the modified temporary file to `makedbm` by typing the following.

```
% makedbm mymap.temp homedomain/mymap
% rm mymap.temp
```

Then propagate the map to the slave servers, by becoming root and typing the following.

```
# yppush mymap
```

The preceding paragraphs explained how to use `makedbm` to create maps; however, almost everything you actually have to do can be done by `ypinit` and `Makefile` unless you add nondefault maps to the database or change the set of NIS servers after the system is already up and running.

Whether you use the `Makefile` in `/var/yp` or some other procedure the goal is the same. A new pair of well-formed dbm files must end up in the maps directory on the master server.
Adding a Slave Server

After NIS is running, you might need to create an NIS slave server that you did not include in the initial list given to ypinit.

To add an NIS slave server:

▼ How to Add a Slave Server

1. **On the master server, become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, "Using Role-Based Access Control (Tasks)," in System Administration Guide: Security Services.

2. **Change to the NIS domain directory.**
   
   ```
   # cd /var/yp/domainname
   ```

3. **Disassemble the ypservers file.**
   
   ```
   # makedbm -u ypservers >/tmp/temp_file
   ```
   The `makedbm` command converts `ypservers` from ndbm format to a temporary ASCII file `/tmp/temp_file`.

4. **Edit the `/tmp/temp_file` file using a text editor. Add the name of the new slave server to the list of servers. Then save and close the file.**

5. **Run the makedbm command with `temp_file` as the input file and `ypservers` as the output file.**
   
   ```
   # makedbm /tmp/temp_file ypservers
   ```
   The `makedbm` command then converts `ypservers` back into ndbm format.

6. **Verify that the ypservers map is correct (since there is no ASCII file for ypservers) by typing the following on the slave.**
   
   ```
   slave3# makedbm -u ypservers
   ```
   The `makedbm` command displays each entry in `ypservers` on your screen.

**Note** – If a machine name is not in `ypservers`, it will not receive updates to the map files because `yppush` consults this map for the list of slave servers.
On the new NIS slave, become superuser or assume an equivalent role. Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

Set up the new slave server’s NIS domain directory. Copy the NIS map set from the master server, then start the NIS client. When running the ypinit command, follow the prompts and list the NIS servers in order of preference.

```
slave3# cd /var/yp
slave3# ypinit -c
slave3# svcadm enable network/nis/client
```

Initialize this machine as a slave.

```
slave3# /usr/sbin/ypinit -s ypmaster
```

where ypmaster is the machine name of the existing NIS master server.

Stop the machine running as an NIS client.

```
# svcadm disable network/nis/client
```

Start NIS slave service.

```
# svcadm enable network/nis/server
```

Using NIS With C2 Security

If the $PWDIR/security/passwd.adjunct file is present, C2 security is started automatically. ($PWDIR is defined in /var/yp/Makefile.) The C2 security mode uses the passwd.adjunct file to create the passwd.adjunct NIS map. In this implementation, NIS allows you to use both the passwd.adjunct file and shadow file to manage security. The passwd.adjunct file is processed only when you type the following.

```
# make passwd.adjunct
```

The make passwd command processes the passwd map only, not the passwd.adjunct map when you run make manually in the C2 security mode.
Binding to a Specific NIS Server

Use the following steps to bind to an NIS server that you specify. For more information, see the `ypinit(1M)`, `ypstart(1M)`, and `svcadm(1M)` man pages.

1. Add the hostname of the NIS server and its IP address to the `/etc/hosts` file.
2. Run the `domainname` command to populate the `/etc/defaultdomain` file.

   ```
   # /usr/bin/domainname name-of-NIS-domain
   ```

3. Prompt for the NIS server host name.

   ```
   # /usr/sbin/ypinit -c
   Server name: Type the NIS server hostname
   ```

4. Restart the NIS services by performing one of the following steps.
   - For the services to persist across reboots, run the `svcadm` command:
     ```
     # svcadm enable -r svc:/network/nis/client
     ```
   - For the services to persist until reboot only, run the `ypstop` and `ypstart` commands:
     ```
     # /usr/lib/netsvc/yp/ypstop
     # /usr/lib/netsvc/yp/ypstart
     ```

Changing a Machine's NIS Domain

To change the NIS domain name of a machine, do the following.

▼ How to Change a Machine's NIS Domain Name

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in *System Administration Guide: Security Services.*

2. **Edit the machine's `/etc/defaultdomain` file, exchanging its present contents with the new domain name for the machine.**
   For example, if the current domain name is `sales.doc.com`, you might change it to `research.doc.com`.

3. **Run `domainname 'cat /etc/defaultdomain'**

4. **Set the machine up as an NIS client, slave, or master server.**
Using NIS in Conjunction With DNS

Typically, NIS clients are configured with the `nsswitch.conf` file to use only NIS for machine name and address lookups. If this type of lookup fails, an NIS server can forward these lookups to DNS.

▼ How to Configure Machine Name and Address Lookup Through NIS and DNS

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2. **The two map files, hosts.byname and hosts.byaddr must include the YP_INTERDOMAIN key. To test this key, edit the Makefile and modify the following lines.**
   ```
   #B=-b
   B=
   to
   B=-b
   #B=
   ```

   `makedbm` will now start with the `-b` flag when it makes the maps, and the YP_INTERDOMAIN key will be inserted into the `ndbm` files.

3. **Run the `make` command to rebuild maps.**
   ```
   # /usr/ccs/bin/make hosts
   ```

4. **Check that all the NIS server’s `/etc/resolv.conf` files point to valid nameservers.**

   **Note** – If you have NIS servers that are not running Solaris, Release 2, make sure YP_INTERDOMAIN exists in the hosts maps.

5. **To enable DNS forwarding, restart each server.**
   ```
   # svcadm restart network/nis/server:<instance>
   ```

   In this implementation of NIS, `ypserv` automatically starts with the `-d` option to forward requests to DNS.
Dealing with Mixed NIS Domains

If the master and slave servers are not both running Solaris 2, refer to the following table for how to avoid potential problems. The notation “4.0.3+” refers to that and later releases of the Solaris OS. makedm -b is a reference to the “B” variable in the Makefile.

<table>
<thead>
<tr>
<th>Slave</th>
<th>Master</th>
<th>Slave</th>
<th>Master</th>
<th>Slave</th>
</tr>
</thead>
<tbody>
<tr>
<td>4.0.3+</td>
<td>Master: makedbm -b</td>
<td>Slave: ypxfr</td>
<td>Master: makedbm -b</td>
<td>Slave: ypxfr</td>
</tr>
<tr>
<td>Solaris NIS</td>
<td>Master: makedbm -b</td>
<td>Slave: ypxfr</td>
<td>Master: ypserv -d</td>
<td>Slave: ypxfr -b</td>
</tr>
</tbody>
</table>

Turning Off NIS Services

If ypserv on the NIS master is disabled, you can no longer update any of the NIS maps.

- To disable NIS on a client, type the following.

  # svcadm disable network/nis/client

- To disable NIS on a specific slave or master server, type the following on the server.

  # svcadm disable network/nis/server
This chapter explains how to resolve problems encountered on networks running NIS. It covers problems seen on an NIS client and those seen on an NIS server.

Before trying to debug an NIS server or client, review Chapter 4, “Network Information Service (NIS) (Overview),” which explains the NIS environment. Then look for the subheading in this section that best describes your problem.

**Note** – The NIS service is managed by the Service Management Facility. Administrative actions on this service, such as enabling, disabling, or restarting, can be performed by using the `svcadm` command. See “NIS and the Service Management Facility” on page 84 for more information about using SMF with NIS. For an overview of SMF, refer to Chapter 17, “Managing Services (Overview),” in *System Administration Guide: Basic Administration*. Also refer to the `svcadm(1M)` and `svcs(1)` man pages for more details.

NIS services can also be started and stopped by using the `ypstart` and `ypstop` commands. See the `ypstart(1M)` and `ypstop(1M)` man pages for more information.

## NIS Binding Problems

### Symptoms

Common symptoms of NIS binding problems include the following.

- Messages saying that `ypbind` can’t find or communicate with a server
- Messages saying that server not responding
- Messages saying that NIS is unavailable
- Commands on a client limp along in background mode or function much slower than normal
- Commands on a client hang. Sometimes commands hang even though the system as a whole seems fine and you can run new commands
- Commands on a client crash with obscure messages, or no message at all

**NIS Problems Affecting One Client**

If only one or two clients are experiencing symptoms that indicate NIS binding difficulty, the problems probably are on those clients. If many NIS clients are failing to bind properly, the problem probably exists on one or more of the NIS servers. See “NIS Problems Affecting Many Clients” on page 123.

**ypbind Not Running on Client**

One client has problems, but other clients on the same subnet are operating normally. On the problem client, run `ls -l` on a directory, such as `/usr`, that contains files owned by many users, including some not in the client `/etc/passwd` file. If the resulting display lists file owners who are not in the local `/etc/passwd` as numbers, rather than names, this indicates that NIS service is not working on the client.

These symptoms usually mean that the client ypbind process is not running. Verify whether the NIS client service is running.

```
client# svcs network/nis/client
STATE STIME FMRI
disabled Sep_01 svc:/network/nis/client:default
```

If the client is disabled, log in as superuser, or assume an equivalent role, and start the NIS client service.

```
client# svcadm enable network/nis/client
```

**Missing or Incorrect Domain Name**

One client has problems, the other clients are operating normally, but ypbind is running on the problem client. The client might have an incorrectly set domain.

On the client, run the `domainname` command to see which domain name is set.

```
client7# domainname neverland.com
```

Compare the output with the actual domain name in `/var/yp` on the NIS master server. The actual NIS domain is shown as a subdirectory in the `/var/yp` directory.

```
Client7# ls /var/yp...
-rwxr-xr-x 1 root Makefile
```
If the domain name returned by running `domainname` on a machine is not the same as the server domain name listed as a directory in `/var/yp`, the domain name specified in the machine's `/etc/defaultdomain` file is incorrect. Log in as superuser or assume an equivalent role, and correct the client's domain name in the machine's `/etc/defaultdomain` file. This assures that the domain name is correct every time the machine boots. Now reboot the machine.

---

**Note** – The domain name is case-sensitive.

---

**Client Not Bound to Server**

If your domain name is set correctly, `ypbind` is running, and commands still hang, then make sure that the client is bound to a server by running the `ypwhich` command. If you have just started `ypbind`, then run `ypwhich` several times (typically, the first one reports that the domain is not bound and the second succeeds normally).

---

**No Server Available**

If your domain name is set correctly, `ypbind` is running, and you get messages indicating that the client cannot communicate with a server, this might indicate a number of different problems:

- Does the client have a `/var/yp/binding/domainname/ypservers` file containing a list of servers to bind to? If not, run `ypinit -c` and specify in order of preference the servers that this client should bind to.
- If the client does have a `/var/yp/binding/domainname/ypservers` file, are there enough servers listed in it if one or two become unavailable? If not, add additional servers to the list by running `ypinit -c`.
- Do the servers listed in a clients `ypservers` file have entries in the `/etc/hosts` file? If not, add the servers to the NIS maps hosts input file and rebuild your maps by running `ypinit -c` or `ypinit -s` as described “Working With NIS Maps” on page 101.
- Is the `/etc/nsswitch.conf` file set up to consult the machine's local `hosts` file in addition to NIS? See Chapter 2, “The Name Service Switch (Overview),” for more information on the switch.
- Is the `/etc/nsswitch.conf` file set up to consult files first for `services` and `rpc`? See Chapter 2, “The Name Service Switch (Overview),” for more information on the switch.

---

**ypwhich Displays Are Inconsistent**

When you use `ypwhich` several times on the same client, the resulting display varies because the NIS server changes. This is normal. The binding of the NIS client to the NIS server changes over time when the network or the NIS servers are busy. Whenever possible, the network becomes
stable at a point where all clients get acceptable response time from the NIS servers. As long as your client machine gets NIS service, it does not matter where the service comes from. For example, an NIS server machine can get its own NIS services from another NIS server on the network.

**When Server Binding is Not Possible**

In extreme cases where local server binding is not possible, use of the `ypset` command can temporarily allow binding to another server, if available, on another network or subnet. However, in order to use the `-ypset` option, `ypbind` must be started with either the `-ypset` or `-ypsetme` options. For more information, see the `ypbind(1M)` man page.

```
# /usr/lib/netsvc/yp/ypbind -ypset
```

For another method, see “Binding to a Specific NIS Server” on page 115.

---

**Note** – For security reasons, the use of the `-ypset` and `-ypsetme` options should be limited to debugging purposes under controlled circumstances. Use of the `-ypset` and `-ypsetme` options can result in serious security breaches because while the daemons are running, anyone can alter server bindings causing trouble for others and permitting unauthorized access to sensitive data. If you must start `ypbind` with these options, once you have fixed the problem you should kill `ypbind` and restart it again without those options.

To restart `ypbind`, use the service management facility (SMF):

```
# svcadm enable -r svc:/network/nis/client:default
```

**ypbind Crashes**

If `ypbind` crashes almost immediately each time it is started, look for a problem in some other part of the system. Check for the presence of the `rpcbind` daemon by typing the following.

```
% ps -e | grep rpcbind
```

If `rpcbind` is not present or does not stay up or behaves strangely, consult your RPC documentation.

You might be able to communicate with `rpcbind` on the problematic client from a machine operating normally. From the functioning machine, type the following.

```
% rpcinfo client
```

If `rpcbind` on the problematic machine is fine, `rpcinfo` produces the following output.

```
program version netid address service owner
...
100007 2 udp 0.0.0.0.2.219 ypbind superuser
```
Your machine will have different addresses. If the addresses are not displayed, ypbind has been unable to register its services. Reboot the machine and run rpcinfo again. If the ypbind processes are there and they change each time you try to restart the NIS service, reboot the system, even if the rpcbind daemon is running.

**NIS Problems Affecting Many Clients**

If only one or two clients are experiencing symptoms that indicate NIS binding difficulty, the problems probably are on those clients. See “NIS Problems Affecting One Client” on page 120. If many NIS clients are failing to bind properly, the problem probably exists on one or more of the NIS servers.

**rpc.yppasswdd Considers a Non-Restricted Shell That Begins With r to be Restricted**

1. Create /etc/default/yppasswdd that contains a special string: "check_restricted_shell_name=1".
2. If the "check_restricted_shell_name=1" string is commented out, the 'r' check will no occur.

**Network or Servers Are Overloaded**

NIS can hang if the network or NIS servers are so overloaded that ypserv cannot get a response back to the client ypbind process within the time-out period.

Under these circumstances, every client on the network experiences the same or similar problems. In most cases, the condition is temporary. The messages usually go away when the NIS server reboots and restarts ypserv, or when the load on the NIS servers or network itself decreases.

**Server Malfunction**

Make sure the servers are up and running. If you are not physically near the servers, use the ping command.
NIS Daemons Not Running

If the servers are up and running, try to find a client machine behaving normally, and run the `ypwhich` command. If `ypwhich` does not respond, kill it. Then log in as `root` on the NIS server and check if the NIS process is running by entering the following.

```
# ps -e | grep yp
```

**Note** – Do not use the `-f` option with `ps` because this option attempts to translate user IDs to names, which causes more naming service lookups that might not succeed.

If neither the NIS server (`ypserv`) nor the NIS client (`ypbind`) daemons are running, restart them by typing one of the following.

```
# svcadm restart network/nis/server
or
# /usr/lib/netsvc/yp/ypstop
# /usr/lib/netsvc/yp/ypstart
```

If both the `ypserv` and `ypbind` processes are running on the NIS server, then run `ypwhich`. If `ypwhich` does not respond, `ypserv` has probably hung and should be restarted. While logged in as `root` on the server, restart the NIS service by typing one of the following.

```
# svcadm restart network/nis/server
or
# /usr/lib/netsvc/yp/ypstop
# /usr/lib/netsvc/yp/ypstart
```

Servers Have Different Versions of an NIS Map

Because NIS propagates maps among servers, occasionally you might find different versions of the same map on various NIS servers on the network. This version discrepancy is normal and acceptable if the differences do not last for more than a short time.

The most common cause of map discrepancy is that something is preventing normal map propagation. For example, an NIS server or router between NIS servers is down. When all NIS servers and the routers between them are running, `ypxf`r should succeed.

If the servers and routers are functioning properly, check the following:

- Log `ypxf`r output (see “Logging `ypxf`r Output” on page 125).
- Check the control files (see “Check the `crontab` File and `ypxf`r Shell Script” on page 125).
- Check the `ypservers` map on the master. See “Check the `ypservers` Map” on page 125.
**Logging ypfr Output**

If a particular slave server has problems updating maps, log in to that server and run ypfr interactively. If ypfr fails, it tells you why it failed, and you can fix the problem. If ypfr succeeds, but you suspect it has occasionally failed, create a log file to enable logging of messages. To create a log file, enter the following on the slave.

```bash
ypslave# cd /var/yp
ypslave# touch ypfr.log
```

This creates a ypfr.log file that saves all output from ypfr.

The output resembles the output ypfr displays when run interactively, but each line in the log file is time stamped. (You might see unusual ordering in the time-stamps. That is okay – the time-stamp tells you when ypfr started to run. If copies of ypfr ran simultaneously but their work took differing amounts of time, they might actually write their summary status line to the log files in an order different from that which they were invoked.) Any pattern of intermittent failure shows up in the log.

---

**Note** – When you have fixed the problem, turn off logging by removing the log file. If you forget to remove it, it continues to grow without limit.

---

**Check the crontab File and ypfr Shell Script**

Inspect the root crontab file, and check the ypfr shell script it invokes. Typographical errors in these files can cause propagation problems. Failures to refer to a shell script within the /var/spool/cron/crontabs/root file, or failures to refer to a map within any shell script can also cause errors.

**Check the ypservers Map**

Also, make sure that the NIS slave server is listed in the ypservers map on the master server for the domain. If it is not, the slave server still operates perfectly as a server, but yppush does not propagate map changes to the slave server.

**Work Around**

If the NIS slave server problem is not obvious, you can work around it while you debug using rcp or ftp to copy a recent version of the inconsistent map from any healthy NIS server. The following shows how to transfer the problem map.

```bash
ypslave# rcp ypmaster:/var/yp/mydomain/map.* /var/yp/mydomain
```

The * character has been escaped in the command line, so that it will be expanded on ypmaster, instead of locally on ypslave.
ypserv **Crashes**

When the `ypserv` process crashes almost immediately, and does not stay up even with repeated activations, the debug process is virtually identical to that described in "**ypbind Crashes**" on page 122. Check for the existence of the `rpcbind` daemon as follows.

```bash
ypserver% ps -e | grep rpcbind
```

Reboot the server if you do not find the daemon. Otherwise, if the daemon is running, type the following and look for similar output.

```bash
% rpcinfo -p ypserv
```

```
% program vers proto port service
100000 4 tcp 111 portmapper
100000 3 tcp 111 portmapper
100068 2 udp 32813 cmsd
...
100007 1 tcp 34900 ypbind
100004 2 udp 731 ypserv
100004 1 udp 731 ypserv
100004 1 tcp 732 ypserv
100004 2 tcp 32772 ypserv
```

Your machine might have different port numbers. The four entries representing the `ypserv` process are the following.

```bash
100004 2 udp 731 ypserv
100004 1 udp 731 ypserv
100004 1 tcp 732 ypserv
100004 2 tcp 32772 ypserv
```

If there are no entries, and `ypserv` is unable to register its services with `rpcbind`, reboot the machine. If there are entries, de-register the service from `rpcbind` before restarting `ypserv`. To de-register the service from `rpcbind`, on the server type the following.

```bash
# rpcinfo -d number 1
# rpcinfo -d number 2
```

where `number` is the ID number reported by `rpcinfo` (100004, in the example above).
LDAP Naming Services Setup and Administration

This part provides an overview of the LDAP naming services. Additionally, it covers the setup, configuration, administration, and troubleshooting of LDAP naming services in the Solaris OS, with a focus on the use of Sun Java™ System Directory Server (formerly Sun ONE Directory Server).
Introduction to LDAP Naming Services
(Overview/Reference)

The LDAP chapters describe how to set up a Solaris LDAP naming services client to work with Sun Java System Directory Server (formerly Sun ONE Directory Server). However, while using the Sun Java System Directory Server is recommended, it is not required. A brief description of generic directory server requirements appears in Chapter 14, "LDAP General Reference (Reference)."

**Note** – A directory server is not necessarily an LDAP server. However, in the context of these chapters, the term “directory server” is synonymous with “LDAP server.”

**Audience Assumptions**

The LDAP naming services chapters are written for system administrators who already have a working knowledge of LDAP. Following is a partial list of concepts with which you must be very familiar. Otherwise, you might have difficulty using this guide to deploy LDAP naming services in the Solaris system.

- LDAP Information Model (entries, object classes, attributes, types, values)
- LDAP Naming Model (Directory Information Tree (DIT) structure)
- LDAP Functional Model (search parameters: base object (DN), scope, size limit, time limit, filters (browsing indexes for the Sun Java System Directory Server), attribute list)
- LDAP Security Model (authentication methods, access control models)
- Overall planning and design of an LDAP directory service, including how to plan the data and how to design the DIT, topology, replication, and security
Suggested Background Reading

To learn more about any of the preceding concepts or to study LDAP and the deployment of directory services in general, refer to the following sources:

- *Understanding and Deploying LDAP Directory Services* by Timothy A. Howes, Ph.D. and Mark C. Smith
  
  In addition to providing a thorough treatment of LDAP directory services, this book includes useful case studies on deploying LDAP. Examples of deployments include a large university, a large multinational enterprise, and an enterprise with an extranet.

- Sun Java System Directory Server *Deployment Guide*, which is included with the Sun Java Enterprise System documentation
  
  This guide provides a foundation for planning your directory, including directory design, schema design, the directory tree, topology, replication, and security. The last chapter provides sample deployment scenarios to help you plan both simple, smaller-scale deployments and complex worldwide deployments.

- Sun Java System Directory Server *Administration Guide*, which is included with the Sun Java Enterprise System documentation

Additional Prerequisite

If you need to install Sun Java System Directory Server, refer to the *Installation Guide* for the version of Sun Java System Directory Server that you are using.

LDAP Naming Services Compared to Other Naming Services

The following table shows a comparison between the DNS, NIS, and LDAP naming services.

<table>

</table>
Advantages of LDAP Naming Services

- LDAP enables you to consolidate information by replacing application-specific databases, which reduces the number of distinct databases to be managed.
- LDAP allows data to be shared by different naming services.
- LDAP provides a central repository for data.
- LDAP allows for more frequent data synchronization between masters and replicas.
- LDAP is multi-platform and multi-vendor compatible.

Restrictions of LDAP Naming Services

Following are some restrictions associated with LDAP naming services:

- Clients prior to Solaris 8 are not supported.
- An LDAP server cannot be its own client.
- Setting up and managing an LDAP naming services is more complex and requires careful planning.
- A NIS client and a Native LDAP client cannot co-exist on the same client machine.

Note – A directory server (an LDAP server) cannot be its own client. That is, you cannot configure the machine that is running the directory server software to become an LDAP naming services client.

