Preface

This guide describes the ways to troubleshoot some common issues related to Sun Java™ System Web Server 7.0.

See Also Sun Java System Web Server 7.0 Administrator’s Guide.

Who Should Use This Book

This book is intended for Sun Java System Web Server administrators to troubleshoot the server in production environments. The guide assumes familiarity with the following areas:

- Installing software
- Using web browsers
- Performing basic system administration tasks
- Issuing commands in a terminal window

Before You Read This Book

Web Server can be installed as a standalone product or as a component of Sun Java Enterprise System (Java ES), a software infrastructure that supports enterprise applications distributed across a network or Internet environment. If you are installing Web Server as a component of Java ES, you should be familiar with the system documentation at http://docs.sun.com/coll/1286.1.

Web Server Documentation Set

The Web Server documentation set describes how to install and administer the Web Server. The URL for Web Server documentation is http://docs.sun.com/coll/1308.3. For an introduction to Web Server, refer to the books in the order in which they are listed in the following table.
### TABLE P–1 Books in the Web Server Documentation Set

<table>

</tr>
</tbody>
</table>
| **Sun Java System Web Server 7.0 Release Notes**        | ■ Late-breaking information about the software and documentation  
■ Supported platforms and patch requirements for installing Web Server                                                                                                                                  |
| **Sun Java System Web Server 7.0 Installation and Migration Guide** | Performing installation and migration tasks:  
■ Installing Web Server and its various components,  
■ Migrating data from Sun ONE Web Server 6.0 or 6.1 to Sun Java System Web Server                                                                                                               |
| **Sun Java System Web Server 7.0 Administrator’s Guide** | Performing the following administration tasks:  
■ Using the Administration and command-line interfaces  
■ Configuring server preferences  
■ Using server instances  
■ Monitoring and logging server activity  
■ Using certificates and public key cryptography to secure the server  
■ Configuring access control to secure the server  
■ Using Java Platform Enterprise Edition (Java EE) security features  
■ Deploying applications  
■ Managing virtual servers  
■ Defining server workload and sizing the system to meet performance needs  
■ Searching the contents and attributes of server documents, and creating a text search interface  
■ Configuring the server for content compression  
■ Configuring the server for web publishing and content authoring using WebDAV                                                                 |
| **Sun Java System Web Server 7.0 Developer’s Guide**     | Using programming technologies and APIs to do the following:  
■ Extend and modify Sun Java System Web Server  
■ Dynamically generate content in response to client requests and modify the content of the server                                                                                       |
| **Sun Java System Web Server 7.0 NSAPI Developer’s Guide** | Creating custom Netscape Server Application Programmer’s Interface (NSAPI) plug-ins                                                                                                                       |
| **Sun Java System Web Server 7.0 Developer’s Guide to Java Web Applications** | Implementing Java Servlets and JavaServer Pages™ (JSP™) technology in Sun Java System Web Server                                                                                                     |

Accessing Sun Resources Online

The [http://docs.sun.com](http://docs.sun.com) (docs.sun.com) web site enables you to access Sun technical documentation online. You can browse the docs.sun.com archive or search for a specific book title or subject. Books are available as online files in PDF and HTML formats. Both formats are readable by assistive technologies for users with disabilities.

To access the following Sun resources, go to [http://www.sun.com](http://www.sun.com)

- Downloads of Sun products
- Services and solutions
- Support (including patches and updates)
- Training
- Research
- Communities (for example, Sun Developer Network)
Searching Sun Product Documentation

Besides searching Sun product documentation from the docs.sun.com web site, you can use a search engine by typing the following syntax in the search field:

```
search-term  site:docs.sun.com
```

For example, to search for “Web Server,” type the following:

```
Web Server site:docs.sun.com
```

To include other Sun web sites in your search (for example, java.sun.com, www.sun.com and developers.sun.com), use “sun.com” in place of “docs.sun.com” in the search field.

Third-Party Web Site References

Third-party URLs are referenced in this document and provide additional, related information.

---

**Note** – Sun is not responsible for the availability of third-party web sites mentioned in this document. Sun does not endorse and is not responsible or liable for any content, advertising, products, or other materials that are available on or through such sites or resources. Sun will not be responsible or liable for any actual or alleged damage or loss caused or alleged to be caused by or in connection with use of or reliance on any such content, goods, or services that are available on or through such sites or resources.

