Preface

This book describes software features that apply only to the Sun Enterprise™ 6x00/5x00/4x00/3x00 family of servers.

Related Documents

For detailed information on the software features described in this book, refer to the man pages for Solaris 8. For information on DR features, refer to the Sun Enterprise 6x00, 5x00, 4x00, and 3x00 Systems Dynamic Reconfiguration User’s Guide.

Using UNIX Commands

This document may not contain information on basic UNIX® commands and procedures such as shutting down the system, booting the system, and configuring devices.

See one or more of the following for this information:

- Solaris Handbook for SMCC Peripherals
- AnswerBook™ online documentation for the Solaris™ software environment
- Other software documentation that you received with your system

Ordering Sun Documentation

Fatbrain.com, an Internet professional bookstore, stocks select product documentation from Sun Microsystems, Inc.

For a list of documents and how to order them, visit the Sun Documentation Center on Fatbrain.com at:

http://www1.fatbrain.com/documentation/sun

Accessing Sun Documentation Online

The docs.sun.com℠ web site enables you to access Sun technical documentation on the Web. You can browse the docs.sun.com℠ archive or search for a specific book title or subject at:

http://docs.sun.com
Sun Welcomes Your Comments

We are interested in improving our documentation and welcome your comments and suggestions. You can email your comments to us at:

docfeedback@sun.com

Please include the part number (806-4647-10) of your document in the subject line of your email.
CHAPTER 1

OpenBoot Commands

This chapter describes the OpenBoot™ commands for Sun Enterprise 6x00/5x00/4x00/3x00 servers.

OpenBoot Command Syntax

This is an explanation of the syntax used in the examples of OpenBoot commands shown in the following sections.

In the examples a notation “( -- )” represents the stack diagram, where any entries to the left of the “--” represent the state of the stack before the command is executed. Any any entries to the right represent the stack after the command is executed. If there are any such entries, the top of the stack is listed at the far right, preceded by entries that are lower in the stack. In the example below, the entries c and z are the top of the stack, before and after the command is executed, respectively.

```
command ( a b c -- x y z )
```

For more information about OpenBoot command usage, refer to OpenBoot documentation, such as the OpenBoot 3.x Command Reference Manual, part number 806-1377.
Environmental Monitoring Commands

The following commands are used for environmental monitoring.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>disable-environmental-monitor</td>
<td>To stop monitoring power supply status, board temperatures, and board hot plug while the screen displays the ok prompt.</td>
</tr>
<tr>
<td>Usage: disable-environmental-monitor ( -- )</td>
<td></td>
</tr>
<tr>
<td>enable-environmental-monitor</td>
<td>To start monitoring power supply status, board temperatures, and board hot plug while the screen displays the ok prompt.</td>
</tr>
<tr>
<td>Usage: enable-environmental-monitor ( -- )</td>
<td></td>
</tr>
</tbody>
</table>
Externally Initiated Reset XIR

If a hard failure occurs, use XIR to reset the system, then immediately get information about the system state at the time of the hard failure.

▼ To Initiate an XIR

● Use either the XIR button on the clock board or the remote console XIR sequence. When an XIR occurs, memory is cleared but some CPU states are temporarily saved. See the following section.

▼ To Display XIR Information

● Type the following command at the ok prompt immediately after the XIR:

```
ok .xir-state-all
```

The output displays the CPU state for each CPU:

<table>
<thead>
<tr>
<th>CPU ID</th>
<th>TL</th>
<th>TT</th>
<th>TPC</th>
<th>TnPC</th>
<th>TSTATE</th>
</tr>
</thead>
<tbody>
<tr>
<td>#1</td>
<td>1</td>
<td>3</td>
<td>e0028688</td>
<td>e0028688</td>
<td>99000001e06</td>
</tr>
<tr>
<td>CPU ID</td>
<td>5</td>
<td>1</td>
<td>e002755c</td>
<td>e0027560</td>
<td>4477001e03</td>
</tr>
</tbody>
</table>

Where:

TL is the trap level.

TT is the trap type.

TPC is the trap program counter.
**TState** is the trap state.

