Preface

The Application Packaging Developer’s Guide provides step-by-step instructions and relevant background information for designing, building, and verifying packages. This guide also includes advanced techniques that you might find helpful during the package creation process.

Note – This Solaris™ release supports systems that use the SPARC® and x86 families of processor architectures: UltraSPARC®, SPARC64, AMD64, Pentium, and Xeon EM64T. The supported systems appear in the Solaris OS: Hardware Compatibility Lists at http://www.sun.com/bigadmin/hcl. This document cites any implementation differences between the platform types.

In this document these x86 related terms mean the following:

- “x86” refers to the larger family of 64-bit and 32-bit x86 compatible products.
- “x64” points out specific 64-bit information about AMD64 or EM64T systems.
- “32-bit x86” points out specific 32-bit information about x86 based systems.

For supported systems, see the Solaris OS: Hardware Compatibility Lists.

Who Should Use This Book

This book is intended for application developers whose responsibilities include designing and building packages.

Though much of the book is directed towards novice package developers, it also contains information useful to more experienced package developers.
How This Book Is Organized

The following table describes the chapters in this book.

<table>
<thead>
<tr>
<th>Chapter Name</th>
<th>Chapter Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chapter 1, &quot;Designing a Package&quot;</td>
<td>Describes package components and package design criteria. Also describes related commands, files, and scripts.</td>
</tr>
<tr>
<td>Chapter 2, &quot;Building a Package&quot;</td>
<td>Describes the process and required tasks for building a package. Also provides step-by-step instructions for each task.</td>
</tr>
<tr>
<td>Chapter 3, &quot;Enhancing the Functionality of a Package (Tasks)&quot;</td>
<td>Provides step-by-step instructions for adding optional features to a package.</td>
</tr>
<tr>
<td>Chapter 4, &quot;Verifying and Transferring a Package&quot;</td>
<td>Describes how to verify the integrity of a package and how to transfer a package to a distribution medium.</td>
</tr>
<tr>
<td>Chapter 5, &quot;Case Studies of Package Creation&quot;</td>
<td>Provides case studies for creating packages.</td>
</tr>
<tr>
<td>Chapter 6, &quot;Advanced Techniques for Creating Packages&quot;</td>
<td>Describes advanced techniques for creating packages.</td>
</tr>
<tr>
<td>Glossary</td>
<td>Defines terms used in this book.</td>
</tr>
</tbody>
</table>

Related Books

The following documentation, available through retail booksellers, can provide additional background information on building System V packages.

- System V Application Binary Interface
- System V Application Binary Interface - SPARC Processor Supplement
- System V Application Binary Interface - Intel386 Processor Supplement

Documentation, Support, and Training

The Sun web site provides information about the following additional resources:

- Documentation (http://www.sun.com/documentation/)
- Support (http://www.sun.com/support/)
- Training (http://www.sun.com/training/)
Sun Welcomes Your Comments

Sun is interested in improving its documentation and welcomes your comments and suggestions. To share your comments, go to http://docs.sun.com and click Feedback.

Typographic Conventions

The following table describes the typographic conventions that are used in this book.

<table>
<thead>
<tr>
<th>Typeface</th>
<th>Meaning</th>
<th>Example</th>
</tr>
</thead>
<tbody>
<tr>
<td>AaBbCc123</td>
<td>The names of commands, files, and directories, and onscreen computer output</td>
<td>Edit your .login file. Use ls -a to list all files. machine_name% you have mail.</td>
</tr>
<tr>
<td>AaBbCc123</td>
<td>What you type, contrasted with onscreen computer output</td>
<td>machine_name% su Password:</td>
</tr>
<tr>
<td>aabbcc123</td>
<td>Placeholder: replace with a real name or value</td>
<td>The command to remove a file is rm filename.</td>
</tr>
<tr>
<td>AaBbCc123</td>
<td>Book titles, new terms, and terms to be emphasized</td>
<td>Read Chapter 6 in the User’s Guide. A cache is a copy that is stored locally. Do not save the file. Note: Some emphasized items appear bold online.</td>
</tr>
</tbody>

</table>
Before you build a package, you need to know which files you need to create and the commands you need to execute. You also need to consider your application software’s requirements and the needs of your customers. Your customers are the administrators who will be installing your package. This chapter discusses the files, commands, and criteria you should know and consider before building a package.

This is a list of the information in this chapter.

- “Where to Find Packaging Tasks” on page 13
- “What Are Packages?” on page 13
- “Package Components” on page 14
- “Considerations Before Building a Package” on page 17
- “Packaging Commands, Files, and Scripts” on page 20

**Where to Find Packaging Tasks**

Use these task maps to find step-by-step instructions for building and verifying packages.

- “The Process of Building a Package (Task Map)” on page 23
- “Creating Information Files and Installation Scripts (Task Map)” on page 49
- “Verifying and Transferring a Package (Task Map)” on page 83

**What Are Packages?**

Application software is delivered in units called *packages*. A package is a collection of files and directories that are required for a software product. A package is usually designed and built by the application developer after completing the development of the application code. A software product needs to be built into one or more packages so that it can easily be transferred to a distribution medium. Then, the software product can be mass produced and installed by administrators.
A package is a collection of files and directories in a defined format. This format conforms to the application binary interface (ABI), which is a supplement to the System V Interface Definition.

**Package Components**

The components of a package fall into two categories.

- **package objects** are the application files to be installed.
- **control files** control how, where, and if the package is installed.

The control files are also divided into two categories: **information files** and **installation scripts**. Some control files are required. Some control files are optional.

To package your applications, you must first create the required components, and any optional components, that make up your package. You can then build the package by using the `pkgmk` command.

To build a package, you must provide the following:

- Package objects (the application software's files and directories)
- Two required information files (the `pkginfo` and `prototype` files)
- Optional information files
- Optional installation scripts

The following figure describes the contents of a package.
You must create the following components before you build your package:

- **Package objects**
  These components make up the application. They can consist of the following items:
  - Files (executable files or data files)
  - Directories
  - Named pipes
  - Links
  - Devices

- **The pkginfo file**
  The pkginfo file is a required package information file that defines parameter values. Parameter values include the package abbreviation, the full package name, and the package architecture. For more information, see "Creating a pkginfo File" on page 26 and the pkginfo(4) man page.
Note – There are two `pkginfo(1)` man pages. The first man page describes a section 1 command that displays information about installed packages. The second man page describes a section 4 file that describes the characteristics of a package. When accessing the man pages, be sure to specify the applicable man page section. For example: `man -s 4 pkginfo`.

- The `prototype` file
  
The prototype file is a required package information file that lists the components of the package. One entry exists for each package object, information file, and installation script. An entry consists of several fields of information that describe each component, including its location, attributes, and file type. For more information, see “Creating a prototype File” on page 31 and the `prototype(4)` man page.

Optional Package Components

Package Information Files

You can include four optional package information files in your package:

- The `compver` file
  
  Defines previous versions of the package that are compatible with this version of your package.

- The `depend` file
  
  Indicates other packages that have a special relationship with your package.

- The `space` file
  
  Defines disk space requirements for the target environment, beyond what is required by the objects defined in the `prototype` file. For example, additional space might be needed for files that are dynamically created at installation time.

- The `copyright` file
  
  Defines the text for a copyright message that displays at the time of package installation.

Each package information file should have an entry in the `prototype` file. See “Creating Information Files” on page 50 for more information on creating these files.

Package Installation Scripts

Installation scripts are not required. However, you can provide scripts that perform customized actions during the installation of your package. An installation script has the following characteristics:
The script is composed of Bourne shell commands.
- The script's file permissions should be set to 0644.
- The script does not need to contain the shell identifier (#!/bin/sh).

The four script types are as follows:
- The request script
  The request script requests input from the administrator who is installing the package.
- The checkinstall script
  The checkinstall script performs special file system verification.

Note – The checkinstall script is only available with the Solaris™ 2.5 release and compatible releases.

- Procedure scripts
  Procedure scripts define actions that occur at particular points during package installation and removal. You can create four procedure scripts with these predefined names: preinstall, postinstall, preremove, and postremove.
- Class action scripts
  Class action scripts define a set of actions to be performed on a group of objects.

See “Creating Installation Scripts” on page 56 for a more information on installation scripts.

Considerations Before Building a Package

Before building a package, you need to decide whether your product will consist of one or more packages. Note that many small packages take longer to install than one big package. Although creating a single package is a good idea, doing so is not always possible. If you decide to build more than one package, you need to determine how to segment the application code. This section provides a list of criteria to use when planning to build a package.

Many of the packaging criteria present trade-offs among themselves. Satisfying all requirements equally is often difficult. These criteria are presented in order of importance. However, this sequence is meant to serve as a flexible guide depending on the circumstances. Although each criterion is important, it is up to you to optimize these requirements to produce a good set of packages.

For more design ideas, see Chapter 6, “Advanced Techniques for Creating Packages.”
Make Packages Remotely Installable

All packages must be remotely installable. Being remotely installable means that the administrator installing your package might be trying to install it on a client system, not necessarily to the root (/) file system where the pkgadd command is being executed.

Optimize for Client-Server Configurations

Consider the various types of system software configurations (for example, standalone system and server) when laying out packages. Good packaging design divides the affected files to optimize installation of each configuration type. For example, the contents of the root (/) and /usr file systems should be segmented so that server configurations can easily be supported.

Package by Functional Boundaries

Packages should be self-contained and distinctly identified with a set of functionality. For example, a package that contains UFS should contain all UFS utilities and be limited to only UFS binaries.

Packages should be organized from a customer’s point of view into functional units.

Package Along Royalty Boundaries

Put code that requires royalty payments due to contractual agreements in a dedicated package or group of packages. Do not disperse the code into more packages than necessary.

Package by System Dependencies

Keep system-dependent binaries in dedicated packages. For example, the kernel code should be in a dedicated package, with each implementation architecture consisting of a distinct package instance. This rule also applies to binaries for different architectures. For example, binaries for a SPARC system would be in one package and binaries for an x86 system would be in another package.

Eliminate Overlap in Packages

When constructing packages, eliminate duplicate files whenever possible. Unnecessary duplication of files results in support and version difficulties. If your product has multiple packages, repeatedly compare the contents of these packages for duplicated files.
Package Along Localization Boundaries

Localization-specific items should be in their own package. An ideal packaging model would have a product’s localizations delivered as one package per locale. Unfortunately, in some cases organizational boundaries conflict with the functional and product boundaries criteria.

International defaults can also be delivered in a package. This design isolates the files that are necessary for localization changes and standardizes the delivery format of localization packages.

Image Packaging System (IPS) Packages

This document discusses SVR4 packages. For delivery into the OpenSolaris OS, consider using Image Packaging System (IPS) packages. The OpenSolaris OS supports both SVR4 and IPS packages. The IPS software interacts with network repositories and uses the ZFS file system. In the OpenSolaris OS, you can publish existing SVR4 packages to an IPS repository with the `pkgsend(1)` command.

The following table contains a comparison of commands for the SVR4 packaging system and the IPS packaging system. For detailed information on IPS, see Getting Started With the Image Packaging System (http://dlc.sun.com/osol/docs/content/IPS/ggcph.html).

<table>

Packaging Commands, Files, and Scripts

This section describes the commands, files, and scripts that you might use when manipulating packages. They are described in man pages and in detail throughout this book, in relation to the specific task they perform.

The following table shows the commands to help you build, verify, install, and obtain information about a package.

<table>
<thead>
<tr>

This chapter describes the process and the tasks involved in building a package. Some of these tasks are required. Some of these tasks are optional. The required tasks are discussed in detail in this chapter. For information on the optional tasks, which enable you to add more features to your package, see Chapter 3, “Enhancing the Functionality of a Package (Tasks),” and Chapter 6, “Advanced Techniques for Creating Packages.”

This is a list of the information in this chapter.

- “The Process of Building a Package (Task Map)” on page 23
- “Package Environment Variables” on page 24
- “Creating a pkginfo File” on page 26
- “Organizing a Package’s Contents” on page 29
- “Creating a prototype File” on page 31
- “Building a Package” on page 43

The Process of Building a Package (Task Map)

Table 2-1 describes a process for you to follow when building packages, especially if you are inexperienced at building them. Although it is not mandatory for you to complete the first four tasks in the exact order listed, your package building experience will be easier if you do. Once you are an experienced package designer, you can shuffle the sequence of these tasks to your preference.

As an experienced package designer, you can automate the package building process by using the make command and makefiles. For more information, see the make(1S) man page.
TABLE 2–1 The Process of Building a Package Task Map

<table>

</tr>
</tbody>
</table>

Package Environment Variables

You can use variables in the required information files, pkginfo and prototype. You can also use an option to the pkgmk command, which is used to build a package. As these files and commands are discussed in this chapter, more context-sensitive information on variables is provided. However, before you begin building your package, you should understand the different types of variables and how they can affect the successful creation of a package.

There are two types of variables:

- **Build variables**
  
  *Build variables* begin with a lowercase letter and are evaluated at *build time*, as the package is being built with the pkgmk command.

- **Install variables**
  
  *Install variables* begin with an uppercase letter and are evaluated at *install time*, as the package is being installed with the pkgadd command.

General Rules on Using Environment Variables

In the pkginfo file, a variable definition takes the form *PARAM=value*, where the first letter of *PARAM* is an uppercase letter. These variables are evaluated only at install time. If any of these variables cannot be evaluated, the pkgadd command aborts with an error.
In the prototype file, a variable definition can take the form `PARAM=value` or `$variable`. Both `PARAM` and `variable` can begin with either an uppercase or a lowercase letter. Only variables whose values are known at build time are evaluated. If `PARAM` or `variable` is a build or install variable whose value is not known at build time, the `pkgmk` command aborts with an error.

You can also include the option `PARAM=value` as an option to the `pkgmk` command. This option works the same as in the prototype file, except that its scope is global to the entire package. The `PARAM=value` definition in a prototype file is local to that file and the part of the package it defines.

If `PARAM` is an install variable, and `variable` is an install variable or build variable with a known value, the `pkgmk` command inserts the definition into the `pkginfo` file so that the definition will be available at install time. However, the `pkgmk` command does not evaluate `PARAM` that are in any path names that are specified in the prototype file.

**Package Environment Variables Summary**

The following table summarizes variable specification formats, location, and scope.

<table>
<thead>
<tr>
<th>Where Variable Is Defined</th>
<th>Variable Definition Format</th>

Creating a pkginfo File

The pkginfo file is an ASCII file that describes the characteristics of a package along with information that helps control the flow of installation.

Each entry in the pkginfo file is a line that establishes the value of a parameter using the format PARAM=value. PARAM can be any of the standard parameters described in the pkginfo(4) man page. There is no required order in which the parameters must be specified.

Note – Each value can be enclosed with single or double quotation marks (for example, 'value' or "value"). If value contains any characters that are considered special to a shell environment, you should use quotation marks. The examples and case studies in this book do not use quotation marks. See the pkginfo(4) man page for an example that uses double quotation marks.

You can also create your own package parameters by assigning a value to them in the pkginfo file. Your parameters must begin with a capital letter followed by either uppercase or lowercase letters. An uppercase letter indicates that the parameter (variable) will be evaluated at install time (as opposed to build time). For information on the difference between install variables and build variables, see "Package Environment Variables" on page 24.

Note – Trailing whitespace after any parameter value is ignored.

You must define these five parameters in a pkginfo file: PKG, NAME, ARCH, VERSION, and CATEGORY. The PATH, PKGINST, and INSTDATE parameters are inserted automatically by the software when the package is built. Do not modify these eight parameters. For information on the remaining parameters, see the pkginfo(4) man page.

Defining a Package Instance

The same package can have different versions, be compatible with different architectures, or both. Each variation of a package is known as a package instance. A package instance is determined by combining the definitions of the PKG, ARCH, and VERSION parameters in the pkginfo file.

The pkgadd command assigns a package identifier to each package instance at installation time. The package identifier is the package abbreviation with a numerical suffix, for example SUNWadm.2. This identifier distinguishes a package instance from any other package, including instances of the same package.

Defining a Package Abbreviation (PKG)

A package abbreviation is a short name for a package that is defined by the PKG parameter in the pkginfo file. A package abbreviation must have these characteristics:
The abbreviation must consist of alphanumeric characters. The first character cannot be a number.

- The abbreviation cannot exceed 32 characters in length.
- The abbreviation cannot be one of the reserved abbreviations: install, new, or all.

**Note** – The first four characters should be unique to your company. For example, packages built by Sun Microsystems™ all have “SUNW” as the first four characters of their package abbreviation.

An example of a package abbreviation entry in a pkginfo file is PKG=SUNWcadap.

### Specifying a Package Architecture (ARCH)

The ARCH parameter in the pkginfo file identifies which architectures are associated with the package. The architecture name has a maximum length of 16 alphanumeric characters. If a package is associated with more than one architecture, specify the architectures in a comma-separated list.

This is an example of a package architecture specification in a pkginfo file:

ARCH=sparc

### Specifying a Package Instruction Set Architecture (SUNW_ISA)

The SUNW_ISA parameter in the pkginfo file identifies which instruction set architecture is associated with a Sun Microsystems package. The values are as follows:

- sparcv9, for a package that contains 64–bit objects
- sparc, for a package that contains 32–bit objects

For example, the SUNW_ISA value in a pkginfo file for a package containing 64–bit objects would be:

SUNW_ISA=sparcv9

If SUNW_ISA is not set, the default instruction set architecture of the package is set to the value of the ARCH parameter.

### Specifying a Package Version (VERSION)

The VERSION parameter in the pkginfo file identifies the version of the package. The version has a maximum length of 256 ASCII characters, and cannot begin with a left parenthesis.

This is an example version of a specification in a pkginfo file:

VERSION=release 1.0
Defining a Package Name (NAME)

A package name is the full name of the package, which is defined by the NAME parameter in the pkginfo file.

Because system administrators often use package names to determine whether a package needs to be installed, writing clear, concise, and complete package names is important. Package names must meet the following criteria:

- State when a package is needed (for example, to provide certain commands or functionality, or state if the package is needed for specific hardware).
- State what the package is used for (for example, the development of device drivers).
- Include a description of the package abbreviation mnemonic, using key words that indicate the abbreviation is a short form of the description. For example, the package name for the package abbreviation SUNWbnuu is "Basic Networking UUCP Utilities, (Usr)".
- Name the partition into which the package is installed.
- Use terms consistently with their industry meaning.
- Take advantage of the 256-character limit.

Here is an example package name defined in a pkginfo file:

NAME=Chip designers need CAD application software to design abc chips. Runs only on xyz hardware and is installed in the usr partition.

Defining a Package Category (CATEGORY)

The CATEGORY parameter in the pkginfo file specifies in which categories a package belongs. At a minimum, a package must belong to either the system or application category. Category names consist of alphanumeric characters. Category names have a maximum length of 16 characters and are case insensitive.

If a package belongs to more than one category, specify the categories in a comma-separated list.

Here is an example CATEGORY specification in a pkginfo file:

CATEGORY=system
How to Create a pkginfo File

1. **Using your favorite text editor, create a file named pkginfo.**
   You can create this file anywhere on your system.

2. **Edit the file and define the five required parameters.**
   The five required parameters are: PKG, NAME, ARCH, VERSION, and CATEGORY. For more information on these parameters, see “Creating a pkginfo File” on page 26.

3. **Add any optional parameters to the file.**
   Create your own parameters or see the pkginfo(4) man page for information on the standard parameters.

4. **Save your changes and quit the editor.**

Example 2–1 Creating a pkginfo File

This example shows the contents of a valid pkginfo file, with the five required parameters defined, as well as the BASEDIR parameter. The BASEDIR parameter is discussed in more detail in “The path Field” on page 32.

```
PKG=SUNWcadap
NAME=Chip designers need CAD application software to design abc chips.
Runs only on xyz hardware and is installed in the/usr partition.
ARCH=sparc
VERSION=release 1.0
CATEGORY=system
BASEDIR=/opt
```

**See Also** See “How to Organize a Package’s Contents” on page 30.

Organizing a Package’s Contents

Organize your package objects in a hierarchical directory structure that mimics the structure that the package objects will have on the target system after installation. If you do this step before you create a prototype file, you can save yourself some time and effort when creating that file.
How to Organize a Package's Contents

1 Determine how many packages you need to create and which package objects shall be located in each package.
   For help in completing this step, see “Considerations Before Building a Package” on page 17.

2 Create a directory for each package you need to build.
   You can create this directory anywhere on your system and name it anything you like. The examples in this chapter assume that a package directory has the same name as the package abbreviation.
   $ cd /home/jane
   $ mkdir SUNWcadap

3 Organize the package objects in each package into a directory structure beneath their corresponding package directory. The directory structure must mimic the structure that the package objects will have on the target system.
   For example, the CAD application package, SUNWcadap, requires the following directory structure.

```
/home/jane
    SUNWcadap
        demo
        lib
        man
        srcfiles
            file1
            file2
            windex
            man1
            file5
            file6
            file3.1
            file4.1
```

4 Decide where you will keep your information files. If appropriate, create a directory to keep the files in one location.
   This example assumes that the example pkginfo file from “How to Create a pkginfo File” on page 29 was created in Jane’s home directory.
   $ cd /home/jane
   $ mkdir InfoFiles
   $ mv pkginfo InfoFiles

See Also See “How to Create a prototype File by Using the pkgproto Command” on page 42.
Creating a prototype File

The prototype file is an ASCII file used to specify information about the objects in a package. Each entry in the prototype file describes a single object, such as a data file, directory, source file, or executable object. Entries in a prototype file consist of several fields of information separated by white space. Note that the fields must appear in a specific order. Comment lines begin with a pound sign (#) and are ignored.

You can create a prototype file with a text editor or by using the pkgproto command. When you first create this file, it is probably easier to do so with the pkgproto command, because it creates the file based on the directory hierarchy you created previously. If you have not organized your files as described in “Organizing a Package’s Contents” on page 29, you have the cumbersome task of creating the prototype file from scratch with your favorite text editor.

Format of the prototype File

Here is the format for each line in the prototype file:

```
part ftype class path major minor mode owner group
```

- **part**
  - Is an optional, numeric field that enables you to group package objects into parts. The default value is part 1.

- **ftype**
  - Is a one-character field that specifies the object’s type. See "The ftype Field" on page 32.

- **class**
  - Is the installation class to which the object belongs. See "The class Field" on page 32.

- **path**
  - Is the absolute or relative path name indicating where the package object will reside on the target system. See "The path Field" on page 32.

- **major**
  - Is the major device number for block or character special devices.

- **minor**
  - Is the minor device number for block or character special devices.

- **mode**
  - Is the octal mode of the object (for example, 0644). See "The mode Field" on page 35.

- **owner**
  - Is the owner of the object (for example, `bin` or `root`). See "The owner Field" on page 35.

- **group**
  - Is the group to which the object belongs (for example, `bin` or `sys`). See "The group Field" on page 36.

Usually, only the **ftype**, **class**, **path**, **mode**, **owner**, and **group** fields are defined. These fields are described in the following sections. See the `prototype(4)` man page for additional information on these fields.
The **ftype Field**

The *ftype*, or file type, field is a one-character field that specifies a package object’s file type. Valid file types are described in the following table.

<table>
<thead>
<tr>
<th>File type field value</th>
<th>File Type Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>f</td>
<td>Standard executable file or data file</td>
</tr>
<tr>
<td>e</td>
<td>File to be edited upon installation or removal (may be shared by several packages)</td>
</tr>
<tr>
<td>v</td>
<td>Volatile file (whose contents are expected to change, such as a log file)</td>
</tr>
<tr>
<td>d</td>
<td>Directory</td>
</tr>
<tr>
<td>x</td>
<td>Exclusive directory accessible only by this package (may contain unregistered logs or database information)</td>
</tr>
<tr>
<td>l</td>
<td>Linked file</td>
</tr>
<tr>
<td>p</td>
<td>Named pipe</td>
</tr>
<tr>
<td>c</td>
<td>Character special device</td>
</tr>
<tr>
<td>b</td>
<td>Block special device</td>
</tr>
<tr>
<td>i</td>
<td>Information file or installation script</td>
</tr>
<tr>
<td>s</td>
<td>Symbolic link</td>
</tr>
</tbody>
</table>

The **class Field**

The *class* field names the class to which an object belongs. Using classes is an optional package design feature. This feature is discussed in detail in “Writing Class Action Scripts” on page 67.

If you do not use classes, an object belongs to the none class. When you execute the `pkgmk` command to build your package, the command inserts the CLASSES=none parameter in the `pkginfo` file. Files with file type i must have a blank *class* field.

The **path Field**

The *path* field is used to define where the package object will reside on the target system. You may indicate the location with either an absolute path name (for example, `/usr/bin/mail`) or a relative path name (for example, `bin/mail`). Using an absolute path name means that the object’s location on the target system is defined by the package and cannot be changed. Package objects with relative path names indicate that the object is relocatable.

A *relocatable object* does not need an absolute path location on the target system. Instead, the object’s location is determined during the installation process.
All or some of a package's objects can be defined as relocatable. Before writing any installation scripts or creating the prototype file, decide if package objects will have fixed locations (such as start-up scripts in /etc) or be relocatable.