- “LDAP Naming Services Security Model” on page 144

**LDAP Data Interchange Format (LDIF)**

LDIF is a text-based format for describing directory service entities and their attributes. Using LDIF format you can move information from one directory to another with commands such as `ldapadd` and `ldapmodify`. The following are examples of LDIF format for each service. Use `ldaplist(1)` with the `-l` option to display the following information.

```
% ldaplist -l hosts myhost
hosts

dn: cn=myhost+ipHostNumber=7.7.7.115,ou=Hosts,dc=mydc,dc=mycom,dc=com
cn: myhost
iphostnumber: 7.7.7.115
objectclass: top
objectclass: device
objectclass: ipHost
description: host 1 - floor 1 - Lab a - building b

% ldaplist -l passwd user1
```
LDAP Data Interchange Format (LDIF)

```plaintext

Using Fully Qualified Domain Names With LDAP

Unlike NIS clients, an LDAP client always returns a fully qualified domain name (FQDN) for a host name. The LDAP FQDN is similar to the FQDN returned by DNS. For example, suppose your domain name is the following:

west.example.net

Both `gethostbyname()` and `getnameinfo()` return the FQDN version when looking up the host name `server`:

`server.west.example.net`

Also, if you use interface-specific aliases such as `server-#`, a long list of fully qualified host names are returned. If you are using host names to share file systems or have other such checks, you must account for the checks. For example, if you assume non-FQDNs for local hosts and FQDNs only for remote DNS-resolved hosts, you must account for the difference. If you set up LDAP with a different domain name from DNS, the same host might end up with two different FQDNs, depending on the lookup source.

Default Directory Information Tree (DIT)

By default, Solaris LDAP clients access the information assuming that the DIT has a given structure. For each domain supported by the LDAP server, there is a subtree with an assumed structure. This default structure, however, can be overriden by specifying Service Search Descriptors (SSDs). For a given domain, the default DIT will have a base container that holds a number of well known containers that hold entries for a specific information type. See the following table for the names of these subtrees. (This information can be found in RFC 2307 and others.)

<table>

**Default LDAP Schema**

Schemas are definitions describing what types of information can be stored as entries in an LDAP directory. To support LDAP naming clients, the directory server’s schema might need to be extended. Detailed information about IETF and Solaris specific schemas is included in Chapter 14, “LDAP General Reference (Reference).” The various RFCs can also be accessed on the IETF Web site http://www.ietf.org.

**Service Search Descriptors (SSDs) and Schema Mapping**

**Note** – If you use schema mapping, you must do so in a very careful and consistent manner. Make sure the syntax of the mapped attribute is consistent with the attribute it is mapped to. In other words, make sure that single-valued attributes map to single-valued attributes, that the attribute syntaxes are in agreement, and that mapped object classes have the correct mandatory (possibly mapped) attributes.

As previously discussed, LDAP naming services expect, by default, the DIT to be structured in a certain way. If you want, you can instruct the Solaris LDAP naming service to search in other locations than the default locations in the DIT. Additionally, you can specify that different attributes and object classes be used in place of those specified by the default schema. For a list of default filters, see “Default Filters Used by LDAP Naming Services” on page 238.
Description of SSDs

The `serviceSearchDescriptor` attribute defines how and where an LDAP naming service client should search for information for a particular service. The `serviceSearchDescriptor` contains a service name, followed by one or more semicolon-separated base-scope-filter triples. These base-scope-filter triples are used to define searches only for the specific service and are searched in order. If multiple base-scope-filters are specified for a given service, then when that service looks for a particular entry, it will search in each base with the specified scope and filter.

**Note** – The default location is not searched for a service (database) with an SSD unless it is included in the SSD. Unpredictable behavior will result if multiple SSDs are given for a service.

In the following example, the Solaris LDAP naming service client performs a one-level search in ou=west,dc=example,dc=com followed by a one-level search in ou=east,dc=example,dc=com for the passwd service. To look up the passwd data for a user's username, the default LDAP filter `(&(objectClass=posixAccount)(uid=username))` is used for each BaseDN.

```
serviceSearchDescriptor: passwd:ou=west,dc=example,dc=com;ou=east,dc=example,dc=com
```

In the following example, the Solaris LDAP naming service client would perform a subtree search in ou=west,dc=example,dc=com for the passwd service. To look up the passwd data for user username, the subtree ou=west,dc=example,dc=com would be searched with the LDAP filter `(&(fulltimeEmployee=TRUE)(uid=username))`.

```
serviceSearchDescriptor: passwd:ou=west,dc=example,dc=com?sub?fulltimeEmployee=TRUE
```

It is also possible to associate multiple containers with a particular service type. In the following example, the service search descriptor specifies searching for the password entries in three containers.

```
ou=myuser,dc=example,dc=com
ou=newuser,dc=example,dc=com
ou=extuser,dc=example,dc=com
```

Note that a trailing ‘,’ in the example implies that the `defaultSearchBase` is appended to the relative base in the SSD.

```
defaultSearchBase: dc=example,dc=com
serviceSearchDescriptor: \
passwd:ou=myuser,;ou=newuser,;ou=extuser,dc=example,dc=com
```
Attribute Map

The Solaris LDAP naming service allows one or more attribute names to be remapped for any of its services. (The Solaris LDAP client uses the well-known attributes documented in Chapter 14, “LDAP General Reference (Reference).”) If you map an attribute, you must be sure that the attribute has the same meaning and syntax as the original attribute. Note that mapping the userPassword attribute might cause problems.

There are a couple of reasons you might want to use schema mappings.

- You want to map attributes in an existing directory server
- If you have user names that differ only in case, you must map the uid attribute, which ignores case, to an attribute that does not ignore case

The format for this attribute is service:attribute-name=mapped-attribute-name.

If you want to map more than one attribute for a given service, you can define multiple attributeMap attributes.

In the following example, the `employeeName` and `home` attributes would be used whenever the `uid` and `homeDirectory` attributes would be used for the passwd service.

```
attributeMap: passwd:uid=employeeName
attributeMap: passwd:homeDirectory=home
```

There exists one special case where you can map the passwd service’s gecos attribute to several attributes. The following is an example.

```
attributemap: gecos=cn sn title
```

This maps the gecos values to a space separated list of the cn, sn, and title attribute values.

objectClass Map

The Solaris LDAP naming service allows object classes to be remapped for any of its services. If you want to map more than one object class for a given service, you can define multiple objectclassMap attributes. In the following example, the myUnixAccount object class is used whenever the posixAccount object class is used.

```
objectclassMap: passwd:posixAccount=myUnixAccount
```
LDAP Client Profiles

To simplify Solaris client setup, and avoid having to reenter the same information for each and every client, create a single client profile on the directory server. This way, a single profile defines the configuration for all clients configured to use it. Any subsequent change to the profile attributes is propagated to the clients at a rate defined by the refresh interval.

These client profiles should be stored in a well-known location on the LDAP server. The root DN for the given domain must have an object class of nisDomainObject and a nisDomain attribute containing the client’s domain. All profiles are located in the ou=profile container relative to this container. These profiles should be readable anonymously.

Client Profile Attributes

The following table shows the Solaris LDAP client’s profile attributes, which can be set automatically when you run idsconfig. See “Initializing a Client Manually” on page 194 and the idsconfig(1M) man page for information on how to set a client profile manually.

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cn</td>
<td>The profile name. The attribute has no default value. The value must be specified.</td>
</tr>
<tr>
<td>preferredServerList</td>
<td>The host addresses of the preferred servers is a space separated list of server addresses. (Do not use host names.) The servers in this list are tried in order before those in defaultServerList until a successful connection is made. This has no default value. At least one server must be specified in either preferredServerList or defaultServerList.</td>
</tr>
<tr>
<td>defaultServerList</td>
<td>The host addresses of the default servers is a space separated list of server addresses. (Do not use host names.) After the servers in preferredServerList are tried, those default servers on the client’s subnet are tried, followed by the remaining default servers, until a connection is made. At least one server must be specified in either preferredServerList or defaultServerList. The servers in this list are tried only after those on the preferred server list. This attribute has no default value.</td>
</tr>
<tr>
<td>defaultSearchBase</td>
<td>The DN relative to which to locate the well-known containers. There is no default for this value. However, this can be overridden for a given service by the serviceSearchDescriptor attribute.</td>
</tr>
<tr>
<td>defaultSearchScope</td>
<td>Defines the scope of a database search by a client. It can be overridden by the serviceSearchDescriptor attribute. The possible values are one or sub. The default value is a one level search.</td>
</tr>
</tbody>
</table>
### TABLE 9-2 Client Profile Attributes  

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>authenticationMethod</td>
<td>Identifies the method of authentication used by the client. The default is none (anonymous). See “Choosing Authentication Methods” on page 150 for more information.</td>
</tr>
<tr>
<td>credentialLevel</td>
<td>Identifies the type of credentials a client should use to authenticate. The choices are anonymous, proxy, or self (also known as per user). The default is anonymous.</td>
</tr>
<tr>
<td>serviceSearchDescriptor</td>
<td>Defines how and where a client should search for a naming database, for example, if the client should look in one or more points in the DIT. By default no SSDs are defined.</td>
</tr>
<tr>
<td>serviceAuthenticationMethod</td>
<td>Authentication method used by a client for the specified service. By default, no service authentication methods are defined. If a service does not have serviceAuthenticationMethod defined, it will default to the value of authenticationMethod.</td>
</tr>
<tr>
<td>attributeMap</td>
<td>Attribute mappings used by client. By default no attributeMap is defined.</td>
</tr>
<tr>
<td>objectClassMap</td>
<td>Object class mappings used by client. By default no objectClassMap is defined.</td>
</tr>
<tr>
<td>searchTimeLimit</td>
<td>Maximum time [in seconds] a client should allow for a search to complete before timing out. This does not affect the time the LDAP server will allow for a search to complete. The default value is 30 seconds.</td>
</tr>
<tr>
<td>bindTimeLimit</td>
<td>Maximum time in seconds a client should allow to bind with a server before timing out. Default value is 30 seconds.</td>
</tr>
<tr>
<td>followReferrals</td>
<td>Specifies whether a client should follow an LDAP referral. Possible values TRUE or FALSE. The default value is TRUE.</td>
</tr>
<tr>
<td>profileTTL</td>
<td>Time between refreshes of the client profile from the LDAP server by the <code>ldap_cachemgr(1M)</code>. Default is 43200 seconds or 12 hours. If a given value of 0, the profile will never be refreshed.</td>
</tr>
</tbody>
</table>

### Local Client Attributes

The following table lists the client attributes that can be set locally using `ldapclient`. See the `ldapclient(1M)` man page for more information.
### TABLE 9–3 Local Client Attributes

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>adminDN</td>
<td>Specifies the administrator entry’s distinguished name for the admin credential. If the value of the enableShadowUpdate switch is true on the client system, and credentialLevel has a value other than self, then adminDN must be specified.</td>
</tr>
<tr>
<td>adminPassword</td>
<td>Specifies the administrator entry’s password for the admin credential. If the value of the enableShadowUpdate switch is true on the client system, and credentialLevel has a value other than self, then adminPassword must be defined.</td>
</tr>
<tr>
<td>domainName</td>
<td>Specifies the client’s domain name (which becomes the default domain for the client system). This attribute has no default value and must be specified.</td>
</tr>
<tr>
<td>proxyDN</td>
<td>The proxy’s distinguished name. If the client system is configured with credentialLevel of proxy, the proxyDN must be specified.</td>
</tr>
<tr>
<td>proxyPassword</td>
<td>The proxy’s password. If the client system is configured with credentialLevel of proxy, proxyPassword must be defined.</td>
</tr>
<tr>
<td>certificatePath</td>
<td>The directory on the local file system containing the certificate databases. If a client system is configured with authenticationMethod or serviceAuthenticationMethod using TLS, then this attribute is used. The default value is /var/ldap.</td>
</tr>
</tbody>
</table>

**Note** – If the BaseDN in an SSD contains a trailing comma, it is treated as a relative value of the defaultSearchBase. The values of the defaultSearchBase are appended to the BaseDN before a search is performed.

### ldap_cachemgr Daemon

ldap_cachemgr is a daemon that runs on LDAP client machines. When you start the LDAP client, the ldap_cachemgr daemon is invoked. The daemon performs the following key functions.

- Gains access to the configuration files, running as root
- Refreshes the client configuration information stored in the profiles on the server and pulls this data from the clients
- Maintains a sorted list of active LDAP servers to use
- Improves lookup efficiency by caching some common lookup requests submitted by various clients
- Improves the efficiency of host lookups
LDAP Naming Services Security Model

- If the enableShadowUpdate switch is set to true, gains access to the configured administrator credential and performs updates to the shadow data.

**Note** – `ldap_cachemgr` must be running at all times for LDAP naming services to work.

Refer to the `ldap_cachemgr(1M)` man page for detailed information.

**LDAP Naming Services Security Model**

**Introduction**

Solaris LDAP naming services can use the LDAP repository in two different ways. One is as a source of both a naming service and an authentication service. The other is strictly as the source of naming data. This section discusses the concepts of client identity, authentication methods, `pam_ldap` and `pam_unix` modules, and account management when the LDAP repository is used as both a naming service and authentication service. This section also discusses the use of LDAP naming services in conjunction with the Kerberos environment (Part VI, “Kerberos Service,” in *System Administration Guide: Security Services*) and `pam_krb5(5)` modules.
Note – Previously, if you enabled `pam_ldap` account management, all users needed to provide a login password for authentication any time they logged in to the system. Therefore, nonpassword-based logins using tools such as `rsh`, `rlogin`, or `ssh` would fail.

Now, however, `pam_ldap(5)`, when used with Sun Java System Directory Servers DS5.2p4 and newer releases, enables users to log in with `rsh`, `rlogin`, `rcp` and `ssh` without giving a password. `pam_ldap(5)` is now modified to perform account management and retrieve the account status of users without authenticating to Directory Server as the user logging in. The new control to this on Directory Server is 1.3.6.1.4.1.42.2.27.9.5.8, which is enabled by default.

To modify this control for other than default, add Access Control Instructions (ACI) on Directory Server:

```
dn: oid=1.3.6.1.4.1.42.2.27.9.5.8, cn=features, cn=config
objectClass: top
objectClass: directoryServerFeature
oid:1.3.6.1.4.1.42.2.27.9.5.8
cn:Password Policy Account Usable Request Control
aci: (targetattr != "aci") (version 3.0; acl "Account Usable";
   allow (read, search, compare, proxy)
   (groupdn = "ldap://cn=Administrators,cn=config");)
creatorsName: cn=server,cn=plugins,cn=config
modifiersName: cn=server,cn=plugins,cn=config
```

Note – If you use Kerberos as your authentication system and integrate it with the LDAP naming system, you will be able to support a single sign on (SSO) environment in your enterprise through Kerberos. You will also be able to use that same identity system when querying LDAP naming data on a per-user or per-host basis.

To access the information in the LDAP repository, clients can first establish identity with the directory server. This identity can be either anonymous or as an object recognized by the LDAP server. Based on the client’s identity and the server’s access control information (ACI), the LDAP server will allow the client to read or write directory information. For more information on ACIs, consult the Administration Guide for the version of Sun Java System Directory Server that you are using.

If the client is connecting as anything other than anonymous for any given request, the client must prove its identity to the server using an authentication method supported by both the client and the server. Once the client has established its identity, it can then make the various LDAP requests.
When you use `pam_ldap` there is a distinction between how the naming service and the authentication service (`pam_ldap`) access the directory. The naming service reads various entries and their attributes from the directory based on predefined identity. The authentication service establishes whether the user has entered the correct password by using that user’s name and password to authenticate to the LDAP server. See the `pam_ldap(5)` man page for more information about the authentication service.

When Kerberos is used to perform authentication, and when authentication in LDAP naming services is also enabled (as is required for per-user mode), Kerberos can provide dual functions. Kerberos authenticates to the server and the Kerberos identity for the principal (user or host) is used to authenticate to the directory. In this way, the same user identity that is used to authenticate to the system is also used to authenticate to the directory for lookups and updates. Administrators can use access control information (ACI) in the directory to limit the results out of the naming service if desired.

**Transport Layer Security (TLS)**

*Note* – In order to use TLS for Solaris LDAP naming services, the directory server must use the default ports, 389 and 636, for LDAP and SSL, respectively. If your directory server does not use these ports, you cannot use TLS at this time.

TLS can be used to secure communication between an LDAP client and the directory server, providing both privacy and data integrity. The TLS protocol is a superset of the Secure Sockets Layer (SSL) protocol. Solaris LDAP naming services support TLS connections. Be aware that using SSL adds load to the directory server and the client.

You will need to set up your directory server for SSL. For more information about setting up Sun Java System Directory Server for SSL, see the Administration Guide for the version of Sun Java System Directory Server that you are using. You will also need to set up your LDAP client for SSL.

If using TLS, the necessary security databases must be installed. In particular, the certificate and key database files are needed. For example, if you adopt an older database format from Netscape Communicator, two files, `cert7.db` and `key3.db`, are required. Or if you use a new database format from Mozilla, three files, `cert8.db`, `key3.db`, and `secmod.db` are needed. The `cert7.db` or `cert8.db` file contains trusted certificates. The `key3.db` file contains the client’s keys. Even if the LDAP naming service client does not use client keys, this file must be present. The `secmod.db` file contains the security modules such as the PKCS#11 module. This file is not required if the older format is used.

See “Setting Up TLS Security” on page 196 for more information.
Assigning Client Credential Levels

LDAP naming services clients authenticate to the LDAP server according to a client’s credential level. LDAP clients can be assigned four possible credential levels with which to authenticate to a directory server.

- anonymous
- proxy
- proxy anonymous
- self (called per user in this document)

Anonymous

If you use anonymous access, you can access only the data that is available to everyone. In anonymous mode, an LDAP BIND operation does not take place. Also, you should consider the security implications. Allowing anonymous access for certain parts of the directory implies that anyone with access to the directory has read access. If you use an anonymous credential level, you need to allow read access to all the LDAP naming entries and attributes.

**Caution** – Allowing anonymous write to a directory should never be done, as anyone could change information in the DIT to which they have write access, including another user’s password, or their own identity.

**Note** – Sun Java System Directory Server allows you to restrict access based on IP addresses, DNS name, authentication method, and time-of-day. You might want to limit access with further restrictions. For more information, see “Managing Access Control” in the Administration Guide for the version of Sun Java System Directory Server that you are using.

Proxy

The client authenticates or binds to the directory using a single proxy account. This proxy account can be any entry that is allowed to bind to the directory. This proxy account needs sufficient access to perform the naming service functions on the LDAP server. The proxy account is a shared-per-system resource. That is, each user logged in to a system using proxy access, including the root user, sees the same results as all other users on that system. You need to configure the proxyDN and proxyPassword on every client using the proxy credential level. The encrypted proxyPassword is stored locally on the client. You can set up different proxies for different groups of clients. For example, you can configure a proxy for all the sales clients to access both the company-wide-accessible and sales directories, while preventing sales clients from accessing human resource directories with payroll information. Or, in the most extreme cases, you can either assign different proxies to each client or assign just one proxy to all clients. A typical LDAP deployment would probably lie between the two extremes. Consider the...
choices carefully. Too few proxy agents might limit your ability to control user access to resources. However, having too many proxies complicates the setup and maintenance of the system. You need to grant the appropriate rights to the proxy user, depending on your environment. See “Credential Storage” on page 149 for information on how to determine which authentication method makes the most sense for your configuration.

If the password changes for a proxy user, you need to update it on every client that uses that proxy user. If you use password aging on LDAP accounts, be sure to turn it off for proxy users.

**Note** – Be aware that the proxy credential level applies to all users and processes on any given system. If two users need to use different naming policies, they must use different machines, or they must use the per-user authentication model.

In addition, if clients are using a proxy credential to authenticate, the `proxyDN` must have the same `proxyPassword` on all of the servers.

*Proxy anonymous*

*Proxy anonymous* is a multi-valued entry, in that more than one credential level is defined. A client assigned the `proxy anonymous` level will first attempt to authenticate with its proxy identity. If the client is unable to authenticate as the proxy user for whatever reason (user lockout, password expired, for example), then the client will use anonymous access. This might lead to a different level of service, depending on how the directory is configured.

*Per User*

Per-user (self) authentication uses the Kerberos identity (principal) to perform a lookup for each user or each system when authenticating to the directory server. With per-user authentication, the system administrator can use access control instructions (ACI’s), access control lists (ACL’s), roles, groups or other directory access control mechanisms to grant or deny access to specific naming service data for specific users or systems.

**Note** – When configuring per-user mode, the configuration value to enable this mode is “self,” which denotes per-user mode.

To use the per-user authentication model, the Kerberos single sign-on service must be deployed. In addition, the one or more directory servers used in the deployment must support SASL and the SASL/GSSAPI authentication mechanism. Because Kerberos expects to use files and DNS for host name lookups, instead of LDAP, DNS should be deployed in this environment. Also, to use per-user authentication, `nscd` must be enabled. The `nscd` daemon is not an optional component in this configuration.
enableShadowUpdate Switch

If the `enableShadowUpdate` switch is set to `true` on the client, the admin credentials will be used to update the shadow data. Shadow data is stored in the `shadowAccount` object class on the directory server. Admin credentials are defined by the values of the `adminDN` and `adminPassword` attributes, as described in "Local Client Attributes" on page 142. These admin credentials are not used for any other purpose.

Admin credentials have properties similar to Proxy credentials. The exception is that for admin credentials, the user must have all privileges for the zone or have an effective UID of `root` to read or update the shadow data. Admin credentials can be assigned to any entry that is allowed to bind to the directory. However, do not use the same directory manager identity (`cn=Directory Manager`) of the LDAP server.

This entry with admin credentials must have sufficient access to read and write the shadow data in the directory. Because the entry is a shared-per-system resource, the `adminDN` and `adminPassword` attributes must be configured on every client. The encrypted `adminPassword` is stored locally on the client. The password uses the same authentication methods that are configured for the client. The admin credentials are used by all users and processes on a given system to read and update the shadow data.

Credential Storage

If you configure a client to use a proxy identity, the client saves its `proxyDN` and `proxyPassword` in `/var/ldap/ldap_client_cred`. For the sake of increased security, this file is restricted to root access only, and the value of `proxyPassword` is encrypted. While past LDAP implementations have stored proxy credentials in a client's profile, Solaris 9 LDAP naming services do not. Any proxy credentials set using `ldapclient` during initialization are stored locally. This results in improved security surrounding a proxy's DN and password information. See Chapter 12, "Setting Up LDAP Clients (Tasks)," for more information on setting up client profiles.

Similarly, if you configure a client to enable shadow data updates, and the client credential level is `self`, the client saves its `adminDN` and `adminPassword` attributes locally in the `/var/ldap/ldap_client_cred` file. The value of `adminPassword` is also encrypted and is used only by the `ldap_cachemgr` daemon process.

If you configure a client to use per-user authentication, the Kerberos identity and Kerberos ticket information for each principal (each user or host) are used during authentication. In this environment the directory server maps the Kerberos principal to a DN and the Kerberos credentials are used to authenticate to that DN. The directory server can then use its access control instruction (ACI) mechanisms to allow or deny access to naming service data as necessary. In this situation, Kerberos ticket information is used to authenticate to the directory server and the system does not store authentication DNs or passwords on the system. Therefore, for this type of configuration, you do not need to specify the `adminDN` and `adminPassword` attributes when the client is initialized with the `ldapclient` command.
Choosing Authentication Methods

When you assign the proxy or proxy-anonymous credential level to a client, you also need to select a method by which the proxy authenticates to the directory server. By default, the authentication method is none, which implies anonymous access. The authentication method may also have a transport security option associated with it.

The authentication method, like the credential level, may be multivalued. For example, in the client profile you could specify that the client first tries to bind using the simple method secured by TLS. If unsuccessful, the client would try to bind with the sasl/digest-MD5 method. The authenticationMethod would then be tls:simple;sasl/digest-MD5.

LDAP naming services support some Simple Authentication and Security Layer (SASL) mechanisms. These mechanisms allow for a secure password exchange without requiring TLS. However, these mechanisms do not provide data integrity or privacy. See RFC 2222 for information on SASL.

The following authentication mechanisms are supported.

- none
  The client does not authenticate to the directory. This is equivalent to the anonymous credential level.

- simple
  If the client system uses the simple authentication method, it binds to the server by sending the user's password in the clear. The password is thus subject to snooping unless the session is protected by IPsec. The primary advantages of using the simple authentication method are that all directory servers support it and that it is easy to set up.

- sasl/digest-MD5
  The client's password is protected during authentication, but the session is not encrypted. Some directory servers, including Sun Java System Directory Server, also support the sasl/digest-MD5 authentication method. The primary advantage of digest-MD5 is that the password does not go over the wire in the clear during authentication and therefore is more secure than the simple authentication method. See RFC 2831 for information on digest-MD5. digest-MD5 is considered an improvement over cram-MD5 for its improved security.
  When using sasl/digest-MD5, the authentication is secure, but the session is not protected.

Note – If you are using Sun Java System Directory Server, the password must be stored in the clear in the directory.

- sasl/cram-MD5
In this case, the LDAP session is not encrypted, but the client’s password is protected during authentication, as authentication is performed by using **sasl/cram-MD5**.

See RFC 2195 for information on the **cram-MD5** authentication method. **cram-MD5** is only supported by some directory servers. For instance, Sun Java System Directory Server does not support **cram-MD5**.

- **sasl/GSSAPI**

  This authentication method is used in conjunction with the self credential mode to enable per-user lookups. A per-user nscd assigned to use the client's credentials binds to the directory server using the sasl/GSSAPI method and the client's Kerberos credentials. Access can be controlled in the directory server on a per-user basis.

- **tls:simple**

  The client binds using the **simple** method and the session is encrypted. The password is protected.

- **tls:sasl/cram-MD5**

  The LDAP session is encrypted and the client authenticates to the directory server using **sasl/cram-MD5**.

- **tls:sasl/digest-MD5**

  The LDAP session is encrypted and the client authenticates to the directory server using **sasl/digest-MD5**.

**Caution** – Sun Java System Directory Server requires passwords to be stored in the clear in order to use **digest-MD5**. If the authentication method is set to **sasl/digest-MD5** or **tls:sasl/digest-MD5**, then the passwords for the proxy user will need to be stored in the clear. Be especially careful that the **userPassword** attribute has the proper ACIs if it is stored in the clear, so that it is not readable.

The following table summarizes the various authentication methods and their respective characteristics:

**Authentication and Services**

The authentication method can be specified for a given service in the `serviceAuthenticationMethod` attribute. The following services currently support this.

- **passwd-cmd**
  This service is used by `passwd(1)` to change the login password and password attributes.

- **keyserv**
  This service is used by the `chkey(1)` and `newkey(1M)` utilities to create and change a user's Diffie-Hellman key pair.

- **pam_ldap**
  This service is used for authenticating users with `pam_ldap(5)`.
  `pam_ldap` supports account management.

**Note** – If the service does not have a `serviceAuthenticationMethod` set, it will default to the value of the `authenticationMethod` attribute.

**Note** – In per-user mode, “`pam_krb5 Service Module` on page 154 (pam Kerberos) is used as the authentication service. `ServiceAuthenticationMethod` is not needed in this mode of operation.

**Note** – If the `enableShadowUpdate` switch is set to `true`, the `ldap_cachemgr` daemon binds to the LDAP server by using the authentication method that is defined in the `serviceAuthenticationMethod` parameter of `passwd-cmd`, if the method is defined. Otherwise, `authenticationMethod` is used. The daemon will not use the `none` authentication method.
The following example shows a section of a client profile in which the users will use sasl/digest-MD5 to authenticate to the directory server, but will use an SSL session to change their password.