---

**Note** – The XIR does not override the NVRAM auto-boot? variable.

---

**Hardware Watchdog**

The Sun Enterprise xx00 family of servers provide the ability to enable a hardware timer that will hard-reset the system if it times out. To enable this feature, `watchdog_enable` must be set to 1 in the `/etc/system` file.

---

**Flash PROM Management**

The following OpenBoot 3.x commands are used in flash PROM management:

**TABLE 1-3** Flash PROM Management Commands

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>flash-update-system</code></td>
<td>To download the default flash images on all the boards in the system.</td>
</tr>
<tr>
<td><code>prom-copy</code></td>
<td>To copy a flash PROM from board <code>src</code> to board <code>dst</code>. Source (<code>src</code>) and Destination (<code>dst</code>) are specified by slot number.</td>
</tr>
<tr>
<td><code>update-proms</code></td>
<td>To synchronize the latest copy of each type of PROM on all other boards of the same type.</td>
</tr>
</tbody>
</table>
System Configuration and Diagnostic Information

To print system configuration and diagnostic information, use prtdiag instead of using an OpenBoot command. The diagnostic information displayed lists the failed field-replaceable units (FRUs) in the system. For more information on prtdiag, see the prtdiag man page.

prtdiag(1M) Options

- **v** lists the most recent AC Power failure, the most recent hardware fatal error information, and, if applicable, environmental status.
- **l** logs its output to syslogd(1M) only if failures or errors exist in the system.

TOD Clock Management

The following command is used for time-of-day (TOD) clock management, which includes NVRAM located on I/O boards.

<table>
<thead>
<tr>
<th>Command</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>copy-clock-tod-to-io-boards</td>
<td>To download the default flash images on all the boards in the system.</td>
</tr>
<tr>
<td>Usgr: copy-clock-tod-to-io-boards ( -- )</td>
<td>In the system.</td>
</tr>
</tbody>
</table>
NVRAM Variables

The following table lists selected NVRAM variables and associated values that can be used with the dynamic reconfiguration (DR) feature on Sun Enterprise 6x00, 5x00, 4x00, and 3x00 systems:

**TABLE 1-5  Specific NVRAM Variables**

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Comments</th>
</tr>
</thead>
<tbody>
<tr>
<td>configuration-policy</td>
<td>This variable determines how the dynamic reconfiguration feature handles failing hardware. The value (component board, or system) of the variable determines the level of hardware that is to be disabled if a failure occurs. The default value is component.</td>
</tr>
<tr>
<td>disabled-board-list</td>
<td>The value may be a list of hexadecimal slot numbers or it may be blank, meaning no boards are disabled. The default value is blank.</td>
</tr>
<tr>
<td>memory-interleave</td>
<td>This variable determines how memory is interleaved between CPU/Memory boards. The value may be min or max. Setting the value to min allows dynamic reconfiguration operations. Setting the value to max allows large memory configurations. The default value is max.</td>
</tr>
<tr>
<td>sbus-probe-default</td>
<td>The value may be a combination of numbers for the Sbus devices (0-3) and other on-board devices (hexadecimal d represents the on-board SOC) on an I/O board. Devices are probed in the order in which they are listed.</td>
</tr>
<tr>
<td>sbus-specific-probe</td>
<td>The value consists of a board number and a list of device numbers (0-3 and d), separated by a colon.</td>
</tr>
</tbody>
</table>

To set or unset these variables, use the `setenv` or `set-default` commands, as appropriate. Commands take effect on the next system reset or at power-on.

Here are some examples of command syntax:

```
ok setenv configuration-policy component
(Disables only the component, if it fails.)

ok setenv configuration-policy board
(Disables the entire board if a component fails.)
```
ok `setenv disabled-board-list 7af`
(Disables boards in slots 7, 10 (hexidecimal a), and 15 (hexidecimal f).)

ok `set-default disabled-board-list`
(Removes all boards from the board list by setting it to null.)

ok `setenv memory-interleave min`
(Turns off interleaving between boards.)

ok `setenv sbus-probe-default 123d0`
(Sets order of probing to the second, third, and fourth SBus devices, followed by the SOC device and the first SBus device.)

ok `setenv sbus-specific-probe 4:320`
(Specifies board 4 and SBus devices 3, 2, and 0, in order.)
(Devices 1 and d are omitted and are therefore not probed.)
Board Hot-Plug Software and Dynamic Reconfiguration

This chapter explains how to use the board hot-plug capability and Dynamic Reconfiguration (DR), where applicable. Hot-plug is a hardware feature that allows the replacement of components while a server is running. However, the system cannot use the new component until the system is rebooted. The Dynamic Reconfiguration software enhancement allows replacement of certain I/O boards without needing to reboot the server.