There are two kinds of relocatable objects, collectively relocatable and individually relocatable.

**Collectively Relocatable Objects**

Collectively relocatable objects are located relative to a common installation base called the base directory. A base directory is defined in the pkginfo file, using the BASEDIR parameter. For example, a relocatable object in the prototype file named tests/generic requires that the pkginfo file define the default BASEDIR parameter. For example:

```
BASEDIR=/opt
```

This example means that when the object is installed, it will be located in the /opt/tests/generic directory.

**Note** – The /opt directory is the only directory to which software that is not part of the base Solaris software may be delivered.

Use collectively relocatable objects whenever possible. In general, the major part of a package can be relocatable with a few files (such as files in /etc or /var) specified as absolute. However, if a package contains many different relocations, consider dividing the package into multiple packages with distinct BASEDIR values in their pkginfo files.

**Individually Relocatable Objects**

Individually relocatable objects are not restricted to the same directory location as collectively relocatable objects. To define an individually relocatable object, you need to specify an install variable in the path field in the prototype file. After specifying the install variable, create a request script to prompt the installer for the relocatable base directory, or a checkinstall script to determine the path name from file system data. For more information on request scripts, see “Writing a request Script” on page 60 and for information on checkinstall scripts, see “How to Gather File System Data” on page 64.

**Caution** – Individually relocatable objects are difficult to manage. Use of individually relocatable objects might result in widely scattered package components that are difficult to isolate when installing multiple versions or architectures of the package. Use collectively relocatable objects whenever possible.
**Parametric Path Names**

A parametric path name is a path name that includes a variable specification. For example, `/opt/$PKGINST/filename` is a parametric path name because of the `$PKGINST` variable specification. A default value for the variable specification must be defined in the `pkginfo` file. The value may then be changed by a request script or a `checkinstall` script.

A variable specification in a path must begin or end the path name, or be bounded by slashes (`/`). Valid parametric path names take the following form:

```
$PARAM/tests
tests/$PARAM/generic
/tests/$PARAM
```

The variable specification, once defined, may cause the path to be evaluated as absolute or relocatable. In the following example, the prototype file contains this entry:

```
f none $DIRLOC/tests/generic
```

The `pkginfo` file contains this entry:

```
DIRLOC=/myopt
```

The path name `$DIRLOC/tests/generic` evaluates to the absolute path name `/myopt/tests/generic`, regardless of whether the BASEDIR parameter is set in the `pkginfo` file.

In this example, the prototype file is identical to the one in the previous example and the `pkginfo` file contains the following entries:

```
DIRLOC=firstcut
BASEDIR=/opt
```

The path name `$DIRLOC/tests/generic` will evaluate to the relocatable path name `/opt/firstcut/tests/generic`.

For more information on parametric path names, see “Using Parametric Base Directories” on page 128.

**A Brief Word on an Object’s Source and Destination Locations**

The path field in the prototype file defines where the object will be located on the target system. Specify the present location of the package’s objects in the prototype file if their directory structure does not mimic the intended structure on the target system. See “Organizing a Package’s Contents” on page 29 for more information on structuring objects in a package.

If your development area is not structured in the same way that you want your package structured, you can use the `path1=path2` format in the path field. In this format, `path1` is the location the object should have on the target system, and `path2` is the location the object has on your system.
You can also use the path1=path2 path name format with path1 as a relocatable object name and path2 as a full path name to that object on your system.

**Note** – path1 may not contain undefined build variables, but may contain undefined install variables. path2 may not contain any undefined variables, although both build variables and install variables may be used. For information on the difference between install variables and build variables, see “Package Environment Variables” on page 24.

Links must use the path1=path2 format because they are created by the pkgadd command. As a general rule, path2 of a link should never be absolute, but should instead be relative to the directory portion of path1.

An option to using the path1=path2 format is to use the !search command. For more information, see “Providing a Search Path for the pkgmk Command” on page 41.

**The mode Field**

The mode field may contain an octal number, a question mark (?), or a variable specification. An octal number specifies the mode of the object when it is installed on the target system. A ? means that the mode will be unchanged as the object is installed, implying that the object of the same name already exists on the target system.

A variable specification of the form $mode, where the first letter of the variable must be a lowercase letter, means that this field will be set as the package is built. Note that this variable must be defined at build time in either the prototype file or as an option to the pkgmk command. For information on the difference between install variables and build variables, see “Package Environment Variables” on page 24.

Files with file type i (information file), l (hard link), and s (symbolic link) should leave this field blank.

**The owner Field**

The owner field may contain a user name, a question mark (?), or a variable specification. A user name has a maximum of 14 characters and should be a name that already exists on the target system (such as bin or root). A ? means that the owner will be unchanged as the object is installed, implying that the object of the same name already exists on the target system.

A variable specification can be of the form $Owner or $owner, where the first letter of the variable is either an uppercase letter or a lowercase letter. If the variable begins with a lowercase letter, it must be defined as the package is built, either in the prototype file or as an option to the pkgmk command. If the variable begins with an uppercase letter, the variable specification will be inserted into the pkginfo file as a default value, and may be redefined at install time by a request script. For information on the difference between install variables and build variables, see “Package Environment Variables” on page 24.
Files with file type `i` (information file) and `l` (hard link) should leave this field blank.

The group Field

The group field may contain a group name, a question mark (?), or a variable specification. A group name has a maximum of 14 characters and should be a name that already exists on the target system (such as, `bin` or `sys`). A ? means that the group will be unchanged as the object is installed, implying that the object of the same name already exists on the target system.

A variable specification can be of the form `$Group` or `$group`, where the first letter of the variable is either an uppercase letter or a lowercase letter. If the variable begins with a lowercase letter, it must be defined as the package is built, either in the prototype file or as an option to the `pkgmk` command. If the variable begins with an uppercase letter, the variable specification will be inserted into the `pkginfo` file as a default value, and may be redefined at install time by a request script. For information on the difference between install variables and build variables, see "Package Environment Variables" on page 24.

Files with file type `i` (information file) and `l` (hard link) should leave this field blank.

Creating a prototype File From Scratch

If you want to create a prototype file from scratch, you can do so with your favorite text editor, adding one entry per package object. See “Format of the prototype File” on page 31 and the `pkgproto(4)` man page for more information on the format of this file. However, after you have defined each package object, you might want to include some of the features described in “Adding Functionality to a prototype File” on page 39.

Example—Creating a prototype File With the `pkgproto` Command

You can use the `pkgproto` command to build a basic prototype file, as long as you have organized your package directory structure as described in “Organizing a Package's Contents” on page 29. For example, using the sample directory structure and `pkginfo` file described in previous sections, the commands for creating the prototype file are as follows:

```
$ cd /home/jane
$ pkgproto ./SUNWcadap > InfoFiles/prototype
```

The prototype file looks like the following:

d none SUNWcadap 0755 jane staff
d none SUNWcadap/demo 0755 jane staff
f none SUNWcadap/demo/file1 0555 jane staff
Note – The actual owner and group of the person building the package is recorded by the `pkgproto` command. A good technique is to use the `chown -R` and the `chgrp -R` commands, setting the owner and group as intended before running the `pkgproto` command.

This example prototype file is not complete. See the following section for information on completing this file.

**Fine-Tuning a prototype File Created With the pkgproto Command**

Although the `pkgproto` command is useful in creating an initial prototype file, it does not create entries for every package object that needs to be defined. This command does not make complete entries. The `pkgproto` command does not do any of the following:

- Create complete entries for objects with file types `v` (volatile files), `e` (editable files), `x` (exclusive directories), or `i` (information files or installation scripts)
- Support multiple classes with a single invocation

**Creating Object Entries With File Types `v`, `e`, `x`, and `i`**

At the very least, you need to modify the prototype file to add objects with file type `i`. If you stored your information files and installation scripts in the first level of your package directory (for example, `/home/jane/SUNWcadap/pkginfo`), then an entry in the prototype file would look like the following:

```
i pkginfo
```

If you did not store your information files and installation scripts in the first level of your package directory, then you need to specify their source location. For example:

```
i pkginfo=/home/jane/InfoFiles/pkginfo
```
Or, you can use the `!search` command to specify the location for the `pkgmk` command to look when building the package. See “Providing a Search Path for the `pkgmk` Command” on page 41 for more information.

To add entries for objects with file types `v`, `e`, and `x`, follow the format described in “Format of the prototype File” on page 31, or refer to the `prototype(4)` man page.

**Note** – Remember to always assign a class to files with a file type of `e` (editable) and have an associated class action script for that class. Otherwise, the files will be removed during package removal, even if the path name is shared with other packages.

### Using Multiple Class Definitions

If you use the `pkgproto` command to create your basic prototype file, you can assign all the package objects to the `none` class or to one, specific class. As shown in “Example—Creating a prototype File With the `pkgproto` Command” on page 36, the basic `pkgproto` command assigns all objects to the `none` class. To assign all objects to a specific class, you can use the `-c` option. For example:

```bash
$ pkgproto -c classname /home/jane/SUNWcadap > /home/jane/InfoFiles/prototype
```

If you use multiple classes, you might need to manually edit the prototype file and modify the `class` field for each object. If you use classes, you also need to define the `CLASSES` parameter in the `pkginfo` file and write class action scripts. Using classes is an optional feature and is discussed in detail in “Writing Class Action Scripts” on page 67.

**Example—Fine-Tuning a prototype File Created Using the `pkgproto` Command**

Given the prototype file created by the `pkgproto` command in “Example—Creating a prototype File With the `pkgproto` Command” on page 36, several modifications need to be made.

- There needs to be an entry for the `pkginfo` file.
- The `path` fields need to be changed to the `path1=path2` format because the package source is in `/home/jane`. Since the package source is a hierarchical directory, and the `!search` command does not search recursively, it might be easier to use the `path1=path2` format.
- The `owner` and `group` fields should contain the names of existing users and groups on the target system. That is, the `owner jane` will result in an error because this owner is not part of the SunOS™ operating system.

The modified prototype file looks like the following:

```
i pkginfo=/home/jane/InfoFiles/pkginfo
d none SUNWcadap=/home/jane/SUNWcadap 0755 root sys
d none SUNWcadap/demo=/home/jane/SUNWcadap/demo 0755 root bin
```
Adding Functionality to a prototype File

Besides defining every package object in the prototype file, you can also do the following:

- Define additional objects to be created at install time.
- Create links at install time.
- Distribute packages over multiple volumes.
- Nest prototype files.
- Set a default value for the mode, owner, and group fields.
- Provide a search path for the pkgadd command.
- Set environment variables.

See the following sections for information on making these changes.

Defining Additional Objects to Be Created at Install Time

You can use the prototype file to define objects that are not actually delivered on the installation medium. During installation, using the pkgadd command, these objects are created with the required file types, if they do not already exist at the time of installation.

To specify that an object be created on the target system, add an entry for it in the prototype file with the appropriate file type.

For example, if you want a directory created on the target system, but do not want to deliver it on the installation medium, add the following entry for the directory in the prototype file:

d none /directory 0644 root other

If you want to create an empty file on the target system, an entry for the file in the prototype file might look like the following:

f none filename=/dev/null 0644 bin bin
The only objects that must be delivered on the installation medium are regular files and edit scripts (file types e, v, f) and the directories required to contain them. Any additional objects are created without reference to the delivered objects, directories, named pipes, devices, hard links, and symbolic links.

Creating Links at Install Time

To create links during package installation, define the following in the prototype file entry for the linked object:

- Its file type as l (a link) or s (a symbolic link).
- The linked object’s path name with the format path1=path2 where path1 is the destination and path2 is the source file. As a general rule, path2 of a link should never be absolute, but should instead be relative to the directory portion of path1. For example, a prototype file entry that defines a symbolic link could be as follows:

```plaintext
s none etc/mount=../usr/etc/mount
```

Relative links would be specified in this manner whether the package is installed as absolute or relocatable.

Distributing Packages Over Multiple Volumes

When you build your package with the pkgmk command, the command performs the calculations and actions necessary to organize a multiple volume package. A multiple volume package is called a segmented package.

However, you can use the optional part field in the prototype file to define which part you want an object to be located. A number in this field overrides the pkgmk command and forces the placement of the component into the part given in the field. Note that a one-to-one correspondence exists between parts and volumes for removable media formatted as file systems. If the volumes are preassigned by the developer, the pkgmk command issues an error if there is insufficient space on any volume.

Nesting prototype Files

You can create multiple prototype files and then include them by using the !include command in the prototype file. You might want to nest files for easier maintenance.

In the following example there are three prototype files. The main file (prototype) is being edited. The other two files (proto2 and proto3) are being included.

```plaintext
!include /source-dir/proto2
!include /source-dir/proto3
```
Setting Default Values for the mode, owner, and group Fields

To set default values for the mode, owner, and group fields for specific package objects, you can insert the !default command into the prototype file. For example:

!default 0644 root other

Note – The !default command's range starts from where it is inserted and extends to the end of the file. The command's range does not span to included files.

However, for directories (file type d) and editable files (file type e) that you know exist on target systems (like /usr or /etc/vfstab), make sure that the mode, owner, and group fields in the prototype file are set to question marks (?). That way you will not destroy existing settings that a site administrator may have modified.

Providing a Search Path for the pkgmk Command

If the source location for package objects is different than their destination location, and you do not want to use the path1=path2 format as described in "A Brief Word on an Object's Source and Destination Locations" on page 34, then you can use the !search command in the prototype file.

For example, if you created a directory, pkgfiles, in your home directory, and it contains all of your information files and installation scripts, you can specify that this directory be searched when the package is built with the pkgmk command.

The command in the prototype file would look like the following:

!search /home-dir/pkgfiles

Note – Search requests do not span to included files. In addition, a search is limited to the specific directories listed and does not search recursively.

Setting Environment Variables

You can also add commands to the prototype file of the form !PARAM=value. Commands of this form define variables in the current environment. If you have multiple prototype files, the scope of this command is local to the prototype file where it is defined.

The variable PARAM can begin with either a lowercase letter or an uppercase letter. If the value of the PARAM variable is not known at build time, the pkgmk command aborts with an error. For more information on the difference between build variables and install variables, see "Package Environment Variables" on page 24.
How to Create a prototype File by Using the pkgproto Command

**Note** – It is easier to create information files and installation scripts before you create a prototype file. However, this order is not required. You can always edit the prototype file after changing your package contents. For more information on information files and installation scripts, see Chapter 3, “Enhancing the Functionality of a Package (Tasks).”

1. **Determine which package objects will be absolute and which package objects will be relocatable, if not done already.**
   For information that will help you complete this step, see “The path Field” on page 32.

2. **Organize your package’s objects to mimic their location on the target system.**
   If you already organized your packages as described in “Organizing a Package’s Contents” on page 29, note that you might need to make some changes based on your decisions in Step 1. If you have not organized your package yet, you should do so now. If you do not organize your package, you cannot use the pkgproto command to create a basic prototype file.

3. **If your package has collectively relocatable objects, edit the pkginfo file to set the BASEDIR parameter to the appropriate value.**
   For example:
   ```
   BASEDIR=/opt
   ```
   For information on collectively relocatable objects, see “Collectively Relocatable Objects” on page 33.

4. **If your package has individually relocatable objects, create a request script to prompt the installer for the appropriate path name. Alternatively, create a checkinstall script to determine the appropriate path from file system data.**
   The following list gives page numbers for your reference regarding common tasks:
   - To create a request script, see “How to Write a request Script” on page 62.
   - To create a checkinstall script, see “How to Gather File System Data” on page 64.
   - For more information on individually relocatable objects, see “Individually Relocatable Objects” on page 33.

5. **Change the owner and group on all of your package components to be the intended owner and group on the target systems.**
   Use the chown -R and the chgrp -R commands on your package directory and information files directory.
6 **Execute the `pkgproto` command to create a basic prototype file.**

The `pkgproto` command scans your directories to create a basic file. For example:

```bash
$ cd package-directory
$ pkgproto ./package-directory > prototype
```

The prototype file can be located anywhere on your system. Keeping your information files and installation scripts in one place simplifies access and maintenance. For additional information on the `pkgproto` command, see the `pkgproto(1)` man page.

7 **Edit the prototype file by using your favorite text editor, and add entries for files of type v, e, x, and i.**

For information on the specific changes you might need to make, see “Fine-Tuning a prototype File Created With the `pkgproto` Command” on page 37.

8 (Optional) If you are using multiple classes, edit the `prototype` and `pkginfo` files. Use your favorite text editor to make the necessary changes, and create corresponding class action scripts.

For information on the specific changes you might need to make, see “Fine-Tuning a prototype File Created With the `pkgproto` Command” on page 37 and “Writing Class Action Scripts” on page 67.

9 **Edit the prototype file by using your favorite text editor to redefine path names and change other field settings.**

For more information, see “Fine-Tuning a prototype File Created With the `pkgproto` Command” on page 37.

10 (Optional) **Edit the prototype file by using your favorite text editor to add functionality to your prototype file.**

For more information, see “Adding Functionality to a prototype File” on page 39.

11 **Save your changes and quit the editor.**

**See Also** If you are ready for the next task, see “How to Build a Package” on page 45.

---

**Building a Package**

Use the `pkgmk` command to build your package. The `pkgmk` command performs the following tasks:

- Puts all the objects defined in the prototype file into directory format.
- Creates the `pkgmap` file, which replaces the prototype file.
- Produces an installable package that is used as input to the `pkgadd` command.
Using the Simplest pkgmk Command

The simplest form of this command is the pkgmk command without any options. Before using the pkgmk command without options, make sure that your current working directory contains the package’s prototype file. The output of the command, files and directories, are written to the /var/spool/pkg directory.

The pkgmap File

When you build a package with the pkgmk command, it creates a pkgmap file that replaces the prototype file. The pkgmap file from the previous example has the following contents:

```
$ more pkgmap
: 1 3170
1 d none SUNWcadap 0755 root sys
1 d none SUNWcadap/demo 0755 root bin
1 f none SUNWcadap/demo/file1 0555 root bin 14868 45617 837527496
1 d none SUNWcadap/lib 0755 root bin
1 f none SUNWcadap/lib/file2 0644 root bin 1551792 62372 837527499
1 d none SUNWcadap/man 0755 bin bin
1 d none SUNWcadap/man/man1 0755 bin bin
1 f none SUNWcadap/man/man1/file3.1 0444 bin bin 3700 42989 837527500
1 f none SUNWcadap/man/man1/file4.1 0444 bin bin 1338 44010 837527499
1 f none SUNWcadap/man/windex 0644 root other 157 13275 837527499
1 d none SUNWcadap/srcfiles 0755 root bin
1 f none SUNWcadap/srcfiles/file5 0555 root bin 12208 20280 837527497
1 f none SUNWcadap/srcfiles/file6 0555 root bin 12256 63236 837527497
1 i pkginfo 140 10941 837531104
$
```

The format of this file is very similar to the format of the prototype file. However, the pkgmap file includes the following information:

- The first line indicates the number of volumes that the package spans, and the approximate size the package will be when it is installed.
  For example, : 1 3170 indicates that the package spans one volume and will use approximately 3170 512-byte blocks when it is installed.
- There are three additional fields that define the size, checksum, and modification time for each package object.
- The package objects are listed in alphabetical order by class and by path name to reduce the time it takes to install the package.
How to Build a Package

1. Create a pkginfo file, if not done already.
   For step-by-step instructions, see "How to Create a pkginfo File" on page 29.

2. Create a prototype file, if not done already.
   For step-by-step instructions, see "How to Create a prototype File by Using the pkgproto Command" on page 42.

3. Make your current working directory the same directory that contains your package's prototype file.

4. Build the package.
   ```
   $ pkgmk [-o] [-a arch] [-b base-src-dir] [-d device]
           [-f filename] [-l limit] [-p pstamp] [-r rootpath]
           [-v version] [PARAM=value] [pkginst]
   
   -o Overwrites the existing version of the package.
   -a arch Overrides the architecture information in the pkginfo file.
   -b base-src-dir Requests that base-src-dir be added to the beginning of relocatable path names when the pkgmk command is searching for objects on the development system.
   -d device Specifies that the package should be copied onto device, which may be a an absolute directory path name, diskette, or removable disk.
   -f filename Names a file, filename, that is used as your prototype file. The default names are prototype or Prototype.
   -l limit Specifies the maximum size, in 512-byte blocks, of the output device.
   -p pstamp Overrides the production stamp definition in the pkginfo file.
   -r rootpath Requests that the root directory rootpath be used to locate objects on the development system.
   -v version Overrides the version information in the pkginfo file.
   PARAM=value Sets global environment variables. Variables beginning with lowercase letters are resolved at build time. Those beginning with uppercase letters are placed into the pkginfo file for use at install time.
   pkginst Specifies a package by its package abbreviation or a specific instance (for example, SUNWcadap.4).
   ```

   For more information, see the pkgmk(1) man page.
Verify the contents of the package.

$ pkgchk -d device-name pkg-abbrev
Checking uninstall directory format package pkg-abbrev
from device-name
## Checking control scripts.
## Checking package objects.
## Checking is complete.
$

-d device-name Specifies the location of the package. Note that device-name can be a full directory path name or the identifiers for a tape or removable disk.

pkg-abbrev Is the name of one or more packages (separated by spaces) to be checked. If omitted, the pkgchk command checks all available packages.

The pkgchk command prints what aspects of the package are being checked and displays warnings or errors, as appropriate. For more information on the pkgchk command, see “Verifying the Integrity of a Package” on page 86.

Caution – Errors should be considered very seriously. An error could mean that a script needs fixing. Check all errors and move on if you disagree with the output from the pkgchk command.

Example 2–2 Building a Package

This example uses the prototype file created in “Fine-Tuning a prototype File Created With the pkgproto Command” on page 37.

$ cd /home/jane/InfoFiles
$ pkgmk
## Building pkgmap from package prototype file.
## Processing pkginfo file.
WARNING: parameter set to "system990708093144"
WARNING: parameter set to "none"
## Attempting to volumize 13 entries in pkgmap.
part 1 -- 3170 blocks, 17 entries
## Validating control scripts.
Example 2–3 Specifying a Source Directory for Relocatable Files

If your package contains relocatable files, you can use the 
\texttt{-b base-src-dir} option to the \texttt{pkgmk} command to specify a path name to be added to the beginning of the relocatable path names while the package is being created. This option is useful if you haven't used the \texttt{path1=path2} format for relocatable files or specified a search path with the \texttt{!search} command in the prototype file.

The following command builds a package with the following characteristics:

\begin{itemize}
  \item The package is built by using the sample prototype file that is created by the \texttt{pkgproto} command. See "Example—Creating a prototype File With the \texttt{pkgproto} Command" on page 36 for more information.
  \item The package is built without modifying the \texttt{path} fields.
  \item The package adds an entry for the \texttt{pkginfo} file.
\end{itemize}

\begin{verbatim}
$ cd /home/jane/InfoFiles
$ pkgmk -o -b /home/jane
## Building pkgmap from package prototype file.
## Processing pkginfo file.
WARNING: parameter set to "system960716102636"
WARNING: parameter set to "none"
## Attempting to volumize 13 entries in pkgmap.
part 1 -- 3170 blocks, 17 entries
## Packaging one part.
/var/spool/pkg/SUNWcadap/pkgmap
/var/spool/pkg/SUNWcadap/pkginfo
/var/spool/pkg/SUNWcadap/reloc/SUNWcadap/demo/file1
/var/spool/pkg/SUNWcadap/reloc/SUNWcadap/lib/file2
/var/spool/pkg/SUNWcadap/reloc/SUNWcadap/man/man1/file3.1
/var/spool/pkg/SUNWcadap/reloc/SUNWcadap/man/man1/file4.1
/var/spool/pkg/SUNWcadap/reloc/SUNWcadap/man/windex
/var/spool/pkg/SUNWcadap/reloc/SUNWcadap/srcfiles/file5
/var/spool/pkg/SUNWcadap/reloc/SUNWcadap/srcfiles/file6
## Validating control scripts.
## Packaging complete.
\end{verbatim}

In this example, the package is built in the default directory, \texttt{/var/spool/pkg}, by specifying the \texttt{-o} option. This option overwrites the package that was created in Example 2–2.
If you put package information files (such as `pkginfo` and `prototype`) and the package objects in two different directories, you can create your package by using the `-b` `base-src-dir` and `-r` `rootpath` options to the `pkgmk` command. If you have your package objects in a directory called `/product/pkgbin` and the other package information files in a directory called `/product/pkgsrc`, you could use the following command to place the package in the `/var/spool/pkg` directory:

```
$ pkgmk -b /product/pkgbin -r /product/pkgsrc -f /product/pkgsrc/prototype
```

Optionally, you could use these commands to achieve the same result:

```
$ cd /product/pkgsrc
$ pkgmk -o -b /product/pkgbin
```

In this example, the `pkgmk` command uses the current working directory to find the remaining parts of the package (such as the `prototype` and `pkginfo` information files).