```
serviceAuthenticationMethod=pam_ldap:sasl/digest-MD5
serviceAuthenticationMethod=passwd-cmd:tls:simple
```

### Pluggable Authentication Methods

By using the PAM framework, you can choose among several authentication services, including `pam_unix`, `pam_krb5`, and `pam_ldap`.

If the per-user authentication method is used, `pam_krb5`, the strongest authentication service of the three methods listed above, must be enabled. See `pam_krb5(5)` and the *System Administration Guide: Security Services*.

The `pam_krb5` authentication system may be used even if per-user authentication is not enabled. If proxy or anonymous credential levels are used to access directory server data then restricting access to directory data on a per-user basis is not possible.

Because of its increased flexibility, support of stronger authentication methods, and ability to use account management, the use of `pam_ldap` is recommended over the use of `pam_unix` when anonymous or proxy authentication methods are used.

**pam_unix** **Service Modules**

If you have not changed the `pam.conf(4)` file, `pam_unix` functionality is enabled by default.

---

**Note** – The `pam_unix` module has been removed and is no longer supported with Solaris. A set of other service modules provides equivalent or greater functionality. Therefore, in this guide, `pam_unix` refers to the equivalent functionality, not to the `pam_unix` module itself.

Following is a list of the modules that provide the equivalent `pam_unix` functionality.

```
pam_authtok_check(5)
pam_authtok_get(5)
pam_authtok_store(5)
pam_dhkeys(5)
pam_passwd_auth(5)
pam_unix_account(5)
pam_unix_auth(5)
pam_unix_cred(5)
pam_unix_session(5)
```
pam_unix follows the traditional model of UNIX authentication, as described in the following list.

1. The client retrieves the user’s encrypted password from the name service.
2. The user is prompted for the user’s password.
3. The user’s password is encrypted.
4. The client compares the two encrypted passwords to determine whether the user should be authenticated.

Additionally, there are two restrictions when using pam_unix.

- The password must be stored in UNIX crypt format and not in any other encryption methods, including clear.
- The userPassword attribute must be readable by the name service.

For example, if you set the credential level to anonymous, then anyone must be able to read the userPassword attribute. Similarly, if you set the credential level to proxy, then the proxy user must be able to read the userPassword attribute.

Note – pam_unix is not compatible with the sasl authentication method digest-MD5, since Sun Java System Directory Server requires passwords to be stored in the clear in order to use digest-MD5. pam_unix requires the password be stored in crypt format.

Note – pam_unix supports account management when the enableShadowUpdate switch is set to true. The controls for a remote LDAP user account are applied just as the controls are applied to a local user account that is defined in the passwd and shadow files. In enableShadowUpdate mode, for the LDAP account, the system updates and uses the shadow data on the LDAP server for password aging and account locking. Of course, the shadow data of the local account only applies to the local client system, whereas the shadow data of an LDAP user account applies to the user on all client systems.

Password history checking is only supported for the local client, not for an LDAP user account.

pam_krb5 Service Module

Refer to pam_krb5(5) and the System Administration Guide: Security Services.

pam_ldap Service Module

When implementing pam_ldap, the user binds to the LDAP server by using the authentication method defined in pam_ldap’s serviceAuthenticationMethod parameter, if one exists. Otherwise, authenticationMethod is used.
If `pam_ldap` is able to bind to the server with the user's identity and supplied password, it authenticates the user.

**Note** – Previously, if you enabled `pam_ldap` account management, all users needed to provide a login password for authentication any time they logged in to the system. Therefore, nonpassword-based logins using tools such as `rsh`, `rlogin`, or `ssh` would fail.

Now, however, `pam_ldap(5)`, when used with Sun Java System Directory Servers DS5.2p4 and newer releases, enables users to log in with `rsh`, `rlogin`, `rcp`, and `ssh` without giving a password. `pam_ldap(5)` is now modified to perform account management and retrieve the account status of users without authenticating to Directory Server as the user logging in. The new control to this on Directory Server is `1.3.6.1.4.1.42.2.27.9.5.8`, which is enabled by default.

To modify this control for other than default, add Access Control Instructions (ACI) on Directory Server:

```plaintext
dn: oid=1.3.6.1.4.1.42.2.27.9.5.8, cn=features,cn=config
objectClass: top
objectClass: directoryServerFeature
oid:1.3.6.1.4.1.42.2.27.9.5.8

cn:Password Policy Account Usable Request Control
aci: (targetattr != "aci") (version 3.0; acl "Account Usable";
  allow (read, search, compare, proxy)
  (groupdn = "ldap://cn=Administrators,cn=config"));
creatorsName: cn=server,cn=plugins,cn=config
modifiersName: cn=server,cn=plugins,cn=config
```

`pam_ldap` does not read the `userPassword` attribute. Therefore, there is no need to grant access to read the `userPassword` attribute unless there are other clients using `pam_unix`. Also, `pam_ldap` does not support the `none` authentication method. Thus, you must define the `serviceAuthenticationMethod` or the `authenticationMethod` attributes so clients can use `pam_ldap`. See the `pam_ldap(5)` man page for more information.

**Caution** – If the simple authentication method is used, the `userPassword` attribute can be read on the wire by third parties.

See "Example `pam.conf` File for `pam_ldap`" on page 213.

The following table summarizes the main differences between `pam_unix`, `pam_ldap`, and `pam_krb5`. 
### TABLE 9–5  Authentication Behavior in LDAP With pam_unix, pam_ldap, and pam_krb5

</table>

### PAM and Changing Passwords

Use the `passwd` command to change a password. If the `enableShadowUpdate` switch is not set to true, the `userPassword` attribute must be writable by the user. If the `enableShadowUpdate` switch is set to true, the admin credentials must be able to update the `userPassword` attribute. Remember that the `serviceAuthenticationMethod` for `passwd-cmd` overrides the `authenticationMethod` for this operation. Depending on the authentication method that is used, the current password might be unencrypted on the wire.

In the case of `pam_unix`, the new `userPassword` attribute is encrypted using UNIX crypt format and tagged before being written to LDAP. Therefore, the new password is encrypted on the wire, regardless of the authentication method used to bind to the server. See the `pam_authtok_store(5)` man page for more information.

If the `enableShadowUpdate` switch is set to true, `pam_unix` also updates the related shadow information when the user password is changed. `pam_unix` updates the same shadow fields in the local shadow files that `pam_unix` updates when the local user password is changed.
As of the Solaris 10 software release, pam_ldap no longer supports password update. The previously recommended use of pam_authtok_store with the server_policy option now replaces the pam_ldap password update capability. When you use pam_authtok_store, the new password is sent to the LDAP server in the clear. Therefore, to ensure privacy, use TLS. If TLS is not used, the new userPassword is subject to snooping. If you set an untagged password with Sun Java System Directory Server, the software encrypts the password by using the passwordStorageScheme attribute. For more information about the passwordStorageScheme, see the section on user account management in the Administration Guide for the version of Sun Java System Directory Server that you are using.

**Note** – You need to consider the following configuration issues when setting the passwordStorageScheme attribute. If an NIS, or another client using pam_unix is using LDAP as a repository, then passwordStorageScheme needs to be crypt. Also, if using pam_ldap with sasl/digest-MD5 with Sun Java System Directory Server, passwordStorageScheme must be set to clear.

### Account Management

If you select pam_krb5 as your account and password management system, the Kerberos environment will manage all your account, password, account lockout, and other account management details. Refer to **pam_krb5(5)** and the System Administration Guide: Security Services.

If you do not use pam_krb5, then LDAP naming services can be configured to take advantage of the password and account lockout policy support in Sun Java System Directory Server. You can configure **pam_ldap(5)** to support user account management. **passwd(1)** enforces password syntax rules set by the Sun Java System Directory Server password policy, when used with the proper PAM configuration.

The following account management features are supported through **pam_ldap(5)**. These features depend on Sun Java System Directory Server’s password and account lockout policy configuration. You can enable as many or as few of the features as you want.

- **Password aging and expiration notification**
  
  Users must change their passwords according to a schedule. A password expires if it is not changed within the time configured. An expired password causes user authentication to fail. Users see a warning message whenever they log in within the expiration warning period. The message specifies the number of hours or days until the password expires.

- **Password syntax checking**
  
  New passwords must meet the minimum password length requirements. In addition, a password cannot match the value of the uid, cn, sn, or mail attributes in the user’s directory entry.
- **Password in history checking**
  Users cannot reuse passwords. If a user attempts to change the password to one that was previously used, `passwd(1)` fails. LDAP administrators can configure the number of passwords kept in the server’s history list.

- **User account lockout**
  A user account can be locked out after a given number of repeated authentication failures. A user can also be locked out if his account is inactivated by an administrator. Authentication will continue to fail until the account lockout time is passed or the administrator reactivates the account.

**Note** – The preceding account management features only work with the Sun Java System Directory Server. For information about configuring the password and account lockout policy on the server, see the “User Account Management” chapter in the Administration Guide for the version of Sun Java System Directory Server that you are using. Also see “Example `pam_conf` file for `pam_ldap` Configured for Account Management” on page 215. Do not enable account management for proxy accounts.

Before configuring the password and account lockout policy on Sun Java System Directory Server, make sure all hosts use the “newest” LDAP client with `pam_ldap` account management.

In addition, make sure the clients have a properly configured `pam.conf(4)` file. Otherwise, LDAP naming services will not work when proxy or user passwords expire.
Note – Previously, if you enabled `pam_ldap` account management, all users needed to provide a login password for authentication any time they logged in to the system. Therefore, non-password-based logins using tools such as rsh, rlogin, or ssh would fail.

Now, however, `pam_ldap(5)`, when used with Sun Java System Directory Servers DS5.2p4 and newer releases, enables users to log in with rsh, rlogin, rcp and ssh without giving a password. `pam_ldap(5)` is now modified to perform account management and retrieve the account status of users without authenticating to Directory Server as the user logging in. The new control to this on Directory Server is 1.3.6.1.4.1.42.2.27.9.5.8, which is enabled by default.

To modify this control for other than default, add Access Control Instructions (ACI) on Directory Server:

```
dn: oid=1.3.6.1.4.1.42.2.27.9.5.8,cn=features,cn=config
objectClass: top
objectClass: directoryServerFeature
oid:1.3.6.1.4.1.42.2.27.9.5.8
cn:Password Policy Account Usable Request Control
aci: (targetattr != "aci") (version 3.0; acl "Account Usable":
    allow (read, search, compare, proxy)
    (groupdn = "ldap://cn=Administrators,cn=config");)
creatorsName: cn=server,cn=plugins,cn=config
modifiersName: cn=server,cn=plugins,cn=config
```

**Account Management With pam_unix**

If the `enableShadowUpdate` switch is set to `true` on the client, account management functionality that is available to local accounts is also available to LDAP accounts. Functionality includes password aging, account expiry and notification, failed login account locking, and so on. Also, the `-dluNfnwx` options to the `passwd` command are now supported in LDAP. Thus, the full functionality of the `passwd` command and the `pam_unix*` modules in the files naming service is supported in the LDAP naming service. The `enableShadowUpdate` switch provides a way to implement consistent account management for users who are defined in both the files and the LDAP scope.

To prevent users from modifying their own account management data and thereby circumventing password policy, the LDAP server is configured to prevent user write access to the user’s own shadow data on the server. An administrator with admin credentials performs the shadow data updates for a client system. Such a configuration, however, conflicts with the `pam_ldap` module, which requires that passwords be modifiable by users. Therefore, account management by `pam_ldap` and `pam_unix` are incompatible.
Caution – Do not use both pam ldap and pam unix in the same LDAP naming domain. Either all clients use pam ldap or all clients use pam_unix. This limitation might indicate that you need a dedicated LDAP server. For example, a web or email application might expect users to change their own password on the LDAP server.

The implementation of enableShadowUpdate also requires that the admin credential (adminDN plus adminPassword) be stored locally on every client. Even though adminPassword is encrypted and can only be read from the /var/ldap/ldap_client_cred file by the ldap_cachemgr daemon, special care must be taken to protect the admin credential. To protect the credential, make it different from the server's directory manager (cn=directory manager). Another protection would be to configure the serviceAuthenticationMethod with a value of tls:simple or better for the passwd-cmd service, so that the value of adminPassword is not sent in the clear and therefore becomes vulnerable to snooping.

Unlike using pam ldap for account management, using pam_unix for account management does not require a change to the /etc/pam.conf file. The default /etc/pam.conf file is sufficient.
This chapter discusses the high-level planning you should do before beginning the server and client setup and installation processes.

This chapter covers the following topics.

- "LDAP Planning Overview" on page 161
- "Planning the LDAP Network Model" on page 161
- "Planning the Directory Information Tree (DIT)" on page 162
- "LDAP and Replica Servers" on page 163
- "Planning the LDAP Security Model" on page 164
- "Planning Client Profiles and Default Attribute Values for LDAP" on page 166
- "Planning the LDAP Data Population" on page 166

LDAP Planning Overview

The LDAP client profile is a collection of configuration information an LDAP client uses to access LDAP naming services information about the supporting LDAP server. This chapter discusses the planning of the various aspects of the LDAP naming services. These include the network model, the directory information tree, the security model, the default values of the various profile attributes, and finally, the preparation for data population.

Planning the LDAP Network Model

For availability and performance considerations, each subnet of the company-wide network should have its own LDAP server to service all the LDAP clients in the subnet. Only one of the servers needs to be a master LDAP server. The rest could all be replicas of the master server.

To plan for the network configuration, consider how many servers are available, how a client would be able to get to the servers, and in what order the servers should be accessed. If there is one per subnet, you could use the defaultServerList attribute to list all the servers and have
the LDAP client sort and manipulate the access order. If the servers need to be accessed in a certain order due to speed or data management reasons, you should use the preferredServerList attribute to define the fixed order of accessing the servers. Note that you might not want to put the master server on either of these lists to reduce the load on the master server.

In addition, you might find three more attributes worth consideration when planning for the server and network configuration. The bindTimeLimit attribute can be used to set the time-out value for a TCP connect request. The searchTimeLimit attribute can be used to set the time-out value for an LDAP search operation. The profileTTL attribute can be used to control how often the LDAP client should download its profile from the servers. For a slow or unstable network, the bindTimeLimit and searchTimeLimit attributes might need a larger value than the defaults. For early stage testing of the deployment, you might want to reduce the value of the profileTTL attribute to have the clients pick up the frequent changes made to the profile stored in the LDAP servers.

Planning the Directory Information Tree (DIT)

LDAP naming services have a default directory information tree (DIT) and an associated default schema. For example, the ou=people container contains the user account, password, and shadow information. The ou=hosts container contains information about systems in the network. Each entry in the ou=people container would be of objectclass posixAccount and shadowAccount.

The default DIT is a well designed directory structure and is based on open standards. It should be sufficient for most of naming service needs, and is recommended to be used without changes. If you choose to use the default DIT, the only thing you need to decide is from which node (base DN) in the directory tree the naming services information will be searched for a given domain. This node is specified with the defaultSearchBase attribute. Additionally, you might want to set the defaultSearchScope attribute to tell the clients the scope of search a naming service lookup should perform. Is it just searching one level under the DN (one), or the entire subtree under the DN (sub)?

There are times, however, that more flexibility is needed for the LDAP naming service to either work with an existing DIT or handle a more complicated DIT with naming service data scattered around the directory tree. For example, user account entries may exist in different part of the tree. The serviceSearchDescriptor, attributeMap, and objectclassMap attributes in the client profile are designed to handle these situations.

A service search descriptor can be used to override the default search base, search scope, and search filter for a particular service. See “Service Search Descriptors (SSDs) and Schema Mapping” on page 138.

The AttributeMap and ObjectclassMap attributes provide a way for schema mapping. They make it possible for the LDAP naming services to work with an existing DIT. You can map the
posixAccount object class to an existing object class, myAccount, for example. You can map an attribute in the posixAccount object class to an attribute in the myAccount object class.

Multiple Directory Servers

Multiple LDAP servers can serve one DIT. For example, some subtrees of the DIT reside on other LDAP servers. In this case, an LDAP server may refer the LDAP client to a different server for the naming data it knows about but is not in its own database. If you plan such a DIT configuration, you should set the clients’ profile attribute followReferrals to indicate to the LDAP naming service to follow server referrals to continue naming service lookups. However, it is best to have all naming data for a given domain reside on a single directory server, if at all possible.

Referrals can be useful if you want to have clients access read-only replicas most of the time and follow referrals to a read/write master server only when necessary. In this way, the master server does not get overloaded with requests that could be handled by replicas.

Data Sharing With Other Applications

To make best use of LDAP, you should have a single LDAP entry for each logical entry. For example, for a user you can have not only company white-page information, but also Solaris account information, and possibly application-specific data. Since posixAccount and shadowAccount are auxiliary object classes, they can be added to any entry in the directory. This will require careful planning, setup, and administration.

Choosing the Directory Suffix

See the Sun Java System Directory Server (formerly Sun ONE Directory Server) documentation for information about how to choose an appropriate directory suffix.

LDAP and Replica Servers

There are three different strategies to employ when setting up replica servers.

- Single-master replication
- Floating-master replication
- Multi-master replication

Single-master

With single-master replication, only one master server for any given partition or non-partitioned network holds writable copies of directory entries. Any replica servers have
read-only copies of the directory entries. While both replicas and masters can perform searches, compares, and bind operations, only the master server can perform write operations.

The potential disadvantage to the single-master replication strategy is that the master server is a single point of failure. If the master server goes down, none of the replicas can process write operations.

**Floating-master**

The floating-master strategy is similar to the single-master strategy in that there is only one master server with write capabilities at any given time for a given partitioned or non-partitioned network. However, when implementing the floating-master strategy, when the master server goes down, a replica is automatically transformed into a master server by way of an algorithm.

One potential disadvantage to the floating-master replication strategy is that if your network becomes partitioned and replicas on either side of the partition become masters, the process of reconciling the new masters can be very complicated if the network is rejoined.

**Multi-master**

With multi-master replication, there are multiple master servers with their own read-write copies of the directory entry data. While the multi-master strategy eliminates the problem of having a single point of failure, update conflicts can occur between servers. In other words, if an entry’s attribute is modified around the same time on two masters, an update conflict resolution policy, such as “last writer wins,” must be in place.

For information about how to set up replica servers, refer to the Administration Guide for the version of Sun Java System Directory Server that you are using.

---

### Planning the LDAP Security Model

To plan for the security model, you should first consider what identity the LDAP client should be using to talk to the LDAP server. For example, you must decide if you want an enterprise-wide single sign-on solution, with no passwords being sent over the wire, or the wire encryption of data and the ability to access control data results from the directory server on a per-user basis. You must also decide whether you want strong authentication to protect the user password flow across the wire, and/or if you need to encrypt the session between the LDAP client and the LDAP server to protect the LDAP data transmitted.

The `credentialLevel` and `authenticationMethod` attributes in the profile are used for this. There are four possible credential levels for `credentialLevel`: `anonymous`, `proxy`, `proxy anonymous` and `self`. See “LDAP Naming Services Security Model” on page 144 for a detailed discussion of LDAP naming service security concepts.
Note – Previously, if you enabled `pam_ldap` account management, all users needed to provide a login password for authentication any time they logged in to the system. Therefore, nonpassword-based logins using tools such as `rsh`, `rlogin`, or `ssh` would fail.

Now, however, `pam_ldap(5)`, when used with Sun Java System Directory Servers DS5.2p4 and newer releases, enables users to log in with `rsh`, `rlogin`, `rcp` and `ssh` without giving a password. `pam_ldap(5)` is now modified to perform account management and retrieve the account status of users without authenticating to Directory Server as the user logging in. The new control to this on Directory Server is 1.3.6.1.4.1.42.2.27.9.5.8, which is enabled by default.

To modify this control for other than default, add Access Control Instructions (ACI) on Directory Server:

```
    dn: oid=1.3.6.1.4.1.42.2.27.9.5.8,cn=features,cn=config
    objectClass: top
    objectClass: directoryServerFeature
    oid:1.3.6.1.4.1.42.2.27.9.5.8
    cn:Password Policy Account Usable Request Control
    aci: (targetattr != "aci") (version 3.0; acl "Account Usable";
      allow (read, search, compare, proxy)
      (groupdn = "ldap://cn=Administrators,cn=config");)
    creatorsName: cn=server,cn=plugins,cn=config
    modifiersName: cn=server,cn=plugins,cn=config
```

Note – If you enable `pam_krb5` and Kerberos as an enterprise-wide single sign on solution, you can design a system whereby login passwords are only needed once at the start of a session. See `System Administration Guide: Security Services` for further details. If you enable Kerberos you will generally also need to enable DNS. See the chapters on DNS in this manual for further details.

The main decisions you need to make when planning your security model are the following.

- Will you use Kerberos and per-user authentication?
- What credential level and authentication methods will LDAP clients use?
- Will you use TLS?
- Do you need to be backward compatible with NIS? In other words, will clients use `pam_unix` or `pam_ldap`?
- What will the servers' `passwordStorageScheme` attribute settings be?
- How will you set up the Access Control Information?
For more information about ACIs, consult the Administration Guide for the version of Sun Java System Directory Server that you are using.

- Will clients use pam_unix or pam_ldap to perform account management?

### Planning Client Profiles and Default Attribute Values for LDAP

By going through the previous planning steps (network model, DIT, and security model), you should have some idea of the values for the following profile attributes.

- `cn`
- `defaultServerList`
- `preferredServerList`
- `bindTimeLimit`
- `searchTimeLimit`
- `profileTTL`
- `defaultSearchBase`
- `defaultSearchScope`
- `serviceSearchDescriptor`
- `attributeMap`
- `objectclassMap`
- `followReferrals`
- `credentialLevel`
- `authenticationMethod`
- `serviceCredentialLevel`
- `serviceAuthenticationMethod`

Of the preceding attributes, only `cn`, `defaultServerList`, and `defaultSearchBase` are required. They have no default values. The rest are optional, and some have default values.

See Chapter 12, “Setting Up LDAP Clients (Tasks),” for more information about setting up LDAP clients.

### Planning the LDAP Data Population

To populate the LDAP server with data, after the LDAP server has been configured with the proper DIT and schema. Use the new `ldapaddent` tool. This tool will create entries in LDAP containers from their corresponding /etc files. It can be used to populate data into the containers for the following types of data: aliases, auto_*, bootparams, ethers, group, hosts (including IPv6 addresses), netgroup, netmasks, networks, passwd, shadow, protocols, publickey, rpc, and services.

By default, `ldapaddent` reads from the standard input and adds this data to the LDAP container associated with the database specified on the command line. But an input file from which data should be read can be specified using the `-f` option.
Because the entries are stored in the directory based on the client's configuration, the client must be configured to use the LDAP naming services.

For better performance, load the databases in this order:

1. `passwd` database followed by `shadow` database
2. `networks` database followed by `netmasks` database
3. `bootparams` database followed by `ethers` database

Note that when adding automounter entries, the database name is in the form of `auto_*` (for example, `auto_home`).

If you have `/etc` files from different hosts to add to the LDAP server, you can either merge all of them into the same `/etc` file and then use `ldapaddent` on one host to add the files, or perform `ldapaddent` on the different hosts one by one, with the expectation that each host is already configured as a LDAP client.

If your naming service data is already in an NIS server, and you want to move the data to the LDAP server for LDAP naming services, use the `ypcat` (or `niscat`) command to dump the NIS map into files. Then, run `ldapaddent` against these files to add the data to the LDAP server.

---

**Note** – `ldapaddent` can only be run on an LDAP client.

The following procedure assumes that the tables are to be extracted from a yp client.

### How to Populate a Server With Host Entries Using `ldapaddent`

1. **Make sure that Sun Java System Directory Server was set up using** `idsconfig`.

2. **On a client machine, become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in *System Administration Guide: Security Services*.

3. **Make the machine an LDAP client.**
   ```bash
   # ldapclient init -a profileName=new -a domainName=west.example.com \
   192.168.0.1
   ```

4. **Populate the server with data.**
   ```bash
   # ldapaddent -D "cn=directory manager" -f /etc/hosts hosts
   ```
   You will be prompted for a password.
In this example, `ldapaddent` will use the authentication method that has been configured in the profile `new`. Selecting `simple` will cause the password to be sent in the clear. For more information, refer to the `ldapaddent(1M)` man page.
This chapter describes how to configure Sun Java System Directory Server (formerly Sun ONE Directory Server) to support a network of Solaris LDAP naming services clients. The information is specific to the Sun Java System Directory Server. For information about installing and configuring the directory server, see the Sun Java System Directory Server documentation, that is included with the Sun Java Enterprise System.

**Note** – You must have already performed all the procedures described in the installation and configuration documentation that shipped with your Sun Java System Directory Server before you can configure Sun Java System Directory Server to work with Solaris LDAP clients.

**Note** – A directory server (an LDAP server) cannot be its own client.

This chapter covers the following topics.

- “Configuring Sun Java System Directory Server by Using idsconfig” on page 170
- “Using Service Search Descriptors to Modify Client Access to Various Services” on page 172
- “Running idsconfig” on page 174
- “Populating the Directory Server Using ldapaddent” on page 179
- “Managing Printer Entries” on page 180
- “Populating the Directory Server With Additional Profiles” on page 181
- “Configuring the Directory Server to Enable Account Management” on page 182
- “Migrating Your Sun Java System Directory Server” on page 186
Configuring Sun Java System Directory Server by Using idsconfig

Creating a Checklist Based on Your Server Installation

During the server installation process, you will have defined crucial variables, with which you should create a checklist similar to the one below before launching idsconfig. You can use the blank checklist provided in “Blank Checklists” on page 209.

Note – The information included below will serve as the basis for all examples that follow in the LDAP related chapters. The example domain is of an widget company, Example, Inc. with stores nationwide. The examples will deal with the West Coast Division, with the domain west.example.com

<table>
<thead>
<tr>
<th>Variable</th>
<th>Definition for Example Network</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port number at which an instance of the directory server is installed</td>
<td>389 (default)</td>
</tr>
<tr>
<td>Name of server</td>
<td>myserver (from the FQDN myserver.west.example.com or 192.168.0.1)</td>
</tr>
<tr>
<td>Replica server(s) (IP number:port number)</td>
<td>192.168.0.2 [for myreplica.west.example.com]</td>
</tr>
<tr>
<td>Directory manager</td>
<td>cn=directory manager (default)</td>
</tr>
<tr>
<td>Domain name to be served</td>
<td>west.example.com</td>
</tr>
<tr>
<td>Maximum time (in seconds) to process client requests before timing out</td>
<td>-1-</td>
</tr>
<tr>
<td>Maximum number of entries returned for each search request</td>
<td>-1-</td>
</tr>
</tbody>
</table>

Note – If you are using hostnames in defining defaultServerList or preferredServerList, you MUST ensure LDAP is not used for hosts lookup. This means ldap must not be in /etc/nsswitch.conf hosts line.
### TABLE 11-2  Client Profile Variables Defined

<table>
<thead>
<tr>
<th>Variable</th>
<th>Definition for Example Network</th>
</tr>
</thead>
<tbody>
<tr>
<td>Profile name (the default name is default)</td>
<td>WestUserProfile</td>
</tr>
<tr>
<td>Server list (defaults to the local subnet)</td>
<td>192.168.0.1</td>
</tr>
<tr>
<td>Preferred server list (listed in order of which server to try first, second, and so on)</td>
<td>none</td>
</tr>
<tr>
<td>Search scope (number of levels down through the directory tree. 'One', the default, or 'Sub')</td>
<td>one (default)</td>
</tr>
<tr>
<td>Credential used to gain access to server. Default is anonymous</td>
<td>proxy</td>
</tr>
<tr>
<td>Follow Referrals? (a pointer to another server if the main server is unavailable) Default is no.</td>
<td>Y</td>
</tr>
<tr>
<td>Search time limit (default is 30 seconds) for waiting for server to return information.</td>
<td>default</td>
</tr>
<tr>
<td>Bind time limit (default is 10 seconds) for contacting the server.</td>
<td>default</td>
</tr>
<tr>
<td>Authentication method Default is none.</td>
<td>simple</td>
</tr>
</tbody>
</table>

**Note** – Client profiles are defined per domain. At least one profile must be defined for a given domain.

### Attribute Indexes

dconfig indexes the following list of attributes for improved performance.

- member
- nisnetgroup
- nisnetgrouptriple
- ipHostNumber
- uidNumber
- gidNumber
- ipNetworkNumber
- automountkey
- oncRpcNumber

---

Configure Sun Java System Directory Server by Using dconfig

Chapter 11 • Setting Up Sun Java System Directory Server With LDAP Clients (Tasks) 171
Schema Definitions

`idsconfig(1M)` automatically adds the necessary schema definitions. Unless you are very experienced in LDAP administration, do not manually modify the server schema. See Chapter 14, “LDAP General Reference (Reference),” for an extended list of schemas used by the LDAP naming service.

Using Browsing Indexes

The browsing index functionality of the Sun Java System Directory Server, otherwise known as the virtual list view (VLV), provides a way in which a client can view a select group or number of entries from very long list, thus making the search process less time consuming for each client. Browsing indexes provide optimized, predefined search parameters with which the Solaris LDAP naming client can access specific information from the various services more quickly. Keep in mind that if you do not create browsing indexes, the clients may not get all the entries of a given type because the server limits for search time or number of entries might be enforced.

VLV indexes are configured on the directory server and the proxy user has read access to these indexes.

Before configuring browsing indexes on the Sun Java System Directory Server, consider the performance cost associated with using these indexes. For more information, refer to the Administration Guide for the version of Sun Java System Directory Server that you are using.

`idsconfig` creates entries for several VLV indexes. Use the `directoryserver` script to stop the server and to create the actual VLV indexes. See the `idsconfig(1M)` and the `directoryserver(1M)` man pages for more information. Refer to the output of the `idsconfig` command to determine the VLV entries created by `idsconfig` and the syntax of the corresponding `directoryserver` commands that you need to run. See “Example idsconfig Setup” on page 175 for sample `idsconfig` output.

Using Service Search Descriptors to Modify Client Access to Various Services

A service search descriptor (SSD) changes the default search request for a given operation in LDAP to a search you define. SSDs are particularly useful if, for example, you have been using LDAP with customized container definitions or another operating system and are now transitional to the latest Solaris release. Using SSDs, you can configure Solaris LDAP naming services without having to change your existing LDAP database and data.
Setting Up SSDs Using idsconfig

Assume your predecessor at Example, Inc. had configured LDAP, storing users in ou=Users container. You are now upgrading to the latest Solaris release. By definition, Solaris LDAP client assumes that user entries are stored in ou=People container. Thus, when it comes to searching the passwd service, LDAP client will search the ou=people level of the DIT and not find the correct values.

One laborious solution to the above problem would be to completely overwrite Example, Inc.’s existing DIT and to rewrite all the exiting applications on Example, Inc.’s network so that they are compatible with the new LDAP naming service. A second, far preferable solution would be to use an SSD that would tell LDAP client to look for user info in an ou=Users container instead the default ou=people container.

You would define the necessary SSD during the configuration of the Sun Java System Directory Server using idsconfig. The prompt line appears as follows.

Do you wish to setup Service Search Descriptors (y/n/h? y
  A Add a Service Search Descriptor
  D Delete a SSD
  M Modify a SSD
  P Display all SSD’s
  H Help
  X Clear all SSD’s

Q Exit menu
Enter menu choice: [Quit] a
Enter the service id: passwd
Enter the base: service ou=user,dc=west,dc=example,dc=com
Enter the scope: one[default]
  A Add a Service Search Descriptor
  D Delete a SSD
  M Modify a SSD
  P Display all SSD’s
  H Help
  X Clear all SSD’s

Q Exit menu
Enter menu choice: [Quit] p

Current Service Search Descriptors:
==========================================================================
Passwd:ou=Users,ou=west,ou=example,ou=com?

Hit return to continue.
Running idsconfig

A  Add a Service Search Descriptor
D  Delete a SSD
M  Modify a SSD
P  Display all SSD’s
H  Help
X  Clear all SSD’s
Q  Exit menu
Enter menu choice: [Quit] q

Running idsconfig

Note – You do not need special rights to run idsconfig, nor do you need to be an LDAP naming client. Remember to create a checklist as mentioned in “Creating a Checklist Based on Your Server Installation” on page 170 in preparation for running idsconfig. You do not have to run idsconfig from a server or an LDAP naming service client machine. You can run idsconfig from any Solaris machine on the network.

Caution – idsconfig sends the Directory Manager’s password in the clear. If you do not want this to happen, you must run idsconfig on the directory server itself, not on a client.

How to Configure Sun Java System Directory Server by Using idsconfig

1. Make sure the target Sun Java System Directory Server is up and running.

2. Run idsconfig.
   
   # /usr/lib/ldap/idsconfig

   Refer to Example 11–1 for an example run of idsconfig using the definitions listed in the server and client checklists at the beginning of this chapter in “Creating a Checklist Based on Your Server Installation” on page 170.

3. Answer the questions when prompted.
   Note that 'no' [n] is the default user input. If you need clarification on any given question, type h
   and a brief help paragraph will appear.
After idsconfig has completed the setup of the directory, you need to run the specified commands on the server before the server setup is complete and the server is ready to serve clients.

**Example idsconfig Setup**

This section provides an example of a basic idsconfig setup that uses many of the defaults. The most complicated method of modifying client profiles is to create SSDs. Refer to “Using Service Search Descriptors to Modify Client Access to Various Services” on page 172 for a detailed discussion.

The data in square brackets after a prompt indicates the default value for that prompt. To accept the default value, press Return.

**Note** – Any parameters that are left blank in the summary screen are not set up.

After idsconfig has completed the setup of the directory, you need to run the specified commands on the server before the server setup is complete and the server is ready to serve clients.

EXAMPLE 11-1 Running idsconfig for the Example, Inc. Network

In the following example, the idsconfig utility is run immediately after a server instance is created on the LDAP server.

```
# /usr/lib/ldap/idsconfig
It is strongly recommended that you BACKUP the directory server before running idsconfig.

Hit Ctrl-C at any time before the final confirmation to exit.

Do you wish to continue with server setup (y/n/h)? [n] y
Enter the JES Directory Server’s hostname to setup: myserver
Enter the port number for iDS (h=help): [389]
Enter the directory manager DN: [cn=Directory Manager]
Enter passwd for cn=Directory Manager:
Enter the domainname to be served (h=help): [west.example.com]
Enter LDAP Base DN (h=help): [dc=west,dc=example,dc=com]
   Checking LDAP Base DN ...
   Validating LDAP Base DN and Suffix ...
   No valid suffixes were found for Base DN dc=west,dc=example,dc=com
Enter suffix to be created (b=back/h=help): [dc=west,dc=example,dc=com]
Enter ldbm database name (b=back/h=help): [west]
```
EXAMPLE 11-1  Running idsconfig for the Example, Inc. Network  (Continued)

    sasl/GSSAPI is not supported by this LDAP server
Enter the profile name (h=help): [default] WestUserProfile
Default server list (h=help): [192.168.0.1]
Preferred server list (h=help):
Choose desired search scope (one, sub, h=help): [one]
The following are the supported credential levels:
    1  anonymous
    2  proxy
    3  proxy anonymous
    4  self
Choose Credential level [h=help]: [1] 2
The following are the supported Authentication Methods:
    1  none
    2  simple
    3  sasl/DIGEST-MD5
    4  tls:simple
    5  tls:sasl/DIGEST-MD5
    6  sasl/GSSAPI
Choose Authentication Method (h=help): [1] 2

Current authenticationMethod: simple
Do you want to add another Authentication Method? n
Do you want the clients to follow referrals (y/n/h)? [n]
Do you want to modify the server timelimit value (y/n/h)? [n] y
Enter the time limit for iDS (current=3600): [-1]
Do you want to modify the server sizelimit value (y/n/h)? [n] y
Enter the size limit for iDS (current=2000): [-1]
Do you want to store passwords in "crypt" format (y/n/h)? [n] y
Do you want to setup a Service Authentication Methods (y/n/h)? [n]
Client search time limit in seconds (h=help): [30]
Profile Time To Live in seconds (h=help): [43200]
Bind time limit in seconds (h=help): [10]
Do you want to enable shadow update (y/n/h)? [n]
Do you wish to setup Service Search Descriptors (y/n/h)? [n]

Summary of Configuration

1  Domain to serve : west.example.com
2  Base DN to setup : dc=west,dc=example,dc=com
   Suffix to create : dc=west,dc=example,dc=com
   Database to create : west
3  Profile name to create : WestUserProfile
4  Default Server List : 192.168.0.1
5  Preferred Server List : 192.168.0.1
EXAMPLE 11-1  Running idsconfig for the Example, Inc. Network  (Continued)

6  Default Search Scope : one
7  Credential Level : proxy
8  Authentication Method : simple
9  Enable Follow Referrals : FALSE
10 iDS Time Limit : -1
11 iDS Size Limit : -1
12 Enable crypt password storage : TRUE
13 Service Auth Method pam ldap :
14 Service Auth Method keyserv :
15 Service Auth Method passwd-cmd:
16 Search Time Limit : 30
17 Profile Time to Live : 43200
18 Bind Limit : 10
19 Enable shadow update : FALSE
20 Service Search Descriptors Menu

Enter config value to change: (1-20 0=commit changes) [0]
Enter DN for proxy agent: [cn=proxyagent,ou=profile,dc=west,dc=example,dc=com]
Enter passwd for proxyagent:
Re-enter passwd:

WARNING: About to start committing changes. (y=continue, n=EXIT) y

1. Changed timelimit to -1 in cn=config.
2. Changed sizelimit to -1 in cn=config.
3. Changed passwordstoragescheme to "crypt" in cn=config.
4. Schema attributes have been updated.
5. Schema objectclass definitions have been added.
6. Database west successfully created.
7. Suffix dc=west,dc=example,dc=com successfully created.
8. NisDomainObject added to dc=west,dc=example,dc=com.
9. Top level "ou" containers complete.
10. automount maps: auto home auto direct auto master auto shared processed.
11. ACI for dc=west,dc=example,dc=com modified to disable self modify.
13. Proxy Agent cn=proxyagent,ou=profile,dc=west,dc=example,dc=com added.
14. Give cn=proxyagent,ou=profile,dc=west,dc=example,dc=com read permission for password.
15. Generated client profile and loaded on server.
16. Processing eq,pres indexes:
   uidNumber (eq,pres)  Finished indexing.
   ipNetworkNumber (eq,pres)  Finished indexing.
   gidnumber (eq,pres)  Finished indexing.
   oncrpcnumber (eq,pres)  Finished indexing.
   automountKey (eq,pres)  Finished indexing.
17. Processing eq,pres,sub indexes:
   ipHostNumber (eq,pres,sub) Finished indexing.
   membernisnetgroup (eq,pres,sub) Finished indexing.
   nisnetgrouptriple (eq,pres,sub) Finished indexing.
18. Processing VLV indexes:
   west.example.com.getgrent vlv_index Entry created
   west.example.com.gethostent vlv_index Entry created
   west.example.com.getnetent vlv_index Entry created
   west.example.com.getpwent vlv_index Entry created
   west.example.com.getrpcvnt vlv_index Entry created
   west.example.com.getspent vlv_index Entry created
   west.example.com.getauhoent vlv_index Entry created

   west.example.com.getip4ent vlv_index Entry created
   west.example.com.getip6ent vlv_index Entry created

didsconfig: Setup of IDS server myserver is complete.

Note: idsconfig has created entries for VLV indexes.

For DS5.x, use the directoryserver(1m) script on myserver
to stop the server. Then, using directoryserver, follow the
directoryserver examples below to create the actual VLV indexes.

For DS6.x, use dsadm command delivered with DS6.x on myserver
to stop the server. Then, using dsadm, follow the
dsadm examples below to create the actual VLV indexes.

directoryserver -s <server-instance> vlvindex -n west -T west.example.com.getgrent
directoryserver -s <server-instance> vlvindex -n west -T west.example.com.gethostent
directoryserver -s <server-instance> vlvindex -n west -T west.example.com.getnetent
directoryserver -s <server-instance> vlvindex -n west -T west.example.com.getpwent
Populating the Directory Server Using `ldapaddent`

**Note** – Before populating the directory server with data, you must configure the server to store passwords in UNIX `crypt` format if you are using `pam_unix`. If you are using `pam_ldap`, you can store passwords in any format. For more information about setting the password in UNIX `crypt` format, see the Sun Java System Directory Server documents.

`ldapaddent` reads from the standard input (that being an `/etc/filename` like `passwd`) and places this data to the container associated with the service. Client configuration determines how the data will be written by default.
How to Populate Sun Java System Directory Server With User Password Data Using `ldapaddent`

See `ldapaddent(1M)`. See Chapter 9, “LDAP Basic Components and Concepts (Overview),” for information about LDAP security and write-access to the directory server.

- Use the `ldapaddent` command to add `/etc/passwd` entries to the server.

  ```sh
  # ldapaddent -D "cn=directory manager" -f /etc/passwd passwd
  ```

Managing Printer Entries

Adding Printers

To add printer entries to the LDAP directory, use either the `printmgr` configuration tool or the `lpset -n ldap` command-line utility. See `lpset(1M)`. Note that the printer objects added to the directory only define the connection parameter, required by print system clients, of printers. Local print server configuration data is still held in files. A typical printer entry would look like the following:

```ldif
printer-uri=myprinter,ou=printers,dc=mkg,dc=example,dc=com
objectclass=top
objectclass=printerService
objectclass=printerAbstract
objectclass=sunPrinter
printer-name=myprinter
sun-printer-bsdaddr=printsrvr.example.com,myprinter,Solaris
sun-printer-kvp=description=HP LaserJet (PS)
printer-uri=myprinter
```
Using `lpget`:

`lpget(1M)` can be used to list all printer entries known by the LDAP client’s LDAP directory. If the LDAP client’s LDAP server is a replica server, then printers listed might not be the same as that in the master LDAP server depending on the update replication agreement. See `lpget(1M)` for more information.

For example, to list all printers for a given base DN, type the following:

```
# lpget -n ldap list myprinter:
myprinter:
  dn=myprinter,ou=printers,dc=mkt,dc=example,dc=com
  bsdaddr=printsrv.example.com,myprinter,Solaris
  description=HP LaserJet (PS)
```

Populating the Directory Server With Additional Profiles:

Use `ldapclient` with the `genprofile` option to create an LDIF representation of a configuration profile, based on the attributes specified. The profile you create can then be loaded into an LDAP server to be used as the client profile. The client profile can be downloaded by the client by using `ldapclient init`.

Refer to `ldapclient(1M)` for information about using `ldapclient genprofile`.

How to Populate the Directory Server With Additional Profiles Using `ldapclient`:

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2. **Use `ldapclient` with the `genprofile` command.**
   ```
   # ldapclient genprofile \
   -a profileName=myprofile \
   -a defaultSearchBase=dc=west,dc=example,dc=com \
   -a "defaultServerList=192.168.0.1 192.168.0.2:386" \
   > myprofile.ldif
   ```
3  Upload the new profile to the server.
   # ldapadd -h 192.168.0.1 -D "cn=directory manager" -f myprofile.ldif

**Configuring the Directory Server to Enable Account Management**

Account management can be implemented for clients that use `pam_ldap` and for clients that use `pam_unix`.

---

**Caution** – Do not use both `pam_ldap` and `pam_unix` in the same LDAP naming domain. Either all clients use `pam_ldap` or all clients use `pam_unix`. This limitation might indicate that you need a dedicated LDAP server.

---

**For Clients That Use `pam_ldap`**

In order for `pam_ldap` to work properly, the password and account lockout policy must be properly configured on the server. You can use the Directory Server Console or `ldapmodify` to configure the account management policy for the LDAP directory. For procedures and more information, see the “User Account Management” chapter in the Administration Guide for the version of Sun Java System Directory Server that you are using.
Note – Previously, if you enabled pam_ldap account management, all users needed to provide a login password for authentication any time they logged in to the system. Therefore, nonpassword-based logins using tools such as rsh, rlogin, or ssh would fail.

Now, however, pam_ldap(5), when used with Sun Java System Directory Servers DS5.2p4 and newer releases, enables users to log in with rsh, rlogin, rcp and ssh without giving a password. pam_ldap(5) is now modified to perform account management and retrieve the account status of users without authenticating to Directory Server as the user logging in. The new control to this on Directory Server is 1.3.6.1.4.1.42.2.27.9.5.8, which is enabled by default.

To modify this control for other than default, add Access Control Instructions (ACI) on Directory Server:

```
dn: oid=1.3.6.1.4.1.42.2.27.9.5.8,cn=features,cn=config
objectClass: top
objectClass: directoryServerFeature
oid:1.3.6.1.4.1.42.2.27.9.5.8

 cn:Password Policy Account Usable Request Control
 aci: (targetattr != "aci") (version 3.0; acl "Account Usable";
    allow (read, search, compare, proxy)
    (groupdn = "ldap:///cn=Administrators,cn=config");)

 creatorsName: cn=server,cn=plugins,cn=config
 modifiersName: cn=server,cn=plugins,cn=config
```

Passwords for proxy users should never be allowed to expire. If proxy passwords expire, clients using the proxy credential level cannot retrieve naming service information from the server. To ensure that proxy users have passwords that do not expire, modify the proxy accounts with the following script.

