Index 105
Preface

The Federated Naming Service (FNS) is new to the Solaris™ product family. FNS is a set of application programming interfaces and policies that allow applications to use a common set of names and policies over different name services.

FNS is not a replacement for NIS+, the network name service included in the Solaris software environment. Rather, FNS is implemented on top of NIS+ and allows you to use a set of common names with desktop applications. Sun’s implementation of FNS conforms to the X/Open™ federated naming (XFN) specification.

Who Should Use This Book

The primary audience of Federated Naming Service Guide is software developers who write distributed applications. Use of this guide assumes basic competence in programming, a working familiarity with the C programming language, and a working familiarity with the UNIX® operating system. Developers should read all four parts of this manual.

System and network administrators should look at Solaris Naming Setup and Configuration Guide for FNS setup and configuration information. Information on FNS administration is in Solaris Naming Administration Guide. This manual does not cover NIS+ or the Domain Name System (DNS) except as they relate to FNS.

How This Book Is Organized

Chapter 1 is a high-level overview of FNS and the problems it addresses.
Chapter 2 describes the client programming interfaces for X/Open Federated Naming (XFN).

Chapter 3 presents three self-contained executable programs: a namespace browser, a printer client and server, and a tool to populate attributes of users.

Appendixes

Appendix A describes the XFN composite name string syntax and the resolution techniques for composite names.

Appendix B gives supplemental information about composite name syntax.

Related Books

With the exception of the XFN specification, the following books do not specifically cover FNS but they provide a good background on how name services work in client-server computing:

- P. Albitz and C. Liu. DNS and BIND. O’Reilly, 1992

You may also want to reference the following AnswerBook® on-line documentation:

Introduction to the Federated Naming Service (FNS)

This chapter is an overview of the Federated Naming Service (FNS).

What is Federated Naming?

Federated Naming Service provides a method for hooking up, or federating, multiple naming services under a single, simple uniform interface for the basic naming and directory operations. The service supports resolution of composite names—names that span multiple naming systems—through the naming interface. Each member of a federation has autonomy in its choice of naming conventions, administrative interfaces, and its particular set of operations, other than name resolution.

In the Solaris environment, the FNS implementation consists of a set of enterprise-level naming services with specific policies and conventions for naming organizations, users, hosts, sites, and services, as well as support for global naming services such as DNS and X.500. More specifically, FNS has support for:

- Enterprise-level naming services: NIS+, NIS and files
- Global-level naming services: DNS, and X.500 (over LDAP or DAP). See *Solaris Naming Administration Guide* for information on DNS Text records and X.500 attribute syntax for XFN references
- Application-specific namespaces: file naming, printer naming
- Generic application namespaces for other applications
What Is XFN?

XFN stands for X/Open Federated Naming. XFN is a standard that is actively supported by organizations such as Sun, IBM, Hewlett-Packard, DEC, Siemens, and OSF. The programming interfaces and policies that FNS supports are specified by XFN. An overview of XFN concepts is presented later in this chapter; Chapter 2 describes the XFN programming interface in detail.

Note - In a 64-bit XFN application, the X.500 directory service is not supported.

FNS is compliant with the X/Open CAE Specification for Federated Naming (July 1995). Applications that use FNS are portable across platforms because the interface exported by FNS is XFN, a public, open interface endorsed by other vendors and X/Open. X/Open Co. Ltd. is part of the Open Group, which is an international standards organization committed to defining computing standards that are endorsed and adhered to by major computer vendors.

Why FNS?

FNS is useful for the following reasons:

- A single uniform naming interface is provided to clients for accessing different naming services. As a consequence, the addition of new naming services does not require changes to applications or to existing member naming services. Furthermore, application developers need to learn and use only one naming interface.

- Names can be composed in a uniform way, and the resulting composite names can have any number of components. This allows the composite namespace to serve the needs of many diversified applications.

- Coherent naming is encouraged through the use of shared contexts and shared names. This reduces duplication of effort in individual applications when supplying similar functionality.

FNS Policies

FNS provides applications with a set of policies on how namespaces are arranged and used. These policies specify:

- The namespaces for enterprise objects: organizations, hosts, users, sites, and services. (These naming services support contexts that allow other objects to be named relative to these objects.)
The relationships between the organization, host, user, site, and service namespaces, and the names used to refer to these namespaces

The syntax of names in these namespaces

How to federate the enterprise namespace so that it is accessible in the global namespace

Names and bindings present in the initial context of every process

Table 1–1 is a summary of FNS policy for arranging the enterprise namespace and Figure 1–1 shows that FNS policies provides a common framework for the three levels of service: global, enterprise, and application.

What FNS Policies Do Not Specify

The FNS policies do not specify the specific names used within naming services. In addition, naming within the application is the responsibility of individual applications or groups of related applications. They also do not specify the attributes to use after the object has been named.

![Different Levels of Naming Services](image)

Figure 1–1  Different Levels of Naming Services

What FNS Enterprise Policies Arrange

The FNS enterprise policies deal with the arrangement of objects within the enterprise namespace. The policies are summarized in Table 1–1.

- Organization – Entities such as departments, centers, and divisions. Sites, hosts, users, and services can be named relative to an organization. The XFN term for organization is organizational unit.
- Site – Physical locations, such as buildings, machines in buildings, and conference rooms within buildings. Sites can have files and services associated with them.
- Host – Computers. Hosts can have files and services associated with them.
- User – Human users. Users can have files and services associated with them.
- Service – Services such as printers, faxes, mail, and electronic calendars.
- File – Files within a file system.

![Diagram of FNS concepts]

**Figure 1–2  What FNS Policies Arrange**

The namespace of an enterprise is structured around the hierarchical structure of organizational units of an enterprise. Names of sites, hosts, users, files, and services can be named relative to names of organizational units by composing the organizational unit name with the appropriate namespace identifier and object name.

In Figure 1–3, a user, jsmith in the engineering organization of an enterprise, is named using the name `orgunit/desktop.sw.eng/user/jsmith`
Initial Context Bindings

Resolution of a name in XFN always begins with some context. XFN defines an initial context as a starting point for name resolution. The initial context contains bindings that allow the client application to (eventually) name any object in the enterprise namespace. Figure 1–4 shows the same naming system as the one shown in Figure 1–3, except that the initial context bindings are shaded and shown in italics.
Introduction to the Federated Naming Service (FNS) 17

Figure 1–4  Example of Enterprise Bindings in the Initial Context

The initial context has a flat namespace for namespace identifiers. The bindings of these namespace identifiers are summarized in Table 1–2. The categories of bindings are:

- User-related bindings
- Host-related bindings
- “Shorthand” bindings

In Table 1–2, the user to which the bindings are related is denoted by U, and the host to which the bindings are related is denoted by H. Not all of these names need to appear in all initial contexts. For example, when a program is invoked by the superuser, none of the user-related bindings appears in the initial context.

Examples of Composite Names

This section shows examples of names that follow FNS policies. The specific choices of organization names, site names, user names, host names, file names, and service names (such as “calendar” and “printer”) are illustrative only; these names are not specified by FNS policy.

Composing Names Relative to Organizations

The naming systems to be found under an organization are: user, host, service, fs, and site.

org/csl.parc/site/videoconference.northwing

names a conference room videoconference located in the north wing of the site associated with the organization csl.parc.

org/csl.parc/user/mjones

names a user mjones in the organization csl.parc.

org/csl.parc/host/inmail

names a machine inmail belonging to the organization csl.parc.

org/csl.parc/fs/pub/blue-and-whites/CSL92-124

names a file pub/blue-and-whites/CSL92-124 belonging to the organization csl.parc.
org/csl.parc/service/calendar

names the calendar service for the organization csl.parc. This service might manage the meeting schedules for the organization.

Composing Names Relative to Users
The naming systems associated with users are service and fs.

user/jsmith/service/calendar

names the calendar service of the user jsmith.

user/jsmith/fs/bin/games/riddles

names the file bin/games/riddles under the home directory of the user jsmith.

Composing Names Relative to Hosts
The naming systems associated with hosts are service and fs.

host/mailhop/service/mailbox

names the mailbox service associated with the machine mailhop.

host/mailhop/fs/pub/saf/archives.91

names the directory pub/saf/archives.91 found under the root directory of the file system exported by the machine mailhop.

Composing Names Relative to Sites
The naming systems associated with sites are service and fs.

site/B5.MountainView/service/printer/speedy

names a printer speedy in the B5.MountainView site.

site/B5.MountainView/fs/usr/dist

names a file directory usr/dist available in the B5.MountainView site.
XFN Overview

The following gives an overview of the main concepts in XFN and they are used in defining a federated naming system.

XFN References

An XFN name is bound to a reference, which is the information on how to reach an object. It contains a list of addresses, which identify communication endpoints on how to reach the object. Multiple addresses identify multiple communication endpoints for a single conceptual object or service. For example, a list of addresses might be required because the object is distributed or because the object can be accessed through more than one communication mechanism.

XFN Contexts

An XFN context is an object that exports the XFN base context programming interface. A context contains a list of atomic names bound to references, as shown in Figure 1–5. An atomic name can have zero or more attributes. Contexts are at the heart of the lookup and binding operations, described extensively in Chapter 2.

![Figure 1–5 An XFN Context](image)

XFN Attributes

In addition to references, there can be zero or more attributes associated with each named object, as shown in Figure 1–5. Each attribute has a unique attribute identifier, an attribute syntax, and a set of zero or more distinct attribute values.
XFN defines operations for examining and modifying the values of attributes associated, as well as searching for objects using their associated attributes.

**XFN Compound Names**

An XFN compound name is a sequence of one or more atomic names. An atomic name in one context object can be bound to a reference to another context object of the same type, called a subcontext. Objects in the subcontext are named using a compound name. Compound names are resolved by looking up each successive atomic name in each successive context.

A familiar analogy for UNIX users is the file naming model, where directories are analogous to contexts, and path names serve as compound names. Furthermore, contexts can be arranged in a “tree” structure, just as directories are, with the compound names forming a hierarchical namespace.

- **UNIX example**: `usr/local/bin`. UNIX atomic names are ordered from left to right and are delimited by slash (`/`) characters. The name `usr` is bound to a context in which `local` is bound. The name `local` is bound to a context in which `bin` is bound.

- **DNS example**: `sales.Wiz.COM`. DNS atomic names are ordered from right to left, and are delimited by dot (`.`) characters. The domain name `COM` is bound to a context in which `Wiz` is bound. `Wiz` is bound to a context in which `sales` is bound.

- **X.500 example**: `c=us/o=wiz/ou=sales`. An X.500 atomic name contains an attribute type and an attribute value. Atomic names are known as relative distinguished names in X.500. In this string representation, X.500 atomic names are ordered from left to right, and are delimited by slash (`/`) characters. An attribute type is separated from an attribute value by an equal sign (`=`) character. Abbreviations are defined for commonly used attribute types (for example, “c” represents country name). The country name `US` is bound to a context in which `wiz` is bound. The organization name `wiz` is bound to a context in which the organizational unit name `sales` is bound.

**Note** - In a 64-bit XFN application, the X.500 directory service is not supported.

Figure 1–6 shows an example of a hierarchical naming system with compound names.
XFN Composite Names

An XFN composite name is a name that spans multiple naming systems. It consists of an ordered list of zero or more components. Each component is a name from the namespace of a single naming system. Composite name resolution is the process of resolving a name that spans multiple naming systems. Appendix A, and Appendix B, supply more detail about composite names.

Components are slash-separated (/) and ordered from left to right, according to XFN composite name syntax. For example, the composite name

```
sales.Wiz.COM/usr/local/bin
```

has two components, a DNS name (sales.Wiz.COM) and a UNIX path name (usr/local/bin).