### See Also
If you want to add any optional information files and installation scripts to your package, see Chapter 3, "Enhancing the Functionality of a Package (Tasks)." Otherwise, after you build the package, you should verify its integrity. Chapter 4, "Verifying and Transferring a Package," explains how to do so, and provides step-by-step instructions on how to transfer your verified package to a distribution medium.
This chapter describes how to create optional information files and installation scripts for a package. While Chapter 2, “Building a Package,” discussed the minimum requirements for making a package, this chapter discusses additional functionality that you can build into a package. This additional functionality is based on the criteria you considered when planning how to design your package. For more information, see “Considerations Before Building a Package” on page 17.

This is a list of the overview information in this chapter.

- “Creating Information Files and Installation Scripts (Task Map)” on page 49
- “Creating Information Files” on page 50
- “Creating Installation Scripts” on page 56
- “Creating Signed Packages” on page 75

### Creating Information Files and Installation Scripts (Task Map)

The following task map describes the optional features you can build into a package.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>For Instructions</th>
</tr>
</thead>
</table>
| 1. Create information files | *Define package dependencies*  
A definition of package dependencies allows you to specify whether your package is compatible with previous versions, dependent on other packages, or whether other packages are dependent on yours. | “How to Define Package Dependencies” on page 51 |
Creating Information Files

This section discusses optional package information files. With these files you can define package dependencies, provide a copyright message, and reserve additional space on a target system.

### Defining Package Dependencies

You need to determine whether your package has dependencies on other packages and if any other packages depend on yours. Package dependencies and incompatibilities can be defined with two of the optional package information files, `compver` and `depend`.

Delivering a `compver` file lets you name previous versions of your package that are compatible with the package being installed.
Delivering a depend file lets you define three types of dependencies associated with your package. These dependency types are as follows:

- **A prerequisite package** – Your package depends on the existence of another package
- **A reverse dependency** – Another package depends on the existence of your package

**Note** – Use the reverse dependency type only when a package that cannot deliver a depend file relies on your package.

- **An incompatible package** – Your package is incompatible with the named package

The depend file resolves only very basic dependencies. If your package depends upon a specific file, its contents, or its behavior, the depend file does not supply adequate precision. In this case, a request script or the checkinstall script should be used for detailed dependency checking. The checkinstall script is also the only script capable of cleanly halting the package installation process.

**Note** – Be certain that your depend and compver files have entries in the prototype file. The file type should be i (for package information file).

Refer to the depend(4) and compver(4) man pages for more information.

**▼ How to Define Package Dependencies**

1. **Make the directory that contains your information files the current working directory.**

2. **If previous versions of your package exist and you need to specify that your new package is compatible with them, create a file named compver with your favorite text editor.**

   List the versions with which your package is compatible. Use this format:

   ```
   string string ... 
   ```

   The value of `string` is identical to the value assigned to the VERSION parameter in the `pkginfo` file, for each compatible package.

3. **Save your changes and quit the editor.**
4 If your package depends on the existence of other packages, other packages depend on the existence of your package, or your package is incompatible with another package, create a file named depend with your favorite text editor.

Add an entry for each dependency. Use this format:

    type pkg-abbrev pkg-name
    (arch) version
    (arch) version ...

- **type** Defines the dependency type. Must be one of the following characters: P (prerequisite package), I (incompatible package), or R (reverse dependency).
- **pkg-abbrev** Specifies the package abbreviation, such as SUNWcadap.
- **pkg-name** Specifies the full package name, such as Chip designers need CAD application software to design abc chips. Runs only on xyz hardware and is installed in the usr partition.
- **(arch)** Optional. Specifies the type of hardware on which the package runs. For example, sparc or x86. If you specify an architecture, you must use the parentheses as delimiters.
- **version** Optional. Specifies the value assigned to the VERSION parameter in the pkginfo file.

For more information, see depend(4).

5 Save your changes and quit the editor.

6 Complete one of the following tasks:

- If you want to create additional information files and installation scripts, skip to the next task, “How to Write a Copyright Message” on page 54.

- If you have not created your prototype file, complete the procedure “How to Create a prototype File by Using the pkgproto Command” on page 42. Skip to Step 7.

- If you have already created your prototype file, edit it and add an entry for each file you just created.

7 Build your package.

See “How to Build a Package” on page 45, if needed.

Example 3–1 compver File

In this example, there are four versions of a package: 1.0, 1.1, 2.0, and the new package, 3.0. The new package is compatible with all the three previous versions. The compver file for the newest version might look like the following:
The entries do not have to be in sequential order. However, they should exactly match the definition of the VERSION parameter in each package’s pkginfo file. In this example, the package designers used different formats in the first three versions.

**Example 3–2 depend File**

This example assumes that the sample package, SUNWcadap, requires that the SUNWcsr and SUNWcstage packages already be installed on a target system. The depend file for SUNWcadap looks like the following:

```
P SUNWcsr Core Solaris, (Root)
P SUNWcstage Core Solaris, (Usr)
```

**See Also**

After you build the package, install it to confirm that it installs correctly and verify its integrity. Chapter 4, “Verifying and Transferring a Package,” explains these tasks and provides step-by-step instructions on how to transfer your verified package to a distribution medium.

### Writing a Copyright Message

You need to decide whether your package should display a copyright message while it is being installed. If so, create the copyright file.

**Note** – You should include a copyright file to provide legal protection for your software application. Check with the legal department of your company for the exact wording of the message.

To deliver a copyright message, you must create a file named copyright. During installation, the message is displayed exactly as it appears in the file (with no formatting). See the copyright(4) man page for more information.

**Note** – Be certain that your copyright file has an entry in the prototype file. The file type should be i (for package information file).
**How to Write a Copyright Message**

1. Make the directory that contains your information files the current working directory.

2. Create a file named `copyright` with your favorite text editor.
   Type the text of the copyright message exactly as you want it to appear as your package is installed.

3. Save your changes and quit the editor.

4. Complete one of the following tasks.
   - If you want to create additional information files and installation scripts, skip to the next task, “How to Reserve Additional Space on a Target System” on page 55.
   - If you have not created your prototype file, complete the procedure “How to Create a prototype File by Using the pkgproto Command” on page 42. Skip to Step 5.
   - If you have already created your prototype file, edit it and add an entry for the information file you just created.

5. Build your package.
   See “How to Build a Package” on page 45, if needed.

**Example 3–3** copyright File

For example, a partial copyright message might look like the following:

```plaintext
Copyright (c) 2003 Company Name
All Rights Reserved

This product is protected by copyright and distributed under licenses restricting copying, distribution, and decompilation.
```

**See Also** After you build the package, install it to confirm that it installs correctly and verify its integrity. Chapter 4, “Verifying and Transferring a Package,” explains these tasks and provides step-by-step instructions on how to transfer your verified package to a distribution medium.

**Reserving Additional Space on a Target System**

You need to determine whether your package needs additional disk space on the target system. This space is in addition to the space required by the package objects. If so, create the space
information file. This task is different than creating empty files and directories at installation time, as discussed in “Defining Additional Objects to Be Created at Install Time” on page 39.

The pkgadd command ensures that there is enough disk space to install your package based on the object definitions in the pkgmap file. However, a package may require additional disk space beyond that needed by the objects defined in the pkgmap file. For example, your package might create a file after installation, which may contain a database, log files, or some other growing file that consumes disk space. To be sure that there is space reserved for it, you should include a space file that specifies the disk space requirements. The pkgadd command checks for the additional space specified in a space file. Refer to the space(4) man page for more information.

**Note** – Be certain that your space file has an entry in the prototype file. The file type should be 1 (for package information file).

**How to Reserve Additional Space on a Target System**

1. **Make the directory that contains your information files the current working directory.**

2. **Create a file named space with your favorite text editor.**
   
   Specify any additional disk space requirements needed by your package. Use this format:
   
   ```
   pathname  blocks  inodes
   ```
   
   - `pathname` Specifies a directory name, which may or may not be the mount point for a file system.
   - `blocks` Specifies the number of 512-byte blocks that you want reserved.
   - `inodes` Specifies the number of required inodes.
   
   For more information, see the space(4) man page.

3. **Save your changes and quit the editor.**

4. **Complete one of the following tasks.**
   
   - If you want to create installation scripts, skip to the next task, "How to Write a request Script" on page 62.
   - If you have not created your prototype file, complete the procedure in "How to Create a prototype File by Using the pkgproto Command" on page 42. Skip to Step 5.
   - If you have already created your prototype file, edit it and add an entry for the information file you just created.
5 **Build your package.**

See "How to Build a Package" on page 45, if needed.

**Example 3–4** 

### space File

This example space file specifies that 1000 512-byte blocks and 1 inode be reserved in the /opt directory on the target system.

```
/opt 1000 1
```

**See Also** After you build the package, install it to confirm that it installs correctly and verify its integrity. Chapter 4, "Verifying and Transferring a Package," explains these tasks and provides step-by-step instructions on how to transfer your verified package to a distribution medium.

### Creating Installation Scripts

This section discusses optional package installation scripts. The `pkgadd` command automatically performs all the actions necessary to install a package using the package information files as input. You do not have to supply any package installation scripts. However, if you want to create customized installation procedures for your package, you can do so with installation scripts. Installation scripts:

- Must be executable by the Bourne shell (sh)
- Must contain Bourne shell commands and text
- Do not need to contain the `#!/bin/sh` shell identifier
- Need not be an executable file

There are four types of installation scripts with which you can perform customized actions:

- **The request script**
  
The request script solicits data from the administrator who is installing a package for assigning or redefining environment variables.

- **The checkinstall script**
  
The checkinstall script examines the target system for needed data, can set or modify package environment variables, and determines whether the installation proceeds.

  **Note** – The checkinstall script is available starting with the Solaris 2.5 and compatible releases.

- **Procedure scripts**
Procedure scripts identify a procedure to be invoked before or after the installation or removal of a package. The four procedure scripts are `preinstall`, `postinstall`, `preremove`, and `postremove`.

- **Class action scripts**

  Class action scripts define an action or set of actions that should be applied to a class of files during installation or removal. You can define your own classes. Alternatively, you can use one of the four standard classes (sed, awk, build, and preserve).

### Script Processing During Package Installation

The type of scripts you use depends on when the action of the script is needed during the installation process. As a package is installed, the `pkgadd` command performs the following steps:

1. **Executes the `request` script.**
   - This step is the only point at which your package can solicit input from the administrator who is installing the package.

2. **Executes the `checkinstall` script.**
   - The `checkinstall` script gathers file system data and can create or alter environment variable definitions to control the subsequent installation. For more information on package environment variables, see “Package Environment Variables” on page 24.

3. **Executes the `preinstall` script.**

4. **Installs package objects, for each class to be installed.**
   - Installation of these files occurs class by class, and class action scripts are executed accordingly. The list of classes operated on and the order in which they should be installed is initially defined with the `CLASSES` parameter in your `pkginfo` file. However, your `request` script or `checkinstall` script can change the value of the `CLASSES` parameter. For more information on how classes are processed during installation, see “How Classes Are Processed During Package Installation” on page 68.
   a. Creates symbolic links, devices, named pipes, and required directories.
   b. Installs the regular files (file types e, v, f), based on their class.
      - The class action script is passed only regular files to install. All other package objects are created automatically from information in the `pkgmap` file.
   c. Creates all hard links.

5. **Executes the `postinstall` script.**
Script Processing During Package Removal

When a package is being removed, the `pkgrm` command performs these steps:

1. Executes the `pre remove` script.
2. Removes the package objects, for each class
   - Removal also occurs class by class. Removal scripts are processed in the reverse order of installation, based on the sequence defined in the `CLASSES` parameter. For more information on how classes are processed during installation, see “How Classes Are Processed During Package Installation” on page 68.
   - b. Removes regular files.
   - c. Removes symbolic links, devices, and named pipes.
3. Executes the `post remove` script.

The `request` script is not processed at the time of package removal. However, the script's output is retained in the installed package and made available to removal scripts. The `request` script's output is a list of environment variables.

Package Environment Variables Available to Scripts

The following groups of environment variables are available to all installation scripts. Some of the environment variables can be modified by a `request` script or a `checkinstall` script.

- The `request` script or the `checkinstall` script can set or modify any of the standard parameters in the `pkginfo` file, except for the required parameters. The standard installation parameters are described in detail in the `pkginfo(4)` man page.

Note – The BASEDIR parameter can only be modified starting with the Solaris 2.5 release and compatible releases.

- You can define your own installation environment variables by assigning values to them in the `pkginfo` file. Such environment variables must be alphanumeric with initial capital letters. Any of these environment variables can be changed by a `request` script or a `checkinstall` script.
- Both a `request` script and a `checkinstall` script can define new environment variables by assigning values to them and putting them in the installation environment.
- The following table lists environment variables that are available to all installation scripts through the environment. None of these environment variables can be modified by a script.
Environment Variable | Description
--- | ---
CLIENT_BASEDIR | The base directory with respect to the target system. While BASEDIR is the variable to use if you are referring to a specific package object from the install system (most likely a server), CLIENT_BASEDIR is the path to include in files placed on the client system. CLIENT_BASEDIR exists if BASEDIR exists and is identical to BASEDIR if there is no PKG_INSTALL_ROOT.
INST_DATADIR | The directory where the package now being read is located. If the package is being read from a tape, this variable will be the location of a temporary directory where the package has been transferred into directory format. In other words, assuming there is no extension to the package name (for example, SUNWstuff.d), the request script for the current package would be found at $INST_DATADIR/$PKG/install.
PATH | The search list used by sh to find commands on script invocation. PATH is usually set to /sbin:/usr/sbin:/usr/bin:/usr/sadm/install/bin.
PKGINST | The instance identifier of the package being installed. If another instance of the package is not already installed, the value is the package abbreviation (for example, SUNWcadap). Otherwise, the value is the package abbreviation followed by a suffix, such as SUNWcadap.4.
PKGSAV | The directory where files can be saved for use by removal scripts or where previously saved files can be found. Available only in the Solaris 2.5 release and compatible releases.
PKG_CLIENT_OS | The operating system of the client where the package is being installed. The value of this variable is Solaris.
PKG_CLIENT_VERSION | The Solaris version in x.y format.
PKG_CLIENT_REVISION | The Solaris build revision.
PKG_INSTALL_ROOT | The root file system on the target system where the package is being installed. This variable exists only if the pkgadd and pkgrm commands were invoked with the -R option. This conditional existence facilitates its use in procedure scripts in the form ${PKG_INSTALL_ROOT}/somepath.
PKG_NO_UNIFIED | An environment variable that gets set if the pkgadd and pkgrm commands were invoked with the -M and -R options. This environment variable is passed to any package installation script or package command that is part of the package environment.
UPDATE | This environment variable does not exist under most installation environments. If this variable does exist (with the value yes), it means one of two things. Either a package with the same name, version, and architecture is already installed on the system. Or this package is overwriting an installed package of the same name at the direction of the administrator. In these events, the original base directory is always used.

Obtaining Package Information for a Script

Two commands can be used from scripts to solicit information about a package:
The `pkginfo` command returns information about software packages, such as the instance identifier and package name.

The `pkgparam` command returns values for requested environment variables.

See the `pkginfo(1)` man page, the `pkgparam(1)` man page, and Chapter 4, “Verifying and Transferring a Package,” for more information.

### Exit Codes for Scripts

Each script must exit with one of the exit codes shown in the following table.

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Successful completion of script.</td>
</tr>
<tr>
<td>1</td>
<td>Fatal error. Installation process is terminated at this point.</td>
</tr>
<tr>
<td>2</td>
<td>Warning or possible error condition. Installation continues. A warning message is displayed at the time of completion.</td>
</tr>
<tr>
<td>3</td>
<td>The <code>pkgadd</code> command is cleanly halted. Only the <code>checkinstall</code> script returns this code.</td>
</tr>
<tr>
<td>10</td>
<td>System should be rebooted when installation of all selected packages is completed. (This value should be added to one of the single-digit exit codes.)</td>
</tr>
<tr>
<td>20</td>
<td>System should be rebooted immediately upon completing installation of the current package. (This value should be added to one of the single-digit exit codes.)</td>
</tr>
</tbody>
</table>

See Chapter 5, “Case Studies of Package Creation,” for examples of exit codes that are returned by installation scripts.

**Note** — All installation scripts delivered with your package should have an entry in the `prototype` file. The file type should be 1 (for package installation script).

### Writing a Request Script

The `request` script is the only way your package can interact directly with the administrator who is installing it. This script can be used, for example, to ask the administrator if optional pieces of a package should be installed.

The output of a `request` script must be a list of environment variables and their values. This list can include any of the parameters that you created in the `pkginfo` file, and the `CLASSES` and `BASEDIR` parameters. The list can also introduce environment variables that have not been
defined elsewhere. However, the pkginfo file should always provide default values when practical. For more information on package environment variables, see “Package Environment Variables” on page 24.

When your request script assigns values to an environment variable, it must then make those values available to the pkgadd command and other package scripts.

**request Script Behaviors**

- The request script cannot modify any files. This script only interacts with administrators who are installing the package and creates a list of environment variable assignments based upon that interaction. The request script runs as the non privileged user install if that user exists. Otherwise, the script is executed as root.
- The pkgadd command calls the request script with one argument that names the script’s response file. The response file stores the administrator’s responses.
- The request script is not executed during package removal. However, the environment variables assigned by the script are saved and are available during package removal.

**Design Rules for request Scripts**

- There can be only one request script per package. The script must be named request.
- The environment variable assignments should be added to the installation environment for use by the pkgadd command and other packaging scripts by writing them to the response file (known to the script as $1).
- System environment variables and standard installation environment variables, except for the CLASSES and BASEDIR parameters, cannot be modified by a request script. Any of the other environment variables that you created can be changed.

---

**Note** – A request script can only modify the BASEDIR parameter starting with the Solaris 2.5 and compatible releases.

- Every environment variable that the request script may manipulate should be assigned a default value in the pkginfo file.
- The format of the output list should be \texttt{PARAM=value}. For example:

```bash
CLASSES=none class1
```
- The administrator’s terminal is defined as standard input to the request script.
- Do not perform any special analysis of the target system in a request script. It is risky to test the system for the presence of certain binaries or behaviors, and to set environment variables based upon that analysis. There is no guarantee that the request script will actually be executed at install time. The administrator who is installing the package may
provide a response file that will insert the environment variables without ever calling the request script. If the request script is also evaluating the target file system, that evaluation may not happen. An analysis of the target system for special treatment is best left to the checkinstall script.

**Note** – If the administrators who will be installing your package might use the JumpStart™ product, then the installation of your package must not be interactive. Either you should not provide a request script with your package, or you need to communicate to the administrators that they should use the pkgask command prior to installation. The pkgask command stores their responses to the request script. For more information on the pkgask command, see the pkgask(1M) man page.

### How to Write a request Script

1. Make the directory that contains your information files the current working directory.
2. Create a file named `request` with your favorite text editor.
3. Save your changes and quit the editor when you are done.
4. Complete one of the following tasks.
   - If you want to create additional installation scripts, skip to the next task, “How to Gather File System Data” on page 64.
   - If you have not created your prototype file, complete the procedure “How to Create a prototype File by Using the pkgproto Command” on page 42. Skip to Step 5.
   - If you have already created your prototype file, edit it and add an entry for the installation script you just created.
5. Build your package.
   See “How to Build a Package” on page 45, if needed.

#### Example 3–5 Writing a request Script

When a request script assigns values to environment variables, it must make those values available to the pkgadd command. This example shows a request script segment that performs this task for the four environment variables: CLASSES, NCMPBIN, EMACS, and NCMPMAN. Assume that these variables were defined in an interactive session with the administrator earlier in the script.

```bash
# make environment variables available to installation
# service and any other packaging script we might have
```
After you build the package, install it to confirm that it installs correctly and verify its integrity. Chapter 4, “Verifying and Transferring a Package,” explains these tasks and provides step-by-step instructions on how to transfer your verified package to a distribution medium.

### Gathering File System Data With the `checkinstall` Script

The `checkinstall` script is executed shortly after the optional request script. The `checkinstall` script runs as the user `install`, if such a user exists, or as the user `nobody`. The `checkinstall` script does not have the authority to change file system data. However, based on the information the script gathers, it can create or modify environment variables in order to control the course of the resulting installation. The script is also capable of cleanly halting the installation process.

The `checkinstall` script is intended to perform basic checks on a file system that would not be normal for the `pkgadd` command. For example, this script can be used to check ahead to determine if any files from the current package are going to overwrite existing files, or manage general software dependencies. The `depend` file only manages package-level dependencies. Unlike the request script, the `checkinstall` script is executed whether or not a response file is provided. The script’s presence does not brand the package as interactive. The `checkinstall` script can be used in situations where a request script is forbidden or administrative interaction is not practical.

**Note** – The `checkinstall` script is available starting with the Solaris 2.5 and compatible releases.

### `checkinstall` Script Behaviors

- The `checkinstall` script cannot modify any files. This script only analyzes the state of the system and creates a list of environment variable assignments based upon that interaction. To enforce this restriction, the `checkinstall` script is executed as the non privileged user `install` if that user exists. Otherwise, this script is executed as the non privileged user `nobody`. The `checkinstall` script does not have superuser authority.
The pkgadd command calls the checkinstall script with one argument that names the script's response file. The script's response file is the file that stores the administrator's responses.

The checkinstall script is not executed during package removal. However, the environment variables assigned by the script are saved and are available during package removal.

**Design Rules for checkinstall Scripts**

- There can be only one checkinstall script per package. The script must be named checkinstall.
- The environment variable assignments should be added to the installation environment for use by the pkgadd command and other packaging scripts by writing them to the response file (known to the script as $1).
- System environment variables and standard installation environment variables, except for the CLASSES and BASEDIR parameters, cannot be modified by a checkinstall script. Any of the other environment variables that you created can be changed.
- Every environment variable that the checkinstall script may manipulate should be assigned a default value in the pkginfo file.
- The format of the output list should be PARAM=value. For example:

  CLASSES=none class1

- Administrator interaction is not permitted during execution of a checkinstall script. All administrator interaction is restricted to the request script.

**How to Gather File System Data**

1. Make the directory that contains your information files the current working directory.

2. Create a file named checkinstall with your favorite text editor.

3. Save your changes and quit the editor when you are done.

4. Complete one of the following tasks.

   - If you want to create additional installation scripts, skip to the next task, "How to Write Procedure Scripts" on page 67.
   - If you have not created your prototype file, complete the procedure "How to Create a prototype File by Using the pkgproto Command" on page 42. Skip to Step 5.
   - If you have already created your prototype file, edit it and add an entry for the installation script you just created.
5  **Build your package.**

See “How to Build a Package” on page 45, if needed.

---

**Example 3–6  Writing a checkinstall Script**

This example checkinstall script checks to see if database software needed by the SUNWcadap package is installed.

```bash
# checkinstall script for SUNWcadap
#
# This confirms the existence of the required specU database

# First find which database package has been installed.
pkginfo -q SUNWspcdA # try the older one

if [ $? -ne 0 ]; then
    pkginfo -q SUNWspcdB # now the latest
        if [ $? -ne 0 ]; then # oops
            echo "No database package can be found. Please install the"
            echo "specU database package and try this installation again."
            exit 3 # Suspend
        else
            DBBASE="pkgparam SUNWsbcdB BASEDIR'/db" # new DB software
        fi
    else
        DBBASE="pkgparam SUNWspcdA BASEDIR'/db" # old DB software
    fi

# Now look for the database file we will need for this installation
if [ $DBBASE/specUlatte ]; then
    exit 0 # all OK
else
    echo "No database file can be found. Please create the database"
    echo "using your installed specU software and try this"
    echo "installation again."
    exit 3 # Suspend
fi
```

---

See Also  After you build the package, install it to confirm that it installs correctly and verify its integrity. Chapter 4, “Verifying and Transferring a Package,” explains these tasks and provides step-by-step instructions on how to transfer your verified package to a distribution medium.
Writing Procedure Scripts

The procedure scripts provide a set of instructions to be performed at particular points in package installation or removal. The four procedure scripts must be named one of the predefined names, depending on when the instructions are to be executed. The scripts are executed without arguments.

- The preinstall script
  Runs before class installation begins. No files should be installed by this script.

- The postinstall script
  Runs after all volumes have been installed.

- The preremove script
  Runs before class removal begins. No files should be removed by this script.

- The postremove script
  Runs after all classes have been removed.

Procedure Script Behaviors

Procedure scripts are executed as uid=root and gid=other.

Design Rules for Procedure Scripts

- Each script should be able to be executed more than once because it is executed once for each volume in a package. This means that executing a script any number of times with the same input produces the same results as executing the script only once.

- Each procedure script that installs a package object not in the pkgmap file must use the installf command to notify the package database that it is adding or modifying a path name. After all additions or modifications are complete, this command should be invoked with the -f option. Only the postinstall and postremove scripts may install package objects in this way. See the installf(1M) man page and Chapter 5, “Case Studies of Package Creation,” for more information.

- Administrator interaction is not permitted during execution of a procedure script. All administrator interaction is restricted to the request script.

- Each procedure script that removes files not installed from the pkgmap file must use the removef command to notify the package database that it is removing a path name. After removal is complete, this command should be invoked with the -f option. See the removef(1M) man page and Chapter 5, “Case Studies of Package Creation,” for details and examples.
Creating Installation Scripts

Note – The `installf` and `removef` commands must be used because procedure scripts are not automatically associated with any path names listed in the `pkgmap` file.