```
# ldapmodify -h ldapserver -D administrator DN -w administrator password

 dn: proxy user DN
 DNchangetype: modify
 replace: passwordexpirationtime
 passwordexpirationtime: 20380119031407Z
 EOF
```
Note – pam_ldap account management relies on Sun Java System Directory Server to maintain and provide password aging and account expiration information for users. The directory server does not interpret the corresponding data from shadow entries to validate user accounts. pam_unix, however, examines the shadow data to determine if accounts are locked or if passwords are aged. Since the shadow data is not kept up to date by the LDAP naming services or the directory server, pam_unix should not grant access based on the shadow data. The shadow data is retrieved using the proxy identity. Therefore, do not allow proxy users to have read access to the userPassword attribute. Denying proxy users read access to userPassword prevents pam_unix from making an invalid account validation.

For Clients That Use pam_unix

To enable Solaris LDAP clients to use pam_unix for account management, the server must be set up to enable the updating of shadow data. Unlike pam_ldap account management, pam_unix does not require extra configuration steps. All configuration can be performed by running the idsconfig utility. For a basic idsconfig run, see Example 11–1.

The following shows the output of two idsconfig runs.

The first idsconfig run uses an existing client profile.

# /usr/lib/ldap/idsconfig

It is strongly recommended that you BACKUP the directory server before running idsconfig.

Hit Ctrl-C at any time before the final confirmation to exit.

Do you wish to continue with server setup (y/n/h) [n] y
Enter the JES Directory Server’s hostname to setup: myserver
Enter the port number for iDS (h=help): [389]
Enter the directory manager DN: [cn=Directory Manager]
Enter passwd for cn=Directory Manager :
Enter the domainname to be served (h=help): [west.example.com]
Enter LDAP Base DN (h=help): [dc=west,dc=example,dc=com]
Checking LDAP Base DN ...
Validating LDAP Base DN and Suffix ...
sasl/GSSAPI is not supported by this LDAP server

Enter the profile name (h=help): [default] WestUserProfile

Profile 'WestUserProfile' already exists, it is possible to enable shadow update now. idsconfig will exit after shadow update
is enabled. You can also continue to overwrite the profile or create a new one and be given the chance to enable shadow update later.

Just enable shadow update (y/n/h)? [n] y
Add the administrator identity (y/n/h)? [y]
Enter DN for the administrator: [cn=admin,ou=profile,dc=west,dc=example,dc=com]
Enter passwd for the administrator:
Re-enter passwd:

ADDED: Administrator identity cn=admin,ou=profile,dc=west,dc=example,dc=com.
Proxy ACI LDAP Naming Services proxy_password_read does not exist for dc=west,dc=example,dc=com.
ACI SET: Give cn=admin,ou=profile,dc=west,dc=example,dc=com read/write access to shadow data.
ACI SET: Non-Admin access to shadow data denied.

Shadow update has been enabled.

The second idsconfig run creates a new profile for later use. Only partial output is displayed.

# /usr/lib/ldap/idsconfig

It is strongly recommended that you BACKUP the directory server before running idsconfig.

Hit Ctrl-C at any time before the final confirmation to exit.

Do you wish to continue with server setup (y/n/h)? [n] y
Enter the JES Directory Server’s hostname to setup: myserver
Enter the port number for iDS (h=help): [389]
Enter the directory manager DN: [cn=Directory Manager]
Enter passwd for cn=Directory Manager:
Enter the domainname to be served (h=help): [west.example.com]
Enter LDAP Base DN (h=help): [dc=west,dc=example,dc=com]
Checking LDAP Base DN ...
Validating LDAP Base DN and Suffix ...
sasl/GSSAPI is not supported by this LDAP server

Enter the profile name (h=help): [default] WestUserProfile-new
Default server list (h=help): [192.168.0.1]

Do you want to enable shadow update (y/n/h)? [n] y

Summary of Configuration
1 Domain to serve : west.example.com
2 Base DN to setup : dc=west,dc=example,dc=com
   Suffix to create : dc=west,dc=example,dc=com
3 Profile name to create : WestUserProfile-new

19 Enable shadow update : TRUE

Enter DN for the administrator: [cn=admin,ou=profile,dc=west,dc=example,dc=com]
Enter passwd for the administrator:
Re-enter passwd:

WARNING: About to start committing changes. (y=continue, n=EXIT) y

1. Changed timelimit to -1 in cn=config.
2. Changed sizelimit to -1 in cn=config.
11. ACI for dc=test1,dc=mpklab,dc=sfbay,dc=sun,dc=com modified to
disable self modify.
15. Give cn=admin,ou=profile,dc=west,dc=example,dc=com write permission for shadow.
...

Migrating Your Sun Java System Directory Server

Schema changes were implemented between the release of Sun Java System Directory Server 5.1
(formerly Sun ONE Directory Server) and the release of Sun Java System Directory Server 5.2.
The ldapaddent command now adds objectclass: device to the entries of
ethers/bootparams. Therefore, if you choose to use the LDAP commands to migrate directory
data from Sun Java System Directory Server 5.1 to 5.2, you must use ldapaddent -d to export
data and ldapaddent to import data. Otherwise, if you use the Sun Java System Directory Server
tools db2ldif and ldif2db to migrate data, you must apply Sun Java System Directory Server
5.2 with all patches before migrating the data, or the data import could fail.

For information about configuring the Sun Java System Directory Server 5.2, see the Sun Java
System Directory Server documentation, that is included with the Sun Java Enterprise System.
Chapter 12

Setting Up LDAP Clients (Tasks)

This chapter describes how to set up a Solaris LDAP naming services client. This chapter covers the following topics:

- “Prerequisites to LDAP Client Setup” on page 187
- "LDAP and the Service Management Facility” on page 188
- “Initializing an LDAP Client” on page 189
- “Retrieving LDAP Naming Services Information” on page 199
- “Customizing the LDAP Client Environment” on page 200

Prerequisites to LDAP Client Setup

In order for a Solaris client to use LDAP as a naming service the following needs to be in place.

- The client’s domain name must be served by the LDAP server
- The nsswitch.conf file needs to point to LDAP for the required services
- The client needs to be configured with all the given parameters that define its behavior
- ldap_cachemgr needs to be running on the client
- At least one server for which a client is configured must be up and running

The ldapclient utility is the key to setting up an LDAP client, as it performs all of the above steps, except for starting the server. The rest of this chapter will show examples of how to use the ldapclient utility to set up an LDAP client and use the various other LDAP utilities to get information about, and check the status of, an LDAP client.
LDAP and the Service Management Facility

The LDAP client service is managed by using the Service Management Facility. For an overview of SMF, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the svcadm(1M) and svcs(1) man pages for more details.

- Administrative actions on this service, such as enabling, disabling, or restarting, can be performed by using the svcadm command.

  **Tip** – Temporarily disabling a service by using the -t option provides some protection for the service configuration. If the service is disabled with the -t option, the original settings would be restored for the service after a reboot. If the service is disabled without -t, the service will remain disabled after reboot.

- The Fault Managed Resource Identifier (FMRI) for the LDAP client service is svc:/network/ldap/client:<instance>.

- You can query the status of the LDAP client and ldap_cachemgr by using the svcs command.

  ▪ Example of svcs command and output.

    ```
    # svcs \*ldap\*
    STATE STIME FMRI
    online 15:43:46 svc:/network/ldap/client:default
    ```

  ▪ Example of svcs -l command and output. To get the output shown below, you must use the instance name in the FMRI.

    ```
    # svcs -l network/ldap/client:default
    fmri       svc:/network/ldap/client:default
    enabled    true
    state      online
    next_state none
    restarter  svc:/system/svc/restarter:default
    contract_id 1598
    dependency require_all/none file://localhost/var/ldap/ldap_client_file (-)
    dependency require_all/none svc:/network/initial (online)
    dependency require_all/none svc:/system/filesystem/minimal (online)
    ```

  ▪ You can check a daemon’s presence by using the ps command.

    ```
    # ps -e | grep slapd
    root 23320 1 0 Aug 27 ? 16:30 ./ns-slapd -D
    root 25367 25353 0 15:35:19 pts/1 0:00 grep slapd
    ```
Note – Do not use the -f option with ps because this option attempts to translate user IDs to names, which causes more naming service lookups that might not succeed.

Initializing an LDAP Client

*ldapclient*(1M) is a utility used to set up LDAP clients in the Solaris system. *ldapclient* assumes the server has already been configured with the appropriate client profiles. You must install and configure the server with the appropriate profiles before you can set up clients.

Note – The Solaris OS does not support a configuration in which an NIS client and a native LDAP client co-exist on the same client system.

There are two main ways to set up a client by using *ldapclient*.

- **Profile**
  At a minimum, you need to specify the server address containing the profile and domain you want to use. If no profile is specified, then the "default" profile is assumed. The server will provide the rest of the required information, except for proxy and certificate database information. If a client’s credential level is *proxy* or *proxy anonymous*, you must supply the proxy bind DN and password. See “Assigning Client Credential Levels” on page 147 for more information.
  
  To enable shadow data update, you must provide the admin credential (adminDN plus adminPassword).

- **Manual**
  You configure the profile on the client itself, which means that you define all parameters from the command line. Thus, the profile information is stored in cache files and is never refreshed by the server.

Note – Though you can manually configure clients, it is not recommended. Using the configuration profiles decreases the complexity and cost of managing clients.
Using Profiles to Initialize a Client

▼ How to Initialize a Client Using Profiles

1 Become superuser or assume an equivalent role.
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, "Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2 Run `ldapclient init`.
   
   ```
   # ldapclient init \
   -a profileName=new \
   -a domainName=west.example.com 192.168.0.1
   System successfully configured
   ```

Using Per-User Credentials

Note – Do not edit either of the client configuration files directly. Use the `ldapclient` command to create or modify the content of these files.

▼ How to Initialize a Client Using Per-User Credentials

Before You Begin

Before you set up a client with per-user credentials the following items must already be configured:

- One or more Kerberos KDC servers must be configured and running.
- DNS, client access to a DNS server, and at least one DNS server, must be configured and running.
- Kerberos on the client machine must be configured and enabled.
- A Kerberos client installation profile must exist. Such a profile might be:
  
  ```
  # cat /usr/tmp/krb5.profile
  REALM SPARKS.COM
  KDC kdc.example.com
  ADMIN super/admin
  FILEPATH /usr/tmp/krb5.conf
  NFS 1
  DNSLOOKUP none
  ```
- The LDAP server must be installed and configured to support the sasl/GSSAPI.
- Appropriate identity mapping configurations must exist.
- Kerberos host principals for the directory server and the KDC must be set up in the KDC.
idsconfig must have been run on the directory server DIT to be used.

An appropriate per-user gssapi profile (such as gssapi_EXAMPLE.COM) must have been created.

An illustration of a per-user profile in idsconfig is shown in the following partial example:

```
#/usr/lib/ldap/idsconfig
Do you wish to continue with server setup (y/n/h)? [n] y
Enter the iPlanet Directory Server’s (iDS) hostname to setup: kdc.example.com
Enter the port number for iDS (h=help): [389] <Enter your port>
Enter the directory manager DN: [cn=Directory Manager] <Enter your DN>
Enter passwd for cn=Directory Manager: <Enter your password>
Enter the domainname to be served (h=help): [example.com] <Enter your domain>
Enter LDAP Base DN (h=help): [dc=example,dc=com] <Enter your DN>
GSSAPI is supported. Do you want to set up gssapi: (y/n) [n] y
Enter Kerberos Realm: [EXAMPLE.COM] EXAMPLE.COM
```

**Note** – In addition, for a gssapi profile, you must supply a credential level of 4 self and the authentication method of 6 sasl/GSSAPI.

The necessary user principals must exist in the Key Distribution Center (KDC).

On the client machine, Kerberos must be initialized using the client profile with a command such as:

```
#/usr/sbin/kclient -p /usr/tmp/krb5.profile
```

/etc/nsswitch.ldap must be configured to use dns for hosts and ipnodes. Modify this file with an editor as necessary, as in the following:

```
host: files dns
ipnodes: files dns
```

/etc/resolv.conf must be configured and the dns service must be running. See the DNS chapters in this document for details.

The directory server DIT must be pre-loaded with (at a minimum) the users of this client machine, the client host and necessary auto_home LDAP entries. See other sections of this manual for details on how to add entries using ldapaddent.

1. **Run ldapclient init** to initialize the client by using the gssapi profile:

   ```
   # /usr/sbin/ldapclient init -a profilename=gssapi_SPARKS.COM -a domainname=example.com 9.9.9.50
   ```

2. **Try to log in as a user:**

   Run `kinit -p user`

   Run `ldaplist -l passwd` user in user’s login session and you should see “userpassword.”
But `ldaplist -l passwd bar` can get the entry without `userpassword`. By default root can still see `userpassword` of everybody.

**More Information**

**Notes About Using Per-User Credentials**

- If the syslog has messages: `libsldap: Status: 7 Mesg: openConnection: GSSAPI bind failed - 82 Local error`, it is likely that Kerberos is not initialized or its ticket is expired. Run `klist` to browse it. Run `kinit -p foo` or `kinit -R -p foo` and try again.
- If you want to, you can add `pam_krb5.so.1` to `/etc/pam.conf` so it will automatically `kinit` when you log in.
- For example:
  ```
  login auth optional pam_krb5.so.1
  rlogin auth optional pam_krb5.so.1
  other auth optional pam_krb5.so.1
  ```
- If a user is `kinit`ed and the syslog message indicates `Invalid credential`, then the problem could be the host entry (root) or user entry is not in LDAP directory or mapping rules are not correct.
- When `ldapclient init` is executed, it makes some checks if the LDAP profile contains `self/sasl/GSSAPI` configuration. If it fails at `/etc/nsswitch.ldap` check, then the usual reason is that `dns` was not added to `host:` and `ipnodes:`.
- If it fails because the DNS client not enabled, run `svcs -l dns/client` to see if `/etc/resolv.conf` is missing or it is just disabled. Run `svcadm enable dns/client` to enable it.
- If the check fails because of `sasl/GSSAPI` bind, check `syslog` to find out what went wrong.

See other references in this guide and in the *System Administration Guide: Security Services* for details.

**Using Proxy Credentials**

**How to Initialize a Client Using Proxy Credentials**

*Note – Do not edit either of the client configuration files directly. Use `ldapclient` to create or modify the content of these files.*

1. **Become superuser or assume an equivalent role.**

Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in *System Administration Guide: Security Services.*
2 Run `ldapclient (defining proxy values).

```
# ldapclient init \
- a proxyDN=cn=proxyagent,ou=profile,dc=west,dc=example,dc=com \
- a domainName=west.example.com \
- a profileName=pit1 \
- a proxyPassword=test1234 192.168.0.1
```

System successfully configured

The `-a proxyDN` and `-a proxyPassword` are required if the profile to be used is set up for proxy. As the credentials are not stored in the profile saved on the server, you must supply the information when you initialize the client. This method is more secure than the older method of storing the proxy credentials on the server.

The proxy information is used to create `/var/ldap/ldap_client_cred`. The rest of the information is put in `/var/ldap/ldap_client_file`.

---

**Enabling Shadow Updating in LDAP**

**How to Initialize a Client to Enable the Updating of Shadow Data**

1 Become superuser or assume an equivalent role.

Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2 To set the `enableShadowUpdate` switch and define the admin credential, run the `ldapclient` command.

- To update an already running client, run this command:
  ```
  # ldapclient mod -a enableShadowUpdate=TRUE \
  - a adminDN=cn=admin,ou=profile,dc=west,dc=example,dc=com \
  - a adminPassword=admin-password
  System successfully configured
  ```

- To initialize a client, run this command:
  ```
  # ldapclient init \
  - a adminDN=cn=admin,ou=profile,dc=west,dc=example,dc=com \
  - a adminPassword=admin-password \
  - a domainName=west.example.com \
  - a profileName=WestUserProfile \
  - a proxyDN=cn=proxyagent,ou=profile,dc=west,dc=example,dc=com \
  - a proxyPassword=i<proxy_password> \
  192.168.0.1
  System successfully configured
  ```
To verify the configuration, display the contents of the /var/ldap/ldap_client_cred file.
The output should contain lines similar to the following:

```
# cat /var/ldap/ldap_client_cred

NS_LDAP_BINDDN= cn=proxyagent,ou=profile,dc=west,dc=example,dc=com
NS_LDAP_BINDPASSWD= {NS1}4a3788f8eb85de11
NS_LDAP_ENABLE_SHADOW_UPDATE= TRUE
NS_LDAP_ADMIN_BINDDN= cn=admin,ou=profile,dc=west,dc=example,dc=com
NS_LDAP_ADMIN_BINDPASSWD= {NS1}4a3788f8c053434f
```

### Initializing a Client Manually

Superusers or administrators with an equivalent role, can perform manual client configurations. However, many of the checks are bypassed during the process, so it is relatively easy to misconfigure your system. In addition, you must change settings on every machine, instead of in one central place, as is done when using profiles.

▶ **How to Initialize a Client Manually**

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in *System Administration Guide: Security Services*.

2. **Use `ldapclient manual` to initialize the client.**
   ```
   # ldapclient manual \
   -a domainName=dc=west.example.com \
   -a credentialLevel=proxy \
   -a defaultSearchBase=dc=west,dc=example,dc=com \
   -a proxyDN=cn=proxyagent,ou=profile,dc=west,dc=example,dc=com \
   -a proxyPassword=testtest 192.168.0.1
   ```

3. **Use `ldapclient list` to verify.**
   ```
   NS_LDAP_FILE_VERSION= 2.0
   NS_LDAP_BINDDN= cn=proxyagent,ou=profile,dc=west,dc=example,dc=com
   NS_LDAP_BINDPASSWD= {NS1}4a3788e8c053424f
   NS_LDAP_SERVERS= 192.168.0.1
   NS_LDAP_SEARCH_BASEDN= dc=west,dc=example,dc=com
   NS_LDAP_CREDENTIAL_LEVEL= proxy
   ```
Modifying a Manual Client Configuration

▼ How to Modify a Manual Configuration

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2. **Use the `ldapclient mod` command to change the authentication method to simple.**
   ```bash
   # ldapclient mod -a authenticationMethod=simple
   ```

3. **Use `ldapclient list` to verify the change was made.**
   ```bash
   # ldapclient list
   NS_LDAP_FILE_VERSION= 2.0
   NS_LDAP_BINDDN= cn=proxyagent,ou=profile,dc=west,dc=example,dc=com
   NS_LDAP_BINDPASSWD= {NS1}4a3788e8c053424f
   NS_LDAP_SERVERS= 192.168.0.1
   NS_LDAP_SEARCH_BASEDN= dc=west,dc=example,dc=com
   NS_LDAP_AUTH= simple
   NS_LDAP_CREDENTIAL_LEVEL= proxy
   ```

**Troubleshooting**

You cannot change some attributes of an LDAP client configuration by using the `mod` subcommand. For example, you cannot change the `profileName` and `profileTTL` attributes. To change these attributes, create a new profile by using the `ldapclient init` command, as described in “Using Profiles to Initialize a Client” on page 190. Or, run the `ldapclient manual` command, as described in “Initializing a Client Manually” on page 194.

Uninitializing a Client

`ldapclient uninit` restores the client name service to what it was prior to the most recent `init`, `modify`, or `manual` operation. In other words, it performs an “undo” on the last step taken. For example, if the client was configured to use `profile1` and was then changed to use `profile2`, using `ldapclient uninit` would revert the client back to using `profile1`.

▼ How to Uninitialize a Client

1. **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.
Use ldapclient uninit.

```bash
# ldapclient uninit
System successfully recovered
```

## Setting Up TLS Security

**Note** – The security database files must be readable by everyone. Do not include any private keys in the key3.db.

If using TLS, the necessary security databases must be installed. In particular, the certificate and key database files are needed. For example, if you adopt an older database format from Netscape Communicator, two files, cert7.db and key3.db, are required. Or, if you use a newer database format from Mozilla, three files, cert8.db, key3.db and secmod.db are needed. The cert7.db or cert8.db file contains trusted certificates. The key3.db file contains the client's keys. Even if the LDAP naming service client does not use client keys, this file must be present. The secmod.db file contains the security modules such as PKCS#11 module. This file is not required if the older format is used.

**Note** – Before running ldapclient, you should set up and install the needed security database files described in this section.

See the section about configuring LDAP clients to use SSL in the “Managing SSL” chapter of the Administrator’s Guide for the version of Sun Java System Directory Server you are using. For information on how to create and manage these files. Once configured, these files must be stored in the location expected by the LDAP naming services client. The attribute certificatePath is used to determine this location. This is by default /var/ldap.

For example, after setting up the necessary cert7.db and key3.db files using Netscape Communicator™, copy the files to the default location.

```bash
# cp $HOME/.netscape/cert7.db /var/ldap
# cp $HOME/.netscape/key3.db /var/ldap
```

Next, give everyone read access.

```bash
# chmod 444 /var/ldap/cert7.db
# chmod 444 /var/ldap/key3.db
```
Note – While Netscape manages the `cert7.db` and `key3.db` files in the `$HOME/.netscape` directory, Mozilla has its `cert8.db`, `key3.db` and `secmod.db` files managed in a sub-directory under `$HOME/.mozilla`. Copies of these security databases must be stored on a local file system if you are using them for an LDAP naming services client.

**Configuring PAM**

`pam_ldap` is one authentication and account management PAM module option for LDAP. See the `pam_ldap(5)` man page for more information about the features currently supported with `pam_ldap`.

If you have selected both the per-user mode and the self credentials option, then you must also enable the PAM Kerberos `pam_krb5(5)` pam modules. See `pam_krb5(5)` and the *System Administration Guide: Security Services* documentation for further details.

**Configuring PAM to Use UNIX policy**

To configure PAM to use UNIX policy, follow the sample in “Example `pam.conf` File for `pam_ldap`” on page 213. Add the lines that contain `pam_ldap.so.1` to the client's `/etc/pam.conf` file. For details, see the `pam.conf(4)` man page.

**Configuring PAM to Use LDAP server_policy**

To configure PAM to use LDAP `server_policy`, follow the sample in “Example `pam.conf` file for `pam_ldap` Configured for Account Management” on page 215. Add the lines that contain `pam_ldap.so.1` to the client's `/etc/pam.conf` file. In addition, if any PAM module in the sample `pam.conf` file specifies the binding flag and the `server_policy` option, use the same flag and option for the corresponding module in the client's `/etc/pam.conf` file. Also, add the `server_policy` option to the line that contains the service module `pam_auth_tok_store.so.1`. 
Note – Previously, if you enabled pam_ldap account management, all users needed to provide a login password for authentication any time they logged in to the system. Therefore, nonpassword-based logins using tools such as rsh, rlogin, or ssh would fail.

Now, however, pam_ldap(5), when used with Sun Java System Directory Servers DS5.2p4 and newer releases, enables users to log in with rsh, rlogin, rcp and ssh without giving a password.

pam_ldap(5) is now modified to perform account management and retrieve the account status of users without authenticating to Directory Server as the user logging in. The new control to this on Directory Server is 1.3.6.1.4.1.42.2.27.9.5.8, which is enabled by default.

To modify this control for other than default, add Access Control Instructions (ACI) on Directory Server:

dn: oid=1.3.6.1.4.1.42.2.27.9.5.8,cn=features,cn=config
objectClass: top
objectClass: directoryServerFeature
oid:1.3.6.1.4.1.42.2.27.9.5.8
cn:Password Policy Account Usable Request Control
aci: (targetattr != "aci") (version 3.0; acl "Account Usable";
   allow (read, search, compare, proxy)
   (groupdn = "ldap:///cn=Administrators,cn=config");)
creatorsName: cn=server,cn=plugins,cn=config
modifiersName: cn=server,cn=plugins,cn=config

- The binding control flag

  Using the binding control flag allows a local password override of a remote (LDAP) password. For example, if a user account is found on both the local files and the LDAP namespace, the password associated with the local account takes precedence over the remote password. Thus, if the local password expires, authentication fails even if the remote LDAP password is still valid.

- The server_policy option

  The server_policy option instructs pam_unix_auth, pam_unix_account, and pam_passwd_auth to ignore a user found in the LDAP namespace and to allow pam_ldap to perform authentication or account validation. In the case of pam_authok_store, a new password is passed to the LDAP server without encryption. The password is thereby stored in the directory according to the password encryption scheme configured on the server. For more information, see pam.conf(4) and pam_ldap(5).
Retrieving LDAP Naming Services Information

You can retrieve information about LDAP naming services by using the `ldaplist` utility. This LDAP utility lists the naming information from the LDAP servers in LDIF format. It can be useful for troubleshooting. See `ldaplist(1)` for further information.

Listing All LDAP Containers

`ldaplist` displays its output with a blank line separating records, which is helpful for big multiline records.

*Note* – The output of `ldaplist` depends upon the client configuration. For example, if the value of `ns ldap_search` is `sub` rather than `one`, `ldaplist` lists all the entries under the current search baseDN.

The following is an example of `ldaplist` output.

```
# ldaplist
dn: ou=people,dc=west,dc=example,dc=com
dn: ou=group,dc=west,dc=example,dc=com
dn: ou=rpc,dc=west,dc=example,dc=com
dn: ou=protocols,dc=west,dc=example,dc=com
dn: ou=networks,dc=west,dc=example,dc=com
dn: ou=netgroup,dc=west,dc=example,dc=com
dn: ou=aliases,dc=west,dc=example,dc=com
dn: ou=hosts,dc=west,dc=example,dc=com
dn: ou=services,dc=west,dc=example,dc=com
dn: ou=ethers,dc=west,dc=example,dc=com
dn: ou=profile,dc=west,dc=example,dc=com
```

```
dn: automountmap=auto_home,dc=west,dc=example,dc=com
```

```
dn: automountmap=auto_direct,dc=west,dc=example,dc=com
```
Listing All User Entry Attributes

To list specific information such as a user's passwd entry, use getent as follows:

```
# getent passwd user1
user1::30641:10:Joe Q. User:/home/user1:/bin/csh
```

If you want to list all attributes, use ldaplist with the -l option.

```
# ldaplist -l passwd user1
  dn: uid=user1,ou=People,dc=west,dc=example,dc=com
  uid: user1
cn: user1
uidNumber: 30641
gidNumber: 10
gecos: Joe Q. User
homeDirectory: /home/user1
loginShell: /bin/csh
objectClass: top
objectClass: shadowAccount
objectClass: account
objectClass: posixAccount
shadowLastChange: 6445
```

Customizing the LDAP Client Environment

The following sections describe how you can customize the client environment.

You can change any of the services, but be careful, because if the data is not populated on the server for the service specified, things will stop working. Also, in some cases files may not be set up by default.

Modifying the nsswitch.conf File for LDAP

You can modify your /etc/nsswitch.conf file to customize where each service gets its information. The default settings are stored in /etc/nsswitch.ldap and ldapclient uses this file to create your /etc/nsswitch.conf file when the client is initialized.
Enabling DNS With LDAP

If you want to enable DNS by setting up a `/etc/resolv.conf` file, add DNS to your hosts lines as shown below.

hosts: ldap dns [NOTFOUND=return] files

The recommended configuration is:

hosts: files dns

ipnodes: files dns

If per-user authentication is used, the `sasl/GSSAPI` and Kerberos mechanisms expect the dns naming service to be configured and enabled. See the chapters on DNS in this administration guide for further details.
This chapter describes configuration problems and suggests solutions for resolving them.

Note – The LDAP service is managed by the Service Management Facility. Administrative actions on this service, such as enabling, disabling, or restarting, can be performed by using the `svcadm` command. See “LDAP and the Service Management Facility” on page 188 for more information about using the Facility with LDAP. For an overview of the Facility, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the `svcadm(1M)` and `svcs(1)` man pages for more details.

### Monitoring LDAP Client Status

The following sections show various commands to help determine the state of the LDAP client environment. Also see the man pages for additional information about the options that can be used.

For an overview of the Service Management Facility, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the `svcadm(1M)` and `svcs(1)` man pages for more details.

#### Verifying `ldap_cachemgr` Is Running

The `ldap_cachemgr` daemon must be running and functioning correctly at all times. Otherwise, the system doesn’t work. When you start the LDAP client, the client starts `ldap_cachemgr` daemon automatically. So, if the `ldap_cachemgr` is not running, the LDAP client will be disabled. Following are two methods for determining if the LDAP client is online.

- Use the `svcs` command.

