Preface

The Sun Enterprise 10000 SSP 3.3 User Guide describes the System Service Processor (SSP), which enables you to monitor and control the Sun Enterprise™ 10000 system.

How This Book Is Organized

This document contains the following chapters:

Chapter 1 introduces the System Service Processor (SSP).

Chapter 2 introduces the Hostview Graphical User Interface (GUI).

Chapter 3 describes how to create, remove, rename, and bring up domains and also describes how to get status information on a domain.

Chapter 4 describes how to use Automated Dynamic Reconfiguration to add boards to, or remove them from, domains.

Chapter 5 describes how to use netcon(1M) and netcontool(1M).

Chapter 6 describes how to control the system power resources from within Hostview or from the command line, to control the peripherals power resources from the command line, and to monitor the power levels in Hostview.

Chapter 7 describes how to administer the thermal conditions from within Hostview and how to monitor the fans from within Hostview.

Chapter 8 describes how to configure components out of the system using the blacklist file.

Chapter 9 describes the procedure for switching between the main and spare SSP.

Chapter 10 provides information on the use of dual control boards.
Chapter 11 provides more detailed information for system administrators interested in how the SSP works. Included are descriptions of the SSP booting process and the edd(1M) daemon, which monitors the Sun Enterprise 10000 system.

Before You Read This Book

This manual is intended for Sun Enterprise 10000 system administrators, who have a working knowledge of UNIX® systems, particularly those based on the Solaris™ operating environment. If you do not have such knowledge, you should first read the Solaris User and System Administrator AnswerBook2™ provided with this system, and consider UNIX system administration training.

Using UNIX Commands

This document does not contain information on basic UNIX commands and procedures such as shutting down the system, booting the system, and configuring devices.

See one or more of the following for this information:

■ AnswerBook2 online documentation for the Solaris software environment, particularly those dealing with Solaris system administration
■ Other software documentation that you received with your system

Sun Welcomes Your Comments

We are interested in improving our documentation and welcome your comments and suggestions. You can email your comments to us at:

docfeedback@sun.com

Please include the part number (806-2887-10) of your document in the subject line of your email.
Introduction to the SSP

The System Service Processor (SSP) is a SPARC™ workstation or SPARC server that enables you to control and monitor the Sun Enterprise 10000 system. You can use a SPARCstation™ 5, Sun Ultra™ 5, or Sun Enterprise 250 workstation or server as an SSP. In this book, the SSP workstation or server is simply called the SSP. The SSP 3.3 software packages must be installed on the SSP. In addition, the SSP must be able to communicate with the Sun Enterprise 10000 system over an Ethernet connection.

The Sun Enterprise 10000 system is often referred to as the platform. System boards within the platform may be logically grouped together into separately bootable systems called Dynamic System Domains, or simply domains. Up to 16 domains may exist simultaneously on a single platform. (Domains are introduced in this chapter, and are described in more detail in Chapter 3 “Domain Administration”.) The SSP lets you control and monitor domains, as well as the platform itself.

Note – Do not run any third party software on the SSP machine.

If you have a Sun Enterprise 10000 Capacity on Demand system, refer to the Sun Enterprise 10000 Capacity on Demand 1.0 Administrator Guide and Sun Enterprise 10000 Capacity on Demand 1.0 Reference Manual. If you are not sure if your system is a Capacity on Demand system, you can execute the following command to determine whether the Capacity on Demand packages are installed:

```
ssp# pkginfo | grep SUNWcod
application SUNWcod        Capacity On Demand (COD)
application SUNWcodmn      Capacity On Demand (COD) Manual
```
SSP 3.3 Features

SSP 3.3 software can be loaded only on Sun workstations or Sun servers running the Solaris 2.6, 7, or 8 operating environment with the Common Desktop Environment (CDE). SSP 3.3 software is compatible with Sun Enterprise 10000 domains that are running the Solaris 2.5.1, 2.6, 7, or 8 operating environments. The commands and GUI programs that are provided with the SSP 3.3 software can be used remotely.

The SSP enables the system administrator to perform the following tasks:

- Perform an emergency shutdown in an orderly fashion. For example, the SSP 3.3 software automatically shuts down a domain if the temperature of a processor within that domain rises above a preset level.
- Create domains by logically grouping system boards together. Domains are able to run their own operating system and handle their own workload. See Chapter 3 “Domain Administration”.
- Boot domains.
- Dynamically reconfigure a domain so that currently installed system boards can be logically attached to or detached from the operating system while the domain continues running in multiuser mode. This feature is known as Sun Enterprise 10000 dynamic reconfiguration and is described in the Sun Enterprise 10000 Dynamic Reconfiguration User Guide. (A system board can easily be physically swapped in and out when it is not attached to a domain, even while the system continues running in multiuser mode.)
- Perform automated dynamic reconfiguration of domains. See Chapter 4 “Automated Dynamic Reconfiguration”.
- Assign paths to different controllers for I/O devices, which enables the system to continue running in the event of certain types of failures. This feature is known as Alternate Pathing (AP) and is described in the Sun Enterprise Server Alternate Pathing 2.3 User Guide.
- Monitor and display the temperatures, currents, and voltage levels of one or more system boards or domains.
- Monitor and control power to the components within a platform.
- Execute diagnostic programs such as power-on self-test (POST).

In addition, the SSP environment:

- Warns you of impending problems, such as high temperatures or malfunctioning power supplies.
- Notifies you when a software error or failure has occurred.
- Automatically reboots a domain after a system software failure (such as a panic).
- Keeps logs of interactions between the SSP environment and the domains.
- Provides support for InterDomain Networks (IDN)
- Provides support for the Sun Enterprise 10000 dual grid power option.
System Architecture

The Sun Enterprise 10000 platform, the SSP, and other workstations communicate over Ethernet (FIGURE 1-1).

Dual control boards are supported within the Sun Enterprise 10000 platform. Each control board runs a control board executive (CBE) that communicates with the SSP over a private network. One control board is designated as the primary control board, and the other is designated as the alternate control board. Only one control board is active at a time. If the primary control board fails, you can manually switch to the alternate control board as described in Chapter 10 “Dual Control Board Handling”.

SSP operations can be performed by entering commands on the SSP console or by remotely logging in to the SSP from another workstation on the local area network. Whether you log in to the SSP remotely or locally, you must log in as user ssp and provide the appropriate password if you want to perform SSP operations (such as monitoring and controlling the platform).
SSP User Environment

You can interact with the SSP and the domains on the Sun Enterprise 10000 by using SSP commands and the SSP GUI programs.

▼ To Begin Using the SSP

1. Boot the SSP.
2. Log in to the SSP as user `ssp` and type:

```bash
ssp% tail -f $SSPLOGGER/messages
```

3. Wait until you see the following message:

```
Startup of SSP programs complete
```

At this point you can begin using SSP programs such as Hostview and netcontool(IM).

SSP 3.3 Window

An SSP window provides a command line interface to the Solaris operating environment and SSP 3.3 environment (FIGURE 1-2).
To Display an SSP Window Locally in the Common Desktop Environment (CDE)

1. Log in to the SSP as user `ssp`.

2. Open an SSP window using one of the following methods:
   - From the CDE front panel under the Solaris 2.6 operating environment, select the Personal Applications sub-panel (which looks like a notepad), and then select Terminal.
   - From the CDE front panel under the Solaris 7 or 8 operating environment, select the Hosts sub-panel, and then select This Host.
   - From the Workspace Menu (right mouse click) choose Programs and then select Terminal.

To Display an SSP Window Remotely

1. Use the `rlogin(1)` command to remotely log in to the SSP 3.3 machine as user `ssp`, and enter the `ssp` password.

2. When prompted, type in the name of the platform or domain you wish to work with, and then press Return.
   The `SUNW_HOSTNAME` environment variable is set to the value you enter.

SSP Console Window

The SSP console window is the console for the SSP workstation or server. The system uses it to log operating system messages.
To Display an SSP Console Window Locally with CDE

1. Log in to the SSP as user ssp.

2. Open an SSP window using one of the following methods:
   - From the Workspace Menu (right mouse click) choose Programs and then select Console.
   - From the CDE front panel under the Solaris 7 or 8 operating environment, select the Hosts sub-panel, and then select Console.

Network Console Window

The network console window, or netcon(1M) window, receives system console messages (operating system messages) from a domain (FIGURE 1-3).

A netcon(1M) window behaves as if a console is physically connected to a domain. Domain console messages, such as those generated by dynamic reconfiguration operations, are displayed in the netcon(1M) window. For more information, see “Using netcon(1M)” on page 41 and the netcon(1M) man page.
Hostview

The Hostview program provides a graphical user interface (GUI) with the same functionality as many of the SSP commands (FIGURE 1-4).

**FIGURE 1-4** Hostview GUI Program

Hostview is described in detail in Chapter 2 “Hostview”. It is also described in the `hostview(1M)` man page in the *Sun Enterprise 10000 SSP 3.3 Reference Manual* (man pages).
Hostview

This chapter describes Hostview, a GUI front-end to SSP 3.3 commands.

Hostview enables you to perform administration operations such as:

- Dynamically grouping the system boards into domains. Each domain runs its own instance of the Solaris operating environment and has its own log messages file.
- Booting the Solaris operating environment for a domain.
- Accessing the SSP log messages file for each platform or domain.
- Remotely logging in to each domain.
- Displaying a netcon(1M) window for each domain.
- Editing the blacklist(4) file to enable or disable hardware components in a domain.
- Dynamically reconfiguring the boards within a platform, logically attaching or detaching them from the operating system. This feature is described in the Sun Enterprise 10000 Dynamic Reconfiguration User Guide.
- Powering the system boards on and off.
- Monitoring the temperature and voltage levels of hardware components.

If you want to run Hostview, you only need to run one instance for a given platform. However, it is possible to run more than one instance simultaneously (perhaps on different workstations) to work with the same platform.

If you have logged into the SSP environment from a remote login session, make sure your DISPLAY environment variable is set to your current display and that your xhost settings enable the SSP to display on your workstation (see xhost(1) in the Solaris X Window System Reference Manual).
To Start Up Hostview From a Remote Login Session

1. Enable external hosts to display on your local workstation:

```
xhost +
```

2. Log in to the SSP as user `ssp` and type:

```
ssp% hostview -display machine_name:0.0 &
```

To Start Up Hostview From the Workspace Menu Locally on the SSP

- From the Workspace Menu (right mouse button click), select SSP, and then select Hostview.

This is available only when you use the SSP console, not when you use a remote login session to the SSP.

To Start Up Hostview Under CDE From the Front Panel

- Use one of the following methods:
  - Click the SSP icon on the front panel. The icon shows a hand holding tools.
  - Click the arrow above the SSP icon on the front panel, and select Hostview.
  - Open an SSP window and type:

```
ssp% hostview &
```

Hostview Main Window

When you start Hostview, the main window is displayed (FIGURE 2-1 on page 11).
The menu bar on the main window provides the commands that you use to control the platform. The commands are described in “Main Window Menu Bar” on page 13.

The buttons on the main window (Power, Temperature, and Fans) bring up status details. The buttons are described in “Main Window Buttons” on page 17.

The rest of the main window provides a graphical view of the platform boards and buses. The system boards are named SB0 through SB15, and their processor numbers are shown. The control boards are named CB0 and CB1. The support boards are named CSB0 and CSB1. The buses are named ABUS0 through ABUS3, DBUS0, and DBUS1.
The system boards along the top of the display are arranged in the order they appear on the front side of the physical platform. The system boards along the bottom of the display are arranged in the order they appear on the back side of the physical platform.