▼ How to Write Procedure Scripts

1. Make the directory that contains your information files the current working directory.

2. Create one or more procedure scripts with your favorite text editor.
   A procedure script must be named one of the predefined names: `preinstall`, `postinstall`, `preremove`, or `postremove`.

3. Save your changes and quit the editor.

4. Complete one of the following tasks.
   - If you want to create class action scripts, skip to the next task, “How to Write Class Action Scripts” on page 74.
   - If you have not created your prototype file, complete the procedure “How to Create a prototype File by Using the `pkgproto` Command” on page 42. Skip to Step 5.
   - If you have already created your prototype file, edit it and add an entry for each installation script you just created.

5. Build your package.
   See “How to Build a Package” on page 45, if needed.

See Also

After you build the package, install it to confirm that it installs correctly and verify its integrity. Chapter 4, “Verifying and Transferring a Package,” explains these tasks and provides step-by-step instructions on how to transfer your verified package to a distribution medium.

Writing Class Action Scripts

Defining Object Classes

Object classes allow a series of actions to be performed on a group of package objects at installation or removal. You assign objects to a class in the `prototype` file. All package objects must be given a class, although the class of `none` is used by default for objects that require no special action.

The installation parameter `CLASSES`, defined in the `pkginfo` file, is a list of classes to be installed (including the `none` class).
Note – Objects defined in the pkgmap file that belong to a class not listed in this parameter in the pkginfo file will not be installed.

The CLASSES list determines the order of installation. Class none is always installed first, if present, and removed last. Since directories are the fundamental support structure for all other file system objects, they should all be assigned to the none class. Exceptions can be made, but as a general rule, the none class is safest. This strategy ensures that the directories are created before the objects they will contain. In addition, no attempt is made to delete a directory before it has been emptied.

How Classes Are Processed During Package Installation

The following describes the system actions that occur when a class is installed. The actions are repeated once for each volume of a package, as that volume is being installed.

1. The pkgadd command creates a path name list.

   The pkgadd command creates a list of path names upon which the action script operates. Each line of this list contains source and destination path names, separated by a space. The source path name indicates where the object to be installed resides on the installation volume. The destination path name indicates the location on the target system where the object should be installed. The contents of the list are restricted by the following criteria:
   
   - The list contains only path names that belong to the associated class.
   - If the attempt to create the package object fails, then directories, named pipes, character devices, block devices, and symbolic links are included in the list with the source path name set to /dev/null. Normally, these items are automatically created by the pkgadd command (if not already in existence) and given proper attributes (mode, owner, group) as defined in the pkgmap file.
   - Linked files where the file type is l are not included in the list under any circumstances.
   - Hard links in the given class are created in item 4.

2. If no class action script is provided for installation of a particular class, the path names in the generated list are copied from the volume to the appropriate target location.

3. A class action script is executed if one exists.

   The class action script is invoked with standard input that contains the list generated in item 1. If this volume is the last volume of the package, or no more objects exist in this class, the script is executed with the single argument of ENDOFCLASS.

   Note – Even if no regular files of this class exist in the package, the class action script is called at least once with an empty list and the ENDOFCLASS argument.

4. The pkgadd command performs a content and attribute audit, and creates hard links.
After successfully executing items 2 or 3, the `pkgadd` command audits both content and attribute information for the list of path names. The `pkgadd` command creates the links associated with the class automatically. Detected attribute inconsistencies are corrected for all path names in the generated list.

**How Classes Are Processed During Package Removal**

Objects are removed class by class. Classes that exist for a package but are not listed in the `CLASSES` parameter are removed first (for example, an object installed with the `installf` command). Classes listed in the `CLASSES` parameter are removed in reverse order. The `none` class is always removed last. The following describes the system actions that occur when a class is removed:

1. The `pkgrm` command creates a path name list.
   - The `pkgrm` command creates a list of installed path names that belong to the indicated class. Path names referenced by another package are excluded from the list unless their file type is `e`. A file type of `e` means the file should be edited upon installation or removal.
   - If the package being removed had modified any files of type `e` during installation, it should remove just the lines it added. Do not delete a non-empty editable file. Remove the lines that the package added.

2. If no class action script exists, the path names are deleted.
   - If your package has no removal class action script for the class, all the path names in the list generated by the `pkgrm` command are deleted.

   **Note** – Files with a file type of `e` (editable) are not assigned to a class and an associated class action script. These files are removed at this point, even if the path name is shared with other packages.

3. If a class action script exists, the script is executed.
   - The `pkgrm` command invokes the class action script with standard input for the script that contains the list generated in item 1.

4. The `pkgrm` command performs an audit.
   - After successfully executing the class action script, the `pkgrm` command removes references to the path names from the package database unless a path name is referenced by another package.

**The Class Action Script**

The class action script defines a set of actions to be executed during installation or removal of a package. The actions are performed on a group of path names based on their class definition. See Chapter 5, “Case Studies of Package Creation,” for examples of class action scripts.
The name of a class action script is based on the class on which it should operate and whether those operations should occur during package installation or package removal. The two name formats are shown in the following table:

<table>
<thead>
<tr>
<th>Name Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>class</code></td>
<td>Operates on path names in the indicated class during package installation</td>
</tr>
<tr>
<td><code>r.class</code></td>
<td>Operates on path names in the indicated class during package removal</td>
</tr>
</tbody>
</table>

For example, the name of the installation script for a class named `manpage` would be `i.manpage`. The removal script would be named `r.manpage`.

Note – This file name format is not used for files that belong to the `sed`, `awk`, or `build` system classes. For more information on these special classes, see “The Special System Classes” on page 71.

Class Action Script Behaviors

- Class action scripts are executed as `uid=root` and `gid=other`.
- A script is executed for all files in the given class on the current volume.
- The `pkgadd` and `pkgrm` commands create a list of all objects listed in the `pkgmap` file that belong to the class. As a result, a class action script can act only upon path names defined in the `pkgmap` that belong to a particular class.
- When a class action script is executed for the last time (that is, no more files belong to that class), the class action script is executed once with the keyword argument `ENDOFCLASS`.
- Administrator interaction is not permitted during execution of a class action script.

Design Rules for Class Action Scripts

- If a package spans more than one volume, the class action script is executed once for each volume that contains at least one file that belongs to a class. Consequently, each script must be able to be executed more than once. This means that executing a script any number of times with the same input must produce the same results as executing the script only once.
- When a file is part of a class that has a class action script, the script must install the file. The `pkgadd` command does not install files for which a class action script exists, although it does verify the installation.
- A class action script should never add, remove, or modify a path name or system attribute that does not appear in the list generated by the `pkgadd` command. For more information on this list, see item 1 in “How Classes Are Processed During Package Installation” on page 68.
When your script sees the ENDOFCLASS argument, put post-processing actions such as clean up into your script.

All administrator interaction is restricted to the requests script. Do not try to obtain information from the administrator by using a class action script.

### The Special System Classes

The system provides four special classes:

- **The sed class**
  
  Provides a method for using sed instructions to edit files upon package installation and removal.

- **The awk class**
  
  Provides a method for using awk instructions to edit files upon package installation and removal.

- **The build class**
  
  Provides a method to dynamically construct or modify a file by using Bourne shell commands.

- **The preserve class**
  
  Provides a method to preserve files that should not be overwritten by future package installations.

- **The manifest class**
  
  Provides automated installation and uninstallation of SMF (Service Management Facility) services associated with a manifest. The manifest class should be used for all SMF manifests in a package.

If several files in a package require special processing that can be fully defined through sed, awk, or sh commands, installation is faster by using the system classes rather than multiple classes and their corresponding class action scripts.

### The sed Class Script

The sed class provides a method to modify an existing object on the target system. The sed class action script executes automatically at installation if a file that belongs to class sed exists. The name of the sed class action script should be the same as the name of the file on which the instructions are executed.

A sed class action script delivers sed instructions in the following format:

Two commands indicate when instructions should be executed. The sed instructions that follow the !install command are executed during package installation. The sed instructions that follow the !remove command are executed during package removal. The order in which these commands are used in the file does not matter.
For more information on sed instructions, see the sed(1) man page. For examples of sed class action scripts, see Chapter 5, “Case Studies of Package Creation.”

**The awk Class Script**

The awk class provides a method to modify an existing object on the target system. Modifications are delivered as awk instructions in an awk class action script.

The awk class action script is executed automatically at installation if a file that belongs to class awk exists. Such a file contains instructions for the awk class script in the following format:

Two commands indicate when instructions should be executed. The awk instructions that follow the !install command are executed during package installation. The instructions that follow the !remove command are executed during package removal. These commands may be used in any order.

The name of the awk class action script should be the same as the name of the file on which the instructions are executed.

The file to be modified is used as input to the awk command and the output of the script ultimately replaces the original object. Environment variables may not be passed to the awk command with this syntax.

For more information on awk instructions, see the awk(1) man page.

**The build Class Script**

The build class creates or modifies a package object file by executing Bourne shell instructions. These instructions are delivered as the package object. The instructions run automatically at installation if the package object belongs to the build class.

The name of the build class action script should be the same as the name of the file on which the instructions are executed. The name must also be executable by the sh command. The script’s output becomes the new version of the file as it is built or modified. If the script produces no output, the file is not created or modified. Therefore, the script can modify or create the file itself.

For example, if a package delivers a default file, /etc/randomtable, and if the file does not already exist on the target system, the prototype file entry might be as follows:

```
e build /etc/randomtable
```

The package object, /etc/randomtable, might look like the following:

```
!install
# randomtable builder
if [ -f $PKG_INSTALL_ROOT/etc/randomtable ]; then
```
echo "/etc/randomtable is already in place.";
else
echo "# /etc/randomtable" > $PKG_INSTALL_ROOT/etc/randomtable
echo "1121554  # first random number" >> $PKG_INSTALL_ROOT/etc/randomtable
fi

!remove
# randomtable deconstructor
if [-f $PKG_INSTALL_ROOT/etc/randomtable ]; then
    # the file can be removed if it's unchanged
    if [ egrep "first random number" $PKG_INSTALL_ROOT/etc/randomtable ]; then
        rm $PKG_INSTALL_ROOT/etc/randomtable;
    fi
fi

See Chapter 5, "Case Studies of Package Creation," for another example using the build class.

**The preserve Class Script**

The preserve class preserves a package object file by determining whether or not an existing file should be overwritten when the package is installed. Two possible scenarios when using a preserve class script are:

- If the file to be installed does not already exist in the target directory, the file will be installed normally.
- If the file to be installed exists in the target directory, a message describing that the file exists is displayed, and the file is not installed.

Both scenario outcomes are considered successful by the preserve script. A failure occurs only in the second scenario when the file is unable to be copied to the target directory.

Starting with the Solaris 7 release, the i.preserve script and a copy of this script, i.CONFIG.prsv, can be found in the /usr/sadm/install/scripts directory with the other class action scripts.

Modify the script to include the filename or filenames you would like to preserve.

**The manifest Class Script**

The manifest class automatically installs and uninstalls SMF (Service Management Facility) services associated with an SMF manifest. If you are not familiar with SMF, see Chapter 17, "Managing Services (Overview)," in *System Administration Guide: Basic Administration* for information about how to use SMF to manage services.

All service manifests within packages should be identified with the class manifest. Class action scripts that install and remove service manifests are included in the packaging subsystem. When pkgadd(1M) is invoked, the service manifest is imported. When pkgrm(1M) is invoked,
instances in the service manifest that are disabled are deleted. Any services in the manifest that
have no remaining instances are also deleted. If the -R option is supplied to pkgadd(1M) or
pkgrm(1M), these service manifest actions will be done when the system is next rebooted with
that alternate root path.

The following portion of code from a package information file shows the use of the manifest
class.

```plaintext
# packaging files
i pkginfo
i copyright
i depend
i preinstall
i postinstall
i i.manifest
i r.manifest
#
# source locations relative to the prototype file
#
d none var 0755 root sys
d none var/svc 0755 root sys
d none var/svc/manifest 0755 root sys
d none var/svc/manifest/network 0755 root sys
d none var/svc/manifest/network/rpc 0755 root sys
f manifest var/svc/manifest/network/rpc/smserver.xml 0444 root sys
```

**▼ How to Write Class Action Scripts**

1. **Make the directory that contains your information files the current working directory.**

2. **Assign the package objects in the prototype file the desired class names.**
   For example, assigning objects to an application and manpage class would look like the
   following:
   ```plaintext
   f manpage /usr/share/man/man1/myappl.1
   f application /usr/bin/myappl
   ```

3. **Modify the CLASSES parameter in the pkginfo file to contain the class names you want to use in
   your package.**
   For example, entries for the application and manpage classes would look like the following:
   ```plaintext
   CLASSES=manpage application none
   ```
Note – The none class is always installed first and removed last, regardless of where it appears in the definition of the CLASSES parameter.

4 If you are creating a class action script for a file that belongs to the sed, awk, or build class, make the directory that contains the package object your current working directory.

5 Create the class action scripts or package objects (for files that belong to the sed, awk, or build class).

   For example, an installation script for a class named application would be named i.application and a removal script would be named r.application.

   Remember, when a file is part of a class that has a class action script, the script must install the file. The pkgadd command does not install files for which a class action script exists, although it does verify the installation. And, if you define a class but do not deliver a class action script, the only action taken for that class is to copy components from the installation medium to the target system (the default pkgadd behavior).

6 Complete one of the following tasks.

   ▪ If you have not created your prototype file, complete the procedure “How to Create a prototype File by Using the pkgproto Command” on page 42, and skip to Step 7.

   ▪ If you have already created your prototype file, edit it and add an entry for each installation script you just created.

7 Build your package.

   See “How to Build a Package” on page 45, if needed.

More Information Where to Go Next

After you build the package, install it to confirm that it installs correctly and verify its integrity. Chapter 4, “Verifying and Transferring a Package,” explains how to do this and provides step-by-step instructions on how to transfer your verified package to a distribution medium.

Creating Signed Packages

The process of creating signed packages involves a number of steps and requires some comprehension of new concepts and terminology. This section provides information about signed packages, its terminology, and information about certificate management. This section also provides step-by-step procedures about how to create a signed package.
Signed Packages

A signed package is a normal stream-format package that has a digital signature (PEM-encoded PKCS7 digital signature which is defined below) that verifies the following:

- The package came from the entity who signed it
- The entity indeed signed it
- The package has not been modified since the entity signed it
- The entity who signed it is a trusted entity

A signed package is identical to an unsigned package, except for the signature. A signed package is binary-compatible with an unsigned package. Therefore, a signed package can be used with older versions of the packaging tools. However, the signature is ignored in this case.

The signed packaging technology introduces some new terminology and abbreviations, which are described in the following table.

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASN.1</td>
<td>Abstract Syntax Notation 1 - A way of expressing abstract objects. For example, ASN.1 defines a public key certificate, all of the objects that make up the certificate, and the order in which the objects are collected. However, ASN.1 does not specify how the objects are serialized for storage or transmission.</td>
</tr>
<tr>
<td>X.509</td>
<td>ITU-T Recommendation X.509 - Specifies the widely-adopted X.509 public key certificate syntax.</td>
</tr>
<tr>
<td>DER</td>
<td>Distinguished Encoding Rules - A binary representation of an ASN.1 object and defines how an ASN.1 object is serialized for storage or transmission in computing environments.</td>
</tr>
<tr>
<td>PEM</td>
<td>Privacy Enhanced Message - A way to encode a file (in DER or another binary format) using base 64 encoding and some optional headers. PEM was initially used for encoding MIME-type email messages. PEM is also used extensively for encoding certificates and private keys into a file that exists on a file system or in an email message.</td>
</tr>
<tr>
<td>PKCS7</td>
<td>Public Key Cryptography Standard #7 - This standard describes a general syntax for data that may have cryptography applied to it, such as digital signatures and digital envelopes. A signed package contains an embedded PKCS7 signature. This signature contains at a minimum the encrypted digest of the package, along with the signer’s X.509 public key certificate. The signed package can also contain chain certificates. Chain certificates can be used when forming a chain of trust from the signer’s certificate to a locally-stored trusted certificate.</td>
</tr>
</tbody>
</table>
PKCS12 PublicKeyCryptographyStandard#12 This standard describes a syntax for storing cryptographic objects on disk. The package keystore is maintained in this format.

Package keystore A repository of certificates and keys that can be queried by the package tools.

**Certificate Management**

Before creating a signed package, you must have a package keystore. This package keystore contains certificates in the form of objects. Two types of objects exist in a package keystore:

- **Trusted certificate**
  
  A trusted certificate contains a single public key certificate that belongs to another entity. The trusted certificate is named as such because the keystore owner trusts that the public key in the certificate indeed belongs to the identity indicated by the “subject” (owner) of the certificate. The issuer of the certificate vouches for this trust by signing the certificate.

  Trusted certificates are used when verifying signatures and when initiating a connection to a secure (SSL) server.

- **User key**

  A user key holds sensitive cryptographic key information. This information is stored in a protected format to prevent unauthorized access. A user key consists of both the user’s private key and the public key certificate that corresponds to the private key.

  User keys are used when creating a signed package.

By default, the package keystore is stored in the `/var/sadm/security` directory. Individual users can also have their own keystore stored by default in the `$HOME/.pkg/security` directory.

On disk, a package keystore can be in two formats: a multiple-file format and a single-file format. A multiple-file format stores its objects in multiple files. Each type of object is stored in a separate file. All of these files must be encrypted using the same passphrase. A single-file keystore stores all of its objects in a single file on the file system.

The primary utility used to manage the certificates and the package keystore is the `pkgadm` command. The following subsections describe the more common tasks used for managing the package keystore.

**Adding Trusted Certificates to the Package Keystore**

A trusted certificate can be added to the package keystore using the `pkgadm` command. The certificate can be in PEM or DER format. For example:
$ pkgadm addcert -t /tmp/mytrustedcert.pem

In this example, the PEM format certificate called mytrustedcert.pem is added to the package keystore.

**Adding a User Certificate and Private Key to the Package Keystore**

The pkgadm command does not generate user certificates or private keys. User certificates and private keys are normally obtained from a Certificate Authority, such as Verisign. Or, they are generated locally as a self-signed certificate. Once the key and certificate are obtained, they can be imported into the package keystore using the pkgadm command. For example:

```
pkgadm addcert -n myname -e /tmp/myprivkey.pem /tmp/mypubcert.pem
```

In this example, the following options are used:

- `-n myname` Identifies the entity (myname) in the package keystore on which you wish to operate. The myname entity becomes the alias under which the objects are stored.

- `-e /tmp/myprivkey.pem` Specifies the file that contains the private key. In this case, the file is myprivkey.pem, which is located in the /tmp directory.

- `/tmp/mypubcert.pem` Specifies the PEM format certificate file called mypubcert.pem.

**Verifying the Contents in the Package Keystore**

The pkgadm command is also used to view the contents of the package keystore. For example:

```
$ pkgadm listcert
```

This command displays the trusted certificates and private keys in the package keystore.

**Deleting Trusted Certificates and Private Keys From the Package Keystore**

The pkgadm command can be used to delete trusted certificates and private keys from the package keystore.

When you delete user certificates, the alias of the certificate/key pair must be specified. For example:

```
$ pkgadm removecert -n myname
```
The alias of the certificate is the common name of the certificate, which can be identified using the `pkgadm listcert` command. For example, this command deletes a trusted certificate entitled Trusted CA Cert 1:

```
$ pkgadm removecert -n "Trusted CA Cert 1"
```

Note – If you have both a trusted certificate and a user certificate stored using the same alias, they are both deleted when you specify the `-n` option.

**Signed Packages Creation**

The process of creating signed packages involves three basic steps:

1. Creating an unsigned, directory-format package.
2. Importing the signing certificate, CA certificates, and private key into the package keystore.
3. Signing the package from Step 1 with the certificates from Step 2.

Note – The packaging tools do not create certificates. These certificates must be obtained from a Certificate Authority, such as Verisign or Thawte.

Each step for creating signed packages is described in the following procedures.

▼ **How to Create an Unsigned, Directory-Format Package**

The procedure for creating an unsigned, directory-format package is the same as the procedure for creating a normal package, as previously described in this manual. The following procedure describes the process of creating this unsigned, directory-format package. If you need more information, refer to the previous sections about building packages.

1. **Create the `pkginfo` file.**

The `pkginfo` file should have the following basic content:

```
PKG=SUNWfoo
BASEDIR=/
NAME=My Test Package
ARCH=sparc
VERSION=1.0.0
CATEGORY=application
```
2 Create the prototype file.

The prototype file should have the following basic content:

```
$ cat prototype
i pkginfo
d none usr 0755 root sys
d none usr/bin 0755 root bin
f none usr/bin/myapp=/tmp/myroot/usr/bin/myapp 0644 root bin
```

3 List the contents of the object source directory.

For example:

```
$ ls -lR /tmp/myroot
```

The output would appear similar to the following:

```
/tmp/myroot:
total 16
drwxr-xr-x  3 abc other 177 Jun  2 16:19 usr

/tmp/myroot/usr:
total 16
drwxr-xr-x  2 abc other 179 Jun  2 16:19 bin

/tmp/myroot/usr/bin:
total 16
-rw-------  1 abc other 1024 Jun  2 16:19 myapp
```

4 Create the unsigned package.

```
pkgmk -d 'pwd'
```

The output would appear similar to the following:

```
## Building pkgmap from package prototype file.
## Processing pkginfo file.
WARNING: parameter <PSTAMP> set to "syrinx20030605115507"
WARNING: parameter <CLASSES> set to "none"
## Attempting to volumize 3 entries in pkgmap.
part 1 -- 84 blocks, 7 entries
## Packaging one part.
/tmp/SUNWfoo/pkgmap
/tmp/SUNWfoo/pkginfo
/tmp/SUNWfoo/reloc/usr/bin/myapp
## Validating control scripts.
## Packaging complete.
```

The package now exists in the current directory.
How to Import the Certificates Into the Package Keystore

The certificate and private key to be imported must exist as a PEM- or DER-encoded X.509 certificate and private key. In addition, any intermediate or “chain” certificates linking your signing certificate to the Certificate Authority certificate must be imported into the package keystore before a package can be signed.

**Note** – Each Certificate Authority can issue certificates in various formats. To extract the certificates and private key out of the PKCS12 file and into a PEM-encoded X.509 file (suitable for importing into the package keystore), use a freeware conversion utility such as OpenSSL.

If your private key is encrypted (which should usually be the case), you are prompted for the passphrase. Also, you are prompted for a password to protect the resulting package keystore. You can optionally not supply any password, but doing so results in an unencrypted package keystore.

The following procedure describes how to import the certificates using the `pkgadm` command once the certificate is in the proper format.

1. **Import all the Certificate Authority certificates found in your PEM- or DER-encoded X.509 certificate file.**

   For example, to import all the Certificate Authority certificates found in the file `ca.pem`, you would type the following:

   ```
   $ pkgadm addcert -k ~/mykeystore -ty ca.pem
   ```

   The output would appear similar to the following:

   ```
   Trusting certificate <VeriSign Class 1 CA Individual \
   Subscriber-Persona Not Validated>
   Trusting certificate </C=US/O=VeriSign, Inc./OU=Class 1 Public \
   Primary Certification Authority
   Type a Keystore protection Password.
   Press ENTER for no protection password (not recommended):
   For Verification: Type a Keystore protection Password.
   Press ENTER for no protection password (not recommended):
   Certificate(s) from <ca.pem> are now trusted
   ```

   In order to import your signing key into the package keystore, you must supply an alias that is used later when signing the package. This alias can also be used if you want to delete the key from the package keystore.

   For example, to import your signing key from the file `sign.pem`, you would type the following:

   ```
   $ pkgadm addcert -k ~/mykeystore -n mycert sign.pem
   ```
The output would appear similar to the following:

Enter PEM passphrase:
Enter Keystore Password:
Successfully added Certificate <sign.pem> with alias <mycert>

2 **Verify that the certificates are in the package keystore.**
For example, to view the certificates in the keystore created in the previous step, you would type the following:

$ pkgadm listcert -k ~/mykeystore

▼ **How to Sign the Package**

Once the certificates are imported into the package keystore, you can now sign the package. The actual signing of the package is done using the **pkgtrans** command.

* Sign the package using the **pkgtrans** command. Supply the location of the unsigned package and the alias of the key to sign the package.

For example, using the examples from the previous procedures, you would type the following to create a signed package called SUNWfoo.signed:

$ pkgtrans -g -k ~/mykeystore -n mycert . ./SUNWfoo.signed SUNWfoo

The output of this command would appear similar to the following:

Retrieving signing certificates from keystore </home/user/mykeystore>
Enter keystore password:
Generating digital signature for signer <Test User>
Transferring <SUNWfoot> package instance

The signed package is created in the file SUNWfoo.signed and is in the package-stream format. This signed package is suitable for copying to a web site and being installed using the pkgadd command and a URL.
Verifying and Transferring a Package

This chapter describes how to verify your package's integrity and transfer it to a distribution medium, such as floppy disk or a CD-ROM.