---

Sun Welcomes Your Comments

Sun is interested in improving its documentation and welcomes your comments and suggestions. To share your comments, go to http://docs.sun.com and click Send Comments. In the online form, provide the full document title and part number. The part number is a 7-digit or 9-digit number that can be found on the book’s title page or in the document’s URL. For example, the part number of this book is 819-4738.
Overview

This chapter provides a description of the tools, methods, and information sources available for troubleshooting the Sun Java System Web Server Server 7.0. Guidelines for evaluating and investigating a problem are included.

- “Planning Ahead” on page 11
- “Identifying the Problem” on page 12
- “Seeking a Solution” on page 13

Planning Ahead

As applications get deployed, un-deployed, and redeploys, and as you experiment with different server configuration settings, there may be times when your server gets into an unstable state. In such cases, it is useful to have a previously saved working configuration on which to fall back. This is not problem solving, but rather a way to avoid problems in the first place.

Refer to the Web Server Administrator's Guide for complete instructions on using the CLI and GUI options. Briefly, however, for the purposes of this Troubleshooting Guide, use the following procedure to backup the virtual servers in your configuration:

To back up your virtual server

1. Go to Common Tasks page.
   The Common Tasks page is the home page when you access the administration console. For more information on accessing the administration console, refer to the Administrator’s Guide.

2. Select the Configuration.
   From the Configuration Tasks page, select the configuration from the drop down box.
Copy Virtual Servers.
Select the virtual server from the list and click Copy button. A window will pop up. Provide the new virtual server name and click OK. The web applications also gets copied.

Identifying the Problem

Sun Java System Web Servers are typically deployed in complex and highly sophisticated operating environments. The Sun Java System Web Server covers a broad range of technologies, including Java, Java Servlets, XSL, JSP, JDBC data sources, and more. Understanding and diagnosing complex issues involving so many disparate components requires thorough knowledge and a careful diagnostic process.

Gathering any or all of the following information will make it easier to classify a problem and search for solutions. Note that operating system utilities, such as `pkginfo` and `showrev` on Solaris and `rpm` on Linux, are helpful in gathering system information.

Verifying Server Platform

1. What are the exact version numbers of the operating system and products installed?
2. Have any patches been applied? If so, specify product and operating system patch numbers.
3. How is the system configured?
   a. What system resources does the system have (memory, disk, swap space, and so on)?
   b. How many web servers and directory servers are installed?
   c. How is the Web Server connected to the directory server?
   d. Are web servers in a cluster or not?
   e. Was any upgrade done? If so, what were source and target versions?
   f. Was a migration done? If so, what were source and target versions?
4. Have any new web applications been deployed?
5. Is SSL enabled or not?
6. What database is being used?
What JDBC driver is being used to access the database?

What JDK version is being used?

What are the JVM heap, stack, and garbage collection-related parameters set to?

What are the JVM options?

What third-party technologies are being used in the installation?

Are the interoperating component versions in compliance with the compatibility matrix specified in the release notes?

After gathering this information:

- Collect web server error and access log data (web server instance-specific).
- Collect any Web Server stack traces. Note that a fresh set of logs associated with the specific problem should be run. This avoids scanning gigabytes of irrelevant log information.
- Determine the sequence of events that occurred when the problem first appeared, including any steps that may already have been taken to resolve the problem.

Note – When you encounter a problem, do not panic. It is better to approach the problem more systematically by collecting the necessary system specific details.

Seeking a Solution

After identifying the problem, you are ready to do some investigation.

The following topics are addressed in this section:

- “Verify System Configuration” on page 14
- “Evaluate Messages” on page 14
- “Examine Log Files” on page 15
- “See if the Problem has been Solved Before” on page 16
- “Search the Product Documentation” on page 16
- “Search the Knowledge Base” on page 16
- “Search or Participate in the Online Forum” on page 17
- “Contact Support” on page 17
Verify System Configuration

Sometimes the most obvious solutions are overlooked, and so the first step is to verify the system configuration. Refer to the Sun Java System Web Server 7.0 Release Notes for the most up-to-date system requirements and dependencies.

Evaluate Messages

Messages generally include information about the attempted action, the outcome of the action, and, if applicable, the cause of jeopardy or failure.