For OpenBoot command information and examples, see Chapter 1.

The board hot-plug procedures described in this chapter need to be followed by a Dynamic Reconfiguration (DR) restart procedure or by a system reboot.

**Note** – For the Solaris 8 software environment, DR applies to Sun Enterprise type 1, 2, 4, and 5 I/O boards. These boards include the Sbus, Graphics, Sbus+, and Graphics+ I/O boards. I/O boards with slots for PCI cards are not yet supported.

Refer to the online Sun Enterprise 6x00, 5x00, 4x00, 3x00 Systems Dynamic Reconfiguration User’s Guide for information about preparing your server to use DR, and instructions for performing DR operations. Check with your Sun Sales representative or system engineer for information on the availability of DR for your system.

Disabled System Board

A system board can be disabled (not used by the operating system) in three ways:
A self-test detects a failure and disables the board.

The board is disabled manually by using disabled-board-list. For example:

```
ok setenv disabled-board-list 72
```

The above command disables boards in slots 7 and 2.

The board was inserted while the operating system was running.

▼ To Swap Out a Disabled Board

1. Verify that system precharge is OK.
   Use the `prtdiag` command. For more information see “System Configuration and Diagnostic Information”.

2. Verify that hot-plug is available.

3. Make sure that the board is disabled (not in use by the operating system and the power light on the target board is off).
   An example of the `setenv disabled-board-list` command is shown above.

4. Remove the disabled board.
   
   **Caution** – If the yellow light is lit on the front panel, use `prtdiag` to determine the cause before installing a new board.

5. Install a new board.

6. To activate the board:
   - For PCI boards, reboot the system.
   - For other I/O boards, use DR commands.

Activated System Board

The system board is activated when the following three conditions are met:

- The board is in place during system startup.
- The slot has not been disabled by disabled-board-list.
- The board passes self-test.
To Swap Out an Activated Type Three (PCI) Board

Dynamic reconfiguration does not yet support I/O boards with slots for PCI cards.
1. Halt the system.
2. Power off the system.
3. Remove and replace the board.
4. Reboot the system to activate the board.

To Swap Out an Activated Board if Your System Supports DR

DR supports Sun Enterprise type 1, 2, 4, and 5 I/O boards. These boards include the Sbus, Graphics, Sbus+, and Graphics+ I/O boards.
1. Use the appropriate `cfgadm` command to unconfigure the board from the system.
   Refer to the *Sun Enterprise 6x00, 5x00, 4x00, 3x00 Systems Dynamic Reconfiguration User’s Guide*, part number 806-3984, for information about this command.
2. Remove and replace the board.
3. To activate the board and reconfigure the board to the system, use DR commands.

Disabling Hardware

By using the `configuration-policy` command, you can disable:
- A component—disables only the failing component
- A board—disables the board if any component on it fails
- A system—stops the system at the POST menu if there is a failure

Examples:
```
ok setenv configuration-policy board
```
To Disable a Defective Board

If you suspect a board is defective and want to request that the system disable the board, perform the following procedure.

1. Isolate the board from the system:
   - For a type three I/O board, use the `setenv` command at the `ok` prompt or the `eeprom` command at the `#` prompt and then reboot the system.
   - For all other boards, use DR commands.
   In the examples that follow, 3 means slot 3.

   ```
   ok setenv disabled-board-list 3
   ```

   or

   ```
   # eeprom "configuration-policy=board"
   ```

2. Remove the defective board and insert a new board.
3. To activate the board:
   - For type 3 (PCI) I/O boards, clear the `disabled-board-list`, and then reboot the system.
   - For all other boards, use DR commands.

   See “Environmental Monitoring Commands” for more information.