This is a list of the overview information in this chapter:
- “Verifying and Transferring a Package (Task Map)” on page 83
- “Installing Software Packages” on page 84
- “Verifying the Integrity of a Package” on page 86
- “Displaying Additional Information About Installed Packages” on page 88
- “Removing a Package” on page 93
- “Transferring a Package to a Distribution Medium” on page 94

Verifying and Transferring a Package (Task Map)

The table below describes the steps you should follow in order to verify your package's integrity and transfer it to a distribution medium.

<table>
<thead>
<tr>
<th>Task</th>
<th>Description</th>
<th>Instructions</th>
</tr>
</thead>
<tbody>
<tr>
<td>2. Install Your Package</td>
<td>Test your package by installing it and making sure that it installs without errors.</td>
<td>“How to Install a Package on a Standalone System or Server” on page 85</td>

</tr>
</tbody>
</table>

Installing Software Packages

Software packages are installed using the `pkgadd` command. This command transfers the contents of a software package from the distribution medium or directory and installs it onto a system.

This section provides basic installation instructions for installing your package in order to verify that it installs correctly.

The Installation Software Database

Information for all packages installed on a system is kept in the installation software database. There is an entry for every object in a package, with information such as the component name, where it resides, and its type. An entry contains a record of the package to which a component belongs; other packages that might reference the component; and information such as path name, where the component resides and the component type. Entries are added and removed automatically by the `pkgadd` and `pkg rm` commands. You can view the information in the database by using the `pkg chk` and the `pkg info` commands.

Two types of information are associated with each package component. The attribute information describes the component itself. For example, the component’s access permissions, owner ID, and group ID are attribute information. The content information describes the contents of the component, such as file size and time of last modification.

The installation software database keeps track of the package status. A package can be either fully installed (it has successfully completed the installation process), or partially installed (it did not successfully complete the installation process).

When a package is partially installed, portions of a package may have been installed before installation was terminated; thus, part of the package is installed, and recorded in the database, and part is not. When you reinstall the package, you are prompted to start at the point where installation stopped because the `pkgadd` command can access the database and detect which portions have already been installed. You can also remove the portions that have been installed, based on the information in the installation software database using the `pkg rm` command.
Interacting With the pkgadd Command

If the pkgadd command encounters a problem, it first checks the installation administration file for instructions. (See admin(4) for more information.) If no instructions exist, or if the relevant parameter in the administration file is set to ask, the pkgadd displays a message describing the problem and prompts for a reply. The prompt is usually Do you want to continue with this installation? You should respond with yes, no, or quit.

If you have specified more than one package, no stops installation of the package being installed but pkgadd continues with installation of the other packages. quit indicates that pkgadd should stop installation of all packages.

Installing Packages on Standalone Systems or Servers in a Homogeneous Environment

This section describes how to install packages on a standalone or a server system in a homogeneous environment.

▼ How to Install a Package on a Standalone System or Server

1. Build your package.
   See "Building a Package" on page 43, if needed.

2. Log in to the system as superuser.

3. Add the software package to the system.
   # pkgadd -d device-name [pkg-abbrev. . .]

   -d device-name Specifies the location of the package. Note that device-name can be a full directory path name or the identifiers for a tape, floppy disk, or removable disk.

   pkg-abbrev Is the name of one or more packages (separated by spaces) to be added. If omitted, pkgadd installs all available packages.

Example 4–1 Installing Packages on Standalones and Servers

To install a software package named pkgA from a tape device named /dev/rmt/0, you would enter the following command:
You can also install multiple packages at the same time, as long as you separate package names with a space, as follows:

# pkgadd -d /dev/rmt/0 pkgA pkgB pkgC

If you do not name the device on which the package resides, the command checks the default spool directory (/var/spool/pkg). If the package is not there, the installation fails.

See Also  If you are ready to go to the next task, see “How to Verify the Integrity of a Package” on page 86.

Verifying the Integrity of a Package

The pkgchk command enables you to check the integrity of packages, whether they are installed on a system or in package format (ready to be installed with the pkgadd command). It confirms package structure or the installed files and directories, or displays information about package objects. The pkgchk command can list or check the following:

- The package installation scripts.
- The contents or attributes, or both, of objects currently installed on the system.
- The contents of a spooled, uninstalled package.
- The contents or attributes, or both, of objects described in the specified pkgmap file.

For more information about this command, refer to pkgchk(1M).

The pkgchk command performs two kinds of checks. It checks file attributes (the permissions and ownership of a file and major/minor numbers for block or character special devices) and the file contents (the size, checksum, and modification date). By default, the command checks both the file attributes and the file contents.

The pkgchk command also compares the file attributes and contents of the installed package against the installation software database. The entries concerning a package may have been changed since the time of installation; for example, another package may have changed a package component. The database reflects that change.

How to Verify the Integrity of a Package

1 Install your package.
   See “How to Install a Package on a Standalone System or Server” on page 85, if needed.

2 Verify the integrity of your package.
   # pkgchk [-v] [-R root-path] [pkg-abbrev...]

86 Application Packaging Developer’s Guide • April 2009
Lists files as they are processed.

- \textit{-R root-path} Specifies the location of the client system's root file system.

\textit{pkg-abbrev} Is the name of one or more packages (separated by spaces) to be checked. If omitted, \texttt{pkgchk} checks all available packages.

**Example 4–2** Verifying the Integrity of a Package

This example shows the command you should use to verify the integrity of an installed package.

```
$ pkgchk \textit{pkg-abbrev}
```

If there are errors, the \texttt{pkgchk} command prints them. Otherwise, it does not print anything and returns an exit code of 0. If you do not supply a package abbreviation, then it will check all of the packages on the system.

Alternately, you could use the \textit{-v} option, which will print a list of files in the package if there are no errors. For example:

```
$ pkgchk \textit{-v \textit{SUNWcadap}}
```

```
/opt/SUNWcadap
/opt/SUNWcadap/demo
/opt/SUNWcadap/demo/file1
/opt/SUNWcadap/lib
/opt/SUNWcadap/lib/file2
/opt/SUNWcadap/man
/opt/SUNWcadap/man/man1
/opt/SUNWcadap/man/man1/file3.1
/opt/SUNWcadap/man/man1/file4.1
/opt/SUNWcadap/man/windex
/opt/SUNWcadap/srcfiles
/opt/SUNWcadap/srcfiles/file5
/opt/SUNWcadap/srcfiles/file6
```

If you need to verify a package that is installed on a client system's root file system, use this command:

```
$ pkgchk \textit{-v \textit{-R root-path pkg-abbrev}}
```

**See Also** If you are ready to go to the next task, see “How to Obtain Information With the \texttt{pkginfo} Command” on page 92.
Displaying Additional Information About Installed Packages

You can use two other commands to display information about installed packages:

- The `pkgparam` command displays parameter values.
- The `pkginfo` command displays information from the installation software database.

**The `pkgparam` Command**

The `pkgparam` command enables you to display the values associated with the parameters you specified on the command line. The values are retrieved from either the `pkginfo` file for a specific package, or from the file you name. One parameter value is shown per line. You can display the values only or the parameters and their values.

**How to Obtain Information With the `pkgparam` Command**

1. **Install your package.**
   See "How to Install a Package on a Standalone System or Server" on page 85, if needed.

2. **Display additional information about your package.**
   ```
   # pkgparam [-v] pkg-abbrev [param...] 
   ```

   - `-v` Displays the name of the parameter and its value.
   - `pkg-abbrev` Is the name of a specific package.
   - `param` Specifies one or more parameters whose value is displayed.

**Example 4–3 Obtaining Information With the `pkgparam` Command**

For example, to display values only, use this command.

```
$ pkgparam SUNWcadap
none
/opt
US/Mountain
/sbin:/usr/sbin:/usr/bin:/usr/sadm/install/bin
/usr/sadm/sysadm
SUNWcadap
Chip designers need CAD application software to design abc chips. Runs only on xyz hardware and is installed in the usr
```
To display parameters and their values, use the following command.

```
$ pkgparam -v SUNWcadap
pkgparam -v SUNWcadap
CLASSES='none'
BASEDIR='/opt'
TZ='US/Mountain'
PATH='/sbin:/usr/sbin:/usr/bin:/usr/sadm/install/bin'
OAMBASE='/usr/sadm/sysadm'
PKG='SUNWcadap'
NAME='Chip designers need CAD application software to design abc chips.
Runs only on xyz hardware and is installed in the usr partition.'
CATEGORY='system'
VERSION='release 1.0'
ARCH='SPARC'
PSTAMP='venus990706083849'
PKGINST='SUNWcadap'
PKGSAV='/var/sadm/pkg/SUNWcadap/save'
INSTDATE='Jul 7 1999 09:58'
```

Or, if you want to display the value of a specific parameter, use this format:

```
$ pkgparam SUNWcadap BASEDIR
/opt
```

For more information, refer to `pkgparam(1)`.

**See Also**
If you are ready to go to the next task, see “How to Remove a Package” on page 93.

**The pkginfo Command**

You can display information about installed packages with the `pkginfo` command. This command has several options that enable you to customize both the format and the contents of the display.
You can request information about any number of package instances.

**The Default `pkginfo` Display**

When the `pkginfo` command is executed without options, it displays the category, package instance, and package name of all packages that have been completely installed on your system. The display is organized by categories as shown in the following example.

```
$ pkginfo

system   SUNWinst   Install Software
system   SUNWipc    Interprocess Communications
system   SUNWisolc  XSH4 conversion for ISO Latin character sets
application SUNWkcspf  KCMS Optional Profiles
application SUNWkcspg  KCMS Programmers Environment
application SUNWkcsrt  KCMS Runtime Environment

$ 
```

**Customizing the Format of the `pkginfo` Display**

You can get a `pkginfo` display in any of three formats: short, extracted, and long.

The short format is the default. It shows only the category, package abbreviation, and full package name, as shown in "The Default `pkginfo` Display" on page 90.

The extracted format shows the package abbreviation, package name, package architecture (if available), and package version (if available). Use the `-x` option to request the extracted format as shown in the next example.

```
$ pkginfo -x

SUNWipc       Interprocess Communications
               (sparc) 11.8.0,REV=1999.08.20.12.37
SUNWisolc     XSH4 conversion for ISO Latin character sets
               (sparc) 1.0,REV=1999.07.10.10.10
SUNWkcspf     KCMS Optional Profiles
               (sparc) 1.1.2,REV=1.5
SUNWkcspg     KCMS Programmers Environment
               (sparc) 1.1.2,REV=1.5
```

Displaying Additional Information About Installed Packages
Using the `-l` option produces a display in the long format showing all of the available information about a package, as in the following example.

```
$ pkginfo -l SUNWcadap
PKGINST: SUNWcadap
   NAME: Chip designers need CAD application software to
design abc chips. Runs only on xyz hardware and is installed
in the usr partition.
   CATEGORY: system
   ARCH: SPARC
   VERSION: release 1.0
   BASEDIR: /opt
   PSTAMP: system980706083849
   INSTDATE: Jul 7 1999 09:58
       STATUS: completely installed
   FILES:  13 installed pathnames
            6 directories
            3 executables
       3121 blocks used (approx)
$```

### Parameter Descriptions for the `pkginfo` Long Format

The table below describes the package parameters that can be displayed for each package. A parameter and its value are displayed only when the parameter has a value assigned to it.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ARCH</td>
<td>The architecture supported by this package.</td>
</tr>
<tr>
<td>BASEDIR</td>
<td>The base directory in which the software package resides (shown if the package is relocatable).</td>
</tr>
<tr>
<td>CATEGORY</td>
<td>The software category, or categories, of which this package is a member (for example, system or application).</td>
</tr>
<tr>
<td>CLASSES</td>
<td>A list of classes defined for a package. The order of the list determines the order in which the classes are installed. Classes listed first will be installed first (on a media by media basis). This parameter may be modified by the request script.</td>
</tr>
<tr>
<td>DESC</td>
<td>Text that describes the package.</td>
</tr>
<tr>
<td>EMAIL</td>
<td>The electronic mail address for user inquiries.</td>
</tr>
</tbody>
</table>
### TABLE 4–2 Package Parameters (Continued)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>HOTLINE</td>
<td>Information on how to receive hotline help about this package.</td>
</tr>
<tr>
<td>INTONLY</td>
<td>Indicates that the package should only be installed interactively when set to any non-NULL value.</td>
</tr>
<tr>
<td>ISTATES</td>
<td>A list of allowable run states for package installation (for example, S ≤ 1).</td>
</tr>
<tr>
<td>MAXINST</td>
<td>The maximum number of package instances that should be allowed on a machine at the same time. By default, only one instance of a package is allowed.</td>
</tr>
<tr>
<td>NAME</td>
<td>The package name, generally text describing the package abbreviation.</td>
</tr>
<tr>
<td>ORDER</td>
<td>A list of classes defining the order in which they should be put on the medium. Used by the <code>pkgmk</code> command in creating the package. Classes not defined in this parameter are placed on the medium using the standard ordering procedures.</td>
</tr>
<tr>
<td>PKGINST</td>
<td>Abbreviation for the package being installed.</td>
</tr>
<tr>
<td>PSTAMP</td>
<td>The production stamp for this package.</td>
</tr>
<tr>
<td>RSTATES</td>
<td>A list of allowable run states for package removal (for example, S ≤ 1).</td>
</tr>
<tr>
<td>ULIMIT</td>
<td>If set, this parameter is passed as an argument to the <code>ulimit</code> command, which establishes the maximum size of a file during installation. This applies only to files created by procedure scripts.</td>
</tr>
<tr>
<td>VENDOR</td>
<td>The name of the vendor who supplied the software package.</td>
</tr>
<tr>
<td>VERSION</td>
<td>The version of this package.</td>
</tr>
<tr>
<td>VSTOCK</td>
<td>The vendor-supplied stock number.</td>
</tr>
</tbody>
</table>

For detailed information about the `pkginfo` command, refer to the `pkginfo(1)` man page.

**▼ How to Obtain Information With the `pkginfo` Command**

1. **Install your package.**
   See “How to Install a Package on a Standalone System or Server” on page 85, if needed.

2. **Display additional information about your package.**
   ```
   # pkginfo [-x] [-l] [pkg-abbrev]
   
   -x          Displays package information in extracted format.
   ```
Removing a Package

Because the `pkgrm` command updates information in the software products database, it is important when you remove a package to use the `pkgrm` command—even though you might be tempted to use the `rm` command instead. For example, you could use the `rm` command to remove a binary executable file, but that is not the same as using `pkgrm` to remove the software package that includes that binary executable. Using the `rm` command to remove a package's files will corrupt the software products database. (If you really only want to remove one file, you can use the `removef` command, which will update the software product database correctly.

- **How to Remove a Package**

  1. Log in to the system as superuser.
  2. Remove an installed package.
     
     ```bash
     # pkgrm pkg-abbrev ...
     ```
     
     `pkg-abbrev` Is the name of one or more packages (separated by spaces). If omitted, `pkgrm` removes all available packages.
  3. Verify that the package has successfully been removed, use the `pkginfo` command.

     ```bash
     $ pkginfo | egrep pkg-abbrev
     ```

     If `pkg-abbrev` is installed, the `pkginfo` command returns a line of information about it. Otherwise, `pkginfo` returns the system prompt.
Transferring a Package to a Distribution Medium

The `pkgtrans` command moves packages and performs package format translations. You can use the `pkgtrans` command to perform the following translations for an installable package:

- File system format to datastream format
- Datastream format to file system format
- One file system format to another file system format

▼ How to Transfer a Package to a Distribution Medium

1. **Build your package, creating a directory format package, if you have not already done so.**
   
   For more information, see “How to Build a Package” on page 45.

2. **Install your package to verify that it installs correctly.**
   
   See “How to Install a Package on a Standalone System or Server” on page 85, if needed.

3. **Verify your package’s integrity.**
   
   See “How to Verify the Integrity of a Package” on page 86, “How to Obtain Information With the `pkginfo` Command” on page 92, and “How to Obtain Information With the `pkgparam` Command” on page 88, if needed.

4. **Remove the installed package from the system.**
   
   See “How to Remove a Package” on page 93, if needed.

5. **Transfer the package (in package format) to a distribution medium.**
   
   To perform a basic translation, execute the following command:

   ```
   $ pkgtrans device1 device2 [pkg-abbrev...]
   ```

   - `device1` is the name of the device where the package currently resides.
   - `device2` is the name of the device onto which the translated package will be written.
   - `[pkg-abbrev]` is one or more package abbreviations.

   If no package names are given, all packages residing in `device1` are translated and written to `device2`. 
Note – If more than one instance of a package resides on device1, you must use an instance identifier for the package. For a description of a package identifier, see “Defining a Package Instance” on page 26. When an instance of the package being translated already exists on device2, the pkgtrans command does not perform the translation. You can use the -o option to tell the pkgtrans command to overwrite any existing instances on the destination device and the -n option to tell it to create a new instance if one already exists. Note that this check does not apply when device2 supports a datastream format.

More Information

Where to Go Next

At this point you have completed the steps necessary to design, build, verify, and transfer your package. If you are interested in looking at some case studies, see Chapter 5, “Case Studies of Package Creation.” If you are interested in advanced package design ideas, see Chapter 6, “Advanced Techniques for Creating Packages.”
This chapter provides case studies to show packaging scenarios such as installing objects conditionally, determining at run time how many files to create, and modifying an existing data file during package installation and removal.

Each case study begins with a description, followed by a list of the packaging techniques used, a narrative description of the approach taken when using those techniques, and sample files and scripts associated with the case study.

This is a list of the case studies in this chapter:

- “Soliciting Input From the Administrator” on page 97
- “Creating a File at Installation and Saving It During Removal” on page 101
- “Defining Package Compatibilities and Dependencies” on page 104
- “Modifying a File by Using Standard Classes and Class Action Scripts” on page 106
- “Modifying a File by Using the sed Class and a postinstall Script” on page 108
- “Modifying a File by Using The build Class” on page 111
- “Modifying crontab Files During Installation” on page 113
- “Installing and Removing a Driver With Procedure Scripts” on page 116
- “Installing a Driver by Using the sed Class and Procedure Scripts” on page 118

**Soliciting Input From the Administrator**

The package in this case study has three types of objects. The administrator may choose which of the three types to install and where to locate the objects on the installation machine.

**Techniques**

This case study demonstrates the following techniques:

- Using parametric path names (variables in object path names) that are used to establish multiple base directories
For information on parametric path names, see "Parametric Path Names" on page 34.

- Using a request script to solicit input from the administrator
  For information on request scripts, see "Writing a request Script" on page 60.
- Setting conditional values for an installation parameter.

**Approach**

To set up the selective installation in this case study, you must complete the following tasks:

- Define a class for each type of object that can be installed.
  In this case study, the three object types are the package executables, the man pages, and the emacs executables. Each type has its own class: `bin`, `man`, and `emacs`, respectively. Notice that in the prototype file all the object files belong to one of these three classes.

- Initialize the CLASSES parameter in the pkginfo file to null.
  Normally when you define a class, you should list that class in the CLASSES parameter in the pkginfo file. Otherwise, no objects in that class are installed. For this case study, the parameter is initially set to null, which means no objects will get installed. The CLASSES parameter will be changed by the request script, based on the choices of the administrator. This way, the CLASSES parameter is set to only those object types that the administrator wants installed.

  **Note** – Usually it is a good idea to set parameters to a default value. If this package had components common to all three object types, you could assign them to the none class, and then set the CLASSES parameter equal to none.

- Insert parametric path names into the prototype file.
  The request script sets these environment variables to the value that the administrator provides. Then, the pkgadd command resolves these environment variables at installation time and knows where to install the package.
  The three environment variables used in this example are set to their default in the pkginfo file and serve the following purposes:

  - `$NCMPBIN` defines the location for object executables
  - `$NCMPMAN` defines the location for man pages
  - `$EMACS` defines the location for emacs executables

  The example prototype file shows how to define the object path names with variables.

- Create a request script to ask the administrator which parts of the package should be installed and where they should be placed.
  The request script for this package asks the administrator two questions:
Should this part of the package be installed?
When the answer is yes, the appropriate class name is added to the CLASSES parameter. For example, when the administrator chooses to install the man pages associated with this package, the class man is added to the CLASSES parameter.

If so, where should this part of the package be placed?
The appropriate environment variable is set to the response to this question. In the man page example, the variable $NCMPMAN is set to the response value.

These two questions are repeated for each of the three object types.

At the end of the request script, the parameters are made available to the installation environment for the pkgadd command and any other packaging scripts. The request script does this by writing these definitions to the file provided by the calling utility. For this case study, no other scripts are provided.

When looking at the request script for this case study, notice that the questions are generated by the data validation tools ckyorn and ckpath. For more information on these tools, see ckyorn(1) and ckpath(1).

# determine if emacs editor should be installed, and if it should
# where should the associated macros be placed
ans=ckeorn -d y \ 
-p "Should emacs editor included in this package be installed"
  ' || exit $?;
if [ "$ans" = y ]
  then
    CLASSES="$CLASSES emacs"
    EMACS=`ckpath -d /usr/ncmp/lib/emacs -aoy 
      -p "Where should emacs macros be installed"
      ' || exit $?;
f1
```

Note that a request script can exit without leaving any files on the file system. For installations on Solaris versions prior to 2.5 and compatible versions (where no checkinstall script may be used) the request script is the correct place to test the file system in any manner necessary to ensure that the installation will succeed. When the request script exits with code 1, the installation will quit cleanly.

These example files show the use of parametric paths to establish multiple basedirectories. However, the preferred method involves use of the BASEDIR parameter which is managed and validated by the pkgadd command. Whenever multiple base directories are used, take special care to provide for installation of multiple versions and architectures on the same platform.
Creating a File at Installation and Saving It During Removal

This case study creates a database file at installation time and saves a copy of the database when the package is removed.

Techniques

This case study demonstrates the following techniques:

■ Using classes and class action scripts to perform special actions on different sets of objects
  For more information, see “Writing Class Action Scripts” on page 67.
■ Using the space file to inform the pkgadd command that extra space is required to install this package properly
  For more information on the space file, see “Reserving Additional Space on a Target System” on page 54.
■ Using the installf command to install a file not defined in the prototype and pkgmap files.

Approach

To create a database file at installation and save a copy on removal for this case study, you must complete the following tasks:

■ Define three classes.
  The package in this case study requires the following three classes be defined in the CLASSES parameter:
  ■ The standard class of none, which contains a set of processes belonging in the subdirectory bin.
  ■ The admin class, which contains an executable file config and a directory containing data files.
  ■ The cfgdata class, which contains a directory.
■ Make the package collectively relocatable.
  Notice in the prototype file that none of the path names begins with a slash or an environment variable. This indicates that they are collectively relocatable.
■ Calculate the amount of space the database file requires and create a space file to deliver with the package. This file notifies the pkgadd command that the package requires extra space and specifies how much.
■ Create a class action script for the admin class (i.admin).
  The sample script initializes a database using the data files belonging to the admin class. To perform this task, it does the following:
Copies the source data file to its proper destination

Creates an empty file named config.data and assigns it to a class of cfgdata

Executes the bin/config command (delivered with the package and already installed) to populate the database file config.data using the data files belonging to the admin class

Executes the installf -f command to finalize installation of config.data

No special action is required for the admin class at removal time so no removal class action script is created. This means that all files and directories in the admin class are removed from the system.

Create a removal class action script for the cfgdata class (r.cfgdata).

The removal script makes a copy of the database file before it is deleted. No special action is required for this class at installation time, so no installation class action script is needed.

Remember that the input to a removal script is a list of path names to remove. Path names always appear in reverse alphabetical order. This removal script copies files to the directory named $PKGSAV. When all the path names have been processed, the script then goes back and removes all directories and files associated with the cfgdata class.

The outcome of this removal script is to copy config.data to $PKGSAV and then remove the config.data file and the data directory.

Case Study Files

The pkginfo File

PKG=krazy
NAME=KrAzY Applications
CATEGORY=applications
BASEDIR=/opt
ARCH=SPARC
VERSION=Version 1
CLASSES=none cfgdata admin

The prototype File

i pkginfo
i request
i i.admin
i r.cfgdata
d none bin 555 root sys
f none bin/process1 555 root other
f none bin/process2 555 root other
f none bin/process3 555 root other
f admin bin/config 500 root sys
The space File

# extra space required by config data which is
# dynamically loaded onto the system

data 500 1

The i.admin Class Action Script

# PKGINST parameter provided by installation service
# BASEDIR parameter provided by installation service
while read src dest
do
cp $src $dest || exit 2
done

# if this is the last time this script will be executed
# during the installation, do additional processing here.
if [ "$1" = ENDOFCLASS ]
then
# our config process will create a data file based on any changes
# made by installing files in this class; make sure the data file
# is in class 'cfgdata' so special rules can apply to it during
# package removal.
installf -c cfgdata $PKGINST $BASEDIR/data/config.data f 444 root
sys || exit 2
$BASEDIR/bin/config > $BASEDIR/data/config.data || exit 2
installf -f -c cfgdata $PKGINST || exit 2
fi
exit 0

This illustrates a rare instance in which installf is appropriate in a class action script. Because a space file has been used to reserve room on a specific file system, this new file may be safely added even though it is not included in the pkgmap file.