Figure 1–7 shows an example of a federated naming system with composite names. The position of the name within a context has no inherent significance in this illustration.

XFN Links

An XFN link is a special form of reference that is bound to an atomic name in a context. Instead of an address, a link contains a composite name. Many naming systems support a native notion of link that can be used within the naming system itself. XFN does not specify whether there is any relationship between such native links and XFN links.
“XFN Links” on page 89 describes links in detail.

![Diagram of naming systems](image)

Composite name: sales.wiz.com, usr/local/bin

*Figure 1–7  Federated Naming System With Composite Names*

**XFN Initial Context**

Every XFN name is interpreted relative to some context, and every XFN naming operation is performed on a context object. The initial context object provides a starting point for the resolution of composite names. The XFN interface provides a function that allows the client to obtain an initial context.

The policies described in *Solaris Naming Administration Guide* specify a set of names that the client can expect to find in this context and the semantics of their bindings. This provides the initial pathway to other XFN contexts.

**API Usage Model**

Many clients of the XFN interface are only interested in lookups. Their usage of the interface amounts to:

- Obtaining the initial context
- Looking up one or more names relative to the initial context

After the client obtains a desired reference from the lookup operation, it constructs a client-side representation of the object from the reference. This need not be code within the application layer but can be code inside the service layer. For example, RPC services can provide clients with a means of constructing client-side handles.
from a composite name for the service or from a reference containing an RPC address for the service. After receiving this handle, the client performs all further operations on the object or service by supplying the handle.

This is the basic model of how the XFN interface is expected to be used. The FNS policies described earlier further encourage a bind/lookup model for how services and clients can rendezvous through the use of the naming service.

FNS and Applications

Applications that are aware of FNS can expect the namespace to be arranged according to the FNS policies, and applications that bind names in the FNS namespace are expected to follow these policies.

Applications use FNS in the following ways:

1. **Applications can use FNS through existing interfaces.** A significant proportion of FNS use is through existing application programming interfaces. For example, consider a UNIX application that obtains a file name that it later supplies to the UNIX `open()` function. With FNS support for resolution of file names, the application need not be aware that the strings it deals with are composite names rather than the traditional local path names. Many applications can thereby support the use of composite names without modification.

2. **Applications can be direct clients of the XFN interface and policies.** Application-level utilities, such as the file system, the printing service, and the desktop tools (calendar manager, file manager) are examples of clients that use the XFN interface directly.

3. **Systems can export the XFN interface.** Naming systems, such as DNS and X.500, and naming systems embedded in other services, like the file system and printing service, in combination with XFN, are examples of naming systems that export the XFN interface.

This book addresses the needs of applications that use the XFN interface. Some examples of these applications are given in the next chapter.

Application Interaction with XFN

The way that client applications interact with XFN to access different naming systems is illustrated in a series of figures. Figure 1–8 shows an application that uses the XFN API and library.
Figure 1–8  Client Application Interaction With XFN

Figure 1–9 shows the details beneath the API. A naming service that is federated is accessed through the XFN client library and a context shared object module. This module translates the XFN calls into naming service–specific calls.

Figure 1–9  Details Beneath XFN API

X.500, DNS, and NIS+ are the naming services that have been federated in the example shown in Figure 1–10.

As resolution of a composite name proceeds, it can cause these different modules to be linked in, depending on the types of contexts referenced in the name.
Figure 1–10  XFN Implementation Examples
Interfaces for Writing XFN Applications

This chapter describes the client programming interfaces for XFN. Additional information on the XFN interfaces is available in the man pages.

- “Interface Conventions” on page 30
- “Usage” on page 30
- “Abstract Data Types” on page 30
- “Memory–Management Policies” on page 31
- “The Base Context Interface” on page 31
- “Base Attribute Interface” on page 40
- “Status Objects and Status Codes” on page 51
- “Parameters Used in the Interface” on page 55
- “Parsing Compound Names” on page 65

XFN Interface Overview

The XFN client interface consists of the base context interface, the base attribute interface, the extended attribute interface, and some supporting interfaces.

The base context interface provides the basic operations for naming, such as binding a name to a reference, looking up the reference bound to a name, and unbinding a name.

The base attribute interface provides operations to examine and modify attributes associated with named objects.

The extended attribute interface provides operations to search and create objects in the namespace with attributes.
The supporting interfaces contain:

- Operations on the status object and status codes used in the context and attribute operations
- Abstract data types that represent objects passed to and returned from the context and attribute operations, such as composite names, references, and attributes
- A standard model and operations for parsing compound names whose syntax is specific to a naming system. These are of interest primarily to service implementers
- Operations for manipulating objects that are used to specify the criteria of extended search operations

“API Usage Model” on page 24 summarizes how an application typically uses the programming interface.

Interface Conventions
The XFN interface is presented in ISO standard C, which is equivalent to ANSI standard C. The symbols defined by the interface are prefixed by fn or FN, for federated naming.

- The FN_ prefix is used for both data types and predefined constants.
  In addition, data types have a _t suffix, such as FN_ref_t. Predefined constants appear in all-uppercase characters, such as FN_ID_STRING.
- The fn_ prefix is used for function names. Names of functions in the base context interface have the prefix fn_ctx_, such as fn_ctx_lookup. Names of functions in the base attribute interface have the prefix fn_attr_, such as fn_attr_get.

Usage
Include the XFN header file in your code.

```c
#include <xfn/xfn.h>
```

Include the XFN library when you compile.

```bash
cc -o program_name file1.c file2.c -lxfn
```

Abstract Data Types
Except for FN_attrvalue_t and FN_identifier_t, the types defined in the interface hide their actual data representation from the client. The client performs every operation on an object of one of these types through a well-defined interface for that data type.
When the client accesses these objects, the client refers to the objects solely through a handle to an object. Operations are provided to create objects of each type and to destroy them. The creation operation returns a handle to the new object. The destroy operation releases all resources associated with the object.

The only information about this handle revealed to the client is that it is a pointer type. The client cannot assume what this handle points to. In particular, the handle might not point directly to the memory containing the object’s actual state.

The value 0 is defined for all pointer types. The functions that return handles in the interface return the value 0 as an indication of failure. The values 0 and NULL are equivalent.

Memory–Management Policies

The following memory–management policies are used for all client interfaces described in this chapter:

- When a function returns a non-\texttt{const} pointer to an object, the client “owns” the object. The client can alter the object and is responsible for freeing the space allocated to it when the object is no longer required.

- When a function returns a \texttt{const} pointer to an object, the service “owns” the object. The client must neither modify the object in any way, nor free the space allocated to it. If the client needs to control a copy, it must make one for itself.

- When a function takes a non-\texttt{const} parameter that is passed by reference, the service “borrows” the object during the function’s execution. It can modify the object during this period, but it does not retain any reference to the object beyond this period.

- When a function takes a \texttt{const} parameter that is passed by reference, the service reads but does not modify the object. The service does not keep any reference to the object beyond the period of the function’s execution.

The Base Context Interface

This section describes the operations in the base context interface. The interfaces to the objects used in the operations are described in “Parameters Used in the Interface” on page 55.

- “Names in Context Operations” on page 32
- “Requirements for Supporting the Context Operations” on page 32
- “Status Objects” on page 33
- “Getting Context Handles” on page 33
Names in Context Operations

In most of the operations of the base context interface, the caller supplies a context and a composite name argument. The supplied composite name is always interpreted relative to the supplied context.

The operation might eventually be effected on a different context called the operation’s target context. Each operation has an initial resolution phase that conveys the operation to its target context, following which the operation is applied. The effect (but not necessarily the implementation) is that of:

- Doing a lookup on that portion of the name that represents the target context
- Invoking the operation on the target context

The contexts involved only in the resolution phase are called intermediate contexts.

Normal resolution of names in context operations always follows XFN links, which are defined in “XFN Links” on page 89.

Requirements for Supporting the Context Operations

The lookup operation fn_ctx_lookup() must be supported by all contexts. When contexts do not support other operations, they can return an FN_E_OPERATION_NOT_SUPPORTED status code (see codes in Table 2–3).

XFN contexts are required to support the resolution phase of every operation in the base context and attribute interface when involved in the operation as intermediate contexts. That is, each intermediate context must participate in the process of conveying the operation to the target context, even if it does not support that operation itself. For example, not all contexts need to allow binding and listing names. However, all contexts must fully support the resolution phase of these operations.

Composite names are passed to an XFN context implementation in a structural form as an ordered sequence of components. When resolving a name, the context implementation is responsible for:

- Determining which set of leading components it must resolve
- Resolving that portion to a reference
- Returning a status object containing this reference and the portion of the name unresolved
Composite name resolution is further discussed in “Composite Name Resolution” on page 87.

Status Objects

In each context operation, the caller supplies an FN_status_t parameter. The called function sets this status object as described in “Status Objects and Status Codes” on page 51. All status objects are handled in this way for each operation in the base context interface (this is not restated in the individual operation descriptions).

Getting Context Handles

All operations on a context require a context handle. There are several ways of obtaining a context handle. If you have a reference, you can use it to construct a context handle. Otherwise, to get a handle to the initial context, you must call fn_ctx_handle_from_initial().

```c
fn_ctx_handle_from_initial
fn_ctx_handle_from_ref
```

Construct Handle to Initial Context

This operation returns a handle to the callers initial context. On successful return, the context handle points to a context containing the bindings described in “Initial Context Bindings” on page 16.

```c
FN_ctx_t *fn_ctx_handle_from_initial(
    unsigned int authoritative,
    FN_status_t *status);
```

authoritative specifies whether the handle to the Initial Context returned should be authoritative, with respect to information the context obtains from the naming service. When the flag is non-zero, subsequent operations on this context handle can access the most authoritative information. When authoritative is zero, the handle to the Initial Context returned need not be authoritative. Authoritatives is determined by specific naming services. In some, the authoritative source is a single “master” servers, while in others, the authoritative source is a quorum of servers.
Construct Context Handle From Reference

This operation returns a handle to an \texttt{FN\_ctx\_t} object given a reference, \texttt{ref}, for that context.

\begin{verbatim}
FN_ctx_t *fn_ctx_handle_from_ref(
    const FN_ref_t *ref,
    unsigned int authoritative,
    FN_status_t *status);
\end{verbatim}

\texttt{authoritative} specifies whether the handle to the context returned should be authoritative, with respect to information the context obtains from the naming service. When the flag is non-zero, subsequent operations on this context handle can access the most authoritative information. When authoritative is zero, the handle to the context returned need not be authoritative. Authoritativeness is determined by specific naming services. In some, the authoritative source is a single “master” server, while in others, the authoritative source is a quorum of servers.

Lookup and List Contexts

\begin{verbatim}
fn_ctx_lookup
fn_ctx_list_names
fn_namelist_next
fn_namelist_destroy
fn_ctx_list_bindings
fn_bindinglist_next
fn_bindlist_destroy
fn_ctx_lookup_link
\end{verbatim}

Lookup

This operation returns the reference bound to \texttt{name} relative to the context \texttt{ctx}.

\begin{verbatim}
FN_ref_t *fn_ctx_lookup(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    FN_status_t *status);
\end{verbatim}
List Names

This set of operations is used to list the set of names bound in the context named
name relative to the context ctx. The name must name a context. If the intent is to list
the contents of ctx, name should be an empty composite name.

```
FN_nameslist_t* fn_ctx_list_names(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    FN_status_t *status);

FN_string_t *fn_namelist_next(
    FN_namelist_t *nl,
    FN_status_t *status);

void fn_namelist_destroy(
    FN_namelist_t *nl);
```

The call to fn_ctx_list_names() initiates the enumeration process for the target
context. It returns an FN_nameslist_t object that you can use for the enumeration.