If a system board is shown with no outline (FIGURE 2-2 on page 12), the board is not part of a domain and is not currently selected.

If a system board is part of a domain (FIGURE 2-3 on page 12), a colored outline surrounds it. The boards within a given domain all have outlines of the same color.

A black outline around the domain color outline indicates that a board is selected (FIGURE 2-4 on page 12). (There are several reasons why you select a board in Hostview. For example, you could select one or more boards, and then create a domain that is based on those boards.)

The processors within the boards are numbered 0 through 63. The processor symbols (diamond, circle, and so forth) indicate the state of the processors and are described in “Main Window Processor Symbols” on page 18.
Selecting Items in the Main Window

You can select one or more boards in the Hostview main window. You can also select one domain in the main window. You must select a set of boards prior to performing certain operations, such as creating a domain.

- To select a single board, click on it with the left mouse button. The selected board is indicated by a black outline, and all other boards are deselected.
- To select additional boards, click on them with the middle mouse button. You can also deselect a currently selected board by clicking on it with the middle mouse button. (The middle mouse button toggles the selection status of the board without affecting the selection status of any other board.)
- To select a domain, click on a board within that domain with the left mouse button. Note that you can select boards from different domains (using the middle mouse button), but the selected domain will correspond to the board that you selected with the left mouse button.

Main Window Menu Bar

The items on the main Hostview menu are described in TABLE 2-1.

<table>

<td>Displays a window that enables you to run the \texttt{fan(1M)} command to control the fans within the platform.</td>
</tr>
<tr>
<td>Configuration Board</td>
<td></td>
<td>Enables you to attach and detach system boards. This feature is described in the \textit{Sun Enterprise 10000 Dynamic Reconfiguration User Guide}.</td>
</tr>
<tr>
<td>Domain</td>
<td></td>
<td>Provides a pull-right menu with several choices. The menu choices enable you to create domains, remove domains, rename domains, obtain the status of domains, and view the history of domains. A domain consists of one or more system boards running the same operating system kernel. Domains function independently of each other. Each domain can carry its own workload and has its own log messages file. For more information, see “To Create Domains From Within Hostview” on page 24 and “To Remove Domains From Within Hostview” on page 28.</td>
</tr>
<tr>
<td>Terminal</td>
<td>netcontool</td>
<td>Displays a window that provides a graphical interface to the \texttt{netcon(1M)} command, enabling you to open a network console window for a domain. This menu item is equivalent to executing the \texttt{netcontool(1M)} command. See “Using \texttt{netcon(1M)}” on page 41.</td>
</tr>
<tr>
<td>SSP</td>
<td></td>
<td>Provides pull-right menu choices that enable you to display an SSP Window in \texttt{xterm}, \texttt{dtterm}, \texttt{shelltool}, or \texttt{cmdtool} format with a platform or domain as its host. Select a domain (by selecting any system board within that domain) before choosing this option.</td>
</tr>
<tr>
<td>rlogin</td>
<td></td>
<td>Provides pull-right menu choices that enable you to remotely log in to the selected platform or domain in an \texttt{xterm}, \texttt{dtterm}, \texttt{shelltool}, or \texttt{cmdtool} window. Select a domain (by selecting any system board within that domain) before choosing this option.</td>
</tr>
</tbody>
</table>
Help Window

When you choose a topic from the Help menu, the Hostview - Help window is displayed (FIGURE 2-5 on page 16).
You can select the desired topic in the upper pane. The corresponding help information is displayed in the lower pane.
Main Window Buttons

The main Hostview window contains the buttons described below. If an out-of-boundary condition exists or an error has occurred, one or more of these buttons turn red.

The Power button (FIGURE 2-6 on page 17) displays the Power Control and Status window, which enables you to view the power status for the platform. See “To Power Components On or Off From Within Hostview” on page 51.

FIGURE 2-6 Power Button

The Temperature button (FIGURE 2-7 on page 17) displays the Thermal Status window, which enables you to view the temperature status for the boards and components within the platform. See “To Monitor Thermal Conditions From Within Hostview” on page 57.

FIGURE 2-7 Temperature Button

The Fan button (FIGURE 2-8) displays the Fan Status window, which enables you to view the status of the fans within the platform. See “To Monitor Fans From Within Hostview” on page 59.

FIGURE 2-8 Fan Button
When certain error conditions occur, the Failure button (FIGURE 2-9) turns red. If you click a red Failure button, a window is displayed showing the error condition(s) that have occurred.

![Failure Button](image)

FIGURE 2-9 Failure Button

TABLE 2-2 describes the types of error conditions that are trapped by this mechanism.

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host panic recovery in progress</td>
<td>The operating system on a domain has failed and is recovering.</td>
</tr>
<tr>
<td>Heartbeat failure recovery in progress</td>
<td>The SSP was not receiving updated platform or domain information as expected.</td>
</tr>
<tr>
<td>Arbitration stop recovery in progress</td>
<td>A parity error or other fatal error has occurred, and the domain is recovering. See arbitration stop in the glossary.</td>
</tr>
</tbody>
</table>

Main Window Processor Symbols

In the main window, the shape and background color of a processor symbol indicate the status of that processor. For example, a diamond on a green background indicates the processor is running the operating system.

TABLE 2-3 lists the shapes and what the processor is running for each shape.

<table>
<thead>
<tr>
<th>Shape</th>
<th>Processor running</th>
</tr>
</thead>
<tbody>
<tr>
<td>◆</td>
<td>Operating system</td>
</tr>
<tr>
<td>.</td>
<td>hpost(1M)</td>

<td>Redlisted (The processor is unavailable to run programs or diagnostics and its state may not be changed.)</td>
</tr>
<tr>
<td>White</td>
<td>Present but not configured (The processor is unavailable, but not blacklisted or redlisted. One example is a board that has been hot-swapped in, but it has not yet been attached to the operating system.)</td>
</tr>
</tbody>
</table>
Hostview Resources

In the Hostview main window, boards that are in the same domain have the same color outline. If you want to change the domain colors or if your workstation does not use the default colors supported by Hostview, you can configure the colors used for each domain. Put the following resources in your `$HOME/.Xdefaults` file and modify the specified colors using valid color names:

```
Hostview*domainColor0: white
Hostview*domainColor1: orange
Hostview*domainColor2: yellow
Hostview*domainColor3: pink
Hostview*domainColor4: brown
Hostview*domainColor5: red
Hostview*domainColor6: green
Hostview*domainColor7: violet
Hostview*domainColor8: purple
Hostview*domainColor9: mediumaquamarine
Hostview*domainColor10: yellowgreen
Hostview*domainColor11: maroon
Hostview*domainColor12: cyan
Hostview*domainColor13: darkgoldenrod
Hostview*domainColor14: navyblue
Hostview*domainColor15: tan
```

You can use the `showrgb (1)` command (for details on this command, see the `SunOS Reference Manual`) to list the valid domain color names on your display workstation. If you specify an invalid domain color in the `.Xdefaults` file, an error is generated and the following occurs:

- Domain outlines for the invalid color and subsequent domain colors are not displayed in the main Hostview window
- Domain names are not listed in the View menu

Hostview Performance Considerations

Each instance of Hostview requires up to 10 Mbytes of the available swap space in the SSP. Before running multiple copies of Hostview, make sure the SSP has sufficient swap space available. For example, if you plan to run three instances of Hostview, make sure you have at least 30 Mbytes of swap space.
SSP Log Files

The SSP processes log, informational, warning, and error messages to a variety of log files.

Messages for the platform that are not specific to a domain are logged in the file:

\$SSPLOGGER/messages

Messages for a particular domain are logged in the file:

\$SSPLOGGER/domain_name/messages

where \textit{domain\_name} is the host name of the domain for which the error occurred.

The SSP environment variables, such as \textit{SSPLOGGER}, are described in “Environment Variables” on page 89.

The message format and logging level are specified in the \$SSPLOGGER/.logger and the /etc/syslog.conf files on the SSP. Do not change the default values in these files unless your service provider instructs you to do so.

\textbf{Note} – During installation of the Solaris operating environment on a domain, the domain /etc/syslog.conf file is modified so that system messages are routed to the SSP /var/adm/messages file and the domain /var/adm/messages file.

\textbf{▼ To View a messages File From Within Hostview}

1. Select the appropriate board.
   - If you want to view the messages file for a particular domain, select that domain in the main Hostview window (by clicking on a board from that domain with the left mouse button).
   - If you want to view the messages file for the platform, make sure that no domain is selected.

2. Choose SSP Logs from the File menu.
   The SSP Logs window is displayed (FIGURE 2-10 on page 22).
The Domain Name field shows the name of the domain that you selected. The messages file is displayed in the main panel of the window.
Domain Administration

The SSP supports commands that let you logically group system boards into Dynamic System Domains, or simply domains, which are able to run their own operating system and handle their own workload. Domains can be created and deleted without interrupting the operation of other domains. You can use domains for many purposes. For example, you can test a new operating system version or set up a development and testing environment in a domain. In this way, if problems occur, the rest of your system is not affected.

You can also configure several domains to support different departments, with one domain per department. You can temporarily reconfigure the system into one domain to run a large job over the weekend.

Domain Configuration Requirements

You can create a domain out of any group of system boards, provided the following conditions are met:

■ The boards are present and not in use in another domain.
■ At least one board has a network interface.
■ The boards have sufficient memory to support an autonomous domain.
■ The name you give the new domain is unique (as specified in the domain_create(1M) command) and this name matches the host name of the domain to be booted (as specified by the SUNW_HOSTNAME environment variable).
■ You have an eeprom.image file for the domain that was shipped to you by the factory. If your eeprom.image file has been accidentally deleted or corrupted and you do not have a backup, see “To Recreate the eeprom.image File” on page 27.
There must be at least one boot disk connected to one of the boards that will be grouped together into a domain. Alternatively, if a domain does not have its own disk, there must be at least one network interface so that you can boot the domain from the network.

▼ To Create Domains From Within Hostview

Note – Before proceeding, read the requirements in the previous section, “Domain Configuration Requirements”. If the system configuration must be changed to meet any of these requirements, call your service provider. Also, after you create a domain, you must update /etc/hosts to reflect the domain’s new name.

1. Click the left mouse button on the first board.

2. Click the middle mouse button on any additional boards.
   Ensure that the boards you select do not currently belong to any domain.

3. Choose Domain then Create from the Configuration menu.
   The Create Domain window is displayed (FIGURE 3-1).
Caution – You must be sure to specify the proper OS Version number for the domain you are creating. The default is 2.5.1. Edit this version number, if necessary, to reflect the version of the operating system for the domain you are creating.

4. Type the domain name.
The name of the domain must be the one given to you by the factory and contained in the eeprom.image file. It cannot be an arbitrary name.
5. If all other fields are acceptable, click execute.

Note that the System Boards field indicates the boards that you selected in the main Hostview window. The default OS version and the default platform type are shown. If Hostview successfully executes the command, it displays the message Command completed in the informational panel of the window.

Note – Hostview can run only one create or remove command at a time. If you attempt to execute a second create or remove command before the first has completed, your second attempt fails.

▼ To Create Domains From the Command Line

Note – Before proceeding, see “Domain Configuration Requirements” on page 23. If the system configuration must be changed to meet any of these requirements, call your service provider.

1. In an SSP window, type:

```bash
ssp% domain_create -d domain_name -b system_board_list -o os_version -p platform_name
```

where:

- `domain_name` is the name you want to give to the new domain. It should be unique among all Sun Enterprise 10000 systems controlled by the SSP.
- `system_board_list` specifies the boards that are to be part of this domain. The specified system boards must be present and not in use. Each domain must have a network interface, disk interface, and sufficient memory to support an autonomous system. List the board numbers, separated by commas or spaces, for all boards you want to include.
- `os_version` is the version of the operating system to be loaded into the domain.
- `platform_name` is the name of the platform managed by the SSP.