```
  # svcs "*ldap\*"
  STATE STIME FMRI
```
### Monitoring LDAP Client Status

```
disabled Aug 24 svc:/network/ldap/client:default
```

or

```
# svcs -l network/ldap/client:default
fmri svc:/network/ldap/client:default
enabled true
state online
next_state none
resterter svc:/system/svc/restarter:default
contract_id 1598
dependency require_all/none file://localhost/var/ldap/ldap_client_file (-)
dependency require_all/none svc:/network/initial (online)
dependency require_all/none svc:/system/filesystem/minimal (online)
```

- Pass the `-g` option to `ldap_cachemgr`.
  This option provides more extensive status information, which is useful when you diagnose a problem.

```
# /usr/lib/ldap/ldap_cachemgr -g
cachemgr configuration:
  server debug level 0
  server log file "/var/ldap/cachemgr.log"
  number of calls to ldapcachemgr 19

  cachemgr cache data statistics:
  Configuration refresh information:
    Previous refresh time: 2001/11/16 18:33:28
    Next refresh time: 2001/11/16 18:43:28
  Server information:
    Previous refresh time: 2001/11/16 18:33:28
    Next refresh time: 2001/11/16 18:36:08
    server: 192.168.0.0, status: UP
    server: 192.168.0.1, status: ERROR
    error message: Can't connect to the LDAP server
  Cache data information:
    Maximum cache entries: 256
    Number of cache entries: 2
```

For more information about the `ldap_cachemgr` daemon, see the `ldap_cachemgr(1M)` man page.

### Checking the Current Profile Information

Become superuser or assume an equivalent role, and run `ldapclient` with the `list` option.

```
# ldapclient list
NS_LDAP_FILE_VERSION= 2.0
NS_LDAP_BINDDN= cn=proxyagent,ou=profile,dc=west,dc=example,dc=com
```
Currently the /var/ldap files are in ASCII format. Because the files could change to binary at some time, concatenating the files would cause problems. `ldapclient list` is the supported method for accessing this information. See the `ldapclient(1M)` man page for more information.

### Verifying Basic Client-Server Communication

The best way to show that your client is talking to the LDAP server is with the `ldaplist` command. Using `ldaplist` with no arguments dumps all the containers on the server. This works as long as the containers exist, and do not have to be populated. See the `ldaplist(1)` man page for more information.

If the first step works, you can try `ldaplist passwd username` or `ldaplist hosts hostname` but if they contain lots of data you might want to pick a less populated service, or pipe them to `head` or `more`.

### Checking Server Data From a Non-Client Machine

Most of the commands in the previous sections assume you already have created an LDAP client. If you have not created a client and want to check the data on the server, use the `ldapsearch` command. The following example lists all of the containers.

```
# ldapsearch -h server1 -b "dc=west,dc=example,dc=com" -s one "objectclass=*"
```

In Solaris 9 and earlier releases, the `ldapsearch` command, by default, produced output in a nonstandard textual representation. The default output for `ldapsearch` in later Solaris releases is the industry standardized LDIF format that is defined by RFC-2849. All versions of `ldapsearch` can output LDIF format using the `-L` option.
LDAP Configuration Problems and Solutions

The following sections describe LDAP configuration problems and suggests solutions to the problems.

Unresolved Hostname

The Solaris platform LDAP client back end returns fully qualified host names for host lookups, such as host names returned by gethostbyname() and getaddrinfo(). If the name stored is qualified, that is, contains at least one dot, the client returns the name as is. For example, if the name stored is hostB.eng, the returned name is hostB.eng.

If the name stored in the LDAP directory is not qualified (it does not contain a dot), the client back end appends the domain part to the name. For example, if the name stored is hostA, the returned name is hostA.domainname.

Unable to Reach Systems in the LDAP Domain Remotely

If the DNS domain name is different from the LDAP domain name, then the LDAP naming service cannot be used to serve host names unless the host names are stored fully qualified.

Login Does Not Work

LDAP clients use the PAM modules for user authentication during login. When using the standard UNIX PAM module, the password is read from the server and checked on the client side. This can fail due to one of the following reasons:

1. ldap is not used by the passwd service in the /etc/nsswitch.conf file.

2. The user’s userPassword attribute on the server list is not readable by the proxy agent. You need to allow at least the proxy agent to read the password because the proxy agent returns it to the client for comparison. pam_ldap does not require read access to the password.

3. The proxy agent might not have the correct password.

4. The entry does not have the shadowAccount object class.

5. No password is defined for the user.

   When you use ldapaddent, you must use the -p option to ensure that the password is added to the user entry. If you use ldapaddent without the -p option, the user’s password is not stored in the directory unless you also add the /etc/shadow file by using ldapaddent.

6. No LDAP servers are reachable.
Check the status of the servers.

```
# /usr/lib/ldap/ldap_cachemgr -g
```

7. `pam.conf` is configured incorrectly.

8. The user is not defined in the LDAP namespace.

9. `NS_LDAP_CREDENTIAL_LEVEL` is set to `anonymous` for `pam_unix`, and `userPassword` is not available to anonymous users.

10. The password is not stored in `crypt` format.

11. If `pam_ldap` is configured to support account management, login failure could be the result of one of the following:
   - The user's password has expired.
   - The user's account is locked out due to too many failed login attempts.
   - The user's account has been deactivated by the administrator.
   - The user tried to log in using a nonpassword-based program, such as `rsh`, `rlogin`, `ssh`, or `sftp`.

12. If per-user authentication and `sasl/GSSAPI` are being used, then some component of Kerberos or the `pam_krb5` configuration is setup incorrectly. Refer to the `System Administration Guide: Security Services` for details on resolving these issues.

**Lookup Too Slow**

The LDAP database relies on indexes to improve search performance. A major performance degradation occurs when indexes are improperly configured. The documentation includes a common set of attributes that should be indexed. You can also add your own indexes to improve performance at your site.

**ldapclient Cannot Bind to Server**

`ldapclient` failed to initialize the client when using the `init` option with the `profileName` attribute specified. Possible reasons for failure include the following:

1. The incorrect domain name was specified on the command line.

2. The `nisDomain` attribute is not set in the DIT to represent the entry point for the specified client domain.

3. Access control information is not set up properly on the server, thus disallowing anonymous search in the LDAP database.

4. An incorrect server address passed to the `ldapclient` command. Use `ldapsearch` to verify the server address.
5. An incorrect profile name passed to the `ldapclient` command. Use `ldapsearch` to verify the profile name in the DIT.

6. Use `snoop` on the client's network interface to see what sort of traffic is going out, and determine to which server it is talking.

**Using `ldap_cachemgr` for Debugging**

Using `ldap_cachemgr` with the `-g` option can be a useful way to debug, as you can view the current client configuration and statistics. For example,

```
# ldap_cachemgr -g
```

would print current configuration and statistics to standard output, including the status of all LDAP servers, as mentioned previously. Note that you do not need to become super user to execute this command.

**ldapclient Hangs During Setup**

If the `ldapclient` command hangs, pressing Ctrl-C will exit after restoring the previous environment. If this happens, check with the server administrator to ensure that the server is running.

Also check the server list attributes in either the profile or from the command line and make sure that the server information is correct.
This chapter covers the following topics.

1. “Blank Checklists” on page 209
2. “LDAP Upgrade Information” on page 210
3. “LDAP Commands” on page 212
4. “Example pam.conf File for pam_ldap” on page 213

**LDAP Upgrade Information**

This section provides information to consider when upgrading from the Solaris 8 release to a Solaris 9 or later release.

**Compatibility**

Clients configured on Solaris 9 or later Solaris software releases are fully compatible with directory servers set up to serve Solaris 8 clients, which only support version 1 profiles. However, to take advantage of newer features built into Solaris 9 and later releases, and to use the newer security model, you must use version 2 profiles.
Servers can serve a mix of both old and new clients. Clients see the same results from the server as long as schema mapping is not enabled and version 2 profiles are not configured to use special filters with the serviceSearchDescriptors attribute. Obviously if the server is not using the default schema, older clients cannot use that server as Solaris 8 clients cannot arbitrarily map nondefault schema.

**Running the `ldap_cachemgr` Daemon**

Beginning with the Solaris 9 release, the `ldap_cachemgr` daemon must be running at all times. The daemon is required for the client to function properly. When you use the Service Management Facility’s `svcadm` command to start the LDAP client, the `ldap_cachemgr` daemon is automatically invoked. See the `ldap_cachemgr(1M)` man page for more information.

**New automount Schema**

Beginning with the Solaris 9 release, by default the Solaris software uses a new schema for automount entries. This new schema replaces the generic NIS map schema that Solaris 8 clients used. This means that if you set up a server with Solaris 9 or later software tools, Solaris 8 clients cannot see the automount entries. For sites where the server being set up is to serve both Solaris 8 and later Solaris software clients, a profile can be created to map the schema to the old one before adding automounter entries. This would ensure that `ldapaddent(1M)` adds the entries using the old schema. However, note that this would also mean that all clients based on Solaris 9 or later software must use a profile where the schema for automount is mapped.

You need to add the following mapping attributes to your profile for this mapping to take effect.

- `attributeMap: automount:automountMapName=nisMapName`
- `attributeMap: automount:automountKey=cn`
- `objectclassMap: automount:automountInformation=nisMapEntry`
- `objectclassMap: automount:automountMap=nisMap`

**pam_ldap Changes**

The Solaris 10 OS release introduced several changes to `pam_ldap`, identified in the following list. Also, see the `pam_ldap(5)` man page for more information.

- The previously supported `use_first_pass` and `try_first_pass` options are obsolete as of the Solaris 10 software release. These options are no longer needed, may safely be removed from `pam.conf`, and are silently ignored. They may be removed in a future release.
- Password prompting must be provided for by stacking `pam_authtok_get` before `pam_ldap` in the authentication and password module stacks, and by including `pam_passwd_auth` in the `passwd` service auth stack.
The previously supported password update function is replaced in this release by the previously recommended use of `pam_authtok_store` with the `server_policy` option.

An upgrade to this release will not automatically update the existing `pam.conf` file to reflect the above changes. If the existing `pam.conf` file contains a `pam_ldap` configuration, you will be notified after the upgrade by the CLEANUP file. You will need to examine the `pam.conf` file and modify it, as needed.

It is not possible to provide a clean automatic update for the changes listed above, primarily password prompting and password update, due to the relevance of other modules used in the same stack and also due to the existence of third party modules.

See `pam_passwd_auth(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, and `pam.conf(4)` man pages for more information.

## LDAP Commands

There are two sets of LDAP-related commands in the Solaris system. One set is the general LDAP tools, which do not require the client to be configured with LDAP naming services. The second set uses the common LDAP configuration on the client and therefore can only be used if the client is configured to use LDAP as its naming service.

### General LDAP Tools

LDAP command line tools support a common set of options, including authentication and bind parameters. The following tools support a common text-based format for representing directory information called the LDAP Data Interchange Format (LDIF). These commands can be used to manipulate directory entries directly.

- `ldapsearch(1)`
- `ldapmodify(1)`
- `ldapadd(1)`
- `ldapdelete(1)`
LDAP Tools Requiring LDAP Naming Services

<table>
<thead>
<tr>
<th>Tool</th>
<th>Function</th>

other password requisite pam_authtok_check.so.1
other password required pam_authtok_store.so.1
#
# Support for Kerberos V5 authentication and example configurations can
# be found in the pam_krb5(5) man page under the "EXAMPLES" section.
#
Example pam_conf file for pam_ldap Configured for Account Management

Note – Previously, if you enabled pam_ldap account management, all users needed to provide a login password for authentication any time they logged in to the system. Therefore, nonpassword-based logins using tools such as rsh, rlogin, or ssh would fail.

Now, however, pam_ldap(5), when used with Sun Java System Directory Servers DS5.2p4 and newer releases, enables users to log in with rsh, rlogin, rcp and ssh without giving a password.

pam_ldap(5) is now modified to perform account management and retrieve the account status of users without authenticating to Directory Server as the user logging in. The new control to this on Directory Server is 1.3.6.1.4.1.42.2.27.9.5.8, which is enabled by default.

To modify this control for other than default, add Access Control Instructions (ACI) on Directory Server:

```
dn: oid=1.3.6.1.4.1.42.2.27.9.5.8, cn=features, cn=config
objectClass: top
objectClass: directoryServerFeature
oid:1.3.6.1.4.1.42.2.27.9.5.8

# Authentication management

#

IETF Schemas for LDAP

Schemas are definitions that describe what types of information can be stored as entries in a server’s directory.

For a directory server to support Solaris LDAP naming clients, schemas defined in this chapter must be configured in the server unless schema is mapped using the schema mapping feature of the clients.

There are three required LDAP schemas defined by IETF: the RFC 2307 Network Information Service schema, the LDAP Mailgroups Internet draft, and the LDAP Internet Print Protocol (IPP) draft schema. To support the Naming Information Service, the definition of these schemas must be added to the directory server. The various RFCs can also be accessed on the IETF Web site http://www.ietf.org.

---

Note – Internet drafts are draft documents valid for a maximum of six months and might be updated, or rendered obsolete, by other documents at any time.

---

RFC 2307 Network Information Service Schema

The LDAP servers must be configured to support the revised RFC 2307.