The r.cfgdata Removal Script

# the product manager for this package has suggested that
# the configuration data is so valuable that it should be
# backed up to $PKGSAV before it is removed!

while read path
do
# path names appear in reverse lexical order.
mv $path $PKGSAV || exit 2
rm -f $path || exit 2
done
exit 0

Defining Package Compatibilities and Dependencies

The package in this case study uses optional information files to define package compatibilities and dependencies, and to present a copyright message during installation.

Techniques

This case study demonstrates the following techniques:

- Using the copyright file
- Using the compver file
- Using the depend file

For more information on these files, see “Creating Information Files” on page 50.

Approach

To meet the requirements in the description, you must:

- Create a copyright file.
  A copyright file contains the ASCII text of a copyright message. The message shown in the sample file is displayed on the screen during package installation.

- Create a compver file.
  The pkginfo file shown in the next figure defines this package version as version 3.0. The compver file defines version 3.0 as being compatible with versions 2.3, 2.2, 2.1, 2.1.1, 2.1.3 and 1.7.

- Create a depend file.
  Files listed in a depend file must already be installed on the system when a package is installed. The example file has 11 packages which must already be on the system at installation time.

Modifying a File by Using Standard Classes and Class Action Scripts

This case study modifies an existing file during package installation using standard classes and class action scripts. It uses one of three modification methods. The other two methods are described in “Modifying a File by Using the sed Class and a postinstall Script” on page 108 and “Modifying a File by Using The build Class” on page 111. The file modified is /etc/inittab.

Techniques

This case study demonstrates how to use installation and removal class action scripts. For more information, see “Writing Class Action Scripts” on page 67.

Approach

To modify /etc/inittab during installation, using classes and class action scripts, you must complete the following tasks:

- Create a class.
  
  Create a class called inittab. You must provide an installation and a removal class action script for this class. Define the inittab class in the CLASSES parameter in the pkginfo file.

- Create an inittab file.
  
  This file contains the information for the entry that you will add to /etc/inittab. Notice in the prototype file figure that inittab is a member of the inittab class and has a file type of e for editable.

- Create an installation class action script (i.inittab).
  
  Remember that class action scripts must produce the same results each time they are executed. The class action script performs the following procedures:

  - Checks if this entry has been added before
  - If it has, removes any previous versions of the entry
  - Edits the inittab file and adds the comment lines so you know where the entry is from
  - Moves the temporary file back into /etc/inittab
  - Executes the init q command when it receives the ENDOFCCLASS indicator
Note that the `init q` command can be performed by this installation script. A one-line postinstall script is not needed by this approach.

- Create a removal class action script (`r.inittab`).
  The removal script is very similar to the installation script. The information added by the installation script is removed and the `init q` command is executed.

This case study is more complicated than the next one; see “Modifying a File by Using the `sed` Class and a postinstall Script” on page 108. Instead of providing two files, three are needed and the delivered `/etc/inittab` file is actually just a placeholder containing a fragment of the entry to be inserted. This could have been placed into the `i.inittab` file except that the `pkgadd` command must have a file to pass to the `i.inittab` file. Also, the removal procedure must be placed into a separate file (`r.inittab`). While this method works fine, it is best reserved for cases involving very complicated installations of multiple files. See “Modifying crontab Files During Installation” on page 113.

The `sed` program used in “Modifying a File by Using the `sed` Class and a postinstall Script” on page 108 supports multiple package instances since the comment at the end of the `inittab` entry is based on package instance. The case study in “Modifying a File by Using The build Class” on page 111 shows a more streamlined approach to editing `/etc/inittab` during installation.

The inittab File

`rb:023456:wait:/usr/robot/bin/setup`

Modifying a File by Using the `sed` Class and a postinstall Script

This case study modifies a file which exists on the installation machine during package installation. It uses one of three modification methods. The other two methods are described in "Modifying a File by Using Standard Classes and Class Action Scripts" on page 106 and "Modifying a File by Using The build Class" on page 111. The file modified is `/etc/inittab`. 
Techniques

This case study demonstrates the following techniques:

- Using the `sed` class
  For more information on the `sed` class, see "The `sed` Class Script" on page 71.

- Using a postinstall script
  For more information on this script, see "Writing Procedure Scripts" on page 66.

Approach

To modify `/etc/inittab` at the time of installation, using the `sed` class, you must complete the following tasks:

- Add the `sed` class script to the prototype file.
  The name of a script must be the name of the file that will be edited. In this case, the file to be edited is `/etc/inittab` and so the `sed` script is named `/etc/inittab`. There are no requirements for the mode, owner, and group of a `sed` script (represented in the sample prototype by question marks). The file type of the `sed` script must be `e` (indicating that it is editable).

- Set the `CLASSES` parameter to include the `sed` class.
  As shown in the example file, `sed` is the only class being installed. However, it could be one of any number of classes.

- Create a `sed` class action script.
  Your package cannot deliver a copy of `/etc/inittab` that looks the way you need it to, since `/etc/inittab` is a dynamic file and you have no way of knowing how it will look at the time of package installation. However, using a `sed` script allows you to modify the `/etc/inittab` file during package installation.

- Create a postinstall script.
  You need to execute the `init q` command to inform the system that `/etc/inittab` has been modified. The only place you can perform that action in this example is in a postinstall script. Looking at the example postinstall script, you will see that its only purpose is to execute the `init q` command.

This approach to editing `/etc/inittab` during installation has one drawback; you have to deliver a full script (the postinstall script) simply to perform the `init q` command.

# inserting the entry before the last line!
$i\nrb:023456:wait:/usr/robot/bin/setup #ROBOT

The postinstall Script
# make init re-read inittab
/sbin/init q ||
exit 2
exit 0
Modifying a File by Using The $build$ Class

This case study modifies a file which exists on the installation machine during package installation. It uses one of three modification methods. The other two methods are described in “Modifying a File by Using Standard Classes and Class Action Scripts” on page 106 and “Modifying a File by Using the sed Class and a postinstall Script” on page 108. The file modified is /etc/inittab.

Techniques

This case study demonstrates how to use the build class. For more information on the build class, see “The build Class Script” on page 72.

Approach

This approach to modifying /etc/inittab uses the build class. A build class script is executed as a shell script and its output becomes the new version of the file being executed. In other words, the data file /etc/inittab that is delivered with this package will be executed and the output of that execution will become /etc/inittab.

The build class script is executed during package installation and package removal. The argument install is passed to the file if it is being executed at installation time. Notice in the sample build class script that installation actions are defined by testing for this argument.

To edit /etc/inittab using the build class, you must complete the following tasks:

- Define the build file in the prototype file.
  
  The entry for the build file in the prototype file should place it in the build class and define its file type as e. Be certain that the CLASSES parameter in the pkginfo file is defined as build.
- Create the build class script.
  
  The sample build class script performs the following procedures:
  
  - Edits the /etc/inittab file to remove any existing changes for this package. Notice that the file name /etc/inittab is hardcoded into the sed command.
  - If the package is being installed, adds the new line to the end of /etc/inittab. A comment tag is included in this new entry to describe where that entry came from.
  - Executes the init q command.

This solution addresses the drawbacks described in the case studies in “Modifying a File by Using Standard Classes and Class Action Scripts” on page 106 and “Modifying a File by Using the sed Class and a postinstall Script” on page 108. Only one short file is needed (beyond the
pkginfo and prototype files). The file works with multiple instances of a package since the PKGINST parameter is used, and no postinstall script is required since the init q command can be executed from the build class script.

Modifying crontab Files During Installation

This case study modifies `crontab` files during package installation.

Techniques

This case study demonstrates the following techniques:

- Using classes and class action scripts
  
  For more information, see "Writing Class Action Scripts" on page 67.

- Using the `crontab` command within a class action script.

Approach

The most efficient way to edit more than one file during installation is to define a class and provide a class action script. If you used the `build` class approach, you would need to deliver one `build` class script for each `crontab` file edited. Defining a `cron` class provides a more general approach. To edit `crontab` files with this approach, you must:

- Define the `crontab` files that are to be edited in the `prototype` file.
  
  Create an entry in the `prototype` file for each `crontab` file that will be edited. Define the class as `cron` and the file type as `e` for each file. Use the actual name of the file to be edited.

- Create the `crontab` files for the package.
  
  These files contain the information you want added to the existing `crontab` files of the same name.

- Create an installation class action script for the `cron` class.
  
  The sample `i.cron` script performs the following procedures:

  - Determines the user ID (UID).
    
    The `i.cron` script sets the variable `user` to the base name of the `cron` class script being processed. That name is the UID. For example, the base name of `/var/spool/cron/crontabs/root` is `root`, which is also the UID.

  - Executes `crontab` using the UID and the `-l` option.
    
    Using the `-l` option tells `crontab` to send the contents of the `crontab` file for the defined user to the standard output.

  - Pipes the output of the `crontab` command to a `sed` script that removes any previous entries added with this installation technique.

  - Puts the edited output into a temporary file.

  - Adds the data file for the root UID (that was delivered with the package) to the temporary file and adds a tag so you will know where these entries came from.
• Executes `crontab` with the same UID and gives it the temporary file as input.
• Create a removal class action script for the `cron` class.
  The `r.cron` script is the same as the installation script except there is no procedure to add information to the `crontab` file.
  These procedures are performed for every file in the `cron` class.

**Case Study Files**

The `i.cron` and `r.cron` scripts described below are executed by superuser. Editing another user’s `crontab` file as superuser may have unpredictable results. If necessary, change the following entry in each script:

```bash
su $user -c "crontab /tmp/$$crontab" ||
```

**The `pkginfo` Command**

```bash
PKG=case7
NAME=Case Study #7
CATEGORY=application
BASEDIR=/opt
ARCH=SPARC
VERSION=Version 1.0
CLASSES=cron
```

**The prototype File**

```bash
i pkginfo
i i.cron
i r.cron
e cron /var/spool/cron/crontabs/root ?? ??
e cron /var/spool/cron/crontabs/sys ?? ?
```

**The `i.cron` Installation Class Action Script**

```bash
# PKGINST parameter provided by installation service
while read src dest
do
  user=`basename $dest` ||
  exit 2
  (crontab -l $user |
    sed -e "/$PKGINST$/d" > /tmp/$$crontab) ||
```
exit 2
sed -e "s/$/#$PKGINST/" $src >> /tmp/$$crontab ||
exit 2
crontab $user < /tmp/$$crontab ||
exit 2
rm -f /tmp/$$crontab
done
exit 0

The r.cron Removal Class Action Script

# PKGINST parameter provided by installation service
while read path
do
  user='basename $path' ||
  exit 2
  (crontab -l $user |
    sed -e "/#$PKGINST$/d" > /tmp/$$crontab) ||
  exit 2
crontab $user < /tmp/$$crontab ||
  exit 2
rm -f /tmp/$$crontab
done
exit

crontab File #1
41,1,21 * * * * /usr/lib/uucp/uudemon.hour > /dev/null
45 23 * * * ulimit 5000; /usr/bin/su uucp -c
"/usr/lib/uucp/uudemon.cleanup" >
/dev/null 2>&1
11,31,51 * * * * /usr/lib/uucp/uudemon.poll > /dev/null

crontab File #2
0 * * 0-6 /usr/lib/sa/sa1
20,40 8-17 * * 1-5 /usr/lib/sa/sa1
5 18 * * 1-5 /usr/lib/sa2 -s 8:00 -e 18:01 -i 1200 -A

Note – If editing of a group of files will increase total file size by more than 10K, supply a space file so the pkgadd command can allow for this increase. For more information on the space file, see “Reserving Additional Space on a Target System” on page 54.
Installing and Removing a Driver With Procedure Scripts

This package installs a driver.

Techniques

This case study demonstrates the following techniques:

■ Installing and loading a driver with a postinstall script
■ Unloading a driver with a preremove script

For more information on these scripts, see “Writing Procedure Scripts” on page 66.

Approach

■ Create a request script.
  
The request script determines where the administrator wants the driver objects to be installed, by questioning the administrator and assigning the answer to the $KERNDIR parameter.
  
The script ends with a routine to make the two parameters CLASSES and KERNDIR available to the installation environment and the postinstall script.

■ Create a postinstall script.
  
The postinstall script actually performs the driver installation. It is executed after the two files buffer and buffer.conf have been installed. The postinstall file shown for this example performs the following actions:
  ■ Uses the add_drv command to load the driver into the system.
  ■ Creates a link for the device using the installf command.
  ■ Finalizes the installation using the installf -f command.
  ■ Creates a preremove script.
    
The preremove script uses the rem_drv command to unload the driver from the system, and then removes the link /dev/buffer0.

Case Study Files

The pkginfo File

PKG=bufdev
NAME=Buffer Device
CATEGORY=system
BASEDIR=/
ARCH=INTEL
VERSION=Software Issue #19
CLASSES=none

The prototype File
To install a driver at the time of installation, you must include the object and configuration files for the driver in the prototype file.

In this example, the executable module for the driver is named buffer; the add_drv command operates on this file. The kernel uses the configuration file, buffer.conf, to help configure the driver.

```
i pkginfo
i request
i postinstall
i preremove
f none $KERNDIR/buffer 444 root root
f none $KERNDIR/buffer.conf 444 root root
```

Looking at the prototype file for this example, notice the following:

- Since no special treatment is required for the package objects, you can put them into the standard none class. The CLASSES parameter is set to none in the pkginfo file.
- The path names for buffer and buffer.conf begin with the variable $KERNDIR. This variable is set in the request script and allows the administrator to decide where the driver files should be installed. The default directory is /kernel/drv.
- There is an entry for the postinstall script (the script that will perform the driver installation).

The request Script
```
trap 'exit 3' 15
# determine where driver object should be placed; location
# must be an absolute path name that is an existing directory
KERNDIR=’ckpath -aoy -d /kernel/drv -p
"Where do you want the driver object installed"’ || exit $?

# make parameters available to installation service, and
# so to any other packaging scripts
cat >$1 <<<!

CLASSES='$CLASSES'
KERNDIR='$KERNDIR'
!
exit 0
```
Installing a Driver by Using the `sed` Class and Procedure Scripts

This case study describes how to install a driver using the `sed` class and procedure scripts. It is also different from the previous case study (see "Installing and Removing a Driver With Procedure Scripts" on page 116) because this package is made up of both absolute and relocatable objects.

Techniques

This case study demonstrates the following techniques:

- Building a prototype file with both absolute and relocatable objects.
  For more information on building a prototype file, see “Creating a prototype File” on page 31.
- Using a postinstall script
  For more information on this script, see “Writing Procedure Scripts” on page 66.
- Using a preremove script
  For more information on this script, see “Writing Procedure Scripts” on page 66.
- Using a copyright file
  For more information on this file, see “Writing a Copyright Message” on page 53.

The postinstall Script

```bash
# KERNDIR parameter provided by 'request' script
err_code=1  # an error is considered fatal
# Load the module into the system
cd $KERNDIR
add_drv -m '* 0666 root sys' buffer || exit $err_code
# Create a /dev entry for the character node
installf $PKGINST /dev/buffer0=/devices/eisa/buffer*:0 s
installf -f $PKGINST
```

The preremove Script

```bash
err_code=1  # an error is considered fatal
# Unload the driver
rem_drv buffer || exit $err_code
# remove /dev file
removef $PKGINST /dev/buffer0 ; rm /dev/buffer0
removef -f $PKGINST
```
Approach

- Create a prototype file containing both absolute and relocatable package objects.
  This is discussed in detail in “The prototype File” on page 119.
- Add the sed class script to the prototype file.
  The name of a script must be the name of the file that will be edited. In this case, the file to be edited is /etc/devlink.tab and so the sed script is named /etc/devlink.tab. There are no requirements for the mode, owner, and group of a sed script (represented in the sample prototype by question marks). The file type of the sed script must be e (indicating that it is editable).
- Set the CLASSES parameter to include the sed class.
- Create a sed class action script (/etc/devlink.tab).
- Create a postinstall script.
  The postinstall script needs to execute the add_drv command to add the device driver to the system.
- Create a preremove script.
  The preremove script needs to execute the rem_drv command to remove the device driver from the system, prior to the package being removed.
- Create a copyright file.
  A copyright file contains the ASCII text of a copyright message. The message shown in the sample file is displayed on the screen during package installation.

Case Study Files

The pkginfo File

```
PKG=SUNWsst
NAME=Simple SCSI Target Driver
VERSION=1
CATEGORY=system
ARCH=sparc
VENDOR=Sun Microsystems
BASEDIR=/opt
CLASSES=sed
```

The prototype File

For example, this case study uses the hierarchical layout of the package objects shown in the figure below.
The package objects are installed in the same places as they are in the pkg directory above. The driver modules (sst and sst.conf) are installed into /usr/kernel/drv and the include file is installed into /usr/include/sys/scsi/targets. The sst, sst.conf, and sst_def.h files are absolute objects. The test program, sstest.c, and its directory SUNWsst are relocatable; their installation location is set by the BASEDIR parameter.

The remaining components of the package (all the control files) go in the top directory of the package on the development machine, except the sed class script. This is called devlink.tab after the file it modifies, and goes into etc, the directory containing the real devlink.tab file.

From the pkg directory, run the pkgproto command as follows:

```
find usr SUNWsst -print | pkgproto > prototype
```

The output from the above command looks like this:

```
d none usr 0775 pms mts
d none usr/include 0775 pms mts
d none usr/include/sys 0775 pms mts
d none usr/include/sys/scsi 0775 pms mts
d none usr/include/sys/scsi/targets 0775 pms mts
f none usr/include/sys/scsi/targets/sst_def.h 0444 pms mts
d none usr/kernel 0775 pms mts
d none usr/kernel/drv 0775 pms mts
f none usr/kernel/drv/sst 0664 pms mts
f none usr/kernel/drv/sst.conf 0444 pms mts
```
This prototype file is not yet complete. To complete this file, you need to make the following modifications:

- Insert the entries for the control files (file type i), because they have a different format than the other package objects.
- Remove entries for directories that already exist on the target system.
- Change the access permission and ownership for each entry.
- Prepend a slash to the absolute package objects.

This is the final prototype file:

```
i pkginfo
i postinstall
i preremove
i copyright
e sed /etc/devlink.tab ???
f none /usr/include/sys/scsi/targets/sst_def.h 0644 bin bin
f none /usr/kernel/drv/sst 0755 root sys
f none /usr/kernel/drv/sst.conf 0644 root sys
d none SUNWsst 0775 root sys
f none SUNWsst/sstest.c 0664 root sys
```

The questions marks in the entry for the `sed` script indicate that the access permissions and ownership of the existing file on the installation machine should not be changed.

**The `sed` Class Action Script (/etc/devlink.tab)**

In the driver example, a `sed` class script is used to add an entry for the driver to the file `/etc/devlink.tab`. This file is used by the `devlinks` command to create symbolic links from `/dev` into `/devices`. This is the `sed` script:

```
# sed class script to modify /etc/devlink.tab
!install /name=sst;/d
$i\n  type=ddi_pseudo;name=sst;minor=character  rsst\A1
!remove /name=sst;/d
```

The `pkgrm` command does not run the removal part of the script. You may need to add a line to the `preremove` script to run `sed` directly to remove the entry from the `/etc/devlink.tab` file.
The postinstall Installation Script

In this example, all the script needs to do is run the add_drv command.

```bash
# Postinstallation script for SUNWsst
# This does not apply to a client.
if [ $PKG_INSTALL_ROOT = "/" -o -z $PKG_INSTALL_ROOT ]; then
    SAVEBASE=$BASEDIR
    BASEDIR=""; export BASEDIR
    /usr/sbin/add_drv sst
    STATUS=$?
    BASEDIR=$SAVEBASE; export BASEDIR
    if [ $STATUS -eq 0 ]
        then
            exit 20
        else
            exit 2
    fi
else
    echo "This cannot be installed onto a client."
    exit 2
fi
```

The add_drv command uses the BASEDIR parameter, so the script has to unset BASEDIR before running the command, and restore it afterwards.

One of the actions of the add_drv command is to run devlinks, which uses the entry placed in /etc/devlink.tab by the sed class script to create the /dev entries for the driver.

The exit code from the postinstall script is significant. The exit code 20 tells the pkgadd command to tell the user to reboot the system (necessary after installing a driver), and the exit code 2 tells the pkgadd command to tell the user that the installation partially failed.

The preremove Removal Script

In the case of this driver example, it removes the links in /dev and runs the rem_drv command on the driver.

```bash
# Pre removal script for the sst driver
echo "Removing /dev entries"
/usr/bin/rm -f /dev/rsst*

echo "Deinstalling driver from the kernel"
SAVEBASE=$BASEDIR
BASEDIR=""; export BASEDIR
/usr/sbin/rem_drv sst
BASEDIR=$SAVEBASE; export BASEDIR
exit
```
The script removes the /dev entries itself; the /devices entries are removed by the ren_drv command.

**The copyright File**

This is a simple ASCII file containing the text of a copyright notice. The notice is displayed at the beginning of package installation exactly as it appears in the file.

Advanced Techniques for Creating Packages

The full capabilities of System V packaging as implemented in the Solaris OS provide a powerful tool for the installation of software products. As a package designer, you can take advantage of these capabilities. Packages that are not part of the Solaris OS (unbundled packages) may use the class mechanism to customize server/client installations. Relocatable packages can be designed to accommodate the desires of the administrator. A complex product can be delivered as a set of composite packages that automatically resolve package dependencies. Upgrading and patching may be customized by the package designer. Patched packages can be delivered in the same way as unpatched packages, and the backout archives can also be included in the product.

This is a list of the overview information in this chapter.

- “Specifying the Base Directory” on page 125
- “Accommodating Relocation” on page 130
- “Supporting Relocation in a Heterogeneous Environment” on page 138
- “Making Packages Remotely Installable” on page 148
- “Patching Packages” on page 150
- “Upgrading Packages” on page 174
- “Creating Class Archive Packages” on page 176

Specifying the Base Directory

You can use several methods to specify where a package will be installed, and it is important to be able to change the installation base dynamically at install time. If this is accomplished correctly, an administrator can install multiple versions and multiple architectures without complications.

This section discusses common methods first, followed by approaches that enhance installations to heterogeneous systems.
The Administrative Defaults File

Administrators responsible for installing packages can use administration files to control package installation. However, as a package designer, you need to know about administration files and how an administrator can alter your intended package installation.

An administration file tells the `pkgadd` command whether to perform any of the checks or prompts that it normally does. Consequently, administrators should fully understand a package's installation process and the scripts involved before using administration files.

A basic administrative defaults file is shipped with the SunOS operating system in `/var/sadm/install/admin/default`. This is the file that establishes the most basic level of administrative policy as regards the installation of software products. The file looks like this as shipped:

```plaintext
#ident "@(#)default 1.4 92/12/23 SMI" /* SVr4.0 1.5.2.1 */
mail=
instance=unique
partial=ask
runlevel=ask
idepend=ask
rdepend=ask
space=ask
setuid=ask
conflict=ask
action=ask
basedir=default
```

The administrator may edit this file to establish new default behaviors, or create a different administration file and specify its existence by using the `-a` option to the `pkgadd` command.

Eleven parameters can be defined in an administration file, but not all need to be defined. For more information, see `admin(4)`.

The `basedir` parameter specifies how the base directory will be derived when a package is installed. Most administrators leave this as `default`, but `basedir` can be set to one of the following:

- ask, which means always ask the administrator for a base directory
- An absolute path name
- An absolute path name containing the `$PKGINST` construction, which means always install to a base directory derived from the package instance
**Note** – If the `pkgadd` command is called with the argument `-a none`, it always asks the administrator for a base directory. Unfortunately, this also sets *all* parameters in the file to the default value of `quit`, which can result in additional problems.

**Becoming Comfortable With Uncertainty**

An administrator has control over all packages being installed on a system by using an administration file. Unfortunately, an alternate administrative defaults file is often provided by the package designer, bypassing the wishes of the administrator.

Package designers sometimes include an alternate administration file so that they, not the administrator, control a package’s installation. Because the `basedir` entry in the administrative defaults file overrides all other base directories, it provides a simple method for selecting the appropriate base directory at install time. In all versions of the Solaris OS prior to the Solaris 2.5 release, this was considered the simplest method for controlling the base directory.

However, it is necessary for you to accept the administrator’s desires regarding the installation of the product. Providing a temporary administrative defaults file for the purpose of controlling the installation leads to mistrust on the part of administrators. You should use a request script and `checkinstall` script to control these installations under the supervision of the administrator. If the request script faithfully involves the administrator in the process, System V packaging will serve both administrators and package designers.

**Using the BASEDIR Parameter**

The `pkginfo` file for any relocatable package must include a default base directory in the form of an entry like this:

```
BASEDIR=absolute_path
```

This is only the default base directory; it can be changed by the administrator during installation.

While some packages require more than one base directory, the advantage to using this parameter to position the package is because the base directory is guaranteed to be in place and writable as a valid directory by the time installation begins. The correct path to the base directory for the server and client is available to all procedure scripts in the form of reserved environment variables, and the `pkginfo -r SUNWstuf` command displays the current installation base for the package.