Types of Messages

The log files contain the following general types of message entries:

- **Error** – These messages mark critical failures that cause status to be reported as Failed. Error messages generally provide detailed information about the nature and the cause of the problem that occurred.
- **Warning** – These messages mark non-critical failures. Warning messages generally contain information about the cause and the nature of the failure, and also provide possible remedies.
- **Information** – These messages mark normal completion of particular tasks.

Error Messages

A problem is often accompanied by an error message that prevents the application from proceeding.

- In some cases, the message is very clear about what is wrong and what needs to be done, if anything, to fix it. For example the 'Deployment Pending' link that appears on the administration console whenever an instance configuration is modified. In this case, the message gives clear guidance and the problem can be disregarded.
- Sometimes an error message gives only general information about the problem or solution, or suggests multiple possibilities. In this case, the problem is not obvious, or there might be multiple things wrong. You might have to consider various possibilities and perhaps a number of solutions. If the proposed fix is time consuming or costly, take steps to ensure that the fix is likely to be correct before actually doing anything.
- Some error messages are either not helpful or provide little guidance. In this case, there is very little information to go on. It is especially important to identify the exact situation that caused the error, and what the symptoms are before proceeding.

For descriptions of all the Web Server error messages, refer to the later sections in this guide.
Examine Log Files

A number of the Web Server subsystems create log files and log their events to these files. The primary purpose of these log files is to provide troubleshooting information.

**Note** – Web Server Error Logs are the first place you should look for information, when you need to troubleshoot a runtime issue. For issues related to installation, see the installation log files.

In addition to the message text, a logged message provides the following information:

- Date and time of the event
- Log level for the event — Web Server-specified log level ID or name
- Process identifier (PID) — PID of the Web Server process
- (optional) Virtual server identifier (VSID) — VSID that generated the message
- Message identifier (MID) — subsystem and a four digit integer
- Message data

The specific logs associated with each Web Server problem area are discussed in the associated chapters of this manual.

Log Levels

The Web Server has many log levels that can be set in the Administration GUI (FINEST, FINER, FINE, CONFIG, INFO, WARNING, SEVERE, ALERT, and FATAL). All messages are logged when the log level is set to FINEST and only serious error messages appear if the log level is set to FATAL.

Note that the more detailed log levels (FINEST, FINER, FINE) can generate high volumes of log information for certain events, which may make it appear at first glance that there is an error condition when in fact there is not.

All messages with a log level less than the default level of INFO (FINEST, FINER, FINE, and CONFIG) provide information related to debugging and must be specifically enabled. Instructions for doing this are contained in the *Sun Java System Web Server Administrator’s Guide*.

In addition to the standard JDK log levels, the Web Server has added log levels designed to map more intuitively to the Web Server log file (server.log) and to tightly integrate with Solaris. The log levels ALERT and FATAL are specific to the Web Server and are not implemented in the JDK1.4 logging API.
Note – For information on the event log mechanism used in the Microsoft Windows operating environment, refer to the Windows help system index using the keywords Event Logging. If you choose to send logs to the Windows server.log file, only messages with a log level of INFO, WARNING, SEVERE, ALERT, or FATAL are logged to the Windows Event Log.

Log Options
The Administration GUI provides the following two logging options:

- **Option 1** — Log stdout (System.out.print) content to the event log
- **Option 2** — Log stderr (System.err.print) content to the event log

When these options are set, stdout and stderr messages are written to the server.log file. (The event log is a syslog daemon on Solaris and Event Log on Microsoft Windows.)

If the above options are not set:

- Anything written to stdout or stderr (that is, using System.out or System.err) will not appear in the logs.
- Messages logged with the JDK logger will appear in the logs.
- Messages written to stdout or stderr appear with the INFO level, but do not have a message ID.

See if the Problem has been Solved Before
A good initial step is to scan this Troubleshooting Guide to see if the problem is addressed here. If so, select the appropriate solution. Many of the solutions contain references to other documents in the Web Server document collection for additional details, explanations, or examples.

Search the Product Documentation
Start by reading the Release Notes for the version of the product you are troubleshooting.

The documentation for this Web Server product release is available at Sun Java System Web Server 7.0 Documentation Center.

Search the Knowledge Base
The Knowledge Base is a collection of articles on product issues that provide information helpful for troubleshooting. To access the Knowledge Base:
To search the Knowledge Base

2. Under SunSolve Collections, click the Search Collections link.
3. Select the checkbox for the collection(s) to search.
4. Click Next.
5. Enter the search criteria.
6. Click Go.