The operation fn_namelist_next() returns the next name in the enumeration
identified by nl and updates nl to indicate the state of the enumeration marker.
Successive calls to fn_namelist_next() using nl return successive names and
further update the state of the enumeration. fn_namelist_next() returns a NULL
pointer when the enumeration has been completed.

fn_namelist_destroy() is used to release resources used during the
enumeration. This call can be invoked at any time to terminate the enumeration.

The names enumerated using the list names operations are not in any order. There is
no guaranteed relation between the order in which names are added to a context and
the order in which names are obtained by enumeration. There is no guarantee that
any two enumerations will return the names in the same order.

When a name is added to or removed from the context, this might not necessarily
invalidate the enumeration handle that the client holds for that context. If the
enumeration handle remains valid, the update might or might not be visible to the
client.

List Bindings

This set of operations is used to list the set of names and bindings in the context
named by name, relative to the context ctx. The name must name a context. If the
intent is to list the contents of ctx, name should be an empty composite name.
The semantics of these operations are similar to those for listing names. In addition to a name string being returned, \texttt{fn_bindinglist_next()} also returns the reference of the binding for each member of the enumeration.

### Lookup Link

This operation returns the XFN link bound to \textit{name}. The terminal atomic part of \textit{name} must be bound to an XFN link.

\begin{verbatim}
FN_ref_t *fn_ctx_lookup_link(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    FN_status_t *status);
\end{verbatim}

The normal \texttt{fn_ctx_lookup()} operation follows all XFN links encountered, including any that are bound to the terminal atomic part of \textit{name}. This operation differs from the normal lookup in that when the terminal atomic part of \textit{name} is an XFN link, this last link is not followed, and the operation returns the link.

### Updating Bindings

\begin{verbatim}
fn_ctx_bind
fn_ctx_unbind
fn_ctx_rename
\end{verbatim}

Bindings can be added, overwritten, removed, or renamed.

### Bind

This operation binds the supplied reference \textit{ref} to the supplied composite name \textit{name}, taken relative to \textit{ctx}. The binding is made in the target context—that named by all
but the terminal atomic part of \textit{name}. The operation binds the terminal atomic name to the supplied reference in the target context. The target context must already exist.

```c
int fn_ctx_bind(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    const FN_ref_t *ref,
    unsigned int exclusive,
    FN_status_t *status);
```

The value of \texttt{exclusive} determines what happens if the terminal atomic part of the name is already bound in the target context. If \texttt{exclusive} is nonzero and \textit{name} is already bound, the operation fails. If \texttt{exclusive} is zero, the new binding replaces any existing binding.

The value of \texttt{ref} cannot be NULL. If you want to reserve a name using the \texttt{fn_ctx_bind()} operation, bind a reference containing no address. This reference can be naming service-specific or it can be the conventional NULL reference.

\textbf{Unbind}

This operation removes the terminal atomic name in \textit{name} from the target context—that named by all but the terminal atomic part of \textit{name}.

```c
int fn_ctx_unbind(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    FN_status_t *status);
```

This operation is successful even if the terminal atomic name was not bound in target context, but fails if any of the intermediate names are not bound.

\texttt{fn_ctx_unbind()} operations are idempotent.

\textbf{Rename}

This operation binds the reference currently bound to \textit{oldname}, resolved relative to \textit{ctx} to \textit{newname}, and unbinds \textit{oldname}. The \textit{newname} is resolved relative to the target context—that named by all but the terminal atomic part of \textit{oldname}.
int fn_ctx_rename(
    FN_ctx_t *ctx,
    const FN_composite_name_t *oldname,
    const FN_composite_name_t *newname,
    unsigned int exclusive,
    FN_status_t *status);

If exclusive is zero, this operation overwrites any old binding of newname. If exclusive is nonzero, the operation fails if newname is already bound.

The only restriction that XFN places on newname is that it be resolved relative to the target context. For example, in some implementations, newname might be restricted to be a name in the same naming system as the terminal component of oldname. In another implementation, newname might be restricted to an atomic name.

Managing Contexts

fn_ctx_create_subcontext
fn_ctx_destroy_subcontext
fn_ctx_get_ref
fn_ctx_get_syntax_attrs
fn_ctx_handle_destroy
fn_ctx_equivalent_name

Contexts can be created, destroyed, and referenced.

Create Subcontext

This operation creates a new context of the same type as the target context—that named by all but the terminal atomic part of name—and binds it to the composite name name resolved relative to the context ctx, and returns a reference to the newly created context.

FN_ref_t *fn_ctx_create_subcontext(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    FN_status_t *status);

As with the bind operation, the target context must already exist. The new context is created and bound in the target context using the terminal atomic name in name. The operation fails if the terminal atomic name already exists in the target context.

The new subcontext exports the context interface and is created in the same naming system as the target context. XFN does not specify any further properties of the new
subcontext. Other properties of the subcontext are determined by the target context and its naming system.

**Destroy Subcontext**

This operation destroys the subcontext named by `name`, interpreted relative to `ctx`, and unbinds the name.

```c
int fn_ctx_destroy_subcontext(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    FN_status_t *status);
```

As with the unbind operation, the operation succeeds if the terminal atomic name is not bound in the target context—that named by all but the terminal atomic part of `name`.

Some aspects of this operation are determined by the target context and its naming system. For example, XFN does not specify what happens if the named subcontext is not empty when the operation is invoked.

**Get Reference to Context**

This operation returns a reference to the supplied context object.

```c
FN_ref_t *fn_ctx_get_ref(
    const FN_ctx_t *ctx,
    FN_status_t *status);
```

**Get Syntax Attributes of Context**

This operation returns the syntax attributes associated with the context named by `name`, relative to the context `ctx`.

```c
FN_attrset_t *fn_ctx_get_syntax_attrs(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    FN_status_t *status);
```
This operation is different from other XFN attribute operations in that these syntax attributes could be obtained directly from the context. Attributes obtained through other XFN attribute operations might not be associated with the context; they might be associated with the reference of the context, rather than with the context itself (see “Relationship toNaming Operations” on page 41).

**Destroy Context Handler**

This operation destroys the context handle \( ctx \) and allows the implementation to free resources associated with the context handle. This operation does not affect the state of the context itself.

```c
void fn_ctx_handle_destroy(FN_ctx_t *ctx);
```

**Construct an Equivalent Name (Preliminary Specification)**

Given the name of an object `name` relative to the context `ctx`, the operation returns an equivalent name for that object, relative to the same context `ctx`, that has `leading_name` as its initial atomic name. Two names are said to be equivalent if they have prefixes that resolve to the same context, and the parts of the names immediately following the prefixes are identical. For example, for user jsmith, the names “myself/service/calendar” is equivalent to “user/jsmith/service/calendar” when resolved relative to the Initial Context.

```c
FN_composite_name_t *fn_ctx_equivalent_name(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    const FN_string_t *leading_name,
    FN_status_t *status);
```

If an equivalent name cannot be constructed, the value 0 is returned and the `status` argument set appropriately.

**Base Attribute Interface**

This section describes the operations in the base attribute interface. The interfaces to the objects used in operations in this interface are described in “Parameters Used in the Interface” on page 55.

- “XFN Attribute Model” on page 41
In the XFN attribute model, a set of zero or more attributes can be associated with a
named object. Each attribute in the set has a unique attribute identifier, an attribute
syntax, and a set of zero or more distinct attribute values. Each attribute value has an
opaque data type. The attribute identifier serves as a name for the attribute. The
attribute syntax indicates how the attribute values are encoded.

The operations in the base attribute interface can be used to examine and modify the
settings of attributes associated with existing named objects. These objects can be
contexts or other types of objects. The attribute operations do not create names or
remove names in contexts.

The range of support for attribute operations can vary widely. Some naming systems
might not support any attribute operations. Other naming systems might support
only read operations or operations on attributes whose identifiers are in some fixed
set. A naming system might limit attributes to have single values or might require at
least one value. Some naming systems might associate attributes only with context
objects, while others might allow associating attributes with noncontext objects.

Typically, attributes of an object are manipulated through operations that operate on
a single attribute, such as reading or updating a single attribute. Moreover, the client
is typically expected to be able to read all attribute values of a single attribute in one
call. However, sometimes there is a requirement to manipulate several attributes of a
single object or to obtain individual attribute values of a single attribute from the
name service. To address these requirements, two kinds of attribute operations are
defined:

- Single-attribute operations
- Multiple-value and multiple-attribute operations

Relationship to Naming Operations

An XFN attribute operation might not be equivalently expressed as an independent
fn_ctx_lookup() operation followed by an attribute operation in which the caller
supplies the resulting reference and an empty name.

This is because some attribute models associate attributes with a named object in the
context in which the object is named. In others, an object’s attributes are stored in the
object itself. XFN accommodates both these models.
Note - Invoking an attribute operation using the target context and the terminal atomic name accesses either the attributes that are associated with the terminal name or the object named by the terminal name—this is dependent upon the underlying attribute model. This document uses the term “attributes associated with a named object” to refer to all of these cases.

XFN does not provide any guarantee about the validity of the relationship between the attributes and the reference associated with a given name. Some naming systems might store the reference bound to a name in one or more attributes associated with a name. Attribute operations might affect the information used to construct a reference.

To avoid undefined results, programmers must use the operations in the context interface and not the attribute operations when manipulating references. Applications should avoid using specific knowledge about how an XFN context implementation over a particular naming system constructs references.

Status Objects

In each attribute operation, the caller supplies an FN_status_t parameter. The called function sets this status object as described in “Status Objects and Status Codes” on page 51. All status objects are handled in this manner for each operation in the base attribute interface; this will not be restated in the individual operation descriptions.

Single-Attribute Operations

fn_attr_get
fn_attr_modify
fn_attr_get_values
fn_valuelist_next
fn_valuelist_destroy

Each of these operations takes as arguments a context and composite name relative to this context and manipulates the attributes associated with the named object. Each operation sets a status object to describe the status of the operation.
Get Attribute

This operation returns the identifier, syntax, and values of a specified attribute, `attribute_id`, for the object named `name` relative to the context `ctx`. If `name` is empty, the attribute associated with `ctx` is returned.

```c
FN_attribute_t *fn_attr_get(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    const FN_identifier_t *attribute_id,
    unsigned int follow_link,
    FN_status_t *status);
```

`fn_attr_get_values()` and its related functions are for getting individual values of an attribute and should be used if the combined size of all the values is expected to be too large to be returned in a single invocation of `fn_attr_get()`.