2. Optionally, create a new SSP window for the domain, as described in “SSP 3.3 Window” on page 4.

Use the domain_switch(1M) command to set the SUNW_HOSTNAME environment variable to the new domain name.
To Recreate the `eeprom.image` File

**Note** – You cannot create a domain if you do not have the corresponding `eeprom.image` file. The `eeprom.image` files for the domains you ordered are shipped to you by the factory. If you accidentally delete an `eeprom.image` file or your boot disk is corrupted, and you do not have a backup copy of your `eeprom.image` file, you can contact your Sun service representative to recreate it. Alternatively, you may be able to recreate the `eeprom.image` file if you have the original serial number and the EEPROM key. In this case, follow the steps in this procedure.

1. Log in to the SSP as user `ssp`.

2. Recreate the `eeprom.image` file.

**Note** – All key and `host_id` numbers are case sensitive and must be entered exactly as they are received.

a. For the first domain, type:

   ```
   ssp% domain_switch domain_name
   ssp% sys_id -k key -s serial_number
   ```

   where:
   
   - `domain_name` is the hostname of the domain
   - `key` is the EEPROM key number
   - `serial_number` is the number provided with the `key` in the form of 0XA65xxx

b. For all subsequent domains, type:

   ```
   ssp% domain_switch domain_name
   ssp% sys_id -k key -h hostid
   ```

   where:
   
   - `domain_name` is the hostname of the domain.
   - `key` is the EEPROM key number.
   - `hostid` is the number provided with the `key` in the form of 0X80A66xxx.
3. Check the result by typing:

```
ssp% sys_id -d
```

In the following example, 49933C54C64C858CD4CF is the key and 0x80a66e05 is the host_id:

```
ssp% domain_switch domain_name
ssp% sys_id -k 49933C54C64C858CD4CF -h 0x80a66e05
ssp% sys_id -d
```

IDPROM in eeprom.image.domain_name

- Format = 0x01
- Machine Type = 0x80
- Ethernet Address = 0:0:be:a6:6e:5
- Manufacturing Date = Wed Dec 31 16:00:00 1998
- Serial number (machine ID) = 0xa66e05
- Checksum = 0x3f

4. Back up the SSP eeprom.image files to tape or disk where they can be accessed in case of SSP boot disk failure.

▼ To Remove Domains From Within Hostview

1. In the main Hostview window, click any board in the domain to be removed.

2. Choose Domain then Remove from the Configuration menu.
   The Remove Domain window is displayed (FIGURE 3-2 on page 29).
3. If the default `domain_remove(1M)` command is satisfactory, click the execute button; otherwise, edit the command first.

   For help on the `domain_remove(1M)` command, click the help button. A help window is displayed (see “Help Window” on page 15).

4. Specify whether or not domain subdirectories should be removed when you are prompted to do so.

   The pathnames of the subdirectories are displayed. These subdirectories contain domain-specific information such as message files, configuration files, and `hpost(1M)` dump files. You can keep these directories if you still need the information. It is easier to recreate a domain if you keep these directories.

   **Note** – If the system cannot remove your domain, see `domain_remove(1M)` for a list of potential errors.
▼ To Remove Domains From the Command Line

1. Type:

```
ssp% domain_remove -d domain_name
```

You must execute this command in an SSP window in which the `SUNW_HOSTNAME` environment variable is set to the name of the domain you want to remove. The domain must not be running the operating system.

2. Specify whether or not domain subdirectories should be removed when you are prompted to do so.

   The pathnames of the subdirectories are displayed. These subdirectories contain domain-specific information such as message files, configuration files, and `hpost(1M)` dump files. You can keep these directories if you still need the information. The domain can be recreated whether or not you keep this information.

3. Type `domain_status(1M)` to verify that the domain was removed.

---

**Note** – If the system cannot remove your domain, an error message is displayed. See `domain_remove(1M)` for a list of potential errors.

▼ To Rename Domains From Within Hostview

---

**Note** – After you rename a domain, you must also update `/etc/hosts` to reflect the domain’s new name.

1. Shut down the domain.

2. In the main Hostview window, select a board from the domain that you want to rename by clicking on it with the left mouse button.

3. Choose Domain then Rename from the Configuration menu.

   The Rename Domain window is displayed (FIGURE 3-3).
4. If the default `domain_rename(1M)` command is satisfactory, click on the execute button. Otherwise, edit the command first.

For help on the `domain_rename(1M)` command, click on the help button. A help window is displayed (see “Help Window” on page 15).

▼ To Rename Domains From the Command Line

---

**Note** – After you rename a domain, you must also update the standard host configuration files to reflect the domain’s new name. See the Solaris 2.6, 7, or 8 User Collection and the Solaris 2.6 System Administrator Collection Vol 1 or Solaris 7 or 8 System Administrator Collection.
To Bring Up a Domain From Within Hostview

1. Use the mouse to select any system board belonging to the domain you want to bring up.
2. Choose Bringup from the Control menu.
   A window is displayed that shows the name of the selected domain.
3. Click Execute to perform the bringup.
4. After the bringup operation has completed, choose netcontool from the Terminal menu.
5. Click the Connect button to open a netcon(1M) window.
6. If the OBP prompt appears (that is, the OK prompt), boot the domain:

   OK boot boot_device

The domain should boot and then display the login prompt. Note that you can use the OBP command devalias to determine the alias for the disk you want to use as boot_device.

To Bring up a Domain From the Command Line

Before you can bring up a domain from the command line in an SSP window, the system boards for the domain must be powered on. Ensure that the SUNW_HOSTNAME environment variable is set to the proper valid domain name.

1. Set the SUNW_HOSTNAME environment variable by typing:

   ssp% domain_switch domain_name

   where domain_name is the name of the domain you want to bring up.

Type:

% domain_rename -d old_domain_name -n new_domain_name

For more information, see the domain_rename(1M) man page.
2. Power on the power supplies for all of the boards in the domain:

```
ssp% power -on
```

3. Bring up the domain by typing:

```
ssp% bringup -A [off|on] [disk]
ssp% netcon
ok boot
```

The -A option is the autoboot option. If the autoboot option is on, the domain will automatically boot. If it is off, you need to explicitly boot the domain from the OBP prompt. For information on other command line options, see the `bringup (1m)` man page.

▼ To Obtain Domain Status From Within Hostview

● Choose Domain then Status from the Configuration menu.

The Domain Status window is displayed (FIGURE 3-4).
The status listing is displayed in the main panel of the window. The following table explains the columns in the Domain Status window.

**TABLE 3-1  Domain Status Columns**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DOMAIN</td>
<td>Lists the name of the domain.</td>
</tr>
<tr>
<td>TYPE</td>
<td>Lists the platform type. It can only have the value Ultra-Enterprise-10000 in the current release.</td>
</tr>
<tr>
<td>PLATFORM</td>
<td>Lists the name of the platform. The platform name is set at the time the SSP packages are installed.</td>
</tr>
<tr>
<td>OS</td>
<td>Lists the operating system version for the domain.</td>
</tr>
<tr>
<td>SYSBDS</td>
<td>Lists the system boards that make up the domain.</td>
</tr>
</tbody>
</table>
Automated Dynamic Reconfiguration

Automated Dynamic Reconfiguration (ADR) enables you to automate Dynamic Reconfiguration (DR) operations. ADR provides commands for attaching, moving, and detaching system boards and obtaining board status information. You can run these commands interactively or in shell scripts.

This chapter describes the ADR commands and the interaction between ADR and DR. For details on DR attach and detach operations, refer to the Sun Enterprise 10000 Dynamic Reconfiguration User Guide.

ADR requires that the DR daemons be running in the host domains and that the host domains be configured. Domains can run the Solaris 2.5.1, 2.6, 7, or 8 operating environment.

ADR Interaction with Dynamic Reconfiguration

You must coordinate DR and ADR operations so as not to cause conflicts. An ADR script is likely to be written with the assumption that a particular subset of boards is under exclusive control of that script for some time period. However, there is no mechanism in ADR to prevent a DR operation from making changes to that particular subset of boards.

For example, if an ADR script moves system board 4 from the domain named transact to the domain named simulate at midnight and moves the board back at 6 A.M. everyday, this script is built on the following assumptions:

- Board 4 exists and is powered on
- Board 4 will be found in the transact domain at midnight
Board 4 will be found in the simulate domain at 6 A.M.

In this example, if an operator were to power off board 4 or move it into a third domain, these assumptions would not all be correct.

ADR on I/O Boards

You must use caution when you attach or detach system boards with I/O devices. Before you can detach a board with I/O devices, all of its devices must be closed and all its file systems must be unmounted; these actions must be coordinated with ADR operations. You must also reconfigure the OpenBoot Prom (OBP) device tree after a board with I/O devices is attached or detached.

Note – As of the Solaris 8 GA release, manual reconfiguration is no longer needed. A new Device Driver Interface (DDI) subsystem, devfsadm, completes all the reconfiguration tasks.

To reconfigure the OBP device tree, you must log in as root on the domain in question and type the following command sequence:

```
# drvconfig; devlinks; disks; ports; tapes;
```

When a board with I/O devices is first attached to a domain, the device tree must be reconfigured to allow the OS to place a path to the I/O devices in the /devices hierarchy. Subsequent removal of that same board does not require reconfiguration, but if reconfiguration is not performed, references to nonexistent devices remain in the /devices directory.

If you need to detach a board with I/O devices from a domain temporarily and then re-attach it before any other boards with I/O devices are attached, reconfiguration is not necessary and need not be performed. In this case, device paths to the board devices will remain unchanged. But if you attach another board with I/O devices after the first was detached, then re-attach the first board, reconfiguration is required because the paths to devices on the first board have changed.

ADR Commands

ADR provides the following commands:
addboard attaches a board to a domain.
deleteboard deletes a board from a domain.
moveboard detaches a board from its domain and attaches it to another domain.
showusage displays board and DR information.

See the addboard(1M), deleteboard(1M), moveboard(1M), and showusage(1M) man pages for more information.

Adding a Board to a Domain

The addboard(1M) command attempts to attach a specific board to a specific domain. The following table describes the addboard(1M) command options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>-b</td>
<td>Number of the system board to be added</td>
</tr>
<tr>
<td>-d</td>
<td>Target domain name</td>
</tr>
<tr>
<td>-q</td>
<td>Quiet mode, which means messages are not written to standard output</td>
</tr>
<tr>
<td>-r</td>
<td>Number of retries that are performed if the attach fails</td>
</tr>
<tr>
<td>-t</td>
<td>Wait time in seconds before a retry</td>
</tr>
</tbody>
</table>

See the addboard(1M) man page for more information.

The following example of the addboard(1M) command attaches system board 2 to the domain specified by domain_name. Two retries are performed, if necessary, with a wait time of 10 minutes.

ssp% addboard -b 2 -d domain_name -r 2 -t 600
Deleting a Board from a Domain

The deleteboard(1M) command attempts to detach the specified board from the domain in which it currently resides. The following table describes the deleteboard(1M) command options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>-b</td>
<td>Number of the system board to be deleted</td>
</tr>
<tr>
<td>-q</td>
<td>Quiet mode, which means informational messages are not written to standard output.</td>
</tr>
<tr>
<td>-r</td>
<td>Number of retries that are performed if the detach fails</td>
</tr>
<tr>
<td>-t</td>
<td>Wait time in seconds before a retry</td>
</tr>
</tbody>
</table>

See the deleteboard(1M) man page for more information.