In the `checkinstall` script, `BASEDIR` is the parameter exactly as defined in the `pkginfo` file (it has not been conditioned yet). In order to inspect the target base directory, the `${PKG_INSTALL_ROOT}$BASEDIR` construction is required. This means that the request or `checkinstall` script can change the value of `BASEDIR` in the installation environment with
predictable results. By the time the preinstall script is called, the BASEDIR parameter is the fully conditioned pointer to the actual base directory on the target system, even if the system is a client.

**Note** – The request script utilizes the BASEDIR parameter differently for different releases of the SunOS operating system. In order to test a BASEDIR parameter in a request script, the following code should be used to determine the actual base directory in use.

```bash
# request script
constructs base directory
if [ "${CLIENT_BASEDIR}" ]; then
    LOCAL_BASE=${BASEDIR}
else
    LOCAL_BASE=${PKG_INSTALL_ROOT}${BASEDIR}
fi
```

### Using Parametric Base Directories

If a package requires multiple base directories, you can establish them with parametric path names. This method has become quite popular, although it has the following drawbacks.

- A package with parametric path names usually behaves like an absolute package but is treated by the pkgadd command like a relocatable package. The BASEDIR parameter must be defined even if it is not used.
- The administrator cannot ascertain the installation base for the package using the System V utilities (the pkginfo -r command will not work).
- The administrator cannot use the established method to relocate the package (it is called relocatable but it acts absolute).
- Multiple architecture or multiple version installations require contingency planning for each of the target base directories which often means multiple complex class action scripts.

While the parameters that determine the base directories are defined in the pkginfo file, they may be modified by the request script. That is one of the primary reasons for the popularity of this approach. The drawbacks, however are chronic and you should consider this configuration a last resort.

### Examples—Using Parametric Base Directories

#### The pkginfo File

```bash
# pkginfo file
PKG=SUNWstuf
NAME=software stuff
```
Managing the Base Directory

Any package that is available in multiple versions or for multiple architectures should be designed to walk the base directory, if needed. Walking a base directory means that if a previous version or a different architecture of the package being installed already exists in the base directory, the package being installed resolves this issue, perhaps by creating a new base directory with a slightly different name. The request and checkinstall scripts in the Solaris 2.5 and compatible releases have the ability to modify the BASEDIR environment variable. This is not true for any prior version of the Solaris OS.
Even in older versions of the Solaris OS, the request script had the authority to redefine directories within the installation base. The request script can do this in a way that still supports most administrative preferences.

**Accommodating Relocation**

While you can select base directories for various packages that are guaranteed unique to an architecture and version, this leads to unnecessary levels of directory hierarchy. For example, for a product designed for SPARC and x86 based processors, you could organize the base directories by processor and version as shown below.

<table>
<thead>
<tr>
<th>Base Directory</th>
<th>Version and Processor</th>
</tr>
</thead>
<tbody>
<tr>
<td>/opt/SUNWstuf/sparc/1.0</td>
<td>Version 1.0, SPARC</td>
</tr>
<tr>
<td>/opt/SUNWstuf/sparc/1.2</td>
<td>Version 1.2, SPARC</td>
</tr>
<tr>
<td>/opt/SUNWstuf/x86/1.0</td>
<td>Version 1.0, x86</td>
</tr>
</tbody>
</table>

This is okay and it does work, but you are treating names and numbers as though they mean something to the administrator. A better approach is to do this automatically *after* explaining it to the administrator and obtaining permission.

This means that you can do the whole job in the package without requiring the administrator to do it manually. You can assign the base directory arbitrarily and then transparently establish the appropriate client links in a `postinstall` script. You can also use the `pkgadd` command to install all or part of the package to the clients in the `postinstall` script. You can even ask the administrator which users or clients need to know about this package and automatically update PATH environment variables and `/etc` files. This is completely acceptable as long as whatever the package does upon installation, it undoes upon removal.

**Walking Base Directories**

You can take advantage of two methods for controlling the base directory at install time. The first is best for new packages that will install only to Solaris 2.5 and compatible releases; it provides very useful data for the administrator and supports multiple installed versions and architectures and requires minimal special work. The second method can be used by any package and makes use of the `request` script's inherent control over build parameters to ensure successful installations.
Using the BASEDIR Parameter

The checkinstall script can select the appropriate base directory at install time, which means that the base directory can be placed very low in the directory tree. This example increments the base directory sequentially, leading to directories of the form /opt/SUNWstuf, /opt/SUNWstuf.1, and /opt/SUNWstuf.2. The administrator can use the pkginfo command to determine which architecture and version are installed in each base directory.

If the SUNWstuf package (containing a set of utilities that do stuff) uses this method, its pkginfo and pkgmap files would look like this.

### The pkginfo File

```plaintext
# pkginfo file
PKG=SUNWstuf
NAME=software stuff
ARCH=sparc
VERSION=1.0.0,REV=1.0.5
CATEGORY=application
DESC=a set of utilities that do stuff
BASEDIR=/opt/SUNWstuf
VENDOR=Sun Microsystems, Inc.
HOTLINE=Please contact your local service provider
EMAIL=
MAXINST=1000
CLASSES=none daemon
PSTAMP=hubert990707141632
```

### The pkgmap File

```plaintext
: 1 1758
1 d none EZstuf 0775 root bin
1 f none EZstuf/dirdel 0555 bin bin 40 773 751310229
1 f none EZstuf/usrdel 0555 bin bin 40 773 751310229
1 f none EZstuf/filedel 0555 bin bin 40 773 751310229
1 d none HRDstuf 0775 root bin

1 d none /etc 751310229
1 d none /etc/rc2.d 751310229
1 f daemon /etc/rc2.d/S70dostuf 0744 root sys 450 223443
1 i pkginfo 348 28411 760740163
1 i postinstall 323 26475 751309908
1 i preinstall 321 26254 751310019
1 i preremove 320 26114 751309865
```
Assumethatthe x86 version of SUNWstuf is already installed on the server in /opt/SUNWstuf. When the administrator uses the pkgadd command to install the SPARC version, the request script needs to detect the existence of the x86 version and interact with the administrator regarding the installation.

Note – The base directory could be walked without administrator interaction in a checkinstall script, but if arbitrary operations like this happen too often, administrators lose confidence in the process.

The request script and checkinstall script for a package that handle this situation might look like this.

The request Script

# request script for SUNWstuf to walk the BASEDIR parameter.

PATH=/usr/sadm/bin:${PATH} # use admin utilities

GENMSG="The base directory $LOCAL_BASE already contains a \ different architecture or version of $PKG."

OLDMSG="If the option '-a none' was used, press the \ key and enter an unused base directory when it is requested."

OLDPROMPT="Do you want to overwrite this version? *

OLDHELP="'y' will replace the installed package, 'n' will \ stop the installation."

SUSPEND="Suspending installation at user request using error \ code 1."

MSG="This package could be installed at the unused base directory $WRKNG_BASE."

PROMPT="Do you want to use to the proposed base directory? "

HELP="A response of 'y' will install to the proposed directory and continue, 'n' will request a different directory. If the option '-a none' was used, press the key and enter an unused base directory when it is requested."
DIRPROMPT="Select a preferred base directory ($WRKNG_BASE) "

DIRHELP="The package $PKG will be installed at the location entered."

NUBD_MSG="The base directory has changed. Be sure to update any applicable search paths with the actual location of the binaries which are at $WRKNG_BASE/EZstuf and $WRKNG_BASE/HRDstuf."

OldSolaris=""
Changed=""
Suffix="0"

# Determine if this product is actually installed in the working base directory.

Product_is_present () {
    if [ -d $WRKNG_BASE/EZstuf -o -d $WRKNG_BASE/HRDstuf ]; then
        return 1
    else
        return 0
    fi
}

if [ ${BASEDIR} ]; then
    # This may be an old version of Solaris. In the latest Solaris # CLIENT_BASEDIR won't be defined yet. In older version it is.
    if [ ${CLIENT_BASEDIR} ]; then
        LOCAL_BASE=$BASEDIR
        OldSolaris="true"
    else
        # The base directory hasn't been processed yet
        LOCAL_BASE=${PKG_INSTALL_ROOT}$BASEDIR
    fi

    WRKNG_BASE=$LOCAL_BASE
    # See if the base directory is already in place and walk it if # possible
    while [ -d $(WRKNG_BASE) -a Product_is_present ]; do
        # There is a conflict
        # Is this an update of the same arch & version?
        if [ ${UPDATE} ]; then
            exit 0 # It's out of our hands.
        else
            # So this is a different architecture or # version than what is already there.
            # Walk the base directory
            Suffix=`expr $Suffix + 1`
    fi

Accommodating Relocation
The checkinstall Script

# checkinstall
script for SUNWstuf to politely suspend

grep quitinstall $1
if [ $? -eq 0 ]; then
  exit 3  # politely suspend installation
fi
This approach would not work very well if the base directory was simply /opt. This package has to call out the BASEDIR more precisely since /opt would be difficult to walk. In fact, depending on the mount scheme, it may not be possible. The example walks the base directory by creating a new directory under /opt, which does not introduce any problems.

This example uses a request script and a checkinstall script even though versions of Solaris prior to the 2.5 release cannot run a checkinstall script. The checkinstall script in this example is used for the purpose of politely halting the installation in response to a private message in the form of the string quitinstall. If this script executes under the Solaris 2.3 release, the checkinstall script is ignored and the request script halts the installation with an error message.

Remember that prior to the Solaris 2.5 and compatible releases, the BASEDIR parameter is a read-only parameter and cannot be changed by the request script. For this reason, if an old version of the SunOS operating system is detected (by testing for a conditioned CLIENT_BASEDIR environment variable), the request script has only two options—continue or quit.

**Using Relative Parametric Paths**

If your software product might be installed on older versions of the SunOS operating system, the request script needs to do all the necessary work. This approach can also be used to manipulate multiple directories. If additional directories are required, they still need to be included under a single base directory in order to provide an easily administrable product. While the BASEDIR parameter does not provide the level of granularity available in the latest Solaris release, your package can still walk the base directory by using the request script to manipulate parametric paths. This is how the pkginfo and pkgmap files might look.

**The pkginfo File**

```
# pkginfo file
PKG=SUNWstuf

 1 i r.daemon 320 24573 742152591

This example is not perfect. A pkginfo -r command returns /opt for the installation base, which is pretty ambiguous. Many packages are in /opt, but at least it is a meaningful directory. Just like the previous example, this next example fully supports multiple architectures and versions. The request script can be tailored to the needs of the specific package and resolve whatever dependencies are applicable.

Example—A request Script That Walks a Relative Parametric Path

# request script
for SUNWstuf to walk a parametric path

PATH=/usr/sadm/bin:${PATH}       # use admin utilities

MSG="The target directory $LOCAL_BASE already contains a different architecture or version of $PKG. This package could be installed at the unused target directory $WRKNG_BASE."

PROMPT="Do you want to use the proposed directory? "

HELP="A response of "y" will install to the proposed directory and continue, "n" will request a different directory. If the option "-a none" was used, press the <RETURN> key and enter an unused base directory when it is requested."

DIRPROMPT="Select a relative target directory under $BASEDIR/"
DIRHELP="The package $PKG will be installed at the location entered."

SUSPEND="Suspending installation at user request using error code 1."

NUBD MSG="The location of this package is not the default. Be sure to update any applicable search paths with the actual location of the binaries which are at $WRKNG_BASE/EZstuf and $WRKNG_BASE/HRDstuf."

Changed=""
Suffix="0"

# Determine if this product is actually installed in the working base directory.
#
Product_is_present () {
    if [ -d $WRKNG_BASE/EZstuf -o -d $WRKNG_BASE/HRDstuf ]; then
        return 1
    else
        return 0
    fi
}

if [ ${BASEDIR} ]; then
    # This may be an old version of Solaris. In the latest Solaris
    # CLIENT_BASEDIR won't be defined yet. In older versions it is.
    if [ ${CLIENT_BASEDIR} ]; then
        LOCAL_BASE=$BASEDIR/$SUBBASE
    else # The base directory hasn't been processed yet
        LOCAL_BASE=${PKG_INSTALL_ROOT}$BASEDIR/$SUBBASE
    fi

    WRKNG_BASE=$LOCAL_BASE

    # See if the base directory is already in place and walk it if possible
    while [ -d $(WRKNG_BASE) -a Product_is_present ]; do
        # There is a conflict
        # Is this an update of the same arch & version?
        if [ ${UPDATE} ]; then
            exit 0 # It’s out of our hands.
        else
            # So this is a different architecture or version than what is already there.
        fi
    done

    # Now handle relocation

Supporting Relocation in a Heterogeneous Environment

The original concept behind System V packaging assumed one architecture per system. The concept of a server did not play a role in the design. Now, of course, a single server may provide support for several architectures, which means there may be several copies of the same software on a server, each for a different architecture. While Solaris packages are sequestered within recommended file system boundaries (for example, / and /usr), with product databases on the server as well as each client, not all installations necessarily support this division. Certain implementations support an entirely different structure and imply a common product database. While pointing the clients to different versions is straightforward, actually installing System V packages to different base directories can introduce complications for the administrator.

When you design your package, you should also consider the common methods administrators use for introducing new software versions. Administrators often seek to install and test the
latest version side-by-side with the currently installed version. The procedure involves installing the new version to a different base directory than the current version and directing a handful of non-critical clients to the new version as a test. As confidence builds, the administrator redirects more and more clients to the new version. Eventually, the administrator retains the old version only for emergencies and then finally deletes it.

What this means is that packages destined for modern heterogeneous systems must support true relocation in the sense that the administrator may put them any reasonable place on the file system and still see full functionality. The Solaris 2.5 and compatible releases provide a number of useful tools which allow multiple architectures and versions to install cleanly to the same system. Solaris 2.4 and compatible versions also support true relocation but accomplishing the task is not quite as obvious.

**Traditional Approach**

**Relocatable Packages**

The System V ABI implies that the original intention behind the relocatable package was to make installing the package more convenient for the administrator. Now the need for relocatable packages goes much further. Convenience is not the only issue, rather it is quite possible that during the installation an active software product is already installed in the default directory. A package that is not designed to deal with this situation either overwrites the existing product or fails to install. However, a package designed handle multiple architectures and multiple versions can install smoothly and offer the administrator a wide range of options that are fully compatible with existing administrative traditions.

In some ways the problem of multiple architectures and the problem of multiple versions is the same. It must be possible to install a variant of the existing package side by side with other variants, and direct clients or standalone consumers of exported file systems to any one of those variants, without degraded functionality. While Sun has established methods for dealing with multiple architectures on a server, the administrator may not adhere to those recommendations. All packages need to be capable of complying with the administrators' reasonable wishes regarding installation.

**Example-A Traditional Relocatable Package**

This example shows what a traditional relocatable package may look like. The package is to be located in /opt/SUNWstuf, and its pkginfo file and pkgmap file might look like this.

**The pkginfo File**

```
# pkginfo file
PKG=SUNWstuf
NAME=software stuff
```
The pkgmap File

```
1 1758
1 d none SUNWstuf 0775 root bin
1 d none SUNWstuf/EZstuf 0775 root bin
1 f none SUNWstuf/EZstuf/dirdel 0555 bin bin 40 773 751310229
1 f none SUNWstuf/EZstuf/usrdel 0555 bin bin 40 773 751310229
1 f none SUNWstuf/EZstuf/filedel 0555 bin bin 40 773 751310229
1 d none SUNWstuf/HRDstuf 0775 root bin
1 f none SUNWstuf/HRDstuf/mksmart 0555 bin bin 40 773 751310229
1 f none SUNWstuf/HRDstuf/mktall 0555 bin bin 40 773 751310229
1 f none SUNWstuf/HRDstuf/mkcute 0555 bin bin 40 773 751310229
1 f none SUNWstuf/HRDstuf/mkeasy 0555 bin bin 40 773 751310229
1 i pkginfo 348 28411 760740163
1 i postinstall 323 26475 751309908
1 i postremove 402 33179 751309945
1 i preinstall 321 26254 751310019
1 i preremove 320 26114 751309865
```

This is referred to as the traditional method because every package object is installed to the base directory defined by the BASEDIR parameter from the pkginfo file. For example, the first object in the pkgmap file is installed as the directory /opt/SUNWstuf.

**Absolute Packages**

An absolute package is one that installs to a particular root (/) file system. These packages are difficult to deal with from the standpoint of multiple versions and architectures. As a general rule, all packages should be relocatable. There are, however very good reasons to include absolute elements in a relocatable package.

**Example-A Traditional Absolute Package**

If the SUNWstuf package was an absolute package, the BASEDIR parameter should not be defined in the pkginfo file, and the pkgmap file would look like this.
The pkgmap File

The pkgmap file contains information about the files that will be installed as part of the package. It is used by the pkgadd command to determine which files should be installed and where.

In this example, if the administrator specified an alternate base directory during installation, it would be ignored by the pkgadd command. This package always installs to /opt/SUNWstuf of the target system.

The -R argument to the pkgadd command works as expected. For example,

```
pkgadd -d . -R /export/opt/client3 SUNWstuf
```

installs the objects in /export/opt/client3/opt/SUNWstuf; but that is the closest this package comes to being relocatable.

Notice the use of the question mark (?) for the /opt directory in the pkgmap file. This indicates that the existing attributes should not be changed. It does not mean “create the directory with default attributes,” although under certain circumstances that may happen. Any directory that is specific to the new package must specify all attributes explicitly.

Composite Packages

Any package containing relocatable objects is referred to as a relocatable package. This can be misleading because a relocatable package may contain absolute paths in its pkgmap file. Using a root (/) entry in a pkgmap file can enhance the relocatable aspects of the package. Packages that have both relocatable and root entries are called composite packages.

Example-A Traditional Solution

Assume that one object in the SUNWstuf package is a startup script executed at run level 2. The file /etc/rc2.d/S70dostuf needs to be installed as a part of the package, but it cannot be placed into the base directory. Assuming that a relocatable package is the only solution, the pkginfo and a pkgmap might look like this.
The pkginfo File

```
# pkginfo file
PKG=SUNWstuf
NAME=software stuff
ARCH=sparc
VERSION=1.0.0,REV=1.0.5
CATEGORY=application
DESC=a set of utilities that do stuff
BASEDIR=/
VENDOR=Sun Microsystems, Inc.
HOTLINE=Please contact your local service provider
EMAIL=
MAXINST=1000
CLASSES=none
PSTAMP=hubert990707141632
```

The pkgmap File

```
1 1758
1 d none opt/SUNWstuf/EZstuf 0775 root bin
1 f none opt/SUNWstuf/EZstuf/dirdel 0555 bin bin 40 773 751310229
1 f none opt/SUNWstuf/EZstuf/usrdel 0555 bin bin 40 773 751310229
1 f none opt/SUNWstuf/EZstuf/filedel 0555 bin bin 40 773 751310229
1 d none opt/SUNWstuf/HRDstuf 0775 root bin
1 f none opt/SUNWstuf/HRDstuf/mksmart 0555 bin bin 40 773 751310229
1 f none opt/SUNWstuf/HRDstuf/mktall 0555 bin bin 40 773 751310229
1 f none opt/SUNWstuf/HRDstuf/mkcute 0555 bin bin 40 773 751310229
1 f none opt/SUNWstuf/HRDstuf/mkeasy 0555 bin bin 40 773 751310229
1 d none etc ? ? ?
1 d none etc/rc2.d ? ? ?
1 f none etc/rc2.d/S70dostuf 0744 root sys 450 223443
1 i pkginfo 348 28411 760740163
1 i postinstall 323 26475 751309908
1 i postremove 402 33179 751309945
1 i preinstall 321 26254 751310019
1 i preremove 320 26114 751309865
```

There is not much difference between this approach and that of the absolute package. In fact, this would be better off as an absolute package—if the administrator provided an alternate base directory for this package, it would not work!

In fact, only one file in this package needs to be root-relative, the rest could be moved anywhere. How to solve this problem through the use of a composite package is discussed throughout the remainder of this section.
Beyond Tradition

The approach described in this section does not apply to all packages, but it does result in improved performance during installation to an heterogeneous environment. Very little of this applies to packages that are delivered as part of the Solaris OS (bundled packages); however, unbundled packages can practice non-traditional packaging.

The reason behind encouraging relocatable packages is to support this requirement:

*When a package is added or removed, the existing desirable behaviors of installed software products will be unchanged.*

Unbundled packages should reside under /opt so as to assure that the new package does not interfere with existing products.

Another Look at Composite Packages

There are two rules to follow when constructing a functional composite package:

- Establish the base directory based upon where the vast majority of the package objects go.
- If a package object goes into a common directory that is not the base directory (for example, /etc), specify it as an absolute path name in the prototype file.

In other words, since “relocatable” means the object can be installed anywhere and still work, no startup script run by init at boot time can be considered relocatable! While there is nothing wrong with specifying /etc/passwd as a relative path in the delivered package, there is only one place it can go.

Making Absolute Path Names Look Relocatable

If you are going to construct a composite package, the absolute paths must operate in a manner which does not interfere with existing installed software. A package that can be entirely contained in /opt gets around this problem since there are no existing files in the way. When a file in /etc is included in the package, you must ensure that the absolute path names behave in the same way that is expected from relative path names. Consider the following two examples.

Example—Modifying a File

Description

An entry is being added to a table, or the object is a new table which is likely to be modified by other programs or packages.

Implementation

Define the object as file type e and belonging to the build, awk, or sed class. The script that performs this task must remove itself as effectively as it adds itself.
Example
An entry needs to be added to /etc/vfstab in support of the new solid state hard disk.

The entry in the pkgmap file might be

```
1 e sed /etc/vfstab ??
```

The request script asks the operator if /etc/vfstab should be modified by the package. If the operator answers "no" then the request script will print instructions on how to do the job manually and will execute

```
echo "CLASSES=none" >> $1
```

If the operator answers "yes" then it executes

```
echo "CLASSES=none sed" >> $1
```

which activates the class action script that will make the necessary modifications. The sed class means that the package file /etc/vfstab is a sed program which contains both the install and remove operations for the same-named file on the target system.

Example—Creating a New File

Description
The object is an entirely new file that is unlikely to be edited at a later time or, it is replacing a file owned by another package.

Implementation
Define the package object as file type f and install it using a class action script capable of undoing the change.

Example
A brand new file is required in /etc to provide the necessary information to support the solid state hard disk, named /etc/shdisk.conf. The entry in the pkgmap file might look like this:

```
1 f newetc /etc/shdisk.conf
```

The class action script `i.newetc` is responsible for installing this and any other files that need to go into `/etc`. It checks to make sure there is not another file there. If there is not, it will simply copy the new file into place. If there is already a file in place, it will back it up before installing the new file. The script `r.newetc` removes these files and restores the originals, if required. Here is the key fragment of the install script.

```
# i.newetc
while read src dst; do
    if [ -f $dst ]; then
        dstfile='basename $dst'
        cp $dst $PKGSAV/$dstfile
    fi
    cp $src $dst
done

if [ "${1}" = "ENDOFCLASS" ]; then
    cd $PKGSAV
    tar cf SAVE.newetc .
    $INST_DATADIR/$PKG/install/squish SAVE.newetc
fi
```

Notice that this script uses the `PKGSAV` environment variable to store a backup of the file to be replaced. When the argument `ENDOFCLASS` is passed to the script, that is the `pkgadd` command informing the script that these are the last entries in this class, at which point the script archives and compresses the files that were saved using a private compression program stored in the install directory of the package.

While the use of the `PKGSAV` environment variable is not reliable during a package update; if the package is not updated (through a patch, for instance) the backup file is secure. The following remove script includes code to deal with the other issue—the fact that older versions of the `pkgrm` command do not pass the scripts the correct path to the `PKGSAV` environment variable.

The removal script might look like this.