Alternate Pathing

Alternate Pathing (AP) is a software enhancement that works in conjunction with DR and hot-plug. AP allows you to bypass a disabled disk or network adapter, avoiding unnecessary downtime. For additional information, refer to the Solaris on Sun Enterprise Servers AnswerBook module in the *Sun Enterprise Servers Alternate Pathing User’s Guide*, part number 806-1934.
CHAPTER 3

CPU Over-Temperature Safeguard

The CPU over-temperature safeguard (COS) is a Sun Enterprise xx00 platform feature for the Solaris 8 software environment and compatible versions available for servers with the proper firmware support. COS ensures that the temperature on any CPU/memory board does not exceed the safe operating range.

COS Requirements

COS is not available if a Sun Enterprise xx00 server lacks enabling firmware. In this case, the system displays the following messages during the boot sequence:

- WARNING: Firmware does not support CPU power off
- WARNING: Automatic CPU shutdown on over-temperature disabled
- WARNING: Firmware does not support CPU restart from power off
- WARNING: The ability to restart individual CPUs is disabled

When equipped with the proper firmware, the system displays the following during the boot sequence. Later firmware will show a similar output.

| Board 0: OBP | 3.2.8 1997/02/27 14:00 | POST 3.5.1 1997/03/05 09:34 |

- To check the firmware revision level, use the `prtdiag -v` command.

The correct firmware version for COS support is 3.2.8 or later.
Factors in Overheating

Many external conditions can raise the CPU/memory board temperature and compound high temperature problems, including:
- Room air-conditioning set incorrectly
- Lateral cooling obstructed

Some Solaris software environment issues can also affect the CPU temperature, such as bound threads or having only one CPU/memory board in the system. These Solaris software environment issues can cause a fallback to the existing shutdown behavior.

The CPU over-temperature safeguard does not affect the Solaris software environment in any way. COS operates only when the temperature of a CPU/memory board exceeds the safe operating range.

COS Operation

COS functions by monitoring the temperatures of all system CPUs. Warning messages are displayed in the system console if a CPU/memory board over-temperature condition occurs. The following example indicates an over-temperature condition for CPU/memory board 0:

WARNING: CPU/Memory board 0 is warm (temperature: 73C). Please check system cooling
NOTICE: Processor 0 powered off.
NOTICE: Processor 1 powered off.

Resolving an Over-Temperature Condition

When the COS feature detects a CPU over-temperature condition, it takes the CPU offline and powers it off.

The system continues to operate with the offending CPU powered off. The CPUs are the chief source of heat on a CPU/Memory board; removing that heat source lowers the temperature into the normal operating range. This prevents sudden down time to the production server.
To Resolve an Over-Temperature Condition

1. Verify the new state with the `psrinfo` command
   
   The `psrinfo` output reflects the new CPU state:
   
   ```
   0  powered-off since 03/11/97 09:48:31
   1  powered-off since 03/11/97 09:48:31
   ```

2. Without powering off the operating system, replace the defective power supply (containing cooling fans) with a working unit.

   **Note** – You can also halt the server using `/etc/halt` or `init 0` at the root or superuser prompt before replacing the defective power supply.

3. Bring the CPU back to normal operation using the `psradm` command:

   ```
   # psradm -n processor_id
   ```

   With the CPU over-temperature safeguard feature, if the temperature sensor again reports an over-temperature (the temperature is still out of range), then the attempt to bring the CPUs back into operation using the `psradm` command fails, an exit status of -1 and an error message is returned.

   If the CPU in question has returned to normal operating temperature, the console displays a message similar to the following.

   ```
   NOTICE: CPU/Memory board 0 has cooled down (temperature: 72C), system OK.
   ```

Failure to Disengage CPUs

In some instances, the CPU power control cannot disengage the affected CPU(s) from the Solaris software environment. For example, if the high temperature condition occurs when only one CPU/memory board with two processors is in the system, processor one will not go offline because it is the last processor in the system.
Failure to Power Off CPUs

If the attempted de-coupling of the problem CPU from the Solaris software environment fails, the temperature may continue to increase. When the temperature reaches the hard upper operational temperature limit, the system shuts down. In this case, a message similar to the following is displayed:

```
WARNING: CPU/Memory board 0 is very hot (temperature: 83C)
WARNING: System shutdown scheduled in 20 seconds due to over-temperature condition on CPU/Memory board 0
WARNING: CPU/Memory board 0 still too hot (temperature: 83C). Overtemp shutdown started
```