Modify Attribute

This operation modifies according to `mod_op` the attribute `attr` associated with the object named `name`, relative to `ctx`. If `name` is empty, the attribute associated with `ctx` is modified.

```c
int fn_attr_modify(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    unsigned int mod_op,
    const FN_attribute_t *attr,
    FN_status_t *status);
```

### TABLE 2–1  XFN Attribute-Modification Operations

<table>
<thead>
<tr>
<th>Operation Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FN_ATTR_OP_ADD()</td>
<td>Add an attribute with given attribute identifier and set of values. If an attribute with this identifier already exists, replace the set of values with those in the given set. The set of values can be empty if the target naming system permits.</td>
</tr>
<tr>
<td>FN_ATTR_OP_ADD_EXCLUSIVE()</td>
<td>Add an attribute with the given attribute identifier and set of values. The operation fails if an attribute with this identifier already exists. The set of values can be empty if the target naming system permits.</td>
</tr>
<tr>
<td>Operation Code</td>
<td>Meaning</td>
</tr>
<tr>
<td>----------------</td>
<td>---------</td>
</tr>
<tr>
<td>FN_ATTR_OP_ADD_VALUES()</td>
<td>Add the given values to those of the given attribute (resulting in the attribute having the union of its prior value set with the given set). Create the attribute if it does not already exist. The set of values can be empty if the target naming system permits.</td>
</tr>
<tr>
<td>FN_ATTR_OP_REMOVE()</td>
<td>Remove the attribute with the given attribute identifier and all its values. The operation succeeds even if the attribute does not exist. The values of the attribute supplied with this operation are ignored.</td>
</tr>
<tr>
<td>FN_ATTR_OP_REMOVE_VALUES()</td>
<td>Remove the given values from those of the given attribute (resulting in the attribute having the set difference of its prior value set and the given set). This succeeds even if some of the given values are not in the set of values that the attribute has. In naming systems that require an attribute to have at least one value, removing the last value removes the attribute as well.</td>
</tr>
</tbody>
</table>

### Get Attribute Values

This set of operations allows the caller to obtain attribute values associated individually with a single attribute.

```c
FN_valuelist_t *fn_attr_get_values(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    const FN_identifier_t *attribute_id,
    unsigned int follow_link,
    FN_status_t *status);

FN_attrvalue_t *fn_valuelist_next(
    FN_valuelist_t *vl,
    FN_identifier_t **attr_syntax,
    FN_status_t *status);

void fn_valuelist_destroy(
    FN_valuelist_t *vl);
```

This set of operations is used to obtain the set of values of a single attribute, identified by `attribute_id`, associated with `name`, relative to `ctx`. If `name` is empty, the attribute associated with `ctx` is obtained.

This interface should be used instead of `fn_attr_get()` if the combined size of all the values is expected to be too large to be returned by `fn_attr_get()`.
The operation `fn_attr_get_values()` initiates the enumeration process. It returns a handle to an `FN_valuelist_t` object that can be used for subsequent `fn_valuelist_next()` calls to enumerate the values requested.

The operation `fn_valuelist_next()` returns the next attribute value in the enumeration and updates `vl` to indicate the state of the enumeration.

The operation `fn_valuelist_destroy()` frees the resources associated with the enumeration. This operation can be invoked at any time to terminate the enumeration.

Multiple-Attribute Operations

```c
fn_attr_get_ids
fn_attr_multiget
fn_multigetlist_next
fn_multigetlist_destroy
fn_attr_multi_modify
```

These operations allow the caller to specify an operation that handles on multiple attributes using one or more calls.

The failure semantics can vary widely across naming systems. In some systems the single function call can contain multiple individual naming system operations, with no guarantees of atomicity.

Get Attribute Identifiers

This operation gets a list of all the attribute identifiers that are associated with the object named `name` relative to the context `ctx`. If `name` is empty, the attribute identifiers associated with `ctx` are returned.

```c
FN_attrset_t *fn_attr_get_ids(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    unsigned int follow_link,
    FN_status_t *status);
```

Get Multiple Attributes

Get one or more attributes associated with the object named `name` relative to the context `ctx`. If `name` is empty, the attributes associated with `ctx` are returned.
The attributes returned are those specified in attr_ids. If the value of attr_ids is 0, all attributes associated with the named object are returned. Any attribute values in attr_ids provided by the caller are ignored; only the identifiers are relevant for this operation. Each attribute (identifier, syntax, and values) is returned one at a time using an enumeration scheme similar to that for listing a context.

fn_attr_multi_get() initiates the enumeration process. It returns a handle to an FN_multigetlist_t object that can be used for subsequent fn_multigetlist_next() calls to enumerate the attributes requested.

The operation fn_multigetlist_next() returns the next attribute (identifier, syntax, and values) in the enumeration and updates ml to indicate the state of the enumeration. Successive calls to fn_multigetlist_next() using ml return successive attributes in the enumeration and further update the state of the enumeration.

The operation fn_multigetlist_destroy() frees the resources used during the enumeration. This operation can be invoked at any time to terminate the enumeration.

Implementations are not required to return all attributes requested by attr_ids. Some might choose to return only the attributes found successfully; such implementations might not necessarily return identifiers for attributes that could not be read.

Modify Multiple Attributes

Modify the attributes associated with the object named name, relative to ctx.

```c
int fn_attr_multi_modify(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    const FN_attrset_t *attr_ids,
    unsigned int follow_link,
    FN_status_t *status,
    FN_attribute_t *fn_multigetlist_next;
    FN_multigetlist_t *ml,
    FN_status_t *status);
void fn_multigetlist_destroy(
    FN_multigetlist_t *ml);
```
In the \textit{mods} parameter, the caller specifies a sequence of modifications that are to be performed in order on the attributes. Each modification in the sequence specifies a modification operation code (shown in Table 2–1) and an attribute on which to operate.

If all the modifications were performed successfully, \textit{unexecuted_mods} is a NULL pointer. If an error is encountered while performing the list of modifications, \textit{status} indicates the type of error and \textit{unexecuted_mods} is set to point to a list of unexecuted modifications. The contents of \textit{unexecuted_mods} do not share any state with \textit{mods}; items in \textit{unexecuted_mods} are copies of items in \textit{mods} and appear in the same order in which they were originally supplied in \textit{mods}. The first operation in \textit{unexecuted_mods} is the first one that failed, and the code in \textit{status} applies to this modification operation in particular. If \textit{status} indicates a failure and a NULL pointer is returned in \textit{unexecuted_mods}, that means no modifications were executed.

### Extended Attribute Interface

(Preliminary Specification)

<table>
<thead>
<tr>
<th>fn_attr_search</th>
</tr>
</thead>
<tbody>
<tr>
<td>fn_searchlist_next</td>
</tr>
<tr>
<td>fn_searchlist_destroy</td>
</tr>
<tr>
<td>fn_attr_ext_search</td>
</tr>
<tr>
<td>fn_ext_searchlist_next</td>
</tr>
<tr>
<td>fn_ext_searchlist_destroy</td>
</tr>
</tbody>
</table>

The XFN extended attribute interface consists of operations that perform searching and creation of objects in the namespace with attributes. The operations in this interface are considered “preliminary,” in that they are not yet standard and might change in the next revision of the specification.

### Attribute Search Interface

The search interface contains several operations: a basic search operation, which performs associative lookup in a single context, and an extended search operation
that allows the search criteria to be specified using an expression. It also allows the scope of the search to encompass a wider scope than only a single context.

Basic Search

This set of operations is used to enumerate names of objects bound in the target context named name relative to the context ctx with attributes whose values match all those specified by match_attrs. Using return_ref specifies whether to return the references of named objects in the search, while return_attr_ids specifies the attributes to be returned in the search.

```c
FN_searchlist_t *fn_attr_search(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    const FN_attrset_t *match_attrs,
    unsigned int return_ref,
    const FN_attrset_t *return_attr_ids,
    FN_status_t *status);

FN_string_t *fn_searchlist_next(
    FN_searchlist_t *sl,
    FN_ref_t **returned_ref,
    FN_attrset_t **returnedattrs,
    FN_status_t *status);

void fn_searchlist_destroy(
    FN_searchlist_t *sl);
```

The call to fn_attr_search() initiates the search in the target context. It returns a handle to an FN_searchlist_t object that is used to enumerate the names of the objects whose attributes match match_attrs.

fn_searchlist_next() returns the next name in the enumeration identified by sl. The reference of the name, if requested, is returned in returned_ref. The attributes specified by return_attr_ids are returned in returnedAttrs. Successive calls to fn_searchlist_next() using sl return successive names, and optionally, references and attributes in the enumeration and further update the state of the enumeration.

fn_searchlist_destroy() releases resources used during the enumeration. It can be called at any time to terminate the enumeration.

Extended Search

This set of operations is used to list names of objects whose attributes satisfy the filter expression filter. The control argument encapsulates the option settings for the search.
These options are:

1. The scope of the search. This can be any of the following:
   - Search the named object
   - Search the context named by name
   - Search the entire subtree rooted at the context named by name
   - Search the context implementation-defined subtree rooted at the context named by name.

2. Whether XFN links are followed during the search

3. A limit on the number of names returned

4. Whether the reference associated with the named object is returned

5. Which attributes associated with the named object are returned

The filter expression is evaluated against the attributes of the objects bound in the scope of the search. The filter evaluates to either true or false.

The call to `fn_attr_ext_search()` initiates the search and, if successful, returns a handle to an `FN_ext_searchlist_t` object, `esl`, that is used to enumerate the names of the objects that satisfy the filter.

`fn_ext_searchlist_next()` returns the next name, and optionally, its reference and attributes, in the enumeration identified by `esl`. The name returned is a composite name, to be resolved relative to the starting context for the search. The starting context is the context named `name` relative to `ctx`, unless the scope of the search is only the named object. If the scope of the search is only the named object, the terminal atomic name is returned. Successive calls to `fn_ext_searchlist_next()` using `esl` return successive names, and optionally, references and attributes, in the enumeration and further update the state of the enumeration.

`fn_ext_searchlist_destroy()` releases resources used during the search and enumeration. It can be called at any time to terminate the enumeration.
Object Creation with Attributes

At times it is useful or necessary to associate attributes with an object at the time the object is created. The XFN extended attribute interface contains functions that provide these capabilities. The two functions in this interface, `fn_attr_bind()` and `fn_attr_create_subcontext()`, are analogous to their counterparts in the base context interface, `fn_ctx_bind()` and `fn_ctx_create_subcontext()`, respectively, except that the versions in the extended attribute interface allow an extra parameter for specifying attributes to be associated with the new binding.

### Bind with Attributes

This operation binds the supplied reference `ref` to the supplied composite name `name` relative to `ctx`, and associates the attributes specified in `attrs` with the named object. The binding is made in the target context—that context named by all but the terminal atomic part of `name`. The operation binds the terminal atomic part of `name` to the supplied reference in the target context. The target context must already exist.

```c
int fn_attr_bind(
    FN_ctx_t *ctx,
    const FN_composite_name_t *name,
    const FN_ref_t *ref,
    unsigned int exclusive,
    FN_status_t *status);
```

The value of `exclusive` determines what happens if the terminal atomic part of the name is already bound in the target context. If `exclusive` is non-zero and `name` is already bound, the operation fails. If `exclusive` is zero, the new binding replaces any existing binding, and `attrs`, if not NULL, replaces any existing attributes associated with the named object.

### Create Subcontext with Attributes

This operation creates a new XFN context of the same type as the target context—that named by all but the terminal atomic component of `name`—and binds it to the supplied composite name `name`. In addition, attributes given in `attrs` are associated with the newly created context. The target context must already exist. The new context is created and bound in the target context using the terminal atomic name in `name`. The operation returns a reference to the newly created context.
Status Objects and Status Codes

The result statuses of operations in the context interface and the attribute interface are encapsulated in `FN_status_t` objects. The `FN_status_t` object contains information about how the operation completed: whether an error occurred in performing the operation, the nature of the error, and information that helps locate where the error occurred. If the error occurred while resolving an XFN link, the status object contains additional information about that error.

The status object contains several items of information as shown in Table 2–2.