The following example of the deleteboard(1M) command detaches system board 2 from its current domain. Two retries are performed, if necessary, with a wait time of 15 minutes.

```
ssp% deleteboard -b 2 -r 2 -t 900
```

Moving a Board from One Domain to Another

The moveboard(1M) command detaches a board from the domain in which it currently resides and attaches it to a specific domain. The following table describes the moveboard(1M) command options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>-b</td>
<td>Number of the system board to be moved</td>
</tr>
<tr>
<td>-d</td>
<td>Target domain name</td>
</tr>
<tr>
<td>-q</td>
<td>Quiet mode, which means messages are not written to standard output</td>
</tr>
<tr>
<td>-r</td>
<td>Number of retries that are performed if the move fails</td>
</tr>
<tr>
<td>-t</td>
<td>Wait time in seconds before a retry</td>
</tr>
</tbody>
</table>

See the moveboard(1M) man page for more information.
The following example of the moveboard(1M) command moves board 5 from its current domain to the domain specified by domain_name. Two retries are performed, if necessary, with a wait time of 15 minutes.

```
ssp% moveboard -b 5 domain_name -r 2 -t 900
```

## Obtaining Board Status Information

The showusage(1M) command displays DR and board resource information. The following table describes the showusage(1M) command options:

<table>
<thead>
<tr>
<th>Option</th>
<th>Specifies</th>
</tr>
</thead>
<tbody>
<tr>
<td>-b</td>
<td>Number of the system board for which status information is to be obtained</td>
</tr>
<tr>
<td>-r</td>
<td>Type of DR and board resource information to be displayed.</td>
</tr>
<tr>
<td>-s</td>
<td>Status information on the board state and current domain to be written to stdout.</td>
</tr>
</tbody>
</table>

For more information on the showusage(1M) command, see the showusage(1M) man page.

The following example of the showusage(1M) command shows how the showusage(1M) command with the -s option could be used in a C shell script to locate a board in a specified pool of boards eligible for attachment and attach it to a domain named xf7-b4.

```
set pool = ( 4 5 6 7 14 15 )
foreach board ( $pool )
   showusage -b $board -s >! /dev/null
   if ( $status == 3 ) then
      addboard -b $board xf7-b4
      exit(0)
   endif
end
```
ADR Example Script

SSP 3.3 provides an example script in the /opt/SUNWssp/adr_examples directory. This directory also contains a README file that describes how to use the script.
netcon and netcontool

This chapter describes netcon(1M) and netcontool(1M), a GUI front-end to the netcon(1M) command. netcontool(1M) simplifies the process of configuring and bringing up netcon(1M) windows. You can also use the netcon(1M) command directly to display a netcon(1M) window. However, when using netcon(1M), you must know escape sequences to perform operations that can be performed by clicking on buttons under netcontool(1M).

Using netcon(1M)

The netcon(1M) command is similar to netcontool(1M) except that no GUI interface is provided, making it more functional for dial-in or other low-speed network access. Typically, you log in to the SSP machine as user ssp, and enter the netcon(1M) command in an SSP window. For example:

```
ssp% domain_switch domain_name
ssp% netcon
```

This action changes the window in which you run the netcon(1M) command into a netcon(1M) window for the domain specified by the domain_switch(1M) command. Multiple netcon(1M) windows can be opened simultaneously, but only one window at a time can have write privileges to a specific domain. When a netcon(1M) window is in read-only mode, you can view messages from the netcon(1M) window, but you cannot enter any commands.

You can specify the netcon(1M) -g option for Unlocked Write permission, -l for Locked Write permission, -f to force Exclusive Session mode, or -r for read-only mode. See TABLE 5-2 for a description of these configuration options and also the netcon(1M) man page for an explanation of how netcon(1M) behaves if you do not specify any of these arguments.
If you have write permission, you can enter commands. In addition, you can enter special commands with the tilde (~) prefix to perform the functions offered by the netcontool(1M) window.

If netcon displays the following message, “netcon_server is not running for domain_name”, the domain may not be up. If it is up, you can run “netcon_server -r &” to restart netcon_server(1M).

▼ To Start netcon(1M) From the Command Line

● Log in to the SSP as user ssp and type:

```
ssp% domain_switch domain_name
ssp% netcon
```

▼ To Start netcon(1M) From the CDE Front Panel

1. From the CDE front panel, select the SSP subpanel and then select the netcon option.
2. Specify the domain name when prompted to do so.

▼ To Start netcon(1M) From the CDE Workspace Menu

1. From the CDE Workspace menu (right click), select the SSP submenu and then select the netcon option.
2. Specify the domain name when prompted to do so.

▼ To Exit From a netcon(1M) Window

● Type a tilde (~) followed by a period in the netcon(1M) window:

```
# ~.
```

The netcon(1M) session is terminated and the window returns to its previous state.
**Note** – If you are logging on remotely to the SSP to run `netcon(1M)`, and depending on the terminal emulation package you are using, the escape sequence of the terminal emulator might be the same as that used to exit from a `netcon(1M)` window. For example, if you enter the tilde period sequence remotely through an `rlogin(1)` session, the `netcon(1M)` session is terminated and the `rlogin(1)` window is terminated as well. If you want to avoid this behavior, you can use the sequence `~.`, that is, tilde tilde period, to exit from a `netcon(1M)` window running inside of an `rlogin(1)` session, without exiting the `rlogin(1)` session.

For more information about escape sequences, see the `netcon(1M)` man page.

### Using `netcontool(1M)`

The `netcontool(1M)` GUI program provides the buttons shown in FIGURE 5-1.

![FIGURE 5-1 netcontool GUI Program](image)

**TABLE 5-1** explains the `netcontool(1M)` buttons.

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Configure</td>
<td>Displays the Console Configuration window. See “To Configure the <code>netcontool(1M)</code> Window” on page 45.</td>
</tr>
<tr>
<td>Connect</td>
<td>Displays the <code>netcon(1M)</code> window and initiates the connection process.</td>
</tr>
<tr>
<td>Disconnect</td>
<td>Disconnects the console window from the domain and removes the console window. The <code>netcontool(1M)</code> window is still available so that you can reconfigure for another connect session.</td>
</tr>
<tr>
<td>OBP/kadb</td>
<td>Breaks to the OpenBoot™ PROM (OBP) or <code>kadb(1M)</code> programs.</td>
</tr>
<tr>
<td>JTAG</td>
<td>Toggles the SSP-to-platform connection between a network connection and a JTAG connection.</td>
</tr>
<tr>
<td>Locked Write, Unlocked Write, and Exclusive Write</td>
<td>Requests the corresponding mode for the console window. For an explanation of the meaning of these modes, see “To Configure the <code>netcontool(1M)</code> Window” on page 45.</td>
</tr>
</tbody>
</table>
To Display a netcontool(1M) Window From the Command Line

- Log in to the SSP as user ssp and type:

```plaintext
ssp% domain_switch domain_name
ssp% netcontool &
```

To Display a netcontool(1M) Window From the CDE Front Panel

1. From the CDE front panel, select the SSP subpanel and then select the netcontool option.
2. Specify the domain name when prompted to do so.

To Display a netcontool(1M) Window From the CDE Workspace Menu

1. From the CDE Workspace menu (right click), select the SSP submenu and then select the netcontool option.
2. Specify the domain name when prompted to do so.

<table>
<thead>
<tr>
<th>Button</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Release Write</td>
<td>Releases write access and places the console in read only mode.</td>
</tr>
<tr>
<td>Status</td>
<td>Displays information about all open consoles that are connected to the same domain as the current session, as well as the connection type currently used.</td>
</tr>
<tr>
<td>Help</td>
<td>Displays information about the netcontool(1M) window.</td>
</tr>
<tr>
<td>Exit</td>
<td>Exits the program and closes the netcon(1M) window if it is still open.</td>
</tr>
</tbody>
</table>
▼ To Display the `netcontool(1M)` Window From Hostview

1. Select a board from the domain for which you want to display a `netcontool(1M)` window by clicking on that board with the left mouse button.

2. Select `Terminal netcontool`.

3. In the `netcontool(1M)` window, click the Connect button.

   The `netcontool(1M)` window (FIGURE 5-2) is displayed beneath the `netcontool(1M)` buttons.

![FIGURE 5-2 netcontool Window in Hostview](image)

▼ To Configure the `netcontool(1M)` Window

1. Click the Configure button if you want to configure the `netcontool(1M)` window before you display a `netcon(1M)` window.

   The Console Configuration window is displayed (FIGURE 5-3).
2. Select the session type in the left panel, and the terminal emulation type in the right panel.
3. When you are satisfied with the contents of the window, click Done to accept the settings and dismiss the window, or click Apply to accept the settings without dismissing the window.

The following table contains the options in the Console Configuration window.

**TABLE 5-2 Console Configuration Options**

<table>
<thead>
<tr>
<th>Console</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Default Session</td>
<td>Causes the default type of session to be started. If no other session is running, the default is unlocked-write mode. If any other session is running, the default is read-only mode.</td>
</tr>
<tr>
<td>Read Only Session</td>
<td>Displays a console window where you can view output from a domain, but you cannot enter commands.</td>
</tr>
<tr>
<td>Unlocked Write Session</td>
<td>Attempts to display a netcon(1M) window with unlocked write permission. If this attempt succeeds, you can enter commands into the console window, but your write permission is taken away whenever another user requests Unlocked Write, Locked Write, or Exclusive Session permission for the same domain.</td>
</tr>
<tr>
<td></td>
<td>• If another user currently has Unlocked Write permission, it is changed to read-only permission, and you are granted Unlocked Write permission.</td>
</tr>
<tr>
<td></td>
<td>• If another user currently has Locked Write permission, you are granted read-only permission.</td>
</tr>
<tr>
<td></td>
<td>• If another user currently has Exclusive Session permission, you are not allowed to display a netcon(1M) window.</td>
</tr>
<tr>
<td></td>
<td>• If you are granted Unlocked Write permission and another user requests Unlocked Write or Locked Write permission, you are notified and your permission is changed to read only. You can attempt to re-establish Unlocked Write permission at any time, subject to the same constraints as your initial attempt to gain Unlocked Write permission.</td>
</tr>
</tbody>
</table>

Chapter 5 netcon and netcontool 47
netcon(1M) Communications

netcon(1M) uses two distinct paths for communicating console input/output between the SSP and a domain: the standard network interface and the CBE interface. Usually, when the domain is up and running, console traffic flows over the network. If the local network becomes inoperable, the communication mode of the netcon(1M) session automatically switches to the Joint Test Action Group (JTAG) protocol through the CBS interface. You can switch to JTAG mode even when the network is inoperable. To perform this switch, use the `~=` command in the netcon(1M) window.