The nisSchema OID is 1.3.6.1.1. The RFC 2307 attributes are the following.

```plaintext
(nisSchema.1.0 NAME 'uidNumber'
DESC 'An integer uniquely identifying a user in an administrative domain'
EQUALITY integerMatch SYNTAX 'INTEGER' SINGLE-VALUE )

Mail Alias Schema

Mail alias information uses the schema defined by the LDAP Mailgroups Internet draft, formerly known as the draft-steinback-ldap-mailgroups draft. Until a new schema becomes available, Solaris LDAP clients will continue to use this schema for mail alias information.

The original LDAP Mailgroups schema contains a large number of attributes and object classes. Only two attributes and a single object class are used by Solaris clients. These are listed below.

The mail alias Attributes are the following.

( 0.9.2342.19200300.100.1.3
  NAME 'mail'
  DESC 'RFC822 email address for this person'
  EQUALITY caseIgnoreIA5Match
  SYNTAX 'IA5String(256)'
  SINGLE-VALUE )

( 2.16.840.1.113730.3.1.30
  NAME 'mgrpRFC822MailMember'
  DESC 'RFC822 mail address of email only member of group'
  EQUALITY CaseIgnoreIA5Match
  SYNTAX 'IA5String(256)'
)

The mail alias objectClass is the following.

( 2.16.840.1.113730.3.2.4
  NAME 'mailGroup'
  SUP top
  STRUCTURAL
  MUST mail
  MAY ( cn $ mailAlternateAddress $ mailHost $ mailRequireAuth $ mgrpAddHeader $ mgrpAllowedBroadcaster $ mgrpAllowedDomain $ mgrpApprovePassword $ mgrpBroadcastModeration $ mgrpDeliverTo $ mgrpErrorsTo $ mgrpModerator $ mgrpMsgMaxSize $ mgrpMsgRejectAction $ mgrpMsgRejectText $ mgrpNoMatchAddrs $ mgrpRemoveHeader $ mgrpRFC822MailMember )
)
Directory User Agent Profile (DUAPrfile) Schema

Solaris Schemas

The schemas required for the Solaris platform are the following.

- Solaris Projects schema
- Role-based access control and execution profile schemas
- Printer schemas

Solaris Projects Schema

/etc/project is a local source of attributes associated with projects. For more information, see user_attr(4).

The Project Attributes are the following.

( 1.3.6.1.4.1.42.2.27.5.1.1 NAME 'SolarisProjectID'
  DESC 'Unique ID for a Solaris Project entry'
  EQUALITY integerMatch
  SYNTAX INTEGER SINGLE )

( 1.3.6.1.4.1.42.2.27.5.1.2 NAME 'SolarisProjectName'
  DESC 'Name of a Solaris Project entry'
  EQUALITY caseExactIA5Match
  SYNTAX IA5String SINGLE )

( 1.3.6.1.4.1.42.2.27.5.1.3 NAME 'SolarisProjectAttr'
  DESC 'Attributes of a Solaris Project entry'
  EQUALITY caseExactIA5Match
  SYNTAX IA5String )

( 1.3.6.1.4.1.42.2.27.5.1.30 NAME 'memberGid'
  DESC 'Posix Group Name'
  EQUALITY caseExactIA5Match
  SYNTAX 'IA5String' )

The Project objectClass is the following.

( 1.3.6.1.4.1.42.2.27.5.2.1 NAME 'SolarisProject'
  SUP top STRUCTURAL)
Role-Based Access Control and Execution Profile Schema

/\etc/\user_attr is a local source of extended attributes associated with users and roles. For more information, see user_attr(4).

The role-based access control Attributes are the following.

( 1.3.6.1.4.1.42.2.27.5.1.4 NAME 'SolarisAttrKeyValue'  
  DESC 'Semi-colon separated key=value pairs of attributes'  
  EQUALITY caseIgnoreIA5Match  
  SUBSTRINGS caseIgnoreIA5Match  
  SYNTAX 'IA5String' SINGLE-VALUE )

( 1.3.6.1.4.1.42.2.27.5.1.7 NAME 'SolarisAttrShortDesc'  
  DESC 'Short description about an entry, used by GUIs'  
  EQUALITY caseIgnoreIA5Match  
  SYNTAX 'IA5String' SINGLE-VALUE )

( 1.3.6.1.4.1.42.2.27.5.1.8 NAME 'SolarisAttrLongDesc'  
  DESC 'Detail description about an entry'  
  EQUALITY caseIgnoreIA5Match  
  SYNTAX 'IA5String' SINGLE-VALUE )

( 1.3.6.1.4.1.42.2.27.5.1.9 NAME 'SolarisKernelSecurityPolicy'  
  DESC 'Solaris kernel security policy'  
  EQUALITY caseIgnoreIA5Match  
  SYNTAX 'IA5String' SINGLE-VALUE )

Generic Directory Server Requirements for LDAP

To support LDAP clients based on Solaris 9 or later Solaris versions, the server, regardless of what brand, must support the LDAP v3 protocol and compound naming and auxiliary object classes. In addition, at least one of the following controls must be supported.

- Simple paged-mode (RFC 2696)
- Virtual List View controls

The server must support at least one of the following authentication methods.

anonymous
simple
sasl/cram-MD5
sasl/digest-MD5
sasl/GSSAPI

If using pam_unix, the server must support storing passwords in UNIX crypt format.

If using TLS, the server must support SSL or TLS.

If using sasl/GSSAPI, the server must support SASL, GSSAPI, Kerberos 5 authentication. Support for GSS encryption over the wire is optional.

Default Filters Used by LDAP Naming Services

If you do not manually specify a parameter for a given service using an SSD, the default filter is used. To list the default filters for a given service, use ldaplist with the -v option.

In the following example, filter=((&(objectclass=iphost)(cn=abcde)) defines the default filters.

database=hosts
filter=((&(objectclass=iphost)(cn=abcde))
user data=(&(%s) (cn=abcde))
ldaplist generates the following list of default filters, where %s signifies a string and %d, a number.

hosts
{(&objectclass=iphost)(cn=%s)}
--------------
passwd
{(&objectclass=posixaccount)(uid=%s)}
--------------
services
{(&objectclass=ipservice)(cn=%s)}
--------------
group
{(&objectclass=posixgroup)(cn=%s)}
--------------
netgroup

This chapter describes how to enable support of NIS clients that use naming information stored in the LDAP directory. By following the procedures in this chapter, you can transition from using an NIS naming service to using LDAP naming services.

To determine the benefits of transitioning to LDAP, see “LDAP Naming Services Compared to Other Naming Services” on page 130.

The following information is included in this chapter.

- “NIS-to-LDAP Service Overview” on page 243
- “Transitioning From NIS to LDAP (Task Map)” on page 248
- “Prerequisites for the NIS-to-LDAP Transition” on page 249
- “Setting Up the NIS-to-LDAP Service” on page 250
- “NIS-to-LDAP Best Practices With Sun Java System Directory Server” on page 257
- “NIS-to-LDAP Restrictions” on page 259
- “NIS-to-LDAP Troubleshooting” on page 260
- “Reverting to NIS” on page 264

**NIS-to-LDAP Service Overview**

The NIS–to–LDAP transition service (N2L service) replaces existing NIS daemons on the NIS master server with NIS–to–LDAP transition daemons. The N2L service also creates an NIS–to–LDAP mapping file on that server. The mapping file specifies the mapping between NIS map entries and equivalent Directory Information Tree (DIT) entries in LDAP. An NIS master server that has gone through this transition is referred to as an N2L server. The slave servers do not have an NIS\_LDAP\_mapping file, so they continue to function in the usual manner. The slave servers periodically update their data from the N2L server as if it were a regular NIS master.

The behavior of the N2L service is controlled by the yp\_serv and NIS\_LDAP\_mapping configuration files. A script, init\_typ21, assists with the initial setup of these configuration files. Once the N2L server has been established, you can maintain N2L by directly editing the configuration files.
The N2L service supports the following:

- Import of NIS maps into the LDAP Directory Information Tree (DIT)
- Client access to DIT information with the speed and extensibility of NIS

In any naming system, only one source of information can be the authoritative source. In traditional NIS, NIS sources are the authoritative information. When using the N2L service, the source of authoritative data is the LDAP directory. The directory is managed by using directory management tools, as described in Chapter 9, "LDAP Basic Components and Concepts (Overview)."

NIS sources are retained for emergency backup or backout only. After using the N2L service, you can gradually phase out NIS clients. Eventually, all NIS clients can be replaced by Solaris LDAP naming services clients.

Additional overview information is provided in the following subsections:

- "NIS-to-LDAP Audience Assumptions" on page 244
- "When Not to Use the NIS-to-LDAP Service" on page 245
- "Effects of the NIS-to-LDAP Service on Users" on page 245
- "NIS-to-LDAP Transition Terminology" on page 246
- "NIS-to-LDAP Commands, Files, and Maps" on page 247
- "Supported Standard Mappings" on page 247

**NIS-to-LDAP Tools and the Service Management Facility**

The NIS and LDAP services are managed by the Service Management Facility. Administrative actions on these services, such as enabling, disabling, or restarting, can be performed by using the `svcadm` command. You can query the status of services by using the `svcs` command. For more information about using SMF with LDAP and NIS, see "LDAP and the Service Management Facility" on page 188 and "NIS and the Service Management Facility" on page 84.

For an overview of SMF, refer to Chapter 17, “Managing Services (Overview),” in System Administration Guide: Basic Administration. Also refer to the `svcadm(1M)` and `svcs(1)` man pages for more details.

**NIS-to-LDAP Audience Assumptions**

You need to be familiar with NIS and LDAP concepts, terminology, and IDs to perform the procedures in this chapter. For more information about the NIS and LDAP naming services, see the following sections of this book.

- Chapter 4, "Network Information Service (NIS) (Overview)," for an overview of NIS
- Chapter 8, "Introduction to LDAP Naming Services (Overview/Reference)," for an overview of LDAP
When Not to Use the NIS-to-LDAP Service

Do not use the N2L service in these situations:

- In an environment where there is no plan to share data between NIS and LDAP naming services clients
  In such an environment, an N2L server would serve as an excessively complex NIS master server.
- In an environment where NIS maps are managed by tools that modify the NIS source files (other than yppasswd)
  Regeneration of NIS sources from DIT maps is an imprecise task that requires manual checking of the resulting maps. Once the N2L service is used, regeneration of NIS sources is provided only for backout or reverting to NIS.
- In an environment with no NIS clients
  In such an environment, use Solaris LDAP naming services clients and their corresponding tools.

Effects of the NIS-to-LDAP Service on Users

Simply installing the files that are related to the N2L service does not change the NIS server’s default behavior. At installation, the administrator will see some changes to NIS man pages and the addition of N2L helper scripts, `inityp2l` and `ypmap2src`, on the servers. But as long as `inityp2l` is not run or the N2L configuration files are not created manually on the NIS server, the NIS components continue to start in traditional NIS mode and function as usual.

After `inityp2l` is run, users see some changes in server and client behavior. Following is a list of NIS and LDAP user types and a description of what each type of user should notice after the N2L service is deployed.

<table>
<thead>
<tr>
<th>User Type</th>
<th>Effect of N2L Service</th>
</tr>
</thead>
<tbody>
<tr>
<td>NIS master server administrators</td>
<td>The NIS master server is converted to an N2L server. The NISLDAPmapping and ypserv configuration files are installed on the N2L server. After the N2L server is established, you can use LDAP commands to administer your naming information.</td>
</tr>
<tr>
<td>NIS slave server administrators</td>
<td>After the N2L transition, an NIS slave server continues to run NIS in the usual manner. The N2L server pushes updated NIS maps to the slave server when <code>yppush</code> is called by <code>ypmake</code>. See the <code>ypmake(1M)</code> man page.</td>
</tr>
</tbody>
</table>
The following terms are related to the implementation of the N2L service.

TABLE 15–1  Termination Related to the N2L Transition

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>

</thead>
<tbody>
<tr>
<td>LDAP client</td>
<td>Any traditional LDAP client that reads and writes to any LDAP server. A traditional LDAP client is a system that reads and writes to any LDAP server. A Solaris LDAP naming services client handles a customized subset of naming information.</td>
</tr>
<tr>
<td>LDAP naming services client</td>
<td>A Solaris LDAP client that handles a customized subset of naming information.</td>
</tr>
<tr>
<td>N2L server</td>
<td>An NIS master server that has been reconfigured as an N2L server by using the N2L service. Reconfiguration includes replacing NIS daemons and adding new configuration files.</td>
</tr>
</tbody>
</table>

NIS-to-LDAP Commands, Files, and Maps

There are two utilities, two configuration files, and a mapping that are associated with the N2L transition.

TABLE 15–2  Descriptions of N2L Commands, Files, and Maps

<table>
<thead>
<tr>
<th>Command/File/Map</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>/usr/lib/netsvc/yp/inityp2l</td>
<td>A utility that assists with the creation of the NISLDAPmapping and ypserv configuration files. This utility is not a general-purpose tool for the management of these files. An advanced user can maintain the N2L configuration files or create custom mappings by using a text editor to examine and customize the inityp2l output. See the inityp2l(1M) man page.</td>
</tr>
<tr>
<td>/usr/lib/netsvc/yp/ypmap2src</td>
<td>A utility that converts standard NIS maps to approximations of the equivalent NIS source files. The primary use for ypmap2src is to convert from an N2L transition server to traditional NIS. See the ypmap2src(1M) man page.</td>
</tr>
<tr>
<td>/var/yp/NISLDAPmapping</td>
<td>A configuration file that specifies the mapping between NIS map entries and equivalent Directory Information Tree (DIT) entries in LDAP. See the NISLDAPmapping(4) man page.</td>
</tr>
<tr>
<td>/var/yp/ypserv</td>
<td>A file that specifies configuration information for the NIS–to–LDAP transition daemons. See the ypserv(4) man page.</td>
</tr>
<tr>
<td>ageing.byname</td>
<td>A mapping used by yppasswd to read and write password aging information to the DIT when the NIS-to-LDAP transition is implemented.</td>
</tr>
</tbody>
</table>

Supported Standard Mappings

By default, the N2L service supports mappings between the following list of maps and RFC 2307, or its successors', LDAP entries. These standard maps do not require manual modification to the mapping file. Any maps on your system that are not in the following list are considered custom maps and require manual modification.
The N2L service also supports automatic mapping of the auto.* maps. However, since most auto.* file names and contents are specific to each network configuration, those files are not specified in this list. The exceptions to this are the auto.home and auto.master maps, which are supported as standard maps.

audit_user
auth_attr
auto.home
auto.master
bootparams
ethers.byaddr ethers.bynames
exec_attr
group.bygid group.bynames group.adjunct.bynames
hosts.byaddr hosts.bynames
ipnodes.byaddr ipnodes.bynames
mail.byaddr mail.aliases
netgroup netgroup.byprojid netgroup.byuser netgroup.byhost
netid.bynames
netmasks.byaddr
networks.byaddr networks.bynames
passwd.bynames passwd.byuid passwd.adjunct.bynames
printers.conf.bynames
prof_attr
project.bynames project.byprojectid
protocols.bynames protocols.bynumber
publickey.bynames
rpc.bynumber
services.bynames services.byservicename
timezone.bynames
user_attr

During the NIS-to-LDAP transition, the yppasswdd daemon uses the N2L-specific map, ageing.byname, to read and write password aging information to the DIT. If you are not using password aging, then the ageing.byname mapping is ignored.

Transitioning From NIS to LDAP (Task Map)

The following table identifies the procedures needed to install and manage the N2L service with standard and with custom NIS-to-LDAP mappings.
Prerequisites for the NIS-to-LDAP Transition

Before implementing the N2L service, you must check or complete the following items.

- Make sure that the system is set up as a working traditional NIS server before running the `in1typ2l` script to enable N2L mode.
- Configure the LDAP directory server on your system.

Sun Java System Directory Server (formerly Sun ONE Directory Server) and compatible versions of directory servers offered by Sun Microsystems, Inc., are supported with the NIS-to-LDAP migration tools. If you use Sun Java System Directory Server, configure the server by using the `idsconfig` command before you set up the N2L service. For more information about `idsconfig`, see Chapter 11, “Setting Up Sun Java System Directory Server With LDAP Clients (Tasks),” and the `idsconfig(1M)` man page.

Other (third party) LDAP servers might work with the N2L service, but they are not supported by Sun. If you are using an LDAP server other than the Sun Java System Directory Server or compatible Sun servers, you must manually configure the server to support RFC 2307, or its successors, schemas before you set up the N2L service.
Make sure that the `nsswitch.conf` file lists `files` before `nis` for the lookup order, at least for the `hosts` and `ipnodes` entries.

Ensure that the addresses of the N2L master server and the LDAP server are present in the `hosts` or `ipnodes` files on the N2L master server. Whether the server addresses must be listed in `hosts`, `ipnodes`, or both files depends on how your system is configured to resolve local host names.

An alternative solution is to list the LDAP server address, not its host name, in `ypserv`. This means that the LDAP server address is listed in another place, so changing the address of either the LDAP server or the N2L master server requires additional file modifications.

### Setting Up the NIS-to-LDAP Service

You can set up the N2L service either by using standard mappings or by using custom mappings, as described in the next two procedures.

As part of the NIS-to-LDAP conversion, you need to run the `inityp2l` command. This command runs an interactive script for which you must provide configuration information. The following list shows the type of information you need to provide. See the `ypserv(1M)` man page for explanations of these attributes:

- The name of the configuration file being created (default = `/etc/default/ypserv`)
- The DN that stores configuration information in LDAP (default = `ypserv`)
- Preferred server list for mapping data to/from LDAP
- Authentication method for mapping data to/from LDAP
- Transport Layer Security (TLS) method for mapping data to/from LDAP
- Proxy user bind DN to read/write data from/to LDAP
- Proxy user password to read/write data from/to LDAP
- Timeout value (in seconds) for LDAP bind operation
- Timeout value (in seconds) for LDAP search operation
- Timeout value (in seconds) for LDAP modify operation
- Timeout value (in seconds) for LDAP add operation
- Timeout value (in seconds) for LDAP delete operation
- Time limit (in seconds) for search operation on LDAP server
- Size limit (in bytes) for search operation on LDAP server
- Whether N2L should follow LDAP referrals
- LDAP retrieval error action, number of retrieval attempts, and timeout (in seconds) between each attempt
- Store error action, number of attempts, and timeout (in seconds) between each attempt
How to Set Up the N2L Service With Standard Mappings

Use this procedure if you are transitioning the maps listed in "Supported Standard Mappings" on page 247. If you are using custom or nonstandard maps, see "How to Set Up the N2L Service With Custom or Nonstandard Mappings" on page 253.

When the LDAP server has been set up, run the inityp2l script and supply configuration information when prompted. inityp2l sets up the configuration and mapping files for standard and auto.* maps.

1 Complete the prerequisite steps that are listed in "Prerequisites for the NIS-to-LDAP Transition" on page 249.

2 On the NIS master server, become superuser or assume an equivalent role.

   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, "Using Role-Based Access Control (Tasks)," in System Administration Guide: Security Services.

3 Convert the NIS master server into an N2L server.

   # inityp2l

   Run the inityp2l script on the NIS master server and follow the prompts. See "Setting Up the NIS-to-LDAP Service" on page 250 for a list of the information you need to provide.

   See the inityp2l(1M) man page for more details.

4 Determine if the LDAP Directory Information Tree (DIT) is fully initialized.

   The DIT is fully initialized if it already contains the information necessary to populate all the maps that are listed in the NISLDAPmapping file.

Note – sasl/cram-md5 authentication is not supported by most LDAP servers, including Sun Java System Directory Server.
If no, continue with Step 5 and skip Step 6.
If yes, skip Step 5 and go to Step 6.

5 Initialize the DIT for the transition from the NIS source files.
Perform these steps only if the DIT has not been fully initialized.

   a. Make sure that the old NIS maps are up-to-date.
      
      # cd /var/yp
      # make
      
      For more information, see the ypmake(1M) man page.

   b. Stop the NIS daemons.
      
      # svcadm disable network/nis/server:default

   c. Copy the old maps to the DIT, then initialize N2L support for the maps.
      
      # ypervas -Ir
      
      Wait for ypervas to exit.

      Tip – The original NIS dbm files are not overwritten. You can recover these files, if needed.

   d. Start the NIS daemons to ensure that they use the new maps.
      
      # svcadm enable network/nis/server:default

      This completes the set up of the N2L service with standard maps. You do not need to complete Step 6.

6 Initialize the NIS maps.
Perform these steps only if the DIT is fully initialized and you skipped Step 5.

   a. Stop the NIS daemons.
      
      # svcadm disable network/nis/server:default

   b. Initialize the NIS maps from information in the DIT.
      
      # ypervas -r
      
      Wait for ypervas to exit.

      Tip – The original NIS dbm files are not overwritten. You can recover these files, if needed.

   c. Start the NIS daemons to ensure that they use the new maps.
      
      # svcadm enable network/nis/server:default
How to Set Up the N2L Service With Custom or Nonstandard Mappings

Use this procedure if the following circumstances apply:

- You have maps that are not listed in “Supported Standard Mappings” on page 247.
- You have standard NIS maps that you want to map to non-RFC 2307 LDAP mappings.

1. Complete the prerequisite steps that are listed in “Prerequisites for the NIS-to-LDAP Transition” on page 249.

2. On the NIS master server, become superuser or assume an equivalent role.
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

3. Configure the NIS master server into the N2L server.
   # inityp2l
   Run the inityp2l script on the NIS master server and follow the prompts. See “Setting Up the NIS-to-LDAP Service” on page 250 for a list of the information you need to provide.
   See the inityp2l(1M) man page for more details.

4. Modify the /var/yp/NISLDAPmapping file.
   See “Examples of Custom Maps” on page 255 for examples of how to modify the mapping file.

5. Determine if the LDAP Directory Information Tree (DIT) is fully initialized.
   The DIT is fully initialized if it already contains the information necessary to populate all the maps that are listed in the NISLDAPmapping file.
   - If no, complete Step 6, Step 8, and Step 9.
   - If yes, skip Step 6 and complete Step 7, Step 8, and Step 9.

6. Initialize the DIT for the transition from the NIS source files.
   a. Make sure that the old NIS maps are up-to-date.
      # cd /var/yp
      # make
      For more information, see the ypmake(1M) man page.
   b. Stop the NIS daemons.
      # svcadm disable network/nis/server:default
c. Copy the old maps to the DIT, then initialize N2L support for the maps.
   
   `# ypserv -Ir`

   Wait for `ypserv` to exit.

   **Tip** – The original NIS dbm files are not overwritten. You can recover these files, if needed.

d. Start the NIS daemons to ensure that they use the new maps.
   
   `# svcadm enable network/nis/server:default`

e. Skip Step 7 and continue with Step 8.

7 Initialize the NIS maps.

Perform this step only if the DIT is fully initialized.

a. Stop the NIS daemons.
   
   `# svcadm disable network/nis/server:default`

b. Initialize the NIS maps from information in the DIT.
   
   `# ypserv -r`

   Wait for `ypserv` to exit.

   **Tip** – The original NIS dbm files are not overwritten. You can recover these files, if needed.

c. Start the NIS daemons to ensure that they use the new maps.
   
   `# svcadm enable network/nis/server:default`

8 Verify that the LDAP entries are correct.

If the entries are not correct, then the entries can not be found by LDAP naming services clients.

`# ldapsearch -h server -s sub -b "ou=servdates, dc=..." 
"objectclass=servDates"

9 Verify the contents of the LDAP maps.

The following sample output shows how to use `makedbm` to verify the contents of the hosts.byaddr map.

`# makedbm -u LDAP_servdate.bynumber
plato: 1/3/2001

If the contents are as expected, the transition from NIS to LDAP was successful.
Note that the original NIS dbm files are not overwritten, so you can always recover those files. See “Reverting to NIS” on page 264 for more information.

**Examples of Custom Maps**

The following two examples show how you might customize maps. Use your preferred text editor to modify the `/var/yp/NISLDAPmapping` file as needed. For more information about file attributes and syntax, see the `NISLDAPmapping(4)` man page and the LDAP naming services information in Chapter 9, “LDAP Basic Components and Concepts (Overview).”

**Example 1–Moving Host Entries**

This example shows how to move host entries from the default location to another (nonstandard) location in the DIT.

Change the `nisLDAPobjectDN` attribute in the `NISLDAPmapping` file to the new base LDAP distinguished name (DN). For this example, the internal structure of the LDAP objects is unchanged, so `objectClass` entries are unchanged.

Change:

```bash
nisLDAPobjectDN hosts: \n  ou=hosts,?one?, \n  objectClass=device, \n  objectClass=ipHost
```

To:

```bash
nisLDAPobjectDN hosts: \n  ou=newHosts,?one?, \n  objectClass=device, \n  objectClass=ipHost
```

This change causes entries to be mapped under

```
dn: ou=newHosts, dom=domain1, dc=sun, dc=com
```

instead of under

```
dn: ou=hosts, dom=domain1, dc=sun, dc=com.
```

**Example 2–Implementing a Custom Map**

This example shows how to implement a custom map.
A hypothetical map, `servdate.bynumber`, contains information about the servicing dates for systems. This map is indexed by the machine's serial number which, in this example, is 123. Each entry consists of the machine owner's name, a colon, and a comma-separated list of service dates, such as John Smith:1/3/2001,4/5/2003.

The old map structure is to be mapped onto LDAP entries of the following form:

```dn: number=123,ou=servdates,dc=... 
  number: 123 
  userName: John Smith 
  date: 1/3/2001 
  date: 4/5/2003 
  
objectClass: servDates```

By examining the NISLDAPmapping file, you can see that the mapping closest to the required pattern is `group`. The custom mappings can be modeled on the `group` mapping. Since there is only one map, no `nisLDAPdatabaseIdMapping` attribute is required. The attributes to be added to `NISLDAPmapping` are the following:

```nisLDAPentryTtl servdate.bynumber:1800:5400:3600
nisLDAPnameFields servdate.bynumber: 
  (%s:%s, uname, dates)
nisLDAPobjectDN servdate.bynumber: 
  ou=servdates, ?one? 
  objectClass=servDates:
nisLDAPattributeFromField servdate.bynumber: 
  dn=("number=%s", rf_key), 
  number=rf_key, 
  userName=uname, 
  (date)=(dates, ",")
nisLDAPfieldFromAttribute servdate.bynumber: 
  rf_key=number, 
  uname=userName, 
  dates=("%s", (date), ",")```
NIS-to-LDAP Best Practices With Sun Java System Directory Server

The N2L service supports Sun Java System Directory Server (formerly Sun ONE Directory Server) and compatible versions of directory servers offered by Sun Microsystems, Inc. Other (third party) LDAP servers might work with the N2L service, but they are not supported by Sun. If you are using an LDAP server other than the Sun Java System Directory Server or compatible Sun servers, you must manually configure the server to support RFC 2307, or its successors', schemas.

If you are using the Sun Java System Directory Server, you can enhance the directory server to improve performance. To make these enhancements, you must have LDAP administrator privileges on the Sun Java System Directory Server. In addition, the directory server might need to be rebooted, a task that must be coordinated with the server's LDAP clients. The Sun Java System Directory Server (and Sun ONE and iPlanet Directory Server) documentation is available on the Sun Java System Directory Server Enterprise Edition 6.2 (http://docs.sun.com/coll/1224.3) web site.

Creating Virtual List View Indexes With Sun Java System Directory Server

For large maps, LDAP virtual list view (VLV) indexes must be used to ensure LDAP searches return complete results. For information about setting up VLV indexes on the Sun Java System Directory Server, see the Sun Java System Directory Server Enterprise Edition 6.2 (http://docs.sun.com/coll/1224.3) documentation.

VLV search results use a fixed page size of 50000. If VLVs are used with Sun Java System Directory Server, both the LDAP server and N2L server must be able to handle transfers of this size. If all of your maps are known to be smaller than this limit, you do not need to use VLV indexes. However, if your maps are larger than the size limit, or you are unsure of the size of all maps, use VLV indexes to avoid incomplete returns.

If you are using VLV indexes, set up the appropriate size limits as follows.

- On the Sun Java System Directory Server: nsslapd-sizelimit attribute must be set greater than or equal to 50000 or -1. See the idsconfig(1M) man page.
- On the N2L server: nisLDAPsearchSizelimit attribute must be set greater than or equal to 50000 or zero. For more information, see the NISLDAPmapping(4) man page.

Once VLV indexes have been created, activate them by running directoryserver with the vlvindex option on the Sun Java System Directory Server. See the directoryserver(1M) man page for more information.
VLVs for Standard Maps

Use the Sun Java System Directory Server idsconfig command to set up VLVs if the following conditions apply:

- You are using the Sun Java System Directory Server.
- You are mapping standard maps to RFC 2307 LDAP entries.

VLVs are domain specific, so each time idsconfig is run, VLVs are created for one NIS domain. Therefore, during the NIS-to-LDAP transition, you must run idsconfig once for each nisLDAPdomainContext attribute included in the NISLDAPmapping file.

VLVs for Custom and Nonstandard Maps

You must manually create new Sun Java System Directory Server VLVs for maps, or copy and modify existing VLV indexes, if the following conditions apply:

- You are using the Sun Java System Directory Server.
- You have large custom maps or have standard maps that are mapped to nonstandard DIT locations.

To view existing VLV indexes, type the following:

```
# ldapsearch -h hostname -s sub -b "cn=ldbm database,cn=plugins,cn=config" \ 
"objectClass=vlvSearch"
```

Avoiding Server Timeouts With Sun Java System Directory Server

When the N2L server refreshes a map, the result might be a large LDAP directory access. If the Sun Java System Directory Server is not correctly configured, the refresh operation might time out before completion. To avoid directory server timeouts, modify the following Sun Java System Directory Server attributes manually or by running the idsconfig command.

For example, to increase the minimum amount of time in seconds that the server should spend performing the search request, modify these attributes:

```
 dn: cn=config
 nsslapd-timelimit: -1
```

For testing purposes, you can use an attribute value of -1, which indicates no limit. When you have determined the optimum limit value, change the attribute value. Do not maintain any attribute settings at -1 on a production server. With no limits, the server might be vulnerable to Denial of Service attacks.

**Avoiding Buffer Overruns With Sun Java System Directory Server**

To avoid buffer overruns, modify the Sun Java System Directory Server attributes manually or by running the `idsconfig` command.

1. For example, to increase the maximum number of entries that are returned for a client search query, modify these attributes:
   ```
   dn: cn=config
   nsslapd-sizelimit: -1
   ```

2. To increase the maximum number of entries that are verified for a client search query, modify these attributes:
   ```
   dn: cn=config, cn=ldbm database, cn=plugins, cn=config
   nsslapd-lookthroughlimit: -1
   ```

For testing purposes, you can use an attribute value of -1, which indicates no limit. When you have determined the optimum limit value, change the attribute value. Do not maintain any attribute settings at -1 on a production server. With no limits, the server might be vulnerable to Denial of Service attacks.

If VLVs are being used, the `sizelimit` attribute values should be set as defined in “Creating Virtual List View Indexes With Sun Java System Directory Server” on page 257. If VLVs are not being used, the size limit should be set large enough to accommodate the largest container.

For more information about configuring Sun Java System Directory Server with LDAP, see Chapter 11, “Setting Up Sun Java System Directory Server With LDAP Clients (Tasks).”

**NIS-to-LDAP Restrictions**

When the N2L server has been set up, the NIS source files are no longer used. Therefore, do not run `ypmake` on an N2L server. If `ypmake` is accidentally run, such as for an existing `cron` job, the N2L service is unaffected. However, a warning is logged suggesting that `yppush` should be called explicitly.
NIS-to-LDAPTroubleshooting

This section covers two areas of troubleshooting:

- “Common LDAP Error Messages” on page 260
- “NIS-to-LDAPIssues” on page 261

Common LDAP Error Messages

Sometimes the N2L server logs errors that relate to internal LDAP problems, resulting in LDAP-related error messages. Although the errors are nonfatal, they indicate problems to investigate. For example, the N2L server might continue to operate, but provide out-of-date or incomplete results.

The following list includes some of the common LDAP error messages that you might encounter when implementing the N2L service. Error descriptions, and possible causes and solutions for the errors, are included.

Administrative limit exceeded

**Error Number:** 11  
**Cause:** An LDAP search was made that was larger than allowed by the directory server’s `nsslapd-sizelimit` attribute. Only partial information will be returned.  
**Solution:** Increase the value of the `nsslapd-sizelimit` attribute, or implement a VLV index for the failing search.

Invalid DN Syntax

**Error Number:** 34  
**Cause:** An attempt has been made to write an LDAP entry with a DN that contains illegal characters. The N2L server attempts to escape illegal characters, such as the + symbol, that are generated in DNs.  
**Solution:** Check the LDAP server error log to find out which illegal DNs were written, then modify the NISLDAPmapping file that generated the illegal DNs.

Object class violation

**Error Number:** 65  
**Cause:** An attempt has been made to write an LDAP entry that is invalid. Generally, this error is due to missing MUST attributes that can be caused by either of the following circumstances.  
- Bugs in the NISLDAPmapping file that create entries with missing attributes  
- Attempts to add an AUXILIARY attribute to an object that does not exist
For example, if a user name has not yet been created from the passwd.byxxx map, an attempt to add auxiliary information to that user will fail.

**Solution:** For bugs in the NISLDAPmapping file, check what was written in the server error log to determine the nature of the problem.

**Can’t contact LDAP server**

**Error Number:** 81

**Cause:** The ypserv file might be incorrectly configured to point to the wrong LDAP directory server. Alternatively, the directory server might not be running.

**Solution:**

- Reconfigure the ypserv file to point to the correct LDAP directory server.
- To confirm that the LDAP server is running, become superuser, or assume an equivalent role, on the directory server and type:

```
# pgrep -l slapd
```

**Timeout**

**Error Number:** 85

**Cause:** An LDAP operation timed out, typically while updating a map from the DIT. The map might now contain out-of-date information.

**Solution:** Increase the nisLDAPxxxTimeout attributes in the ypserv configuration file.

**NIS-to-LDAP Issues**

The following problems could occur while running the N2L server. Possible causes and solutions are provided.

**Debugging the NISLDAPmapping File**

The mapping file, NISLDAPmapping, is complex. Many potential errors might cause the mapping to behave in unexpected ways. Use the following techniques to resolve such problems.

**Console Message Displays When** `ypserv -ir (or -Ir)` **Runs**

**Problem:** A simple message is displayed on the console and the server exits (a detailed description is written to syslog).

**Cause:** The syntax of the mapping file might be incorrect.

**Solution:** Check and correct the syntax in the NISLDAPmapping file.

**NIS Daemon Exits at Startup**

**Problem:** When ypserv or other NIS daemons run, an LDAP-related error message is logged and the daemon exits.
**Cause:** The cause might be one of the following:

- The LDAP server cannot be contacted.
- An entry found in an NIS map or in the DIT is incompatible with the mapping specified.
- An attempt to read or write to the LDAP server returns an error.

**Solution:** Examine the error log on the LDAP server. See the LDAP errors that are listed in “Common LDAP Error Messages” on page 260.

### Unexpected Results From NIS Operations

**Problem:** NIS operations do not return the expected results, but no errors are logged.

**Cause:** Incorrect entries might exist in the LDAP or NIS maps, which results in mappings not completing as intended.

**Solution:** Check and correct entries in the LDAP DIT and in the N2L versions of the NIS maps.

1. Check that the correct entries exist in the LDAP DIT, and correct the entries as needed.
   - If you are using the Sun Java System Directory Server, start the management console by running `directoryserver startconsole`.
2. Check that the N2L versions of the NIS maps in the `/var/yp` directory contain the expected entries by comparing the newly generated map to the original map. Correct entries as needed.

   ```
   # cd /var/yp/
domainname
   # makedbm -u testbyname
   # makedbm -u LDAP_testbyname
   ``

   Be aware of the following when checking the output for the maps:
   - The order of entries might not be the same in both files.
     Use the `sort` command before comparing output.
   - The use of white space might not be the same in both files.
     Use the `diff -b` command when comparing output.