<table>
<thead>
<tr>
<th>Information Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary status code</td>
<td>An unsigned int code describing the disposition of the operation.</td>
</tr>
<tr>
<td>Resolved name</td>
<td>In the case of a failure during the resolution phase of the operation, this is the leading portion of the name that was resolved successfully. Resolution might have been successful beyond this point, but the error can not be pinpointed further.</td>
</tr>
<tr>
<td>Resolved reference</td>
<td>The reference to which the resolved name is bound.</td>
</tr>
<tr>
<td>Remaining name</td>
<td>The remaining unresolved portion of the name.</td>
</tr>
<tr>
<td>Diagnostic message</td>
<td>Any diagnostic message returned by the context implementation.</td>
</tr>
<tr>
<td>Link status code</td>
<td>If an error occurs while resolving an XFN link, the primary status code has the value <code>FN_E_LINK_ERROR</code>, and this code describes the error that occurred while resolving the XFN link.</td>
</tr>
<tr>
<td>Resolved link name</td>
<td>In the case of a link error, this contains the resolved portion of the name in the XFN link.</td>
</tr>
</tbody>
</table>
### TABLE 2–2  Status Object  (continued)

<table>
<thead>
<tr>
<th>Information Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Resolved link reference</td>
<td>In the case of a link error, this contains the reference to which the resolved link name is bound.</td>
</tr>
<tr>
<td>Remaining link name</td>
<td>In the case of a link error, this contains the remaining resolved portion of the name in the XFN link.</td>
</tr>
<tr>
<td>Link diagnostic message</td>
<td>Any diagnostic message related to the resolution of the link.</td>
</tr>
</tbody>
</table>

Both the primary status code and the link status code are values of type `unsigned int` that are drawn from the same set of meaningful values. XFN reserves the values 0 through 127 for standard meanings. Currently, values and interpretations for the codes in Table 2–3 are determined by XFN.

### TABLE 2–3  Status Codes

<table>
<thead>
<tr>
<th>Code</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FN_SUCCESS</td>
<td>The operation succeeded.</td>
</tr>
<tr>
<td>FN_E_ATTR_IN_USE</td>
<td>When an attribute is being modified using the operation FN_ATTR_OP_ADD_EXCLUSIVE and an attribute with the same identifier already exists, the operation fails with FN_E_ATTR_IN_USE.</td>
</tr>
<tr>
<td>FN_E_ATTR_NO_PERMISSION</td>
<td>The caller did not have permission to perform the attempted attribute operation.</td>
</tr>
<tr>
<td>FN_E_ATTR_VALUE_REQUIRED</td>
<td>The operation attempted to create an attribute without a value, and the specific naming system does not allow this.</td>
</tr>
<tr>
<td>FN_E_AUTHENTICATION_FAILURE</td>
<td>The identity of the client principal could not be verified.</td>
</tr>
<tr>
<td>FN_E_COMMUNICATION_FAILURE</td>
<td>An error occurred in communicating with one of the contexts involved in the operation.</td>
</tr>
<tr>
<td>FN_E_CONFIGURATION_ERROR</td>
<td>A problem was detected that indicated an error in the installation of the XFN interfaces.</td>
</tr>
<tr>
<td>FN_E_CONTINUE</td>
<td>The operation should be continued using the remaining name and the resolved reference returned in the status.</td>
</tr>
<tr>

<td>Meaning</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FNＥ_CTX_NO_PERMISSION</td>
<td>The client did not have permission to perform the operation.</td>
</tr>
<tr>
<td>FNＥ_CTX_NOT_EMPTY</td>
<td>Applies only to fn_ctx_destroy_subcontext(). The naming system required that the context be empty before its destruction, and it was not empty.</td>
</tr>
<tr>
<td>FNＥ_CTX_UNAVAILABLE</td>
<td>Service could not be obtained from one of the contexts involved in the operation. This might be because the naming system is busy or is not providing service. In some implementations this might not be distinguished from a communication failure.</td>
</tr>
<tr>
<td>FNＥ_ILLEGAL_NAME</td>
<td>The name supplied to the operation was not a well-formed composite name, or one of the component names was not well formed according to the syntax of the naming systems involved in its resolution.</td>
</tr>
<tr>
<td>FNＥ_INCOMPATIBLE_CODE_SETS</td>
<td>The operation involved character strings of incompatible code sets or the supplied code set is not supported by the implementation.</td>
</tr>
<tr>
<td>FNＥ_INCOMPATIBLE_LOCALES</td>
<td>The operation involved character strings of incompatible language or territory locale information, or the specified locale is not supported by the implementation.</td>
</tr>
<tr>
<td>FNＥ_INSUFFICIENT_RESOURCES</td>
<td>Either the client or one of the involved contexts could not obtain sufficient resources (on memory, file descriptors, communication ports, stable media space, for example) to complete the operation successfully.</td>
</tr>
<tr>
<td>FNＥ_INVALID_ATTR_IDENTIFIER</td>
<td>The attribute identifier was not in a format acceptable to the naming system, or its contents were not valid for the format specified for the identifier.</td>
</tr>
<tr>
<td>FNＥ_INVALID_ATTR_VALUE</td>
<td>One of the values supplied was not in the appropriate form for the given attribute.</td>
</tr>
<tr>
<td>FNＥ_INVALID_ENUM_HANDLE</td>
<td>The enumeration handle supplied was invalid, either because it was from another enumeration, because an update operation occurred during the enumeration, or for some other reason.</td>
</tr>
<tr>
<td>FNＥ_INVALID_SYNTAX_ATTRS</td>
<td>The syntax attributes supplied are invalid or insufficient to fully specify the syntax.</td>
</tr>
<tr>
<td>FNＥ_LINK_ERROR</td>
<td>An error occurred while resolving an XFN link encountered during resolution of the supplied name.</td>
</tr>
<tr>
<td>Code</td>
<td>Meaning</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FN_E_LINK_LOOP_LIMIT</td>
<td>A nonterminating loop (cycle) in the resolution is suspected. This arises due to XFN links encountered during the resolution of a supplied composite name. This code indicates either the definite detection of such a cycle, or that resolution exceeded an implementation-defined limit on the number of XFN links allowed for a single operation invoked by the caller (and thus a cycle is suspected).</td>
</tr>
<tr>
<td>FN_E_MALFORMED_LINK</td>
<td>A malformed link reference was encountered. For fn_ctx_lookup_link(), the name supplied resolved to a reference that was not a link.</td>
</tr>
<tr>
<td>FN_E_MALFORMED_REFERENCE</td>
<td>A context object could not be constructed from the supplied reference because the reference was not properly formed.</td>
</tr>
<tr>
<td>FN_E_NAME_IN_USE</td>
<td>(Only for operations that bind names.) The supplied name was already in use.</td>
</tr>
<tr>
<td>FN_E_NAME_NOT_FOUND</td>
<td>Resolution of the supplied composite name proceeded to a context in which the next atomic component of the name was not bound.</td>
</tr>
<tr>
<td>FN_E_NO_EQUIVALENT_NAME</td>
<td>No equivalent name can be constructed, either because there is no meaningful equivalence between name and leading_name, or the system does not support constructing the requested equivalent name, for implementation-specific reasons.</td>
</tr>
<tr>
<td>FN_E_NO_SUCH_ATTRIBUTE</td>
<td>The object does not have an attribute with the given identifier.</td>
</tr>
<tr>
<td>FN_E_NO_SUPPORTED_ADDRESS</td>
<td>A context object could not be constructed from a particular reference. The reference contained no address type over which the context interface was supported.</td>
</tr>
<tr>
<td>FN_E_NOT_A_CONTEXT</td>
<td>Either one of the intermediate atomic names did not name a context, and resolution could not proceed beyond this point, or the operation required that the caller supply the name of a context, and the name did not resolve to a reference for a context.</td>
</tr>
<tr>
<td>FN_E_OPERATION_NOT_SUPPORTED</td>
<td>The operation attempted is not supported.</td>
</tr>
<tr>
<td>FN_E_PARTIAL_RESULT</td>
<td>The operation attempted is returning a partial result.</td>

Parameters Used in the Interface

- “Composite Names” on page 56
- “References and Addresses” on page 56
- “Identifiers” on page 56
- “Strings” on page 57
- “Attributes and Attribute Values” on page 57
- “Attribute Sets” on page 57
- “Attribute-Modification Lists” on page 58

This section gives an overview of the types of parameters that are passed and returned by operations in the base context and attribute interfaces. Manipulation of these objects using their corresponding interfaces does not affect their representation in the underlying naming system.

Changes to objects in the underlying naming system can only be effected through the use of the interfaces described in “The Base Context Interface” on page 31 and “Base Attribute Interface” on page 40.
Composite Names

A composite name is represented by an object of type `FN_composite_name_t`. A composite name is a sequence of components, where each component is a string (of type `FN_string_t`) intended to contain a name from a single naming system. (See “Syntax” on page 83 for a description of composite name syntax and structure.) Operations are provided to iterate over this sequence, modify it, and compare two composite names.

References and Addresses

A reference is represented by the type `FN_ref_t`. An object of this type contains a reference type and a list of addresses. The ordering in this list at the time of binding might not be preserved when the reference is returned upon lookup.

The reference type is represented by an object of type `FN_identifier_t`. The reference type is intended to identify the class of object referenced, but XFN does not dictate its precise use.

Each address in a reference is represented by an object of type `FN_ref_addr_t`. An address consists of an opaque data buffer and a type field, again of type `FN_identifier_t`. The address type is intended to identify the mechanism that should be used to reach the object using that address.

Multiple addresses in a single reference are intended to identify multiple communication endpoints for the same conceptual object. Multiple addresses can arise for various reasons; for example, because the object offers interfaces over more than one communication mechanism.

The client process must interpret the contents of the opaque buffers based on the type of the address and on the type of the reference. However, this interpretation is intended to occur below the application layer.

Most application developers should not be required to manipulate the contents of either address or reference objects themselves. These interfaces are generally used within service libraries.

Identifiers

Identifiers are used to identify reference types and address types in the reference and to identify attributes and their syntax in the attribute operations.

The `FN_identifier_t` type is used to represent an identifier. It consists of an unsigned integer, which determines the format of identifier, and the actual identifier, which is expressed as a sequence of octets.

XFN defines a small number of standard forms for identifiers, as shown in Table 2–4.
TABLE 2–4  XFN Identifier Formats

<table>
<thead>
<tr>
<th>Identifier Format</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>FN_ID_STRING</td>
<td>The identifier is an ASCII string (ISO 646).</td>
</tr>
<tr>
<td>FN_ID_DCE_UUID</td>
<td>The identifier is an OSF DCE UUID in string representation. See the X/Open DCE RPC (ISBN 1-872630-95-2).</td>
</tr>
<tr>
<td>FN_ID_ISO_OID_STRING</td>
<td>The identifier is an ISO OID in ASN.1 dot-separated integer list string format. See the ISO ASN.1 (ISO 8824).</td>
</tr>
</tbody>
</table>

Strings

The FN_string_t type represents character strings in the XFN interface. It provides a layer of insulation from specific string representations. The FN_string_t operations contain operations for string comparison, substring searches, and manipulation. The FN_string_t type supports multiple code sets. In Solaris 2.5, FNS supports ISO 646.

Attributes and Attribute Values

An attribute is represented by the FN_attribute_t type, and contains:

- An attribute identifier (of type FN_identifier_t)
- A syntax (of type FN_identifier_t)
- A set of distinct values (each value is a sequence of octets of type FN_attrvalue_t)

Various operations allow the construction, destruction, and manipulation of an attribute.

Attribute Sets

An attribute set is a set of attribute objects with distinct attribute identifiers. Attribute sets are represented by the FN_attrset_t type.

There are operations to allow the construction, destruction, and manipulation of an attribute set.
Attribute-Modification Lists

Use an attribute-modification list to specify multiple modification operations to be performed on the attributes associated with a single named object.

An attribute-modification list is represented by the FN_attrmodlist_t type. It consists of an ordered list of attribute-modification specifiers. Each specifier contains an operation and an attribute object. The attribute’s identifier indicates the attribute that is to be operated upon. How the attribute’s values are used depends on the operation.

The operation specifier is one of the values described in Table 2–1. The operations should be done in the order in which they appear in the list.

Parameters Used in Extended Search (Preliminary Specification)

The types of objects used to specify the scope and details of an extended search operation:

- the search control operations (FN_search_control_t)
- the search filter expression (FN_search_filter_t)

Search Control

The FN_search_control_t object encapsulates the different options that the application can specify in controlling the scope and the return values of the extended search operation, fn_attr_ext_search().