### TABLE 5-2 Console Configuration Options (Continued)

<table>
<thead>
<tr>
<th>Console</th>
<th>Options</th>
</tr>
</thead>
<tbody>
<tr>
<td>Locked Write</td>
<td>Attempts to display a console window with Locked Write permission.* If you are granted Locked Write permission, no other user can remove your write permission unless they request Exclusive Session permission.* If another user currently has Locked Write permission, you are granted read-only permission.* If another user currently has Exclusive Session permission, you are not allowed to display a netcon(1M) window.</td>
</tr>
<tr>
<td>Exclusive Session</td>
<td>Displays a console window with Locked Write permission, terminates all other open console sessions for this domain, and prevents new console sessions for this domain from being started. You can change back to multiple session mode by clicking the Release Write button to release write access, or by clicking the Disconnect button to terminate your console session for the domain. You can also simply quit from the console window (using the Control menu of the window). You are not granted Exclusive Session permission if any other user currently has Exclusive Session permission.</td>
</tr>
<tr>
<td>Terminal Emulation</td>
<td>The netcon(1M) window is brought up in the specified type of window, otherwise it is grayed out. The xterm(1), dtterm(1), shelltool(1), or cmdtool(1) terminal emulators are available.</td>
</tr>
</tbody>
</table>

* The `~=` command is used to switch to JTAG mode.
netcon(1M) Message Logging

Certain messages sent from the kernel are not displayed in the domain syslog messages file, such as OpenBoot messages, panic messages, and some console messages. syslogd on the domain (1M) must run on the domain to log the messages; this is not possible when a panic occurs, nor is it possible at certain times during the boot sequence. Moreover, panic dumps often fail, so these types of messages may not even appear in a dump file to help you determine the cause of the failure.

However, you can capture all output displayed on an active netcon(1M) console through the LOCAL1 facility of syslog(1M). This functionality is enabled through the /etc/syslog.conf file. When enabled, netcon(1M) session output is recorded in file $SSPLOGGER/domain_name/netcon, where $SUNW_HOSTNAME is set to the domain name. By default, this functionality is disabled.

▼ To Enable netcon(1M) Logging

1. In the file /etc/syslog.conf on the SSP, uncomment the local1.debug line.

```
#local1.debug /var/opt/SUNWssp/.ssp_private/machine_server_fifo
```

Uncomment the line by removing the # character from the beginning of the line.

2. Force syslogd to reread its configuration file:

```
ssp# cat /etc/syslog.pid | xargs kill -HUP
```

▼ To Disable netcon(1M) Logging Sessions for Specific Hosts

Once logging of netcon sessions is enabled as shown above, logging can be disabled for specific domains.
● **Start netcon_server with the -S flag for a specific domain.**

```
ssp% domain_switch domain_name
ssp% netcon_server -r -S &
```

The -S flag, to suspend netcon session output, can also be used with bringup, which passes the flag on to netcon_server, for example:

```
ssp% bringup -S
```

Either method disables output for netcon sessions when otherwise enabled with the syslog.conf file.

▼ **To Re-Enable netcon(1M) Logging Sessions for Specific Hosts**

If you have disabled netcon(1M) logging as described in “To Disable netcon(1M) Logging Sessions for Specific Hosts”, you can re-enable netcon(1M) logging.

● **Start netcon_server:**

```
ssp% domain_switch domain_name
ssp% netcon_server -r &
```
Power Administration

This chapter describes how to control the system power resources from within Hostview or from the command line, control the peripherals power resources from the command line, monitor the power levels in Hostview, and recover from power failure.

▼ To Power Components On or Off From Within Hostview

**Note** – If you are powering off a board to replace it, use the `power(1M)` command. Do not use the breakers to power off the board; this can cause an arbstop.

1. Click the left mouse button to select a board in the main Hostview window.
2. Choose Power from the Control menu.
   The Power Control and Status window is displayed (FIGURE 6-1 on page 52).
FIGURE 6-1  Power Control and Status Window

The default `power(1M)` command is displayed in the Command field.

3. Type any `power (1M) command options`.

4. Click the Execute button (or press Return) to run the command.
   The results are shown in the main panel of the window.

5. For information about the `power(1M)` command, click the Help button.
   A help window is displayed. See “Help Window” on page 15.
To Power System Boards On and Off From the Command Line

- To power on system boards, type:

  ```
  ssp% power -on -sb board_list
  ```

  where `board_list` is a list of system boards separated by spaces, such as 3 5 6.

  **Note** – If you are powering off a board to replace it, use the `power(1M)` command. Do not use the breakers to power off the board; this can cause an arbstop.

  After powering on the necessary components, you can run the `bringup(1M)` commands on the SSP for the domains you want to boot. See “To Bring Up a Domain From Within Hostview” on page 32.

- To power off system boards, type:

  ```
  ssp% power -off -sb board_list
  ```

  where `board_list` is a list of system boards separated by spaces, such as 3 5 6.

  For more information, see the `power(1M)` man page.

  If you try to power off the system while any domain is actively running the operating system, the command fails and a message is displayed in the message panel of the window. In this case, you have two choices. You can force a power off by executing the `power(1M)` command again with the `-f` (force) option. Or, you can issue a `shutdown(1M)` or a similar command on the domain for the active domain(s) to gracefully shut down the processors, and then reissue the command to power off. Using `shutdown(1M)` on the domain ensures that all resources are de-allocated and users have time to log out before the power is turned off. To use `shutdown(1M)`, you must be logged in to the domain as superuser.

  If the platform loses power due to a power outage, Hostview displays the last state of each domain before power was lost.

To Monitor Power Levels in Hostview

1. Click the Power button.
The Power Status Display window is displayed (FIGURE 6-3 on page 54).

In FIGURE 6-3, the bulk power supplies are named PS0 through PS15. If you do not have the dual grid power option for the Sun Enterprise 10000 system, you will see 8 power supplies instead of 16 (PS0 through PS7). The system board power modules are numbered 0 through 15. The support board power modules are named CSB0 and CSB1. The control board power modules are named CB0 and CB1.

Power modules can be colored green, red, or gray. A green power module is functioning properly. A red power module has failed. A gray power module is not present.
2. Click on a system board.

The Power Detail window for that board is displayed (FIGURE 6-4 on page 55).

![System Board Power Detail Window](image)

FIGURE 6-4 System Board Power Detail Window

The Power Detail window shows the voltage for each of the five power modules on the board. The power levels are indicated in volts. The bars give a visual representation of the relative voltage levels so that you can monitor them more easily. If a bar is green, the voltage level is within the acceptable range. If a bar is red, the voltage level is either too low or too high. (Thus, a red bar can be short or tall.) The bars never grow taller than the height of the window, so voltage levels that exceed the maximum threshold are displayed as red maximum-height bars. Similarly, bars never shrink below a minimum height, so voltage levels below the minimum threshold are displayed as red minimum-height bars.

The only difference between the detail for a system board and the detail for a control board or support board is the number of power modules.

▼ To Recover From Power Failure

**Note** – If you lose power only on the SSP, switch on the power to the SSP. The Sun Enterprise 10000 domains are not affected by the loss of power. If you lose power to both the SSP and the Sun Enterprise 10000 system, use the following procedure to recover from the power failure.

1. Manually switch off the bulk power supplies on the Sun Enterprise 10000 system and the power switch on the SSP.
   This prevents power surge problems that might occur when power is restored.

2. After power is restored, manually switch on the bulk power supplies on the Sun Enterprise 10000 system.
3. **Manually switch on the SSP power.**
   This boots the SSP and starts the SSP daemons. Check your SSP platform message file for completion of the SSP daemons.

4. **Wait for the recovery process to complete.**
   Any domain that was powered on and running the Solaris operating environment returns to the operating environment run state. Domains at OBP eventually return to an OBP run state.

   The recovery process must finish before any SSP operation is performed. You can monitor the domain message files to determine when the recovery process has completed.
Thermal Conditions Administration

This chapter describes how to administer the thermal conditions and fans from within Hostview and how to monitor and control the fans from within Hostview.

▼ To Monitor Thermal Conditions From Within Hostview

You can use Hostview to monitor thermal conditions for power supplies, processors, ASICs, and other sensors located on system boards, support boards, controller boards, and the centerplane.

1. Click the Temperature button.

![Temperature Button](image)

FIGURE 7-1 Temperature Button

The Thermal Status Display window is displayed (FIGURE 7-2 on page 58). If you do not have the dual grid power option for the Sun Enterprise 10000 system, you will see 8 power supplies instead of 16.
FIGURE 7-2  Thermal Status Display

The centerplane, support boards, control boards, and system boards are shown in green if their temperatures are in the normal range, and in red otherwise.

2. **Click on a component with the left mouse button to see the thermal details about that component.**

   The Thermal Detail window for that component is displayed (FIGURE 7-3 on page 59).
The left panel of the system board detail shows the temperatures for the five ASICs, named A0 through A4. The middle panel shows the temperatures for the three power supplies. The right panel shows the temperatures for the four processors, named P0 through P3.

The temperatures are displayed in degrees centigrade, and the values are shown numerically and as vertical bars. The vertical bars are colored green if the temperature is within the normal range, and red otherwise. The bars never grow taller than the height of the window, so temperature levels above the maximum threshold are displayed as red maximum-height bars. Similarly, bars never shrink below a minimum height, so temperature levels below the minimum threshold are displayed as red minimum-height bars.

The detail windows for control boards, support boards, and the center plane are similar.

\[▼\] To Monitor Fans From Within Hostview

You can use Hostview to monitor fan speeds and fan failures for the 32 fans located throughout the Sun Enterprise 10000 platform.

1. Click on the Fan button.

The Fan Status Display window is displayed (FIGURE 7-5 on page 60). If you do not have the Sun Enterprise 10000 dual grid power option, you will see 8 power supplies instead of 16.
The fan trays are named FT0 through FT7 on the back, and FT8 through FT15 on the front. Each fan tray contains two fans. The color of the fan tray symbol is green if both fans in the tray are functioning at normal speed, amber if both fans are functioning at high speed, and red if either fan within the fan tray has failed.

2. Click on a fan tray symbol with the left mouse button to see a detail window about that fan.

The Fan Tray window is displayed (FIGURE 7-6 on page 61).
FIGURE 7-6  Fan Tray Window

The top circle indicates the inner fan when you open the fan tray, and the lower circle indicates the outer fan. The color surrounding each circle in the fan detail indicates the status of that fan. The colors are green for normal operation at normal speed, amber for normal operation at high speed, and red for failure.
CHAPTER 8

Blacklist Administration

The blacklisting feature enables you to configure the following components out of the system:

- System boards
- Processors
- Address buses
- Data buses
- Data routers
- I/O controllers
- I/O adapter card
- System board memory
- Memory DIMM groups
- Sun Enterprise 10000 half-centerplane
- Port controller ASICs
- Data buffer ASICs
- Coherent interface controller ASICs
- 72-bit half of 144-bit, local, data router within system boards

Generally, you may want to blacklist a component if you believe that component is having intermittent problems, or if it is failing sometime after the system is booted.

If a component has a problem that shows up in the power-on self-test (POST) run by hpost(1M) (which is run by the bringup(1M) command), that component is automatically configured out of the system by hpost(1M). However, that component is not blacklisted. hpost(1M) is run on the components in the system before a domain is booted, and on the components on a given board before that board is attached with Dynamic Reconfiguration (DR). See the Sun Enterprise 10000 Dynamic Reconfiguration User Guide.

To blacklist a component, you can edit the blacklist(4) file with a text editor, or use Hostview. Hostview does not allow you to blacklist all possible components, so there may be times when you need to edit blacklist(4) directly. When a domain
runs POST, \hpost(1M) reads the \texttt{blacklist(4)} file and automatically excludes the components specified in that file. Thus, changes that you make to the \texttt{blacklist(4)} file do not take effect until the domain is rebooted.

The file is \texttt{$SSPVAR/etc/platform\_name/blacklist}, where \texttt{platform\_name} is the name of the platform. See the \texttt{blacklist(4)} man page for information about the contents of the \texttt{blacklist(4)} file.

\section*{To Blacklist Components From Within Hostview}

1. Choose \texttt{Blacklist File} from the \texttt{Edit} menu.

   The Blacklist Edit window is displayed (FIGURE 8-1).

\begin{center}
\includegraphics[width=\textwidth]{Blacklist_Edit_Window.png}
\end{center}

\textbf{FIGURE 8-1} Blacklist Edit Window—Board View
2. Select the boards and/or buses that you want to place onto the blacklist.