Search or Participate in the Online Forum

Browse directly in any of the online forums, or log in and register to start posting messages. The Web Server online forum is available at: http://swforum.sun.com/jive/index.jsp?cat=7

Contact Support

When necessary, gather together the information you have acquired and contact technical support at http://www.sun.com/service/contacting.
This chapter describes how to troubleshoot the most common installation, uninstallation, and migration issues.

This chapter contains the following sections:

- "Installation Problems" on page 19
- "Uninstallation Problems" on page 22
- "Migration Problems" on page 22

## Installation Problems

As a critical first step, examine the installation log files.

The install log file is the `Sun_Java_System_Web_Server_install.log` file located in `install_dir/setup/` directory. Install log file entries contain information about the attempted action, the outcome of the action, and the cause of failure if applicable. Entries fall into three categories: INFO, WARNING, and ERROR.

For more information on the installation log, see "Viewing Installation Log Files" in *Sun Java System Web Server 7.0 Installation and Migration Guide*.

---

**Note** – Check if the DISPLAY environment variable is set properly on the machine used for installation. The DISPLAY variable needs to be set to the IP address of that machine, followed by a screen address, which can always be assumed to be :0.0. On Linux/Unix, execute `echo $DISPLAY` to find the value.

## Failed Installation

If your installation fails, investigate the installation log.
Existing Installation Detected

The installer maintains an entry in the product registry. If installation files are removed
incorrectly (for example, if the files are manually deleted instead of being removed by running
the uninstaller), the files may be gone but the Web Server entries remain in the product registry.
If you then try to reinstall to that location, a message displays indicating that an existing
installation has been detected, even though it appears that the installation does not exist. To
remedy the situation, go to the product registry and delete the entries manually.

The location of the product registry differs for each platform.

Note – Again, the information in this section applies only if files were removed in some way
other than by using the Web Server uninstaller.

Product Registry on Solaris

On Solaris, the product registry is in /var/sadm/install/productregistry.

In the productregistry file, remove the content between <components> and </components>,
and you should then be able to install to the location. The following example shows a product
registry file on Solaris.

EXAMPLE 2–1  Example Product Registry File

```xml
<productregistry>
  <version>7.0</version>
  <components>
    <compid>webcore
      <compversion>1.0</compversion>
      <uniquename>webcore</uniquename>
      <compinstance>1</compinstance>
      <comptype>COMPONENT
        <location>/sun/gj/ws7</location>
      </comptype>
    </compid>
    <compid>java
      <compversion>1.0</compversion>
      <uniquename>java</uniquename>
      <compinstance>1</compinstance>
      <comptype>COMPONENT
```

EXAMPLE 2–1  Example Product Registry File  (Continued)

</comptype>
<location>/sun/gj/ws7
</location>
</compinstance>
</compversion>
</compid>
<compid>snmp
<compversion>1.0
  <uniquename>snmp
   </uniquename>
  <compinstance>1
   <comptype>COMPONENT
    </comptype>
    <location>/sun/gj/ws7
     </location>
     </compinstance>
     </compversion>
     </compid>
  </components>
</productregistry>

Product Registry on Linux
On Linux, the product registry is in /var/opt/sun/install/productregistry.

Product Registry on Windows
On Windows, the product registry is in C:\WINNT\system32.

The installation will fail if the Windows registry contains the HKEY_LOCAL_MACHINE\SOFTWARE\Sun Microsystems\WebServer\7.0 entry. Remove this entry using Registry Editor, and you should then be able to install to the desired location.

Note – If you get an error related to the https-admserv70 service, remove the following entry from the registry and try installing again:
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\https-admserv70.

Defaults to Command-Line Mode
On UNIX systems, the installer and uninstaller default to command-line mode if the DISPLAY environment variable has not been exported to your local machine and if X Windows is not supported.
Uninstallation Problems

As a critical first step, examine the uninstallation log file.

Migration Problems

As a critical first step, examine the migration log.
My Server Fails to Start

When your server fails to start, consider the following cases:

1. If you have configured Web Server to run on port 80, then you will need to start the server as 'root' user on Unix/Linux. However in Solaris 10, you don’t need to run the Server as root to bind to port 80 (or < 1024). Execute the following commands:

   ```sh
   # su
   # /usr/sbin/usermod -K defaultpriv=basic,net_privaddr webservd
   ```

2. When you encounter server startup issue, Server’s error log or console output (on UNIX/Linux platforms) should most likely contain the reason for the startup failure.