These options are:

- Scope of search. This determines which contexts and objects will be searched. The default is FN_SEARCH_ONE_CONTEXT.

<table>
<thead>
<tr>
<th>Scope</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FN_SEARCH_NAMED_OBJECT</td>
<td>Search just the given named object.</td>
</tr>
<tr>
<td>FN_SEARCH_ONE_CONTEXT</td>
<td>Search just the given context.</td>
</tr>
</tbody>
</table>
TABLE 2-5  Different Scopes for Searching  (continued)

<table>
<thead>
<tr>
<th>Scope</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>FN_SEARCH_SUBTREE</td>
<td>Search given context and all its subcontexts.</td>
</tr>
<tr>
<td>FN_SEARCH_CONSTRAINED_SUBTREE</td>
<td>Search given context and its subcontexts as constrained by the context-specific policy in place at the named context.</td>
</tr>
</tbody>
</table>

- Follow links during search. This determines whether links encountered during the search will be followed. The initial resolution phase of the operation (the resolution up to the target context) always follow links. This option controls the following of links after reaching the target context. The default is to not follow links.

- Maximum names returned. This specifies the maximum number of names to be returned before terminating the search. A value of 0 indicates that the search is terminated only when all the context and objects specified by the scope have been searched. The default is to return all named objects found.

- Return reference. This determines whether the reference of the object is returned. The default is to not return the reference.

- Return attributes. This determines which attributes associated with the named object, if any, are returned. The default is to not return any attributes.

Search Filter

The fn_attr_ext_search() operation allows the search for named objects whose attributes satisfy a given filter expression. The filter is expressed in terms of logical expressions involving attribute identifiers and their values of named objects examined during the search. The filter is created from an expression string and a list of arguments that replace substitution tokens within the expression string.

BNF of Filter Expression

\[
<\text{FilterExpr}> ::= \{ <\text{Expr}> \}
\]

(continued)
Specification of Filter Expression

The arguments to fn_search_filter_create() are a return status, an expression string, and a list of arguments. The string contains the filter expression with substitution tokens for the attributes, attribute values, strings and identifiers that are part of the expression. The remaining list of arguments contains the attributes and values in the order of appearance of their corresponding substitution tokens in the expression. The arguments are of types FN_attribute_t*, FN_attrvalue_t*, FN_string_t*, or FN_identifier_t*.

Except when attributes appear as arguments in specially defined extended operations, any attribute values in an FN_attribute_t type of argument are ignored; only the attribute identifier and attribute syntax are relevant. The argument type expected by each substitution token is listed in Table 2–6.
TABLE 2–6 Substitute Tokens in Search Filter Expressions

</tr>
</tbody>
</table>

Substitute Tokens in Search Filter Expressions

Precedence
The following precedence relations hold in the absence of parentheses, in the order of lowest to highest:

- or
- and
- not
- relational operators

These Boolean and relational operators are left associative.

Relational Operators
Table 2–7 contains descriptions of the relational operators. Comparisons and ordering are specific to the syntax or rules of the supplied attribute.

Locale (code set, language or territory) mismatches that occur during string comparisons and ordering operations are resolved in an implementation-dependent way. Relational operations that have ordering semantics may be used for strings of locales in which ordering is meaningful, but is not of general use in internationalized environments.

An attribute that occurs in the absence of any relational operator tests for the presence of the attribute.
### TABLE 2–7  Relational Operators in Search Filter Expressions

<table>
<thead>
<tr>
<th>Operator</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>The sub-expression is TRUE if at least one value of the specified attribute is equal to the supplied value.</td>
</tr>
<tr>
<td>!=</td>
<td>The sub-expression is TRUE if no values of the specified attribute equal the supplied value.</td>
</tr>
<tr>
<td>&gt;=</td>
<td>The sub-expression is TRUE if at least one value of the attribute is greater than or equal to the supplied value.</td>
</tr>
<tr>
<td>&gt;</td>
<td>The sub-expression is TRUE if at least one value of the attribute is greater than the supplied value.</td>
</tr>
<tr>
<td>&lt;=</td>
<td>The sub-expression is TRUE if at least one value of the attribute is less than or equal to the supplied value.</td>
</tr>
<tr>
<td>&lt;</td>
<td>The sub-expression is TRUE if at least one value of the attribute is less than the supplied value.</td>
</tr>
<tr>
<td>~=</td>
<td>The sub-expression is TRUE if at least one value of the specified attribute matches the supplied value according to some context-specific approximate matching criterion. This criterion must subsume strict equality.</td>
</tr>
</tbody>
</table>

### Wildcarded Strings

A wildcarded string consists of a sequence of alternating wildcard specifiers and strings. The sequence can start with either a wildcard specifier or a string, and end with either a wildcard specifier or a string.

The wildcard specifier is denoted by the asterisk character (*) and means 0 or more occurrences of any character.

Wildcarded strings can be used to specify substring matches. Table 2–8 contains examples of wildcarded strings and their meaning.
TABLE 2–8 Examples of Wildcarded Strings

<table>
<thead>
<tr>
<th>Wildcarded String</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>*</td>
<td>Any string</td>
</tr>
<tr>
<td>‘tom’</td>
<td>The string tom</td>
</tr>
<tr>
<td>‘harv’*</td>
<td>Any string starting with harv</td>
</tr>
<tr>
<td>*’ing’</td>
<td>Any string ending with ing</td>
</tr>
<tr>
<td>‘a’*’b’</td>
<td>Any string starting with a and ending with b</td>
</tr>
<tr>
<td>‘a*b’</td>
<td>The string a*b</td>
</tr>
<tr>
<td>‘jo’<em>’ph’</em>’ne’*’er’</td>
<td>Any string starting with jo, and containing the substring ph, and which contains the substring ne in the portion of the string following ph, and which ends with er</td>
</tr>
<tr>
<td>%s*</td>
<td>Any string starting with the supplied string</td>
</tr>
<tr>
<td>‘bix’*%s</td>
<td>Any string starting with bix and ending with the supplied string</td>
</tr>
</tbody>
</table>

Extended Operations

In addition to the relational operators, extended operators can be specified. All extended operators return either TRUE or FALSE. A filter expression can contain both relational and extended operations.

Extended operators are specified using an identifier (FN_identifier_t) or a string. If the operator is specified using a string, the string is used to construct an identifier of format FN_ID_STRING. Identifiers of extended operators and signatures of the corresponding extended operations, as well as their suggested semantics, are registered with X/Open.

The extended operations shown in Table 2–9 are currently defined:
The identifier for this operation is `name(FN_ID_STRING)`. The argument to this operation is a wildcarded string. The operation returns TRUE if the name of the object matches the supplied wildcarded string.

The identifier for this operation is `reftype(FN_ID_STRING)`. The argument to this operation is an identifier. The operation returns TRUE if the reference type of the object is equal to the supplied identifier.

The identifier for this operation is `addrtype(FN_ID_STRING)`. The argument to this operation is an identifier. The operation returns TRUE if any of the address types in the reference of the object is equal to the supplied identifier. Support and exact semantics of extended operations are context-specific. If a context does not support an extended operation, or if the filter expression supplies the extended operation with either an incorrect number or type of arguments, the error `FN_E_SEARCH_INVALID_OP` is returned. `FN_E_OPERATION_NOT_SUPPORTED` is returned when `fn_attr_ext_search()` is not supported.

Table 2–10 contains examples of filter expressions that contain extended operations.

### Table 2–10  Extended Operations in Search Filter Expressions

<table>
<thead>
<tr>

<td><code>name</code>('bill*')</td>
<td>Evaluates to TRUE if the name of the object starts with bill.</td>
</tr>
<tr>
<td><code>%i(%a, %v)</code></td>
<td>Evaluates to result of applying the specified operation to the supplied arguments.</td>
</tr>
<tr>
<td><code>(%a == %v) and 'name'('joe*')</code></td>
<td>Evaluates to TRUE if the specified attribute has the given value and if the name of the object starts with joe.</td>
</tr>
</tbody>
</table>
Parsing Compound Names

- “Syntax Attributes” on page 65
- “XFN Standard Syntax Model” on page 65

Because most applications treat names as opaque data, most clients of the XFN interface do not need to parse compound names from specific naming systems. When an application (such as a browser) needs to do this, however, it can use the FN_compound_name_t object.

Syntax Attributes

Each context has an associated set of syntax-related attributes. The attribute fn_syntax_type (FN_ID_STRING format) identifies the naming syntax supported by the context. The value “standard” (ASCII attribute syntax) in the fn_syntax_type attribute specifies that the context supports the XFN standard syntax model that is by default supported by the FN_compound_name_t object.

Implementations can choose to support other syntax types in addition to or in place of the XFN standard syntax model, in which case the value of the fn_syntax_type attribute is set to an implementation-specific string and different or additional syntax attributes are in the set.

Syntax attributes of a context can be generated automatically by a context, in response to fn_ctx_get_syntax_attrs(), or can be created and updated using the attribute operations. This is implementation dependent.

XFN Standard Syntax Model

Each naming system in an XFN federation has a naming convention. XFN defines a standard model of expressing compound name syntax that covers a large number of specific name syntaxes. This model is expressed in terms of syntax properties of the naming convention and it uses XFN attributes to describe properties of the syntax.

Unless otherwise qualified, the syntax attributes described in this section have attribute identifiers that use the FN_ID_STRING format. This does not specify or restrict the use of other formats for identifiers of additional syntax attributes supported by specific implementations.

In the XFN standard syntax model, these attributes are interpreted according to the following rules:

1. In a string without quotes or escapes, any instance of the separator string delimits two atomic names.
2. A separator, quotation mark, or escape string is escaped if preceded immediately (on the left) by the escape string.

3. A non-escaped begin-quote that precedes a component must be matched by a non-escaped end-quote at the end of the component. Quotes embedded in nonquoted names are treated as simple characters and do not need to be matched. An unmatched quotation fails with the status code FN_E_ILLEGAL_NAME.

4. If there are multiple values for begin-quote and end-quote, a specific begin-quote value must be matched with its corresponding end-quote value.

5. When the separator appears between a (nonescaped) begin-quote and the end-quote, it is ignored.

6. When the separator is escaped, it is not treated as a separator. An escaped begin-quote or end-quote string is not treated as a quotation mark. An escaped escape string is not treated as an escape string.

7. A non-escaped escape string appearing within quotes is interpreted as an escape string. This can be used to embed an end-quote within a quoted string.

8. An escape string that precedes a character other than an escape string, a begin-quote or an end-quote is consumed (in other words, escaping a non-meta character returns the non-meta character itself).

After constructing a compound name from a string, the resulting component atoms have one level of escape strings and quotations interpreted and consumed.

Code set mismatches that occur during the construction of the compound name’s string form are resolved in an implementation-dependent way. When an implementation discovers that a compound name has components with incompatible code sets, it returns the error code FN_E_INCOMPATIBLE_CODE_SETS. When an implementation discovers that a compound name has components with incompatible language or territory locale information, it returns the error code FN_E_INCOMPATIBLE_LOCALES.

Table 2–11 lists all the XFN standard syntax model attributes.