   To select a single component and deselect all other components of that type (for example, to select a single board and deselect all other boards), click on that component with the left mouse button. To toggle the selection status of a single component without affecting the selection status of any other component, click on that component with the middle mouse button. The selected components are displayed in black.

3. To save the changes, choose Save from the File menu.

4. To exit the Blacklist Edit window, choose Close from the File menu.

   If you have unsaved changes and you close the Blacklist Edit window by choosing Close from the File menu, you are prompted to save the changes.

▼ To Blacklist Processors From Within Hostview

1. Choose Blacklist File from the Edit menu.

   The Blacklist Edit window is displayed.

2. From the Blacklist Edit window, choose Processors from the View menu.

   The Blacklist Edit window displays the Processor View window (FIGURE 8-2).
3. Select the processors that you want to add to the blacklist.

To select a single processor on a board and deselect all other processors on that board, click on that processor with the left mouse button. To toggle the selection status of a processor on a board without affecting the selection status of any other processors on that board, click on that processor with the middle mouse button. The selected processors are displayed in black.

4. To save the changes, choose Save from the File menu.

5. To exit the Blacklist Edit window, choose Close from the File menu.

If you have unsaved changes and you close the Blacklist Edit window by choosing Close from the File menu, you are prompted to save the changes.
To Clear the Blacklist File From Within Hostview

1. In Hostview, choose Blacklist File from the Edit menu.
2. From the Blacklist Edit window, choose New from the File menu.
3. From the Blacklist Edit window, choose Close from the File menu.
CHAPTER 9

Using a Spare SSP

The SSP is a Sun workstation or Sun server with a defined hardware configuration. You can use a SPARCstation 5, Sun Ultra 5, or Sun Enterprise 250 workstation or server as an SSP. You can also use one of these systems as a spare SSP to serve as a backup if your main SSP fails. In addition, you can order a Sun Enterprise 10000 server with a spare SSP.

Note – The SPARCstation 5 supports up to eight domains. If you plan to use nine or more domains, your main and spare SSP must be a Sun Ultra 5 or a Sun Enterprise 250 workstation or server.

Maintain a spare SSP in a ready state. This allows you to quickly switch to the spare SSP if the main SSP fails. Do not run any third party software on the spare SSP machine.

To maintain a spare SSP, you must adhere to the following requirements:

- The spare SSP must be properly configured to function in the same way as the main SSP within the network.
- The main and spare SSP must run SSP 3.3 if you are using nine or more domains and the Sun Enterprise 10000 dual power grid option.
- You must not install or use any third party software on the spare SSP.
- Any changes that you make to the main SSP must be made to the spare SSP as well. After any system configuration operation, you must immediately run `ssp_backup(1M)` on the main SSP. If the main SSP crashes, you will have a backup file that you can restore to the spare SSP by running the `ssp_restore(1M)`. See “To Switch Between the Main and Spare SSP” on page 70 and the `ssp_backup(1M)` and `ssp_restore(1M)` man pages in the Sun Enterprise 10000 SSP 3.3 Reference Manual.
To Switch Between the Main and Spare SSP

Note – It is recommended that SSP 3.3 be installed on both the main and spare SSP. If you need to upgrade your main and spare SSP to SSP 3.3, or you need to revert your main and spare SSP to a previous version of SSP, see the Sun Enterprise 10000 SSP 3.3 Installation Guide and Release Notes.

1. Verify that the main SSP is correctly configured for switching to the spare SSP.
   If the main SSP is running SSP 3.3 and the spare SSP is running SSP 3.1.1 and you are using IDN on the main SSP, you must do the following before switching to the spare SSP:
   a. On the main SSP, unlink all IDN domains.
      See domain_unlink(1M).
   b. On the domains, remove all /etc/hostname.idnx files, where x is an integer.
   c. On each IDN domain, halt the domain and set the idn-smr-size environment variable to zero.
   d. Reboot the domains you halted in Step c.
      Refer to the Sun Enterprise 10000 InterDomain Network User Guide.

2. Change the main SSP to a spare SSP:
   a. Log in to the main SSP as superuser and type:

      ssp# /opt/SUNWssp/bin/ssp_backup backup_dir

      This command backs up the SSP configuration information to the file backup_dir/ssp_backup.cpio.

   b. Configure the spare SSP by typing:

      ssp# /opt/SUNWssp/bin/ssp_config
      Beginning setup of this workstation to act as a MAIN or SPARE SSP.
      Are you currently configuring the MAIN SSP? (y/n)n
      SPARE SSP configuration completed.
      ssp#

3. Change the spare SSP to a main SSP:
   a. Log in to the spare SSP as superuser.
b. Restore the ssp_backup.cpio file that you created in Step 2:

```
ssp# /opt/SUNWssp/bin/ssp_restore backup_dir/ssp_backup.cpio
```

where backup_dir is the directory in which the backup file is located.

**Note** – Do not change the SSP environment between the time you run ssp_backup(1M) and ssp_restore(1M). For example, after you run ssp_backup(1M), do not shut down a domain, bring up a domain, or power boards on or off until you run ssp_restore(1M).

c. Change the spare SSP to be the main SSP by typing:

```
ssp# /opt/SUNWssp/bin/ssp_config spare
```

Configuring the spare SSP to control the Host

Beginning set up of the SPARE SSP workstation to control the host.

Platform name = allxf4
Control board 0 = xf4-cb0 => 129.153.151.123
Control board 1 = xf4-cb1 => 129.153.152.123
Primary Control Board = 0

Is this correct? (y/n) **y**

This SPARE SSP is NOW configured to control the host.

This machine is the MAIN SSP now.

**Note** – Verify that all SSP daemons have started before proceeding.

4. For each domain on the host, perform the following steps.

If a domain is down when you perform this procedure, the console window may be unusable after the domain is brought up by the spare SSP. If the console is unusable, perform these steps using an rlogin or telnet session.

a. From the new main SSP, or from another workstation on the network, rlogin to the domain as superuser.
b. Edit the `/etc/ssphostname` file to replace the hostname of the main SSP with the hostname of the spare SSP.

For example, if your main SSP is called `xf4-ssp` and your spare SSP is called `xf4-ssp2`, change the contents of `/etc/ssphostname` to `xf4-ssp2`.

c. Switch console communication from the main SSP to the spare SSP:

```
# ps -ef | grep cvcd
# kill -9 cvcd_pid
# cvcd_path/cvcd
```

where `cvcd_path` is `/sbin` under the Solaris 2.6 operating environment, and `cvcd_path` is `/platform/SUNW,Ultra-Enterprise-10000/lib/cvcd` under the Solaris 7 and Solaris 8 operating environments.

d. If needed, update the `/etc/syslog.conf` file on each domain to replace the hostname of the main SSP with the hostname of the spare SSP.
Dual Control Board Handling

A platform can be configured with dual control boards for redundancy purposes. Although you can manually switch between the control boards, only one control board at a time is used by the system.

One of the control boards is identified as the primary control board. The SSP attempts to communicate only with the primary control board. If you decide that it is necessary to switch the primary control board because of a connection failure or for other reasons, you must modify the control board configuration (using the \texttt{ssp\_config} (1M) command) and restart SSP processes to activate the new primary control board. Note that this operation cannot be performed without rebooting all running domains because the control board provides the system clocks for all boards.

Control Board Executive

The control board executive (CBE) runs on the control board and facilitates communication between the SSP and the platform.

When power is applied, both control boards boot from the main SSP. After the CBE is booted, it waits for the control board server running on the SSP to establish a connection.
Primary Control Board

When the control board server running on the SSP connects to the CBE running on a control board, the CBE asserts the control board as the primary control board. The primary control board is responsible for providing the system clock and JTAG clock and for controlling fan trays and bulk power supplies.

Control Board Server

After the SSP is booted, the control board server (CBS), is started automatically. The CBS is responsible for all communication between the SSP and the primary control board.

The CBS attempts to connect only to the primary control board identified in the control board configuration file. The format of the file is as follows:

```
platform_name:platform_type:cb0_hostname:status0:cb1_hostname:status1
```

where:

- `platform_name` is the name assigned by the system administrator.
- `platform_type` is defaulted to `Ultra-Enterprise-10000`.
- `cb0_hostname` is the host name for control board 0, if available.
- `status0` indicates that control board 0 is the primary control board (P indicates primary, and anything else indicates non-primary).
- `cb1_hostname` is the host name for control board 1, if available.
- `status1` indicates that control board 1 is the primary control board.

For example:

```
xf2:Ultra-Enterprise-10000:xf2-cb0:P:xf2-cb1:
```

This example indicates that there are two control boards in the xf2 platform. They are xf2-cb0 and xf2-cb1. xf2-cb0 is specified as the primary. See the `cb_config(4)` man page for more information.
The communication port that is used for communication between the control board server and the control board executive is specified in
/tftpboot/xxxxxxx.cb_port where xxxxxxxx is the control board IP address represented in hexadecimal format.

Control Board Executive Image and Port Specification Files

The main SSP is the boot server for the control board. Two files are downloaded by the control board boot PROM during boot time: the image of CBE and the port number specification file. These files are located in /tftpboot on the SSP and the naming conventions are:

/tftpboot/xxxxxxx for the cbe image
/tftpboot/xxxxxxx.cb_port for the port number

where xxxxxxxx is the control board IP address in hex format.

For example, the files for control board xf2-cb0 are:

/tftpboot/81973213
/tftpboot/81973213.cb_port

If you are using NIS, the IP address of xf2-cb0 can be determined as follows:

```
% ypcat hosts | grep xf2-cb0
```

The returning address is 129.153.49.147. This can be converted to 81993193.

▼ To Switch the Primary Control Board

Caution – Do not edit the /var/opt/SUNWssp/.ssp_private/cb_config file manually. Instead, use the ssp_config(1M) command as described below. Otherwise, your domains may fail and arbitration stops (arbstops) may occur.

1. If any domains are running, shut down those domains using the standard shutdown(1M) command.
2. Log in to the main SSP as ssp.
3. Power off all of the system boards.

   ssp% power -off -all

4. Power on all of the system boards.

   ssp% power -on -all

5. Log in to the main SSP as superuser.

6. Obtain the host names and IP addresses for the two control boards.

7. Verify that control board IP addresses are set up properly in the
   /etc/inet/hosts file or in your local name service system.

8. As superuser, type: /opt/SUNWssp/bin/ssp_config cb
   In this sample session, the primary control board is switched from snax-cb0 to
   snax-cb1.

   ssp# /opt/SUNWssp/bin/ssp_config cb
   Configuring control boards.
   Platform name   = snax
   Control Board 0 = snax-cb0 => 129.153.49.181
   Control Board 1 = snax-cb1 => 129.153.49.182
   Primary Control Board = 0
   Is this correct? (y/n): n
   Do you have a control board 0? (y/n): y
   Please enter the host name of the control board 0 [snax-cb0]:
   Do you have a control board 1? (y/n): y
   Please enter the host name of the control board 1 [snax-cb0]:

   Please identify the primary control board.
   Is Control Board 0 [snax-cb0] the primary? (y/n) n
   Is Control Board 1 [snax-cb1] the primary? (y/n) y

   Platform name   = snax
   Control Board 0 = snax-cb0 => 129.153.49.181
   Control Board 1 = snax-cb1 => 129.153.49.182
   Primary Control Board = 1
   Is this correct? (y/n): y
Note – The platform name identifies the *entire host machine*, not a particular domain.