3. If the Web Server is configured to run in 64-bit and any of the plug-ins mentioned in the magnus.conf is of 32-bit, then Web Server 7.0 would fail to startup, throwing out error message like `wrong ELF class: ELFCLASS32`. Similarly, if you see an error message like `wrong ELF class: ELFCLASS64` it means that 32-bit Web Server is trying to load a 64 bit NSAPI plugin or vice-versa.

4. While starting up the Web Server, if you do not see the message `info: CORE3274: successful server startup` on UNIX/Linux platforms, then it is most likely that the server has startup issues.

5. If you see the error message `catastrophe ( 908): Server crash detected (signal SIGSEGV)` in the server’s error log file, this means that Web Server’s daemon has detected a crash. Web Server crash during startup can happen because of various reasons including:
   - Any of the configured 3rd party NSAPI plug-ins is either not following NSAPI specification.
   - Improper Server Configuration.
6. Web Server requires at least 512 MB of memory to operate optimally. If your system is running low on swap space then you might get error shown below:

```
warning: CORE3283: stderr: Error occurred during initialization of VM
warning: CORE3283: stderr: Could not reserve enough space for object heap
catastrophe: CORE4005: Internal error: unable to create JVM
failure: server initialization failed
```

You will have to increase the swap space on your system. If you are running Web Server 7 under Solaris 10 zones, then you will need to increase the swap space within the global zone.

**Note** – Refer to your operating system document on how to add/increase swap space.

---

**File Descriptor Issues**

Under heavy load condition, Web Server may run out of file descriptors. In such cases you will get an error like the following:

```
```

Increase the file descriptor limit either per process or per system and restart the system.

Linux limits the number of file descriptors that any one process may open; the default limits are 1024 per process. These limits can prevent optimum performance of Web Server. The open file limit is one of the limits that can be tuned with the `ulimit` command. The command `ulimit -aS` displays the current limit, and `ulimit -aH` displays the hard limit (above which the limit cannot be increased without tuning kernel parameters). For setting the limit to hard limit, execute the following command:

```
ulimit -n unlimited
```

---

**Performance Issues**

Running Administration Server As Non-Root

Problem: Unable to bind at port <port_number>.

The administration server and the administration nodes should be run by the same user id in Unix. This is because of the following reason:

1. If the instances are running as part of the root process, the Administration Server will not have sufficient permissions to modify the instance's configuration files, if it is not running as part of the root process.

So for the administration server to perform its job of maintaining the server instances, it either needs to be part of the root process or at least the same user as that of the server instance. However in Solaris 10, you don’t need to run the Administration Server as root to bind to port 80 (or < 1024). Execute the following commands:

```
# su
#/usr/sbin/usermod -K defaultpriv=basic,net_privaddr webservd
```
Pulling Configuration Changes to the Administration Server

Whenever you make manual changes to the configuration, you should replicate the changes back into the Administration server repository as follows:

1. Manually edit server instance’s configuration files as you would do with the earlier version of Web Server.
2. Start the Web Server 7.0 Administration Server. See the Administrator’s Guide.
3. For pulling the changes back to the Administration Server repository, execute the following command.