<table>
<thead>
<tr>
<th>Attribute Identifier</th>
<th>Attribute Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>fn_syntax_type</td>
<td>Its value is the ASCII string “standard” if the context supports the XFN standard syntax model. Its value is an implementation-specific value if another syntax model is supported.</td>
</tr>
<tr>
<td>fnSyntaxDirection</td>
<td>Its value is an ASCII string, one of “left-to-right,” “right-to-left,” or “flat.” This determines whether the order of components in a compound name string goes from left-to-right, right-to-left, or whether the namespace is flat (that is, not hierarchical, with all names atomic).</td>
</tr>
<tr>
<td>Attribute Identifier</td>
<td>Attribute Value</td>
</tr>
<tr>
<td>----------------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>fn_std_syntax_separator</td>
<td>Its value is the separator string for this name syntax. This attribute is required unless the fn_syntax_direction is flat.</td>
</tr>
<tr>
<td>fn_std_syntax_escape</td>
<td>If present, its value is the escape string for this name syntax.</td>
</tr>
<tr>
<td>fn_std_syntax_case_insensitive</td>
<td>If present, it indicates that names differing only in case are considered identical. If this attribute is absent, it indicates that case is significant. If a value is present, it is ignored.</td>

</tr>
</tbody>
</table>
### Compound Names

The **FN_compound_name_t** type is used to represent a compound name.

The **FN_compound_name_t** object has associated operations for applications to process compound names that conform to the XFN standard syntax model of expressing compound name syntax. Operations are provided to iterate over the list of atomic components of the name, modify the list, and compare two compound names.

An **FN_compound_name_t** object is constructed using the operation **fn_compound_name_from_attrset()**, with arguments consisting of a string name and an attribute set that contains the attribute "fn_syntax_type" with the value "standard."

</tbody>
</table>
XFN Programming Examples

This chapter presents self-contained executable programs for the following programs:
- A namespace browser
- A printer client and server
- A tool to populate attributes of users.

Namespace Browser Example

Figure 3–1 illustrates the XFN APIs that are used by the browser application.
The first example is a browser that lists all names that it finds in the namespace. When the program is invoked, the browser is set at the initial context or the composite name given on the command line.

See “Commands” on page 76 and “Sample Output” on page 76.

**CODE EXAMPLE 3–1** fnbrowse Source

```c
/*
 * fnbrowse.c -- FNS namespace browser.
 * To keep this example program relatively short, limited error checking is done.
 */

#include <stdio.h>
#include <stdlib.h>
#include <string.h>
#include <xfn/xfn.h>

#define LINELEN 128 /* maximum length of input line */

typedef enum {CMD_DOWN, CMD_UP, CMD_LIST, CMD_SHOW, CMD_QUIT} command;

static FN_status_t *status;
static unsigned int auth = 0; /* non-authoritative */

/* Lookup a context named relative to the initial context. */
FN_ctx_t *lookup(const FN_composite_name_t *name);

/* Set the browser’s focus to the given context. */
```

(continued)
void browse(FN_ctx_t *ctx);

/* Set the browser’s focus to a subcontext of the given context. */
void cmd_down(FN_ctx_t *ctx, const FN_composite_name_t *child);

/* Print the names bound within a context. */
void cmd_list(FN_ctx_t *ctx);

/*
 * Print a description of the reference bound to "child" in the
 * given context or, if "child" is the empty string, the reference
 * of the context itself.
 */
void cmd_show(FN_ctx_t *ctx, const FN_composite_name_t *child);

/*
 * Read and parse the next command typed by the user. If the
 * command has an argument, set *argp to point to the argument.
 */
command read_command(FN_string_t **argp);

/* Print an error message, and the description associated
 * with "status". */
void error(const char *msg);

int main(int argc, char *argv[])
{
    unsigned char *target;

    switch (argc) {
    case 1:
        target = (unsigned char *)"";
        break;
    case 2:
        target = (unsigned char *)argv[1];
        break;
    default:
        fprintf(stderr, "Usage: %s [<composite_name>]
", argv[0]);
        return (1);
    }

    status = fn_status_create();

    browse(lookup(fn_composite_name_from_str(target)));
    return (0);
}

            child = strtok(NULL, " \	");
            if (child != NULL) {
                *argp = fn_string_from_str((unsigned char *)child);
                return (CMD_DOWN);
            }
        }
        if (strcmp(cmd, "up") == 0) {
            return (CMD_UP);
        }
    }
}
if (strcmp(cmd, "list") == 0) {
    return (CMD_LIST);
}
if (strcmp(cmd, "show") == 0) {
    child = strtok(NULL, " 	");
    *argp = (child != NULL)
    ? fn_string_from_str((unsigned char *)child)
    : fn_string_create();
    return (CMD_SHOW);
}
if (strcmp(cmd, "quit") == 0) {
    return (CMD_QUIT);
}
fprintf(stderr, "Valid commands are: ",
    "down <child>, up, list, show [<child>], quit
    */
}
}

void
error(const char *msg)
{
    FN_string_t *reason;
    unsigned int statcode;
    fprintf(stderr, "%s", msg);
    reason = fn_status_description(status, 0, NULL);
    if (reason != NULL) {
        fprintf(stderr, ": %s",
            (const char *)fn_string_str(reason, &statcode));
        fn_string_destroy(reason);
    }
    fprintf(stderr, 
        "); * EOF */
}

Compiling and Executing Browser Example

To compile Code Example 3–1, type:

```
% cc -o fnbrowse fnbrowse.c -lxfn
```

To browse the namespace starting from the initial context, the program is invoked as:

```
% fnbrowse
```

Or to browse a composite name and its descendents, type:

```
% fnbrowse composite_name
```
Commands

The commands supported by the fnbrowse program are summarized in Table 3–1.

**TABLE 3–1  Namespace Browser Commands**

<table>
<thead>
<tr>
<th>Command</th>
<th>Usage</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>down</em> <em>child</em></td>
<td>Sets the browser at the subcontext of the child</td>
</tr>
<tr>
<td><em>up</em></td>
<td>Sets the browser at one level higher than the current context</td>
</tr>
<tr>
<td><em>list</em></td>
<td>Lists the names bound within the current context</td>
</tr>
<tr>
<td><em>show</em></td>
<td>Prints the reference of the current context</td>
</tr>
<tr>
<td><em>show</em> <em>child</em></td>
<td>Prints the reference of the current context’s child</td>
</tr>
<tr>
<td><em>quit</em></td>
<td>Exits the browser</td>
</tr>
</tbody>
</table>

Sample Output

Sample output for navigating the entire namespace is displayed here.

Note the following:
- The first *list* command shows the initial context bindings.
- The fnbrowse program lists all names it finds in the namespace, including names with underscores. These names are explained in “Initial Context Bindings” on page 16.
- The three dots (…) represent the global namespace.

```
% fnbrowse
> list
_myorgunit ... _myself thishost myself _orgunit _host
_thisens myens thisens org orgunit thisuser _thishost
myorgunit _user thisorgunit host _thisorgunit _myens user
```

Navigating the namespace is accomplished with the *up* and *down* commands. In the following output, the *down* command brings the focus of the browser to the
enterprise root of the namespace, thisens (can also be myens). The show command displays information about the reference and address type for thisens.

```
> down thisens
> show
Reference type: onc_fn_enterprise
Address type: on_fn_nisplus
  length: 20
  context type: enterprise root
  representation: normal
  version: 0
  internal name: eng.wiz.com
> up
> down thisorgunit
```

Continuing with the example, this list command shows the contexts for thisorgunit.

```
> list
  service _fs _host _service _site site _user host fs user
> down usr
  Lookup failed: Name Not Found: 'usr'
> down service
> list
  printer
> down printer
```

The list command shows the printer names that are bound in the printer context. The show command displays the reference for the child, colorful.

```
> list
  celeste _default color colorful quartz nuttree puffin
> show colorful
  printer
Reference type: onc_printers
Address type: onc_printers_bsdaddr
  length: 12
  data: 0x00 0x00 0x00 0x08 0x62 0x6c 0x61 0x63 0x6b 0x63 ....blackc 0x61 0x74 at
> down colorful
  Could not construct context handle: No Supported Address
> quit
```
Printer Programming Example

Printer client and server software can take advantage of FNS to advertise and to browse the printers available with respect to organizations, sites, users, and hosts. The APIs used by the server and the client are XFN APIs, thereby ensuring that the application is portable across the different naming services used for storing printer bindings.

The programming example in this section shows how printer clients and servers obtain and store printer bindings. Users can then make use of the FNS commands, fnlist and fnlookup, to browse the printer context.

For example, use fnlist to look at the user printer context for jsmith:

```
% fnlist user/jsmith/service/printer
  celeste
  lp
  _default
  myprinter
```

Similarly, you can look at the organization’s printers:

```
% fnlist org/wiz.com/service/printer
  sales_printer
  mktg_printer
  eng_printer
```

Alternatively, you can type:

```
% fnlist thisorgunit/service/printer
```

You can look at the printers at a specific site, for example, the printers in the MTV site:

```
% fnlist thisorgunit/site/MTV/service/printer
  b1_printer
  b2_printer
```

Client

The scenario for Code Example 3–2 is a user who would like to print to a printer named colorful in his organization's context, thisorgunit/service/printer/colorful. The example printer client illustrates how the bindings for a specific printer are obtained.
The variable `printer_binding` contains the reference (the binding information) of the named printer. Using the binding information, the printer client can connect to the server and send the printer request. Note that the `fn_ctx_lookup()` function can be replaced by `fn_ctx_list_name()` or `fn_ctx_list_bindings()` to list all the names and their bindings.

**CODE EXAMPLE 3-2**  Print Client source

```c
#include <stdio.h>
#include <xfn/xfn.h>
#include <string.h>
#include <stdlib.h>

/*
 * Routine to obtain the address of a specific printer.
 * This routine takes the printer name and the address type
 * as the input arguments and returns the address
 * of the requested printer.
 */

char *
get_address_of_printer(const char *printer_name,
    const char *address_type)
{
    FN_composite_name_t *printer_name_comp;
    FN_status_t *status = fn_status_create();
    FN_ctx_t *initial_context;
    FN_ref_t *printer_ref;
    const FN_identifier_t *addr_id;
    const FN_ref_addr_t *address;
    char *addr_data; /* Return value */
    void *ip;
    size_t address_type_len, addr_len;

    /* Convert the printer name to a composite name */
    printer_name_comp = fn_composite_name_from_string(
        (const unsigned char *)printer_name);

    /* Get the initial context */
    initial_context = fn_ctx_handle_from_initial(0, status);

    /* Check status for any error messages */
    if (!fn_status_is_success(status)){
        fprintf(stderr, "Unable to obtain the initial context\n");
        return (0);
    }

    /* Perform a lookup for the printer name */
    printer_ref = fn_ctx_lookup(initial_context,
        printer_name_comp, status);

    /* Check status for any error messages */
    if (!fn_status_is_success(status)){
        fprintf(stderr, "Lookup failed on: %s\n",
            (continued)
```

XFN Programming Examples  79
Calling the Printer Client Function

The following code could be used to call the `get_address_of_printer()` routine shown above.

```c
char* printer_server;
printer_server = get_address_of_printer
    "thisorgunit/service/printer/colorful",
    "onc_bsdaddr");
```

Server

Using the XFN APIs, print servers can advertise their services. Code Example 3–3 illustrates a host, labpc, that would like to advertise the binding for the color printer colorful. The FNS name for this printer is `thisorgunit/service/printer/colorful`. 

80 Federated Naming Service Programming Guide ♦ February 2000
The main tasks are to obtain the composite name for the printer name, to generate the binding (reference) for the printer, and to bind the name and references to the FNS namespace.