### Processing Order of NIS Maps

**Problem:** Object class violations occur.

**Cause:** When the `ypserv -i` command is run, each NIS map is read and its contents are written into the DIT. Several maps might contribute attributes to the same DIT object. Generally, one map creates most of the object, including all the object’s MUST attributes. Other maps contribute additional MAY attributes.

Maps are processed in the same order that `nisLDAPObj ectDN` attributes appear in the `NISLDAPmapping` file. If maps containing MAY attributes get processed before maps containing MUST attributes, then object class violations occur. See Error 65 in “Common LDAP Error Messages” on page 260 for more information about this error.
Solution: Reorder the n1sLDAPobjectDN attributes so that maps are processed in the correct order.

As a temporary fix, rerun the `ypserv -i` command several times. Each time the command is executed, more of the LDAP entry is built up.

Note – Mapping in such a way that all of an object's MUST attributes cannot be created from at least one map is not supported.

**N2L Server Timeout Issue**

Problem: The server times out.

Cause: When the N2L server refreshes a map, the result might be a large LDAP directory access. If the Sun Java System Directory Server is not correctly configured, this operation might time out before completion.

Solution: To avoid directory server timeouts, modify the Sun Java System Directory Server attributes manually or by running the `idsconfig` command. See “Common LDAP Error Messages” on page 260 and “NIS-to-LDAP Best Practices With Sun Java System Directory Server” on page 257 for details.

**N2L Lock File Issue**

Problem: The `ypserv` command starts but does not respond to NIS requests.

Cause: The N2L server lock files are not correctly synchronizing access to the NIS maps. This should never happen.

Solution: Type the following commands on the N2L server.

```
# svcadm disable network/nis/server:default
# rm /var/run/yp_maplock /var/run/yp_mapupdate
# svcadm enable network/nis/server:default
```

**N2L Deadlock Issue**

Problem: The N2L server deadlocks.

Cause: If the addresses of the N2L master server and the LDAP server are not listed properly in the `hosts`, `ipnodes`, or `ypserv` files, a deadlock might result. See ”Prerequisites for the NIS-to-LDAP Transition” on page 249 for details about proper address configuration for N2L.

For an example of a deadlock scenario, consider the following sequence of events:

1. An NIS client tries to look up an IP address.
2. The N2L server finds that the `hosts` entry is out-of-date.
3. The N2L server tries to update the `hosts` entry from LDAP.
4. The N2L server gets the name of its LDAP server from ypser v, then does a search by using libldap.

5. Libldap tries to convert the LDAP server’s name to an IP address by making a call to the name service switch.

6. The name service switch might make an NIS call to the N2L server, which deadlocks.

Solution: List the addresses of the N2L master server and the LDAP server in the hosts or ipnodes files on the N2L master server. Whether the server addresses must be listed in hosts, ipnodes, or both files depends on how these files are configured to resolve local host names. Also, check that the hosts and ipnodes entries in the nsswitch.conf file list files before nis in the lookup order.

An alternative solution to this deadlock problem is to list the LDAP server address, not its host name, in the ypser v file. This means that the LDAP server address would be listed in another place. Therefore, changing the address of either the LDAP server or the N2L server would require slightly more effort.

Reverting to NIS

A site that has transitioned from NIS to LDAP using the N2L service is expected to gradually replace all NIS clients with Solaris LDAP naming services clients. Support for NIS clients eventually becomes redundant. However, if required, the N2L service provides two ways to return to traditional NIS, as explained in the next two procedures.

Tip – Traditional NIS ignores the N2L versions of the NIS maps if those maps are present. After reverting to NIS, if you leave the N2L versions of the maps on the server, the N2L maps do not cause problems. Therefore, it might be useful to keep the N2L maps in case you later decide to re-enable N2L. However, the maps do take up disk space.

▼ How to Revert to Maps Based on Old Source Files

1 Become superuser or assume an equivalent role.

Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in System Administration Guide: Security Services.

2 Stop the NIS daemons.

# svcadm disable network/nis/server:default
3  **Disable N2L.**
   This command backs up and moves the N2L mapping file.
   
   ```
   # mv /var/yp/NISLDAPmapping backup_filename
   ```

4  **Set the NOPUSH environment variable so the new maps are not pushed by ypmake.**
   
   ```
   # NOPUSH=1
   ```

5  **Make a new set of NIS maps that are based on the old sources.**
   
   ```
   # cd /var/yp
   # make
   ```

6  **(Optional) Remove N2L versions of the NIS maps.**
   
   ```
   # rm /var/yp/domainname/LDAP_*
   ```

7  **Start the NIS daemons.**
   
   ```
   # svcadm enable network/nis/server:default
   ```

---

### How to Revert to Maps Based on Current DIT Contents

Back up the old NIS source files before performing this procedure.

1  **Become superuser or assume an equivalent role.**
   Roles contain authorizations and privileged commands. For more information about roles, see Chapter 9, “Using Role-Based Access Control (Tasks),” in *System Administration Guide: Security Services.*

2  **Stop the NIS daemons.**
   
   ```
   # svcadm disable network/nis/server:default
   ```

3  **Update the maps from the DIT.**
   
   ```
   # ypserv -r
   ```
   Wait for ypserv to exit.

4  **Disable N2L.**
   This command backs up and moves the N2L mapping file.
   
   ```
   # mv /var/yp/NISLDAPmapping backup_filename
   ```

5  **Regenerate the NIS source files.**
   
   ```
   # ypmap2src
   ```

6  **Manually check that regenerated NIS source files have the correct content and structure.**
Reverting to NIS

7 Move the regenerated NIS source files to the appropriate directories.

8 (Optional) Remove the N2L versions of the mapping files.
   # rm /var/yp/domainname/LDAP_*

9 Start the NIS daemons.
   # svcadm enable network/nis/server:default
This part describes the configuration and administration of the \texttt{nss\_ad} naming service module. This naming service module enables a Solaris system to access user and group information from Active Directory (AD) servers in an AD domain.
Setting Up Solaris Active Directory Clients

The `nss_ad` naming service module provides a backend for the `passwd`, `shadow`, and `group` files. The `nss_ad` module uses Active Directory (AD) and its native schema as the naming service to resolve user and group names and IDs from across an AD forest.

**Overview of the `nss_ad` Naming Service Module**

The Solaris client must be joined to an AD domain before any of the AD interoperability functionality, including `nss_ad`, can be used. The `kclient` utility is used to join the client to AD. During the join operation, `kclient` configures Kerberos v5 on the client. Thereafter, `nss_ad` can be used to resolve naming service requests by specifying `ad` as a source in the `nsswitch.conf` file for the supported databases. The `nss_ad` module uses host credentials to look up naming service information in AD.

The `nss_ad` module uses DNS server records to auto-discover AD directory servers, such as domain controllers and global catalog servers. Therefore, DNS must be properly configured on the Solaris client. The `nss_ad` module also uses the LDAP v3 protocol to access naming information from AD servers. The AD server schema requires no modification because `nss_ad` works with the native AD schema.

The `nss_ad` module does not currently support logins of Windows users onto a Solaris system. Until such logins are supported, such users should continue to log in by using traditional back ends such as `nis` and `ldap`.

The `idmap` and `nscd` services must be enabled to use `nss_ad`. The `nss_ad` module uses the `idmap` service to map between Windows security identifiers (SIDs), Solaris user identifiers (UIDs), and group identifiers (GIDs).

Ensure that all AD user and group names are qualified with domain names such as `user@domain` or `group@domain`. For example, `getpwnam(dana)` will fail, but `getpwnam(dana@domain)` will succeed, provided that dana is a valid Windows user in the domain named `domain`. 
The following additional rules also pertain to the \texttt{nss\_ad} module:

- Like AD, \texttt{nss\_ad} performs case-insensitive matching of user and group names.
- Only use the \texttt{nss\_ad} module in UTF-8 locales or in domains where users and groups have only ASCII characters in their names.
- Well-known SIDs are a set of SIDs that identify generic users or generic groups in the Windows world. They are not domain specific and their values remain constant across all Windows operating systems. The names of well-known SIDs are qualified with the string \texttt{BUILTIN}, for example, \texttt{Remote Desktop Users@BUILTIN}.
- The \texttt{nss\_ad} module does not support enumeration. Therefore, the \texttt{getpwent()} and \texttt{getgrent()} interfaces and commands that use them such as \texttt{getent passwd} and \texttt{getent group} cannot retrieve information from AD.
- The \texttt{nss\_ad} module currently supports only the \texttt{passwd} and \texttt{group} files. \texttt{nss\_ad} does not support other naming service databases that follow the \texttt{passwd} entry, such as \texttt{audit\_user} and \texttt{user\_attr}. If the \texttt{ad} back end is processed (based on the configuration), it returns NOT FOUND for these databases.

## Configuring the \texttt{nss\_ad} Naming Service Module

The \texttt{nss\_ad} module requires that the Solaris client use DNS for host resolution.

### How to Configure the \texttt{nss\_ad} Module

1. **Edit the \texttt{/etc/resolv.conf} file to point to the correct domain, using the correct search order.**
   
   Pointing to the correct DNS domain and servers in the \texttt{/etc/resolv.conf} file usually involves specifying the domain controller as the DNS server.

   ```
   domain ad.example
   nameserver 192.168.11.22
   ```

   - **Note** – The AD domain name must be specified in \texttt{/etc/resolv.conf} either by means of the \texttt{domain} directive or as the first item in the list specified by the \texttt{search} directive.

     If both directives are specified, then whichever is last takes precedence. This is required for the \texttt{idmap} auto-discovery feature to work properly.

     In the following example, the AD domain, \texttt{ad.example}, is specified by the \texttt{domain} directive. The \texttt{dig} commands verify that the AD server, which is specified by the \texttt{nameserver} directive, can be resolved by using its name and IP address.

   ```
   % cat /etc/resolv.conf
   domain ad.example
   nameserver 192.168.11.22
   % dig -x 192.168.11.22 +short
   myserver.ad.example
   ```
% dig myserver.ad.example +short
192.168.11.22

2 Edit the /etc/nsswitch.conf file, and add dns to the list of naming services for hosts and ipnodes.

For example, the file might look like the following:

% egrep '^hosts|^ipnodes' /etc/nsswitch.conf
hosts: files dns
ipnodes: files dns

Note – To include additional naming services such as nis or ldap for host resolution, add them after dns in the /etc/nsswitch.conf file.

3 Verify that the DNS service is enabled and online.

For example:
% svcs svc:/network/dns/client
STATE STIME FMRI
online Oct_14 svc:/network/dns/client:default

4 Use the kclient utility to join the system to the AD domain.

For example:
% /usr/sbin/kclient -T ms_ad

5 Edit the nsswitch.conf file by adding ad to passwd and group.

For example:
% egrep '^passwd|^group' /etc/nsswitch.conf
passwd: files nis ad
group: files nis ad

Note – /etc/nsswitch.ad is a sample configuration file that can be copied to /etc/nsswitch.conf. It uses AD for passwd and group, DNS for host lookups, and files for the remaining databases. Because the AD naming service is not yet a complete Solaris solution, add other naming services as appropriate to the nsswitch.conf file.

6 Enable the idmap service.
% svcadm enable idmap

7 Enable the nscd service.
% svcsc name-service-cache
STATE STIME FMRI
disabled 13:15:48 svc:/system/name-service-cache:default

Chapter 16 • Setting Up Solaris Active Directory Clients 271
% svcadm enable name-service-cache

Note – The nscd module automatically restarts whenever /etc/nsswitch.conf is changed.

8 Verify that you can access user and group information from AD.

For example:

% getent passwd 'test_user@example'
test_user@example:x:2154266625:2154266626:test_user::

% getent passwd 2154266625
test_user@example:x:2154266625:2154266626:test_user::

Password Updates

The passwd(4) man page contains a list of valid formats for the passwd entry in the nsswitch.conf file. Adding ad to these configurations in the nsswitch.conf file is supported. However, changing AD user passwords through the passwd command is not supported. If found in the passwd entry during a password update, ad is skipped. Use the kpasswd command to update AD user passwords.

The ad search order can be added to existing valid passwd and group entries in nsswitch.conf.

For example:

```
passwd: files ad
group: files ad
```

How the nss_ad Naming Service Module Retrieves Data From AD

The following section describes how the nss_ad module resolves naming service requests for the passwd, shadow, and group files by retrieving corresponding data from AD.

Retrieving passwd Information

The following syntax shows the proper form of a passwd entry:

```
```

See the passwd(4) man page for more information.
The nss_ad module retrieves passwd information from AD as follows:

- **username** – Field uses the value of the `samAccountName` AD attribute and is qualified by the domain name in which the object resides, for example, terryb@example.com.
- **password** – Field uses the value of *NP* because the user password is not available in the AD object.
- **uid** – Field uses the Windows user's SID from the `objectSID` AD attribute, which is mapped to the UID by using the `idmap` service.
- **gid** – Field uses the Windows user's primary group SID, which is mapped to the GID by using the `idmap` service. The group SID is obtained by appending the value of the `primaryGroupID` AD attribute to the domain SID. For users in AD, the `primaryGroupID` attribute is an optional attribute, so it might not exist. If the attribute does not exist, nss_ad uses the `idmap` diagonal mapping facility to map the user SID from the `objectSID` attribute.
- **gecos** – Value of the `CN` AD attribute.
- **home-directory** – Value of the `homeDirectory` AD attribute, if a value exists. Otherwise, the field is left empty.
- **login-shell** – Field is left empty because there is no login shell attribute in the native AD schema.

Retrieving *shadow* Information

The following syntax shows the proper form of a *shadow* entry:

```
```

See the `shadow(4)` man page for more information.

The nss_ad module retrieves *shadow* information from AD as follows:

- **username** – Field uses the value of the `samAccountName` AD attribute and is qualified by the domain name in which the object resides, for example, terryb@example.com.
- **password** – Field uses the value of *NP* because the user password is not available in the AD object.

The rest of the shadow fields are left empty because shadow fields are irrelevant with AD and Kerberos v5.

Retrieving *group* Information

The following syntax shows the proper form of a *group* entry:

```
groupName:password:gid:user-list
```

How the nss_ad Naming Service Module Retrieves Data From AD
How the `nss_ad` Naming Service Module Retrieves Data From AD

See the `group(4)` for man page for more information.

The `nss_ad` module retrieves information from AD as follows:

- **`groupname`** – Field uses the value of the `samAccountName` AD attribute and is qualified by the domain name in which the object resides, for example, `admins@example`.
- **`password`** – Field is left empty because the Windows groups do not have passwords.
- **`gid`** – Field uses the Windows group’s SID from the `objectSID` AD attribute, which is mapped to the GID by using the `idmap` service.
- **`user-list`** – Field is left empty.
### Glossary

**application-level naming service**
Application-level naming services are incorporated in applications offering services such as files, mail, and printing. Application-level naming services are bound below enterprise-level naming services. The enterprise-level naming services provide contexts in which contexts of application-level naming services can be bound.

**attribute**
Each LDAP entry consists of a number of named attributes each of which has one or more values. Also: The N2L service mapping and configuration files each consist of a number of named attributes each of which has one or more values.

**authentication**
The means by which a server can verify a client's identity.

**baseDN**
The DN where part of the DIT is rooted. When this is the baseDN for a NIS domains entries it is also referred to as a context.

**client**
(1) The client is a principal (machine or user) requesting an naming service from an naming server.

(2) In the client-server model for file systems, the client is a machine that remotely accesses resources of a compute server, such as compute power and large memory capacity.

(3) In the client-server model, the client is an application that accesses services from a “server process.” In this model, the client and the server can run on the same machine or on separate machines.

**client-server model**
A common way to describe network services and the model user processes (programs) of those services. Examples include the name-server/name-resolver paradigm of the Domain Name System (DNS). See also client.

**context**
For the N2L service, a context is something under which a NIS domain is generally mapped. See also baseDN.

**credentials**
The authentication information that the client software sends along with each request to a naming server. This information verifies the identity of a user or machine.

**data encrypting key**
A key used to encipher and decipher data intended for programs that perform encryption. Contrast with key encrypting key.

**data encryption standard (DES)**
A commonly used, highly sophisticated algorithm developed by the U.S. National Bureau of Standards for encrypting and decrypting data. See also SUN-DES-1.

**databaseID**
For the N2L service, a databaseID is an alias for a group of maps containing NIS entries of the same format (having the same mappings to LDAP). The maps might have differing keys.
DBM

DBM is the database originally used to store NIS maps.

decimal dotted notation

The syntactic representation for a 32-bit integer that consists of four 8-bit numbers written in base 10 with periods (dots) separating them. Used to represent IP addresses in the Internet as in: 192.67.67.20.

DES

See data encryption standard (DES).

directory

(1) An LDAP directory is a container for LDAP objects. In UNIX, a container for files and subdirectories.

directory cache

A local file used to store data associated with directory objects.

directory information tree

The DIT is the distributed directory structure for a given network. By default, Solaris LDAP clients access the information assuming that the DIT has a given structure. For each domain supported by the LDAP server, there is an assumed subtree with an assumed structure.

distinguished name

A distinguished name is an entry in an X.500 directory information base (DIB) composed of selected attributes from each entry in the tree along a path leading from the root down to the named entry.

DIT

See directory information tree.

DN

A distinguished name in LDAP. A tree-like structured addressing scheme of the LDAP directory which gives a unique name to each LDAP entry.

DNS

See Domain Name System.

DNS-forwarding

An NIS server forwards requests it cannot answer to DNS servers.

DNS zone files

A set of files wherein the DNS software stores the names and IP addresses of all the workstations in a domain.

DNS zones

Administrative boundaries within a network domain, often made up of one or more subdomains.

domain

(1) In the Internet, a part of a naming hierarchy usually corresponding to a Local Area Network (LAN) or Wide Area Network (WAN) or a portion of such a network. Syntactically, an Internet domain name consists of a sequence of names (labels) separated by periods (dots). For example, sales.doc.com.

(2) In International Organization for Standardization’s open systems interconnection (OSI), “domain” is generally used as an administrative partition of a complex distributed system, as in MHS private management domain (PRMD), and directory management domain (DMD).

domain name

The name assigned to a group of systems on a local network that share DNS administrative files. The domain name is required for the network information service database to work properly. See also domain.

Domain naming service (DNS)

A service that provides the naming policy and mechanisms for mapping domain and machine names to addresses outside of the enterprise, such as those on the Internet. DNS is the network information service used by the Internet.

encryption

The means by which the privacy of data is protected.

encryption key

See data encrypting key.
### enterprise-level network

An "enterprise-level" network can be a single Local Area Network (LAN) communicating over cables, infra-red beams, or radio broadcast; or a cluster of two or more LANs linked together by cable or direct phone connections. Within an enterprise-level network, every machine is able to communicate with every other machine without reference to a global naming service such as DNS or X.500/LDAP.

### entry

A single row of data in a database table, such as an LDAP element in a DIT.

### field

A NIS map entry might consist of a number of components and separator characters. As part of the N2L service mapping process the entry is first broken down into a number of named fields.

### GID

See group ID.

### global naming service

A global naming service identifies (names) those enterprise-level networks around the world that are linked together by phone, satellite, or other communication systems. This world-wide collection of linked networks is known as the "Internet." In addition to naming networks, a global naming service also identifies individual machines and users within a given network.

### group ID

A number that identifies the default group for a user.

### indexed name

A naming format used to identify an entry in a table.

### Internet address

A 32-bit address assigned to hosts using TCP/IP. See decimal dotted notation.

### IP

Internet Protocol. The network layer protocol for the Internet protocol suite.

### IP address

A unique number that identifies each host in a network.

### key (encrypting)

A key used to encipher and decipher other keys, as part of a key management and distribution system. Contrast with data encrypting key.

### key server

A Solaris operating environment process that stores private keys.

### LDAP

Lightweight Directory Access Protocol is a standard, extensible directory access protocol used by LDAP naming service clients and servers to communicate with each other.

### local-area network (LAN)

Multiple systems at a single geographical site connected together for the purpose of sharing and exchanging data and software.

### mail exchange records

Files that contain a list of DNS domain names and their corresponding mail hosts.

### mail hosts

A workstation that functions as an email router and receiver for a site.

### mapping

The process of converting NIS entries to or from DIT entries. This process is controlled by a mapping file.

### master server

The server that maintains the master copy of the network information service database for a particular domain. Namespace changes are always made to the naming service database kept by the domain's master server. Each domain has only one master server.

### MIS

Management information systems (or services).

### N2L server

NIS-to-LDAP server. An NIS master server that has been reconfigured as an N2L server by using the N2L service. Reconfiguration includes replacing NIS daemons and adding new configuration files.
### name resolution

- **name resolution**: The process of translating workstation or user names to addresses.

- **name server**: Servers that run one or more network naming services.

- **namespace**: (1) A namespace stores information that users, workstations, and applications must have to communicate across the network.  
  (2) The set of all names in a naming system.

- **naming service**: A network service that handles machine, user, printer, domain, router, an other network names and addresses.

- **naming service switch**: A configuration file (/etc/nsswitch.conf) that defines the sources from which an naming client can obtain its network information.

- **NDBM**: NDBM is an improved version of DBM.

- **network mask**: A number used by software to separate the local subnet address from the rest of a given Internet protocol address.

- **network password**: See Secure RPC password.

- **NIS**: A distributed network information service containing key information about the systems and the users on the network. The NIS database is stored on the master server and all the replica or slave servers.

- **NIS maps**: A file used by NIS that holds information of a particular type, for example, the password entries of all users on a network or the names of all host machines on a network. Programs that are part of the NIS service query these maps. See also NIS.

- **preferred server list**: A client_info table or a client_info file. Preferred server lists specify the preferred servers for a client or domain.

- **private key**: The private component of a pair of mathematically generated numbers, which, when combined with a private key, generates the DES key. The DES key in turn is used to encode and decode information. The private key of the sender is only available to the owner of the key. Every user or machine has its own public and private key pair.

- **public key**: The public component of a pair of mathematically generated numbers, which, when combined with a private key, generates the DES key. The DES key in turn is used to encode and decode information. The public key is available to all users and machines. Every user or machine has their own public and private key pair.

- **RDN**: Relative Distinguished Name. One part of a DN.

- **record**: See *entry*.

- **remote procedure call (RPC)**: An easy and popular paradigm for implementing the client-server model of distributed computing. A request is sent to a remote system to execute a designated procedure, using arguments supplied, and the result is returned to the caller.

- **reverse resolution**: The process of converting workstation IP addresses to workstation names using the DNS software.
RFC 2307  RFC specifying a mapping of information from the standard NIS maps to DIT entries. By default, the N2L service implements the mapping specified in an updated version RFC 2307bis.

RPC  See remote procedure call (RPC).

schema  A set of rules defining what types of data can be stored in any given LDAP DIT.

searchTriple  A description of where to look for a given attribute in the DIT. The searchTriple is composed of a 'base dn', 'scope' and 'filter'. This is part of the LDAP URL format as defined in RFC 2255.

Secure RPC password  Password required by Secure RPC protocol. This password is used to encrypt the private key. This password should always be identical to the user’s login password.

server  (1) In NIS, DNS, and LDAP a host machine providing naming services to a network.

(2) In the client-server model for file systems, the server is a machine with computing resources (and is sometimes called the compute server), and large memory capacity. Client machines can remotely access and make use of these resources. In the client-server model for window systems, the server is a process that provides windowing services to an application, or “client process.” In this model, the client and the server can run on the same machine or on separate machines.

(3) A daemon that actually handles the providing of files.

server list  See preferred server list.

slave server  A server system that maintains a copy of the NIS database. It has a disk and a complete copy of the operating environment.

source  NIS source files

SSL  SSL is the secure sockets layer protocol. It is a generic transport-layer security mechanism designed to make application protocols such as LDAP secure.

subnet  A working scheme that divides a single logical network into smaller physical networks to simplify routing.

suffix  In LDAP, the distinguished name (DN) of the DIT.

TCP  See Transport Control Protocol (TCP).

TCP/IP  Acronym for Transport Control Protocol/Interface Program. The protocol suite originally developed for the Internet. It is also called the Internet protocol suite. Solaris networks run on TCP/IP by default.

Transport Control Protocol (TCP)  The major transport protocol in the Internet suite of protocols providing reliable, connection-oriented, full-duplex streams. Uses IP for delivery. See TCP/IP.

Transport Layer Security (TLS)  TLS secures communication between an LDAP client and the directory server, providing both privacy and data integrity. The TLS protocol is a super set of the Secure Sockets Layer (SSL) protocol.

wide-area network (WAN)  A network that connects multiple local-area networks (LANs) or systems at different geographical sites by phone, fiber-optic, or satellite links.
X.500

A global-level directory service defined by an Open Systems Interconnection (OSI) standard. A precursor to LDAP.

yp

Yellow Pages™. The old name for NIS which is still used within the NIS code.