   ```bash
   wadm> pull-config --user=admin --config=CONFIG_NAME
   ``

Note – The operation may take some time depending on the configuration.

Note – Always use the Administration Console or the wadm CLI to edit the settings.

Making Changes to server.policy File

If you are deploying your website containing Java web applications and would like to enable security manager within the web container, then you will need to edit the server instance’s server.policy file. In this scenario, Administration Server does not provide a direct command line interface or GUI to edit this server.policy file. But you can still perform the steps as mentioned in the previous section to make any manual edit to the server.policy file.

Deployment Pending Message in Administration Console

Question: When I make changes to a configuration from the GUI, I see a deployment pending message. What does it mean?

Answer: The deployment pending message indicates that there are changes to the configuration that are saved into the administration server’s configuration store. You need to click the Deploy button to save these changes to the instances.
Do I Need to Save or Deploy?

**Question:** What is the difference between the Save and Deploy buttons that shows up on every page in the Administration Console within a configuration?

**Answer:** If you click on Save, then the changes are saved only in the configuration store. When you click the Deploy button, the changes will be saved to the instances.

Manually Editing Configuration Files

**Question:** Can I make manual edits to my configuration files? Will these be reflected in the CLI and GUI?

**Answer:** If you need to make manual changes to the configuration files, make the changes within the configuration store. These changes will be reflected in the CLI and GUI and can be deployed using the `deploy-config` command or by clicking on Deploy button in the GUI. But if you make changes directly in the instance, the Administration Console will show up a warning stating that there are manual modifications to the configuration files and you need to either overwrite these changes with the configuration in the configuration store or else get these changes back into the configuration store overwriting the existing configuration changes.

---

**Note** – Always use the Administration Console or the `wadm` CLI to edit the settings.

`deploy-config` Command Fails

**Question:** Sometimes the `deploy-config` fails saying that a server restart is needed. Why?

**Answer:** When `deploy-config` is invoked, the configuration changes in the configuration store are propagated to the instances and the running servers are re-configured so that the configuration changes are picked up. But certain changes cannot be applied dynamically and need a server restart. You will hence need to run a `restart-instance` command in order to restart the server instances.

Where Can I Find `wadm` CLI?

**Question:** Where can I find the CLI for Sun Java System Web Server 7.0 administration?

**Answer:** The administration CLI is located at `install-root/bin/wadm`. To use the CLI, you need to know:

- Administration server hostname (default is `localhost`).
- SSL port for the administration server (default is 8989).
- Administration server user name (default is `admin`).
- Administration server password.

**Note** – Administration server needs to be running in order to use the CLI. You can start the server by running `install-root/admin-server/bin/startserv`.

**Note** – If you are using `wadm` CLI on the same machine where the Administration Server is installed, then you do not need to know the Administration Server’s port number. You are required to know the port number only if you have configured Administration Node and need to use `wadm` CLI to connect to a remote Administration Server.
After enabling WebDAV in Sun Java System Web Server 7.0, when you send a WebDAV request that needs write permissions, you get 403 Forbidden error.

This error message means you need to set appropriate ACLs in the ACL file for that virtual server. See the Administrator’s Guide.

Note – If after enabling WebDAV in Sun Java System Web Server 7.0, make sure that the directory in which WebDAV is enabled, has Read and Write permissions for the user that owns webservd process (like “webservd” or “root”).
“Issuing Test Request to an SSL Server” on page 31
“Analyzing SSL Requests” on page 32

Issuing Test Request to an SSL Server

While diagnosing problems between Web Server 7.0 and web browsers, it is useful to analyze the requests and responses. When SSL/TLS is not used, for capturing requests and responses between web browser and the server you can use any network capture tool such as ethereal.

But when SSL/TLS is used for communication, you can use the OpenSSL’s s_client application for tapping the communication.

Execute the following command (after successful SSL connection) and enter the test HTTP request as desired.

```
$openssl s_client -host localhost -port 8080 -quiet
```

By using the same command without the -quiet flag, you can see information about the connection, such as the server DN, Certificate name and negotiated cipher suite.

For testing particular cipher suites, check the -cipher option. For example:

```
$openssl s_client -host localhost -port 8080 -cipher DES-CBC-SHA
```

For more information, see the s_client man page at http://www.openssl.org/docs/apps/s_client.html.
Analyzing SSL Requests

Earlier method of issuing test request works well as long as you can recreate the request content manually. But sometimes you need to diagnose a connection that is being used by a web browser.

There are a number of tools available to observe such request and response data. One such tool is ssltap. ssltap takes the proxy approach—it serves as a simple proxy between the client and the Web Server and displays information about the connections it forwards (you can also use ssltap for observing plain HTTP requests or even requests based on other protocols).

Assume that Web Server is running with an SSL-enabled listener on port 8088 on a machine. Now issue the following command:

```
$ssltap -l -s localhost:8088
Looking up "localhost"...
Proxy socket ready and listening
```

**Note**—Use the -l option so ssltap doesn’t exit after a single request.

By default ssltap listens on port 1924. Now connect to https://localhost:1924 with your browser. You will get an output like the following snippet:

```
Connection #1 [Mon Dec 10 15:49:49 2006]
Connected to localhost:8088
-->
alloclen = 87 bytes
(87 bytes of 87)
[Mon Apr 10 15:49:49 2006] [ssl2] ClientHelloV2 {
  version = {0x03, 0x01}
  cipher-specs-length = 60 (0x3c)
  sid-length = 0 (0x00)
  challenge-length = 16 (0x10)
  cipher-suites = {
    (0x000039) TLS/DHE-RSA/AES256-CBC/SHA
    (0x000038) TLS/DHE-DSS/AES256-CBC/SHA
    (0x000035) TLS/RSA/AES256-CBC/SHA
    (0x000033) TLS/DHE-RSA/AES128-CBC/SHA
    (0x000032) TLS/DHE-DSS/AES128-CBC/SHA
    (0x000004) SSL3/RSA/RC4-128/MD5
    (0x000005) SSL3/RSA/RC4-128/SHA
    (0x00002f) TLS/RSA/AES128-CBC/SHA
    (0x000016) SSL3/DHE-RSA/3DES192EDE-CBC/SHA
    (0x000013) SSL3/DHE-DSS/DES192EDE3CBC/SHA
    (0x00feff) SSL3/RSA-FIPS/3DESEDE-CBC/SHA
```
This is the SSL client hello being sent from the browser to the server. Note the list of cipher suites the browser has sent. This is the set of cipher suites the browser is configured to handle (note that they are sorted in order of preference). The server will pick one of those for the handshake (if the server is not set up to handle any of these, the connection will then immediately fail). In the above snippet, the session-id is empty, which tells you the browser does not have any cached SSL session with this particular server.

For the above request, the Web Server’s response is shown below:

```plaintext
<--
(1015 bytes of 1010)
SSLRecord { [Mon Apr 10 15:49:49 2006]
  type     = 22 (handshake)
  version  = { 3,1 }
  length   = 1010 (0x3f2)
  handshake {
    type      = 2 (server_hello)
    length    = 70 (0x000046)
    ServerHello {
      server_version = {3, 1}
      random        = {...}
      session ID    = {
        length = 32
        contents = {...}
      }
      cipher_suite  = (0x0035) TLS/RSA/AES256-CBC/SHA
    }
    type      = 11 (certificate)
    length    = 928 (0x0003a0)
    CertificateChain {
      chainlength = 925 (0x039d)
      Certificate {
        size = 485 (0x01e5)
      }
    }
  }
}
```
The server picked TLS/RSA/AES256-CBC/SHA as the cipher suite to use. A session ID was sent, which this client will include in subsequent requests. The server also sent its certificate chain for the browser to verify. ss1tap saved these certificates in the files noted cert.001 and cert.002. You can examine these certificates with any tool that can parse X.509 certificates. For example, execute the following command:

```
$openssl x509 -in cert.001 -text -inform DER
```

**Note** - ss1tap is a single threaded proxy server. So if you issue multiple requests through it, the requests will get serialized. If you need to analyze a specific problem with your application that only occurs on concurrent requests through SSL, try running multiple ss1tap instances.
FastCGI

Getting More Information

Fastcgistub is a process manager that manages the life cycle of the FastCGI application processes. Fastcgistub logs its messages into Fastcgistub.log file under the Web Server’s temporary directory. In case of any error, analyzing this file can help in debugging the problem.

FastCGI Requests Are Not Getting Served

FastCGI request not getting served is one of the common problems.

1. While starting the Web Server, did you see the following message?

   FCGI1000: Sun Java System Web Server 7.0 FastCGI NSAPI Plugin <build-information>

   Yes — FastCGI Plug-in has been loaded successfully.

   No — Check the path to the plug-in library within magnus.conf file.

2. Check if the request mapping is correctly specified within obj.conf file. For more information, see Administrator’s Configuration File Reference Guide.

3. Check the Server Log for any error message.

4. Check the permissions for the stub binary and FastCGI applications. Without sufficient permissions, the plug-in will fail to start the stub/application.

5. Check the Fastcgistub.log file for any possible error on the stub side.

6. Try executing the FastCGI application in a standalone mode and check if the application runs normally.
Dependency Issues

If library dependency errors are thrown, then whichever path is required to be added to LD_LIBRARY_PATH for resolving the library dependency errors in the standalone mode, the same library path should be specified within obj.conf file as app-env parameter with LD_LIBRARY_PATH value.
Gathering Debug Data

Gathering Debug Data for Sun Java System Web Server

You can use Sun Gathering Debug Data (Sun GDD) tool that the Sun Support Center requires to debug problems with Sun Java System Web Server.