9. Restart the main SSP processes.
   a. As superuser, type:

   ```bash
   ssp# /etc/init.d/ssp stop
   ssp# /etc/init.d/ssp start
   ```

   b. Log in to the SSP as user `ssp` and type:

   ```bash
   ssp% tail -f $SSPLOGGER/messages
   ```

   Wait until you see the following message:

   ```
   Startup of SSP programs complete
   ```

10. Start Hostview:

    ```bash
    ssp% hostview &
    ```

    Verify that the “J” and “C” symbols are shown on the symbol for the new primary control board in the main Hostview screen. This indicates that the JTAG connection and clock distribution signals are coming from the new primary control board.

    If Hostview fails to respond, verify that you can communicate with the new primary control board. If you are unable to use `ping(1M)` to communicate with the new primary control board, visually examine the LEDs to verify that the new primary control board is operating correctly. For example, verify that the link integrity LED is on. This indicates that the Ethernet connection is good. If the LEDs are cycling through a pattern, the new primary control board is booted. If the LEDs are all off or all on continuously (without cycling through a pattern), the new primary control board is not booted. Try running `snoop(1M)` on the SSP to verify that the control boards are communicating correctly.

11. If you have a spare SSP, repeat Step 6 through Step 8 above, on the spare SSP.

12. Issue the `bringup(1M)` command for all domains.
SSP Internals

SSP operations are generally performed by a set of daemons and commands. This chapter provides an overview of how the SSP works and describes the SSP 3.3 daemons, processes, commands, and system files. For more information about daemons, commands, and system files, refer to the *Sun Enterprise 10000 SSP 3.3 Reference Manual*.

**Caution** – Changes made to files in `/opt/SUNWssp` can cause serious damage to the system.

### Startup Flow

The events that take place when the SSP boots are as follows:

1. User powers on the SSP (monitor, CPU/disk, and CD-ROM). The SSP boots automatically.

2. During the SSP boot process, the `/etc/rc2.d/s99ssp` startup script is called when the system enters run level 2. This script starts `ssp_startup`.

3. `ssp_startup` starts the SSP daemons: `machine_server`, `fad`, `cbs`, `straps`, `snmpd`, and `edd`. It also calls `cb_reset` to start control board initialization.

4. `edd` initiates event monitoring on the Sun Enterprise 10000 system control board, waits for an event to be generated by the event detection task running on the control board, and then responds to the event by running a response action script on the SSP.

5. After the `ssp_startup` complete message is displayed, you can use SSP 3.3 commands such as `domain_create` or `bringup`. 
The SSP uses the event detector daemon, `edd(1M)`, to monitor the Sun Enterprise 10000 system. Each time the SSP boots, it runs `/etc/rc2.d/S99ssp` which in turn loads `edd(1M)` through the startup script, `$SSPETC/ssp_startup.sh`. The startup script checks the environment for availability of certain files and the availability of the Sun Enterprise 10000 system, sets environment variables, and then starts `edd(1M)`. `edd(1M)` obtains many of its initial control parameters from the following configuration files:

- `$SSPVAR/etc/platform_name/edd.erc` provides configuration information for the Sun Enterprise 10000 platform.
- `$SSPVAR/etc/platform_name/domain_name/edd.erc` provides configuration information for a particular domain. The event response configuration files (`edd.erc`) specify how the event detector will respond to events.
- `$SSPVAR/etc/platform_name/edd.emc` lists the events that `edd(1M)` will monitor.

If a domain crashes, `edd(1M)` invokes the `bringup(1M)` script. The `bringup(1M)` script runs the POST program, which tests Sun Enterprise 10000 components. It then uses the `obp_helper(1M)` daemon to download and begin execution of OBP in the domain specified by the `SUNW_HOSTNAME` environment variable. This happens only if a domain fails (for example, after a kernel panic) in which case it is rebooted automatically. After a halt or shutdown, you must manually run `bringup(1M)`, which then causes OBP to be downloaded and run.

`obp_helper(1M)` is responsible for loading `download_helper` in all the configured processors’ bootbus SRAM. All the processors are started, with one processor designated as the boot processor. With the assistance of `download_helper`, `obp_helper(1M)` loads OBP into the memory of the Sun Enterprise 10000 system and starts OBP on the boot processor. See “OBP Daemon” on page 88 for more information about `obp_helper(1M) and OBP`.

The primary task of OBP is to boot and configure the operating system from either a mass storage device or from a network. OBP also provides extensive features for testing hardware and software interactively. As part of the boot procedure, OBP probes all the SBus slots on all the system boards and builds a device tree. This device tree is passed on to the operating system.
Sun Enterprise 10000 Client/Server Architecture

The Sun Enterprise 10000 system control board interface is accessed over an Ethernet connection using the TCP/IP protocol. The control board executive, CBE, runs on the control board. The control board server, cbs(1M), runs on the SSP and makes service requests. The SSP control board server provides services to SSP clients.

FIGURE 11-1 illustrates the Sun Enterprise 10000 system client/server architecture:
Note – There is one instance of edd(1M) for the platform supported by the SSP. There is one instance of obp_helper(1M) and netcon_server(1M) for each domain on the platform.

POST

Power-on self-test (POST) probes and tests the components of uninitialized Sun Enterprise 10000 system hardware, configures what it deems worthwhile into a coherent initialized system, and hands it off to OpenBoot PROM (OBP). POST passes to OBP a list of only those components that have been successfully tested; those in the blacklist(4) file are excluded.

hpost(1M) is the SSP-resident executable program that controls and sequences the operations of POST. hpost(1M) reads directives in the optional file .postrc (see postrc(4)) before it begins operation with the host.

Caution – Running hpost(1M) outside of the bringup(1M) command can cause the system to fail. hpost(1M), when run by itself, does not check the state of the platform, and causes fatal resets.

POST looks at blacklist(4), which is on the SSP, before preparing the system for booting. blacklist(4) specifies the Sun Enterprise 10000 components that POST must not configure.

POST stores the results of its tests in an internal data structure called a board descriptor array. The board descriptor array contains status information for most of the major components of the Sun Enterprise 10000 system, including information about the UltraSPARC™ modules.

POST attempts to connect and disconnect each system board, one at a time, to the system centerplane. POST then connects all the system boards that passed the tests to the system centerplane.
Daemons

The SSP 3.3 daemons play a central role on the SSP. Each daemon is fully described in its corresponding man page. The following table briefly describes the daemons.

**TABLE 11-1  Daemons**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>cbs</td>
<td>The control board server provides central access to the Sun Enterprise 10000 control board for client programs running on the SSP.</td>
</tr>
<tr>
<td>edd</td>
<td>The event detector daemon initiates event monitoring on the control boards. When a monitoring task detects an event, edd(1M) runs a response action script.</td>
</tr>
<tr>
<td>fad</td>
<td>The file access daemon provides distributed file access services to SSP clients that need to monitor, read, and write to the SSP configuration files.</td>
</tr>
<tr>
<td>machine_server</td>
<td>Routes platform and domain messages to the proper messages file. See machine_server(1M).</td>
</tr>
<tr>
<td>netcon_server</td>
<td>The connection point for all netcon(1M) clients. netcon_server(1M) communicates with OBP using a control board protocol. netcon_server(1M) communicates with the OS using the TCP protocol.</td>
</tr>
<tr>
<td>obp_helper</td>
<td>Runs OpenBoot. obp_helper(1M) terminates when OBP is terminated. During execution, obp_helper(1M) provides services to OBP, such as NVRAM simulation, IDPROM simulation, and time of day.</td>
</tr>
<tr>
<td>snmpd</td>
<td>The SNMP proxy agent listens to a UDP port for incoming requests and services the group of objects specified in Ultra-Enterprise-10000.mib.</td>
</tr>
<tr>
<td>straps</td>
<td>The SNMP trap sink server listens to the SNMP trap port for incoming trap messages and forwards received messages to all connected clients.</td>
</tr>
<tr>
<td>xntpd / ntpd</td>
<td>The network time protocol (NTP) daemon provides time synchronization services. (ntpd is the daemon for the Solaris 2.6, 7, and 8 operating environments.) Clients can connect to this service and have their clocks automatically adjusted. This service is used to synchronize SSP and domain times. See xntpd(1M) and the Network Time Protocol User’s Guide.</td>
</tr>
</tbody>
</table>
Event Detector Daemon

The event detector daemon, \texttt{edd(1M)}, is a key component in providing the reliability, availability, and serviceability (RAS) features of Sun Enterprise 10000 system. \texttt{edd(1M)} initiates event monitoring on the Sun Enterprise 10000 control board, waits for an event to be generated by the event detection monitoring task running on the control board, and then responds to the event by executing a response action script on the SSP. The conditions that generate events and the response taken to events are fully configurable.

\texttt{edd(1M)} provides the mechanism for event management, but does not handle the event detection monitoring directly. Event detection is handled by an event monitoring task that runs on the control board. \texttt{edd(1M)} configures the event monitoring task by downloading a vector that specifies the event types to be monitored. Event handling is provided by response action scripts, which are invoked on the SSP by the \texttt{edd(1M)} when an event is received.

The RAS features are provided by several collaborative programs. The control board within the platform runs a control board executive (CBE) program that communicates through the Ethernet with a control board server (\texttt{cbs(1M)}) program on the SSP. These two components provide the data link between the platform and the SSP.

The SSP provides a set of interfaces for accessing the control board through the control board server and the simple network management protocol (SNMP) agent. \texttt{edd(1M)} uses the control board server interface to configure the event detection monitoring task on the control board executive (FIGURE 11-2).

![FIGURE 11-2 Uploading Event Detection Scripts](image)

After it is configured, the event detection monitoring task polls various conditions within the platform, including environmental conditions, signature blocks, power supply voltages, performance data, and so forth. If an event detection script detects a change of state that warrants an event, an event message containing the pertinent information is generated and delivered to the control board server (\texttt{cbs(1M)})
running on the SSP. Upon receipt of the event message, the control board server delivers the event to the SNMP Agent, which in turn generates an SNMP trap (FIGURE 11-3).

**FIGURE 11-3  Event Recognition and Delivery**

Upon receipt of an SNMP trap, `edd(1M)` determines whether to initiate a response action. If a response action is required, `edd(1M)` runs the appropriate response action script as a subprocess (FIGURE 11-4).

**FIGURE 11-4  Response Action**

Event messages of the same type or related types can be generated while the response action script is running. Some of these secondary event messages may be meaningless or unnecessary if a responsive action script is already running for a similar event; for example, if `edd(1M)` is running a response action script for a high-temperature event. While the response action script is running, additional high temperature events can be generated by the event monitoring scripts. `edd(1M)` does not respond to those high temperature events (generated in response to the same
high temperature condition) until the first response script has finished. It is the responsibility of applications (such as eda(1M)) to filter the events they will respond to as necessary. The cycle of event processing is completed at this point.

Control Board Server

The control board server (CBS) is a server that runs on the SSP. Whenever a client program running on the SSP needs to access the Sun Enterprise 10000 system, the communication is funneled through cbs(1M). cbs(1M), in turn, communicates directly with a control board Executive (CBE) running on one of the control boards in the Sun Enterprise 10000 system. cbs(1M) converts client requests to the control board management protocol (CBMP) that is understood by CBE. The following diagram (FIGURE 11-5) shows how the CBS and CBEs are connected.