```
# r.newetc

# make sure we have the correct PKGSAV
if [ -d $PKG_INSTALL_ROOT$PKGSAV ]; then
    PKGSAV="$PKG_INSTALL_ROOT$PKGSAV"
fi

# find the unsquish program
UNSQUSH_CMD='dirname "$0"/unsquish

while read file; do
    rm $file
done
```
if [ "${1}" = ENDOFCCLASS ]; then
    if [ -f $PKGSAV/SAVE.newetc ]; then
        $UNSQUISH_CMD $PKGSAV/SAVE.newetc
    fi

    if [ -f $PKGSAV/SAVE.newetc ]; then
        targetdir=dirname $file  # get the right directory
        cd $targetdir
        tar xf $PKGSAV/SAVE.newetc
        rm $PKGSAV/SAVE.newetc
    fi
fi

This script uses a private uninstalled algorithm (unsquish) which is in the install directory of the package database. This is done automatically by the pkgadd command at install time. All scripts not specifically recognized as install-only by the pkgadd command are left in this directory for use by the pkgrm command. You cannot count on where that directory is, but you can depend on the directory being flat and containing all appropriate information files and installation scripts for the package. This script finds the directory by virtue of the fact that the class action script is guaranteed to be executing from the directory that contains the unsquish program.

Notice, also, that this script does not just assume the target directory is /etc. It may actually be /export/root/client2/etc. The correct directory could be constructed in one of two ways.

- Use the ${{PKG_INSTALL_ROOT}}/etc construction, or.
- Take the directory name of a file passed by the pkgadd command (which is what this script does).

By using this approach for each absolute object in the package, you can be sure that the current desirable behavior is unchanged or at least recoverable.

**Example—A Composite Package**

This is an example of the pkginfo and pkmap files for a composite package.

**The pkginfo File**

PKG=SUNWstuf
NAME=software stuff
ARCH=sparc
VERSION=1.0.0,REV=1.0.5
CATEGORY=application
DESC=a set of utilities that do stuff
BASEDIR=/opt
VENDOR=Sun Microsystems, Inc.
The pkgmap File

While S70dostuf belongs to the daemon class, the directories that lead up to it (which are already in place at install time) belong to the none class. Even if the directories were unique to this package, you should leave them in the none class. The reason for this is that the directories need to be created first and deleted last, and this is always true for the none class. The pkgadd command creates directories; they are not copied from the package and they are not passed to a class action script to be created. Instead, they are created by the pkgadd command before it calls the install class action script, and the pkgrm command deletes directories after completion of the removal class action script.

This means that if a directory in a special class contains objects in the class none, when the pkgrm command attempts to remove the directory, it fails because the directory will not be empty in time. If an object of class none is to be inserted into a directory of some special class, that directory will not exist in time to accept the object. The pkgadd command will create the directory on-the-fly during installation of the object and may not be able to synchronize the attributes of that directory when it finally sees the pkgmap definition.
Note – When assigning a directory to a class, always remember the order of creation and deletion.

Making Packages Remotely Installable

All packages must be installable remotely. Installable remotely means you do not assume the administrator installing your package is installing to the root (/) file system of the system running the pkgadd command. If, in one of your procedure scripts, you need to get to the /etc/vfstab file of the target system, you need to use the PKG_INSTALL_ROOT environment variable. In other words, the path name /etc/vfstab will get you to the /etc/vfstab file of the system running the pkgadd command, but the administrator may be installing to a client at /export/root/client3. The path ${PKG_INSTALL_ROOT}/etc/vfstab is guaranteed to get you to the target file system.

Example – Installing to a Client System

In this example, the SUNWstuf package is installed to client3, which is configured with /opt in its root (/) file system. One other version of this package is already installed on client3, and the base directory is set to basedir=/opt/$PKGINST from an administration file, thisadmin. (For more information on administration files, see “The Administrative Defaults File” on page 126.) The pkgadd command executed on the server is:

```
# pkgadd -a thisadmin -R /export/root/client3 SUNWstuf
```

The table below lists the environment variables and their values that are passed to the procedure scripts.

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>PKGINST</td>
<td>SUNWstuf.2</td>
</tr>
<tr>
<td>PKG_INSTALL_ROOT</td>
<td>/export/root/client3</td>
</tr>
<tr>
<td>CLIENT_BASEDIR</td>
<td>/opt/SUNWstuf.2</td>
</tr>
<tr>
<td>BASEDIR</td>
<td>/export/root/client3/opt/SUNWstuf.2</td>
</tr>
</tbody>
</table>

Example – Installing to a Server or Standalone System

To install to the server or a standalone system under the same circumstances as the previous example, the command is:
The table below lists the environment variables and their values that are passed to the procedure scripts.

### TABLE 6–2 Values Passed to Procedure Scripts

<table>
<thead>
<tr>
<th>Environment Variable</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>PKGINST</td>
<td>SUNWstuf.2</td>
</tr>
<tr>
<td>PKG_INSTALL_ROOT</td>
<td>Not defined.</td>
</tr>
<tr>
<td>CLIENT_BASEDIR</td>
<td>/opt/SUNWstuf.2</td>
</tr>
<tr>
<td>BASEDIR</td>
<td>/opt/SUNWstuf.2</td>
</tr>
</tbody>
</table>

#### Example – Mounting Shared File Systems

Assume that the SUNWstuf package creates and shares a file system on the server at `/export/SUNWstuf/share`. When the package is installed to the client systems, their `/etc/vfstab` files need to be updated to mount this shared file system. This is a situation where you can use the CLIENT_BASEDIR variable.

The entry on the client needs to present the mount point with reference to the client’s file system. This line should be constructed correctly whether the installation is from the server or from the client. Assume that the server’s system name is `$SERVER`. You can go to `$PKG_INSTALL_ROOT/etc/vfstab` and, using the `sed` or `awk` commands, construct the following line for the client’s `/etc/vfstab` file.

```
$SERVER:/export/SUNWstuf/share - $CLIENT_BASEDIR/usr nfs - yes ro
```

For example, for the server `universe` and the client system `client9`, the line in the client system’s `/etc/vfstab` file would look like:

```
universe:/export/SUNWstuf/share - /opt/SUNWstuf.2/usr nfs - yes ro
```

Using these parameters correctly, the entry always mounts the client’s file system, whether it is being constructed locally or from the server.
Patching Packages

A patch to a package is just a sparse package designed to overwrite certain files in the original. There is no real reason for shipping a sparse package except to save space on the delivery medium. You could also ship the entire original package with a few files changed, or provide access to the modified package over a network. As long as only those new files are actually different (the other files were not recompiled), the `pkgadd` command installs the differences.

Review the following guidelines regarding patching packages.

- If the system is complex enough, it is wise to establish a patch identification system which assures that no two patches replace the same file in an attempt to correct different aberrant behaviors. For instance, Sun patch base numbers are assigned mutually exclusive sets of files for which they are responsible.

- It is necessary to be able to back out a patch.

It is crucial that the version number of the patch package be the same as that of the original package. You should keep track of the patch status of the package using a separate `pkginfo` file entry of the form.

```
PATCH=patch_number
```

If the package version is changed for a patch, you create another instance of the package and it becomes extremely difficult to manage the patched product. This method of progressive instance patching carried certain advantages in the early releases of the Solaris OS, but makes management of more complicated systems tedious.

All of the zone parameters in the patch must match the zone parameters in the package.

As far as the packages that make up the Solaris OS are concerned, there should be only one copy of the package in the package database, although there may be multiple patched instances. In order to remove an object from an installed package (using the `removef` command) you need to figure out what instances own that file.

However, if your package (that is not part of the Solaris OS) needs to determine the patch level of a particular package that is part of the Solaris OS, this becomes a problem to be resolved here. The installation scripts can be quite large without significant impact since they are not stored on the target file system. Using class action scripts and various other procedure scripts, you can save changed files using the `PKGSAV` environment variable (or to some other, more permanent directory) in order to allow backing out installed patches. You can also monitor patch history by setting appropriate environment variables through the `request` scripts. The scripts in the next sections assume that there may be multiple patches whose numbering scheme carries some meaning when applied to a single package. In this case, individual patch numbers represent a subset of functionally related files within the package. Two different patch numbers cannot change the same file.
In order to make a regular sparse package into a patch package, the scripts described in the following sections can simply be folded into the package. All of them are recognizable as standard package components with the exception of the last two which are named patch_checkinstall and patch_postinstall. Those two scripts can be incorporated into the backout package, if you want to include the ability to back out the patch. The scripts are fairly simple and their various tasks are straightforward.

**Note** – This method of patching can be used to patch client systems, but client root directories on the server must have the correct permissions to allow reading by the user install or nobody.

### The checkinstall Script

The checkinstall script verifies that the patch is appropriate for this particular package. Once that is confirmed, it constructs the *patch list* and the *patch info* list, and then inserts them into the response file for incorporation into the package database.

A patch list is the list of patches that have affected the current package. This list of patches is recorded in the installed package in the *pkginfo* file with a line that might look like this:

```
PATCHLIST=patch_id patch_id ... 
```

A patch info list is the list of patches on which the current patch is dependent. This list of patches is also recorded in the *pkginfo* file with a line that might look like this:

```
PATCH_INFO_103203-01=Installed... Obsoletes:103201-01 Requires: \ Incompatibles: 120134-01
```

**Note** – These lines (and their format) are declared as a public interface. Any company that ships patches for Solaris packages should update this list appropriately. When a patch is delivered, each package within the patch contains a checkinstall script that performs this task. That same checkinstall script also updates some other patch-specific parameters. This is the new patch architecture, which is called Direct Instance Patching.

In this example, both the original packages and their patches exist in the same directory. The two original packages are named SUNWstuf.v1 and SUNWstuf.v2, and their patches are named SUNWstuf.p1 and SUNWstuf.p2. What this means is that it could be very difficult for a procedure script to figure out what directory these files came from, since everything in the package name after the dot (".") is stripped for the PKG parameter, and the PKGINST environment variable refers to the installed instance not the source instance. So the procedure scripts can find the source directory, the checkinstall script (which is always executed from the source directory) makes the inquiry and passes the location on as the variable SCRIPTS_DIR. If there had been only one package in the source directory called SUNWstuf, then the procedure scripts could have found it using $INSTDIR/$PKG.

The preinstall Script

The preinstall script initializes the prototype file, information files, and installation scripts for the backout package to be constructed. This script is very simple and the remaining scripts in this example only allow a backout package to describe regular files.

If you wanted to restore symbolic links, hard links, devices, and named pipes in a backout package, you could modify the preinstall script to use the pkgproto command to compare the delivered pkgmap file with the installed files, and then create a prototype file entry for each non-file to be changed in the backout package. The method you should use is similar to the method in the class action script.

The scripts patch_checkinstall and patch_postinstall are inserted into the package source tree from the preinstall script. These two scripts undo what the patch does.

```bash
# This script initializes the backout data for a patch package
# directory format options.

    # object will be required for the pkgmk.
The Class Action Script

The class action script creates a copy of each file that replaces an existing file and adds a corresponding line to the prototype file for the backout package. This is all done with fairly simple awk scripts. The class action script receives a list of source/destination pairs consisting of ordinary files that do not match the corresponding installed files. Symbolic links and other non-files must be dealt with in the preinstall script.

# This class action script copies the files being replaced
# into a package being constructed in $BUILD_DIR. This class
# action script is only appropriate for regular files that
# are installed by simply copying them into place.
# # For special package objects such as editable files, the patch
# # producer must supply appropriate class action scripts.

The postinstall Script

The postinstall script creates the backout package using the information provided by the other scripts. Since the pkgmk and pkgtrans commands do not require the package database, they can be executed within a package installation.

In the example, undoing the patch is permitted by constructing a stream format package in the save directory (using the PKGSAV environment variable). It is not obvious, but this package must be in stream format, because the save directory gets moved around during a pkgadd operation. If the pkgadd command is applied to a package in its own save directory, assumptions about where the package source is at any given time become very unreliable. A stream format package is unpacked into a temporary directory and installed from there. (A directory format package would begin installing from the save directory and find itself suddenly relocated during a pkgadd fail-safe operation.)

To determine which patches are applied to a package, use this command:

$ pkgparam SUNWstuf PATCHLIST

With the exception of PATCHLIST, which is a Sun public interface, there is nothing significant in the parameter names in this example. Instead of PATCH you could use the traditional SUNW_PATCHID and the various other lists such as PATCH_EXCL and PATCH_REQD could be renamed accordingly.

If certain patch packages depend upon other patch packages which are available from the same medium, the checkinstall script could determine this and create a script to be executed by the postinstall script in the same way that the upgrade example (see "Upgrading Packages" on page 174) does.
# This script creates the backout package for a patch package
#
# directory format options.

Upgrading Packages

The process of upgrading a package is very different from that of overwriting a package. While there are special tools to support the upgrade of standard packages delivered as part of the Solaris OS, an unbundled package can be designed to support its own upgrade—several previous examples described packages that look ahead and control the precise method of installation under the direction of the administrator. You can design the request script to support direct upgrade of a package as well. If the administrator chooses to have one package install so as to completely replace another, leaving no residual obsolete files, the package scripts can do this.

The request script and postinstall script in this example provide a simple upgradable package. The request script communicates with the administrator and then sets up a simple file in the /tmp directory to remove the old package instance. (Although the request script creates a file which is forbidden), it is okay because everyone has access to /tmp).

The postinstall script then executes the shell script in /tmp, which executes the necessary pkgrm command against the old package and then deletes itself.

This example illustrates a basic upgrade. It is less than fifty lines of code including some fairly long messages. It could be expanded to backout the upgrade or make other major transformations to the package as required by the designer.

The design of the user interface for an upgrade option must be absolutely sure that the administrator is fully aware of the process and has actively requested upgrade rather than parallel installation. There is nothing wrong with performing a well understood complex operation like upgrade as long as the user interface makes the operation clear.

The request Script

# request script
control an upgrade installation
PATH=/usr/sadm/bin:$PATH
UPGR_SCRIPT=/tmp/upgr.$PKGINST

UPGRADE_MSG="Do you want to upgrade the installed version?"

UPGRADE_HLP="If upgrade is desired, the existing version of the package will be replaced by this version. If it is not desired, this new version will be installed into a different base directory and both versions will be usable."

UPGRADE_NOTICE="Conflict approval questions may be displayed. The listed files are the ones that will be upgraded. Please answer "y" to these questions if they are presented."

pkginfo -v 1.0 -q SUNWstuf."

if [ $? -eq 0 ]; then
    # See if upgrade is desired here
    response="ckyorn -p "$UPGRADE_MSG" -h "$UPGRADE_HLP"
    if [ $response = "y" ]; then
        OldPkg="pkginfo -v 1.0 -x SUNWstuf./* | nawk '/SUNW/{print $1}"
        # Initiate upgrade
        echo "PATH=/usr/sadm/bin:$PATH" > $UPGR_SCRIPT
        echo "sleep 3" >> $UPGR_SCRIPT
        echo "echo Now removing old instance of $PKG" >> $UPGR_SCRIPT
        if [ "${PKG_INSTALL_ROOT}" ]; then
            echo "pkgrm -n -R $PKG_INSTALL_ROOT $OldPkg" >> $UPGR_SCRIPT
        else
            echo "pkgrm -n $OldPkg" >> $UPGR_SCRIPT
        fi
        echo "rm $UPGR_SCRIPT" >> $UPGR_SCRIPT
        echo "exit $?" >> $UPGR_SCRIPT
    fi
fi
else
    if [ -f $UPGR_SCRIPT ]; then
        rm -r $UPGR_SCRIPT
    fi
fi
exit 0
The postinstall Script

```bash
# postinstall
to execute a simple upgrade

PATH=/usr/sadm/bin:$PATH
UPGR_SCRIPT=/tmp/upgr.$PKGINST

if [ -f $UPGR_SCRIPT ]; then
    sh $UPGR_SCRIPT &
fi

exit 0
```

Creating Class Archive Packages

A class archive package, which is an enhancement to the Application Binary Interface (ABI), is one in which certain sets of files have been combined into single files, or archives, and optionally compressed or encrypted. Class archive formats increase initial install speed by up to 30% and improves reliability during installation of packages and patches onto potentially active file systems.

The following sections provide information about the archive package directory structure, keywords, and faspac utility.

Structure of the Archive Package Directory

The package entry shown in the figure below represents the directory containing the package files. This directory must be the same name as the package.
The following lists the functions of the files and directories contained within the package directory.

<table>
<thead>
<tr>
<th>Item</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pkginfo</td>
<td>File describing the package as a whole including special environment variables and installation directives</td>
</tr>
<tr>
<td>pkgmap</td>
<td>File describing each object to be installed, such as a file, directory, or pipe</td>
</tr>
<tr>
<td>reloc</td>
<td>Optional directory containing the files to be installed relative to the base directory (the relocatable objects)</td>
</tr>
<tr>
<td>root</td>
<td>Optional directory containing the files to be installed relative to the root directory (the root objects)</td>
</tr>
<tr>
<td>install</td>
<td>Optional directory containing scripts and other auxiliary files (except for pkginfo and pkgmap, all ftype i files to here)</td>
</tr>
</tbody>
</table>

The class archive format allows the package builder to combine files from the reloc and root directories into archives which can be compressed, encrypted, or otherwise processed in any desired way in order to increase install speed, reduce package size, or increase package security.

The ABI allows any file within a package to be assigned to a class. All files within a specific class may be installed to the disk using a custom method defined by a class action script. This custom method may make use of programs available on the target system or programs delivered with the package. The resulting format looks much like the standard ABI format. As shown in the following illustration, another directory is added. Any class of files intended for archive is simply combined into a single file and placed into the archive directory. All archived files are removed from the reloc and root directories and an install class action script is placed into the install directory.
Keywords to Support Class Archive Packages

In order to support this new class archive format, three new interfaces in the form of keywords have special meaning within the pkginfo file. These keywords are used to designate classes requiring special treatment. The format of each keyword statement is: `keyword=class1[ class2 class3 ...]`. Each keyword value is defined in the following table.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PKG_SRC_NOVERIFY</td>
<td>This tells pkgadd not to verify the existence and properties of the files in the delivered package’s reloc or root directories if they belong to the named class. This is required for all archived classes, because those files are no longer in a reloc or root directory. They are a private format file in the archive directory.</td>
</tr>
</tbody>
</table>
The files in these classes are verified after installation using a quick algorithm with little to no text output. The quick verify first sets each file's attributes correctly and then checks to see if the operation succeeded. There is then a test of the file size and modification time against the pkgmap. No checksum verification is performed and there is poorer error recovery than that provided by the standard verification mechanism. In the event of a power outage or disk failure during installation, the contents file may be inconsistent with the installed files. This inconsistency can always be resolved with a pkgrm.

Normally the install class action script receives from stdin a list of source and destination pairs telling it which files to install. The classes assigned to PKG_CAS_PASSRELATIVE do not get the source and destination pairs. Instead they receive a single list, the first entry of which is the location of the source package and the rest of which are the destination paths. This is specifically for the purpose of simplifying extraction from an archive. From the location of the source package, you can find the archive in the archive directory. The destination paths are then passed to the function responsible for extracting the contents of the archive. Each destination path provided is either absolute or relative to the base directory depending on whether the path was located in root or reloc originally. If this option is chosen, it may be difficult to combine both relative and absolute paths into a single class.

For each archived class a class action script is required. This is a file containing Bourne shell commands which is executed by pkgadd to actually install the files from the archive. If a class action script is found in the install directory of the package, pkgadd turns all responsibility for installation over to that script. The class action script is run with root permissions and can place its files just about anywhere on the target system.

Note – The only keyword that is absolutely necessary in order to implement a class archive package is PKG_SRC_NOVERIFY. The others may be used to increase installation speed or conserve code.

The faspac Utility

The faspac utility converts a standard ABI package into a class archive format used for bundled packages. This utility archives using cpio and compresses using compress. The resulting package has an additional directory in the top directory called archive. In this directory will be all of the archives named by class. The install directory will contain the class action scripts necessary to unpack each archive. Absolute paths are not archived.
The faspac utility has the following format:

```
faspac [-m Archive Method] -a -s -q [-d Base Directory] / [-x Exclude List] [List of Packages]
```

Each faspac command option is described in the following table.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-m Archive Method</td>
<td>Indicates a method for archive or compression. bzip2 is the default compression utilities used. To switch to zip or unzip method use -m zip or for cpio or compress use -m cpio.</td>
</tr>
<tr>
<td>-a</td>
<td>Fixes attributes (must be root to do this).</td>
</tr>
<tr>
<td>-s</td>
<td>Indicates standard ABI-type package translation. This option takes a cpio or compresssed packaged and makes it a standard ABI-compliant package format.</td>
</tr>
<tr>
<td>-q</td>
<td>Indicates quiet mode.</td>
</tr>
<tr>
<td>-d Base Directory</td>
<td>Indicates the directory in which all packages present will be acted upon as required by the command line. This is mutually exclusive with the List of Packages entry.</td>
</tr>
<tr>
<td>-x Exclude List</td>
<td>Indicates a comma-separated or quoted, space-separated list of packages to exclude from processing.</td>
</tr>
<tr>
<td>List of Packages</td>
<td>Indicates the list of packages to be processed.</td>
</tr>
</tbody>
</table>
Glossary

ABI
See application binary interface (ABI).

abstract syntax notation 1
A way of expressing abstract objects. For example, ASN.1 defines a public key certificate, all of the objects that make up the certificate, and the order in which the objects are collected. However, ASN.1 does not specify how the objects are serialized for storage or transmission.

application binary interface
Definition of the binary system interface between compiled applications and the operating system on which they run.

ASN.1
See abstract syntax notation 1 (ASN.1)

base directory
The location where relocatable objects will be installed. It is defined in the pkginfo file, using the BASEDIR parameter.

build time
The time during which a package is being built with the pkgmk command.

build variable
A variable that begins with a lowercase letter and is evaluated at build time.

certificate authority
An agency, such as Verisign, that issues certificates used in the signing of packages.

class
A name that is used to group package objects. See also class action script.

class action script
A file that defines a set of actions to be performed on a group of package objects.

collectively relocatable object
A package object that is located relative to a common installation base. See also base directory.

common name
An alias name listed in the package's keystore for signed packages.

composite package
A package that contains both relocatable and absolute path names.

compver file
A method of specifying package backward-compatibility.

control file
File that controls how, where, and if a package is to be installed. See information file and installation script.

copyright
The right to own and sell intellectual property, such as software, source code, or documentation. Ownership must be stated on the CD-ROM and insert text, whether the copyright is owned by SunSoft, or by another party. Copyright ownership is also acknowledged in SunSoft documentation.

depend file
A method of resolving basic package dependencies. See also compver file.

DER
See distinguished encoding rules.
digitalsignature

An encoded message used to verify the integrity and security of a package.

distinguished encoding rules

A binary representation of an ASN.1 object and defines how an ASN.1 object is serialized for storage or transmission in computing environments. Used with signed packages.

incompatible package

A package that is incompatible with the named package. See also depend file.

individually relocatable object

A package object that is not restricted to the same directory location as a collectively relocatable object. It is defined using an install variable in the path field in the prototype file, and the installation location is determined via a request script or a checkinstall script.

information file

A file that can define package dependencies, provide a copyright message, or reserve space on a target system.

install time

The time during which a package is being installed with the pkgadd command.

install variable

A variable that begins with an uppercase letter and is evaluated at install time.

installation script

A script that enables you to provide customized installation procedures for a package.

ITU-T Recommendation X.509

A protocol that specifies the widely-adopted X.509 public key certificate syntax.

package

A collection of files and directories required for a software application.

package abbreviation

A short name for a package that is defined via the PKG parameter in the pkginfo file.

package identifier

A numerical suffix added to a package abbreviation by the pkgadd command.

package instance

A variation of a package, which is determined by combining the definitions of the PKG, ARCH, and VERSION parameters in the pkginfo file for the package.

package keystore

A repository of certificates and keys that can be queried by the package tools.

package object

Another name for an application file that is contained in a package to be installed on a target system.

parametric path name

A path name that includes a variable specification.

patch list

A list of patches that affect the current package. This list of patches is recorded in the installed package in the pkginfo file.

PEM

See privacy enhanced message.

PKCS12

See public key cryptography standard #12.

PKCS7

See public key cryptography standard #7.

prerequisite package

A package that depends on the existence of another package. See also depend file.

<tr>
<td>public key</td>
<td>A value generated as an encryption key that, combined with the private key derived from the public key, can be used to effectively encrypt messages and digital signatures.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>public key</td>
<td>A standard that describes a syntax for storing cryptographic objects on disk. The package keystore is maintained in this format.</td>
</tr>
<tr>
<td>cryptography</td>
<td></td>
</tr>
<tr>
<td>standard #12</td>
<td></td>
</tr>
<tr>
<td>public key</td>
<td>A standard that describes a general syntax for data that may have cryptography applied to it, such as digital signatures and digital envelopes. A signed package contains an embedded PKCS7 signature.</td>
</tr>
<tr>
<td>cryptography</td>
<td></td>
</tr>
<tr>
<td>standard #7</td>
<td></td>
</tr>
<tr>
<td>relocatable</td>
<td>A package object defined in a prototype file with a relative path name.</td>
</tr>
<tr>
<td>relocatable object</td>
<td>A package object that does not need an absolute path location on a target system. Instead, its location is determined during the installation process. See also collectively relocatable object and individually relocatable object.</td>
</tr>
<tr>
<td>reverse dependency</td>
<td>A condition when another package depends on the existence of your package. See also depend file.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>segmented</td>
<td>A package that does not fit on a single volume, such as a floppy disk.</td>
</tr>
<tr>
<td>signed packages</td>
<td>A normal stream-format package with a digital signature that verifies the following: that the package came from the entity that signed it, the entity indeed signed it, the package has not been modified since the entity signed it, and the entity that signed it is a trusted entity.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>tar</td>
<td>Tape archive retrieval. Solaris command for adding or extracting files from a media.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>trusted certificate</td>
<td>A certificate that contains a single public key certificate that belongs to another entity. Trusted certificates are used when verifying digital signatures and when initiating a connection to a secure (SSL) server.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>unsigned package</td>
<td>A normal, ABI package without any encryption or digital signatures.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>user key</td>
<td>A key that holds sensitive cryptographic key information. This information is stored in a protected format to prevent unauthorized use. User keys are used when a signed package is created.</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>X.509</td>
<td>See ITU-T Recommendation X.509.</td>
</tr>