![Diagram showing CBS communication between SSP and Sun Enterprise 10000 System]

FIGURE 11-5 CBS Communication Between SSP and Sun Enterprise 10000 System

cbs(1M) relies on the cb_config(4) file to determine the platform it is to manage, and the control board with which it is to interact. The cb_config(4) file specifies the platforms managed by the SSP. Do not directly modify this file; it is automatically maintained by domain management tools and commands. To make a control board change, use ssp_config(1M) with the cb option.
File Access Daemon

The file access daemon (fad(1M)) is used when ssp_to_domain_hosts(4) or any other configuration file is updated. fad(1M) provides distributed file access services, such as file locking, to all SSP clients that need to monitor, read, and write changes to SSP configuration files. Once a file is locked by a client, other clients are prevented from locking that file until the first client releases the lock.

Network Time Protocol Daemon

The NTP daemon (xntpd(1M) for the Solaris 2.6, 7, and 8 operating environments) provides a mechanism for keeping the time settings synchronized between the SSP and the domains. OBP obtains the time from the SSP when the domain is booted, and NTP keeps the time synchronized from that point on.

The configuration is based on information provided by the system administrator. If the Sun Enterprise 10000 system is not currently running in an NTP subnet, does not have access to the Internet, and is not going to use a radio clock, you can set up the Sun Enterprise 10000 system to use its own internal time-of-day clock as the reference clock. Usually, however, the SSP uses its internal time-of-day clock for the Sun Enterprise 10000 system.

The NTP packages are compiled with support for a local reference clock. This means that your system can poll itself for the time instead of polling another system or network clock. The poll is done through the network loopback interface. The first three numbers in the IP address are 127.127.1. The last numbers in the IP address are the NTP stratum to use for the clock.

When setting up the SSP and domains, set the SSP to stratum 4. Set up the domains as peers to the SSP and set the local clock two stratums higher.

An example of server/peer lines in the /etc/opt/SUNWxntp/ntp.conf file on the SSP is shown below.

```
server 127.127.1.0
fudge 127.127.1.0 stratum 8
```

You can add lines similar to the following in the /etc/inet/ntp.conf file on the domains:

```
peer ssp_name
server 127.127.1.0
fudge 127.127.1.0 stratum 10
```
For more information on the NTP daemon, refer to the *Network Time Protocol User’s Guide* and the *NTP Reference Manual*.

## OBP Daemon

On the SSP, OpenBoot (OBP) is not a hardware PROM; it is loaded from a file on the SSP. An SSP file also replaces the traditional OBP NVRAM and idprom (hostid).

The OBP file is located under a directory path that is specific to the SunOS release. SunOS 5.6 corresponds to the Solaris 2.6 operating environment, SunOS 5.7 corresponds to the Solaris 7 operating environment, and SunOS 5.8 corresponds to the Solaris 8 operating environment. You can determine your SunOS version with `uname -r`. For example, under SunOS 5.7, the OBP file is located in the following directory:

```
/opt/SUNWssp/release.Ultra-Enterprise-10000/5/7/hostobjs/obp
```

where the `/5/7` portion of the path corresponds to the SunOS version number. If your release contains a different version of the operating system, that portion of the path will be different.

`bringup(1M)` starts `obp_helper(1M)` in the background, which kills the previous `obp_helper(1M)`, if one exists. `obp_helper(1M)` runs `download_helper` and subsequently downloads and runs OBP.

`obp_helper(1M)` is essential in starting processors other than the boot processor. It communicates with OBP through bootbus SRAM (BBSRAM), responding to requests to supply the time-of-day, get or put the contents of the pseudo-EEPROM, and release slave processors when in multiprocessor mode. To release the slave processors, `obp_helper(1M)` must load `download_helper` into the BBSRAM of all the slave processors, place an indication in BBSRAM that it is a slave processor, then start the processor by releasing the bootbus controller reset.

For more information, see the `obp_helper(1M)` and `bringup(1M)` man pages and “download_helper File” on page 90.
Environment Variables

Most of the necessary environment variables are set when the ssp user logs in. TABLE 11-2 describes the environment variables.

TABLE 11-2 Environment Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SUNW_HOSTNAME</td>
<td>The name of the domain controlled by the SSP. You set this variable to the hostname of the domain on which you are performing operations.</td>
</tr>
<tr>
<td>SSPETC</td>
<td>The path to the directory containing miscellaneous SSP-related files. You should never change the value of this environment variable.</td>
</tr>
<tr>
<td>SSPLOGGER</td>
<td>The location of the configuration file for message logging. You should never change the value of this environment variable.</td>
</tr>
<tr>
<td>SSPOPT</td>
<td>The path to the SSP package binaries, libraries, and object files. You should never change the value of this environment variable.</td>
</tr>
<tr>
<td>SSPVAR</td>
<td>The path to the directory where modifiable files reside. You should never change the value of this environment variable.</td>
</tr>
</tbody>
</table>

Executable Files Within a Domain

The executable files that are run on the domains reside in the /opt/SUNWssp/release/Ultra-Enterprise-10000/os_version directory. The man pages for these programs reside within the domain.

Some of the commands listed in this section must be used or modified only by your service provider; they are normally called internally by other programs rather than run on the command line.

Caution – Improper use of these commands can result in failure or damage to the system. If you are not sure of the function of any command, contact your service provider for assistance.
*.elf Files

These are executable files that are downloaded by hpost(1M).

download_helper File

download_helper enables programs to be downloaded to the memory used by a domain instead of BBSRAM. This provides an environment in which host programs can run without having to know how to relocate themselves to memory. These programs can be larger than BBSRAM.

download_helper works by running a protocol through a mailbox in BBSRAM. The protocol has commands for allocating and mapping physical to virtual memory, and for moving data between a buffer in BBSRAM and virtual memory. When complete, the thread of execution is usually passed to the new program at an entry point provided by the SSP. After this occurs, download_helper lives on in BBSRAM so it can provide reset handling services. Normally, you do not need to be concerned with the download helper; it is used only by the obp_helper(1M) daemon. See the obp_helper(1M) man page for more information.

obp File

The obp file is fundamental to the boot process of a domain. OBP knows how to probe the SBus to determine which devices are connected where, and provides this information to the operating system in the form of a device tree. The device tree is ultimately visible using the command prtconf (for more information, see the SunOS prtconf(1M) man page).

obp also interprets and runs FCode on SBus cards, which provides loadable, simple drivers for accomplishing boot. In addition, it provides a kernel debugger, which is always loaded.
### Glossary

<table>
<thead>
<tr>
<th>Term</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Alternate Pathing (AP)</strong></td>
<td>AP enables you to set up an alternate path to system components in case of failure, repair, or replacement.</td>
</tr>
<tr>
<td><strong>AP</strong></td>
<td>See Alternate Pathing (AP).</td>
</tr>
<tr>
<td><strong>application specific integrated circuit (ASIC)</strong></td>
<td>In the Sun Enterprise 10000 system, any of the large main chips in the design, including the UltraSPARC processor and data buffer chips.</td>
</tr>
<tr>
<td><strong>arbitration stop</strong></td>
<td>A condition that occurs when one of the Sun Enterprise 10000 system ASICs detects a parity error or equivalent fatal system error. Bus arbitration is frozen, so all bus activity stops. The system is down until the SSP detects the condition by polling the Control and Status Registers CSRs of the Address Arbiter ASICs through JTAG, and clears the error condition.</td>
</tr>
<tr>
<td><strong>ASIC</strong></td>
<td>See application specific integrated circuit (ASIC).</td>
</tr>
<tr>
<td><strong>Automated Dynamic Reconfiguration (ADR)</strong></td>
<td>The dynamic reconfiguration of system boards accomplished through commands that can be used to automatically attach, move, or detach system boards and obtain board status information. You can run these commands interactively or in shell scripts.</td>
</tr>
<tr>
<td><strong>BBSRAM</strong></td>
<td>See bootbus SRAM (BBSRAM).</td>
</tr>
<tr>
<td><strong>blacklist</strong></td>
<td>A text file that <code>hpost(1M)</code> reads when it starts up. The blacklist file specifies the Sun Enterprise 10000 system components that are not to be used or configured into the system. The default path name for this file can be overridden in the <code>.postrc</code> file (see <code>postrc(4)</code>) and on the command line.</td>
</tr>
</tbody>
</table>
**board descriptor array**
The description of the single configuration that `hpost(1M)` chooses. It is part of the structure handed off to OBP.

**bootbus**
A slow-speed, byte-wide bus controlled by the processor port controller ASICs, used for running diagnostics and boot code. UltraSPARC starts running code from bootbus when it exits reset. In the Sun Enterprise 10000 system, the only component on the bootbus is the BBSRAM.

**bootbus SRAM (BBSRAM)**
A 256-Kbyte static RAM attached to each processor PC ASIC. Through the PC, it can be accessed for reading and writing from JTAG or the processor. Bootbus SRAM is downloaded at various times with `hpost(1M)` and OBP startup code, and provides shared data between the downloaded code and the SSP.

**control and status register (CSR)**
A general term for any embedded register in any of the ASICS in the Sun Enterprise 10000 system.

**CSR**
See control and status register (CSR).

**DIMM**
See dual in-line memory module (DIMM).

**domain**
A set of one or more system boards that acts as a separate system capable of booting the OS and running independently of any other domains.

**DRAM**
See dynamic RAM (DRAM).

**dual in-line memory module (DIMM)**
A small printed circuit card containing memory chips and some support logic.

**dual power grid**
Redundant power supplies on the Sun Enterprise 10000 system. The power supplies are divided into two grids, with each grid wired to independent AC sources. Up to 8 power supplies are available for each grid, for a total of 16 power supplies.

**dynamic RAM (DRAM)**
Hardware memory chips that require periodic rewriting to retain their contents. This process is called “refresh”. In the Sun Enterprise 10000 system, DRAM is used only on main memory SIMMs and on the control boards.

**Dynamic Reconfiguration (DR)**
The logical attachment and detachment of system boards to and from the operating system without causing machine downtime. This feature is used to add a new system board, reinstall a repaired system board, or modify the domain configuration on the Sun Enterprise 10000 system.

**Ecache**
See external cache (Ecache).
external cache (Ecache) A 0.5-Mbyte to 4-Mbyte synchronous static RAM second-level cache local to each processor module. Used for both code and data. This is a direct-mapped cache.

JTAG A serial scan interface specified by IEEE standard 1149.1. The name comes from Joint Test Action Group, which initially designed it. See JTAG+.

JTAG+ An extension of JTAG, developed by Sun Microsystems Inc., which adds a control line to signal that board and ring addresses are being shifted on the serial data line. Often referred to simply as JTAG.

InterDomain Networks (IDN) High-speed networking supported between dynamic system domains within a single Sun Enterprise 10000 platform. Domains can communicate with each other using standard networking interfaces, such as Transmission Control Protocol/Internet Protocol (TCP/IP).

OBP See OpenBoot PROM (OBP).

OpenBoot PROM (OBP) A layer of software that takes control of the configured Sun Enterprise 10000 system from hpost(1M), builds some data structures in memory, and boots the operating system.

POST See power-on self-test.

power-on self-test (POST) A test performed by hpost(1M). This is the program that takes uninitialized Sun Enterprise 10000 system hardware and probes and tests its components, configures what seems worthwhile into a coherent initialized system, and hands it off to OBP.

.postrc A text file that controls options in hpost(1M). Some of the functions can also be controlled from the command line. Arguments on the command line take precedence over lines in the .postrc file, which takes precedence over built-in defaults. hpost -- ? postrc gives a terse reminder of the .postrc options and syntax. See postrc(4).

SBus A Sun Microsystems Inc. designed I/O bus, now an open standard.

SRAM See static RAM (SRAM).

static RAM (SRAM) Memory chips that retain their contents as long as power is maintained.

SSP See System Service Processor (SSP).
<table>