**CODE EXAMPLE 3–3**  Print Server Source

```c
#include <stdio.h>
#include <xfn/xfn.h>
#include <string.h>

/*
 * Routine to export the printer binding to the FNS name space.
 * This routine takes the printer name along with its
 * reference type, address type, and address. Returns the status.
 */

int export_printer_to_fns(const char *printer_name,
const char *reference_type,
const char *address_type,
const char *address_data)
{
    int return_status;
    FN_composite_name_t *printer_name_comp;
    FN_identifier_t ref_id, addr_id;
    FN_status_t *status;
    FN_ref_t *printer_ref;
    FN_ref_addr_t *address;
    FN_ctx_t *initial_context;

    /* Obtain the initial context */
    status = fn_status_create();
    initial_context = fn_ctx_handle_from_initial(0, status);
    /* Check status for any error messages */
    if ((return_status = fn_status_code(status)) != FN_SUCCESS) {
        fprintf(stderr, "Unable to obtain the initial context\n");
        return (return_status);
    }

    /* Construct the composite name for the printer name */
    printer_name_comp = fn_composite_name_from_string((unsigned char *)printer_name);

    /* Construct the printer address */
    addr_id.format = FN_ID_STRING;
    addr_id.length = strlen(address_type);
    addr_id.contents = (void *) address_type;
    address = fn_ref_addr_create(&addr_id, strlen(address_data), (const void *) address_data);

    /* Construct the printer reference */
    ref_id.format = FN_ID_STRING;
    ref_id.length = strlen(reference_type);
    ref_id.contents = (void *) reference_type;
    printer_ref = fn_ref_create(&ref_id);

    /* Add the printer address to the printer reference */
    fn_ref_append_addr(printer_ref, address);
}
```

(continued)
/* Bind the reference to the context */
fn_ctx_bind(initial_context, printer_name_comp, printer_ref, 0,
status);
/* Check the error status and return */
return_status = fn_status_code(status);

fn_composite_name_destroy(printer_name_comp);
fn_ref_addr_destroy(address);
fn_ref_destroy(printer_ref);
fn_status_destroy(status);
fn_ctx_handle_destroy(initial_context);
return (return_status);
}

Calling the Printer Server Function
The following code could be used to call the export_printer_to_fns() routine shown above.

```c
export_printer_to_fns
 "thisorgunit/service/printer/colorful",
 "onc_printers",
 "onc_bsdaddr",
 "labpc");
```
XFN Composite Names

This appendix describes XFN composite names in detail.

- “Syntax” on page 83
- “Composite Name and Naming System Boundaries” on page 85
- “Strong Separation” on page 86
- “Weak Separation” on page 86
- “Composite Name Resolution” on page 87
- “Explicit NNSPs: Junctions” on page 87
- “Implicit NNSPs” on page 88
- “XFN Links” on page 89
- “Composite Name Encoding” on page 89
- “Backus-Naur Form (BNF)” on page 90
- “Decomposing the Composite Name String” on page 92
- “Composing the Composite Name String” on page 93

Syntax

The standard string form for XFN composite names is the concatenation of the components of a composite name from left to right, with the XFN component separator character (/) separating each component. Components can be quoted using either double-quote ("\") or single-quote (’\’) pairs. You can use a backslash character (\) to escape the XFN component separator or quote characters if the intention is for these characters not to behave as separators or quotes. Note that quotation marks and escape characters are interpreted as such only when they appear in places that
need quotes or escapes. For example, a quote appearing in an unquoted component is not interpreted as a quote.

XFN defines an abstract data type, \texttt{FN\_composite\_name\_t}, for representing the structural form of a composite name. XFN also defines the syntax of how component string names are composed into an XFN composite name and the corresponding rules for converting an XFN composite name to its structural form from its string form, and vice versa. The XFN client interface includes operations that perform these conversions.

Table A–1 contains some examples of how the string form of XFN composite names are decomposed into components according to the syntax of XFN composite names. See also “Composite Name Encoding” on page 89 for more information.

\begin{table}[h]
\centering
\caption{String and Structural Forms of XFN Composite Names}
\begin{tabular}{ll}
\hline
String form & Components in \texttt{FN\_composite\_name\_t} \\
\hline
a & a \\
a/b/c & a, b, c \\
a/ & a, "" \\
/ & "", a \\
a// & a, "", "" \\
a//b & a, "", b \\
"" & "" \\
/ & "", "" \\
// & "", "", "" \\
"a/b/c"/d & a/b/c, d \\
"a.b.c"/d & a.b.c, d \\
a.b.c/d & a.b.c, d \\
a"b/c & a"b, c \\
\hline
\end{tabular}
\end{table}
### Composite Name and Naming System Boundaries

There might not be a one-to-one correspondence between component separators and naming system boundaries if a composite name contains names from naming systems that use the same character as the XFN component separator to separate their atomic names. Consequently, a component of a composite name might represent an atomic name from a hierarchical naming system that uses the XFN component separator or a compound name. *Strong separation* and *weak separation* refer to how a context considers the XFN component separator as a naming system boundary.

Strong Separation

An XFN context that treats the XFN component separator as a naming system boundary supports strong separation. An XFN component separator that appears within a component to be resolved by the context must be escaped or quoted.

Support for strong separation is a property of a context. A context that supports strong separation expects to receive the name that it is going to resolve entirely in one component of the composite name structure. When a composite name is supplied to such a context, it consumes the leading component of the name; any remaining components are left to be resolved by subordinate naming systems.

An XFN context with a name syntax that is either flat or hierarchical, and does not use the XFN component separator as its atomic separator, supports strong separation. Examples of naming systems that support strong separation are DNS and NIS+, both of which have right-to-left dot-separated names. The following are examples of names with DNS and NIS+ components, respectively.

.../wiz.com/orgunit/ppt
orgunit/accounts_payable.finance/user/jsmith

Weak Separation

An XFN context that does not always treat the XFN component separator as a naming system boundary supports weak separation. This arises when the component naming system associated with the context uses the same character as the XFN component separator as its atomic component separator. The context allows its atomic separator to appear unescaped and unquoted in its compound names when they occur in composite names. This means that an XFN component separator might not necessarily signify a naming system boundary.

Support for weak separation is a property of a context. A context that supports weak separation expects to receive its atomic names in separate components of the composite name structure. When a composite name is supplied to a context that supports weak separation, the context consumes the leading components of the name (and treats them as atomic components); any remaining components are resolved by subordinate naming systems. The number of components consumed is determined either syntactically or dynamically.

CDS names and X.500 names are examples of names that use the XFN component separator as their atomic name separator. X.500 supports weak separation using a syntactic method (by scanning for typed names) while CDS supports weak separation by determining the naming system boundary dynamically.

The following example shows a composite name with an X.500 component.

.../c=us/o=wiz.com/orgunit/ppt
Note - An XFN context that supports weak separation using only syntax-specific
discovery of its naming system boundary might not always be federated with
arbitrary subordinate naming systems. If the subordinate naming system has a
naming syntax that is indistinguishable from that of the superior naming system, the
superior naming system is not able to identify the naming system boundary.

Naming systems that use the same character as the XFN component separator as
their atomic separator, and which cannot support weak separation because it cannot
use a syntactic or dynamic method to determine the naming system boundary, must
provide context implementations that support strong separation. This means that
occurrences of atomic separators must be quoted or escaped when they appear in
compound names within composite names.

Composite Name Resolution

Composite name resolution combines resolution in each component naming system
and resolution across federated naming system boundaries. There are several
techniques for resolving an XFN composite name in the underlying federation of
naming systems.

This section describes two implementation techniques for composite name resolution
across a naming system boundary. One technique uses an explicit next naming
system pointer (NNSP) to resolve across a naming system boundary, while the other
uses an implicit NNSP.

An NNSP is the XFN reference of an XFN context in which composite name
components from subordinate naming systems are to be resolved. NNSPs are entities
that “tie” naming systems together into a federated system. NNSPs can be bound to
names, in which case they are explicit NNSPs or junctions. NNSPs can also be
nameless, in which case they are implicit NNSPs.

Explicit NNSPs: Junctions

A junction is an atomic name that is bound to an NNSP. It is a terminal name in the
superior naming system. There is no limit to the number of junctions bound in a
single context, except that imposed by the context. A context can reserve certain
names for use as junctions or have other policies for selecting names for use as
junctions. The conventions used for identifying junctions and their references are
context-specific.

Composite name resolution involving junctions proceeds as follows, depending on
whether the context supports strong or weak separation.
A context that supports strong separation and junctions consumes the first component of the composite name supplied to it. The last atomic name of the first component must be a junction. Any remaining components are resolved in the context named by the junction.

A context that supports weak separation and junctions resolves a composite name by consuming leading components until a junction is reached, at which point resolution of any remaining components is continued in the context resolved by the junction. Determination of whether a component is a junction can be done statically, using a syntactic policy, or dynamically during resolution.

**Implicit NNSPs**

When a context does not want to use part of its namespace for junctions, it uses implicit NNSPs for federating subordinate naming systems. An implicit NNSP is named using the XFN component separator. For example, the name `wiz.com/` names the implicit NNSP of `wiz.com`. Each context can have one implicit NNSP.

Composite name resolution involving implicit NNSPs proceeds as follows, depending on whether the context supports strong or weak separation.

A context that supports strong separation and resolves composite names using an implicit NNSP consumes the first component of the composite name supplied to it. Any remaining components are resolved in the context pointed to by the implicit NNSP of the first component.

A context that supports weak separation and implicit NNSPs in its implementation needs to distinguish the use of the XFN component separator character as an XFN component separator or an atomic separator. This means that such a context needs to know when to exit the current (native) naming system and follow the NNSP. This can be achieved using a static, syntactic policy or a dynamic, resolution-based policy.

With the syntactic policy, a context syntactically discovers where the boundary between its naming system and the subordinate naming system lies. This can impose certain restrictions on the syntax of subordinate naming systems. Subordinate naming systems must not permit, as valid top-level names, that are syntactically indistinguishable from names allowed in the superior naming system. For example, assume the superior naming system has a name syntax whose distinguishing feature is that each atomic part must have an equal sign (=). The superior naming system might impose as a policy that subordinate naming systems must not have top-level names with an equal sign in them. Resolution in the superior naming system continues until all leading components of the supplied composite name fitting the syntactic rule are consumed. Any remaining components are resolved in the context of the NNSP of the last component fitting the syntactic rule.

If a context is not able to syntactically differentiate between atomic components and composite name components, or does not want to impose any syntactic restrictions, it might be able to determine the naming system boundary at runtime, during
resolution. The policy is to continue resolution in the current naming system until resolution fails, at which point the implicit NNSP associated with the last context at which resolution succeeded is used to continue the resolution. A conflict arises if the same atomic name is bound both in the last context and the context pointed to by the last context’s implicit NNSP. In this case, the binding in the last context takes precedence. This way of supporting weak separation requires the context to have the capability of returning remaining unresolved parts of a given name.

Coexistence of Explicit and Implicit NNSPs

Naming systems that implement either technique can coexist in a federation. A naming system that supports composite name resolution using junctions can be federated with one that supports implicit NNSPs, and vice versa.

XFN Links

An XFN link affects name resolution in the following way. Suppose \textit{lname} is a link bound to the atomic name \textit{aname} in the context \textit{ctx}. If at some point resolution of a composite name \textit{cname} reaches the context \textit{ctx} and the next atomic name is \textit{aname}, resolution of \textit{aname} results in the resolution of the link name \textit{lname}. This is termed “following the link.” If the first component of the link \textit{lname} is the atomic name “.”, the remaining components of \textit{lname} are resolved relative to \textit{ctx}; otherwise, \textit{lname} is resolved from the initial context. The resolution of any remaining portion of the name \textit{cname} proceeds from the reference that results by resolving \textit{lname}.

The link name can itself cause resolution to resolve through other links. This gives rise to the possibility of a cycle of links whose resolution could not terminate normally. As a simple means to avoid such nonterminating resolutions, implementations can define limits on the number of XFN links that can be resolved in any single operation invoked by the caller.

Composite Name Encoding

All XFN implementations are required to support the ISO 646 portable representation (same encoding as ASCII) for XFN composite names. All other representations are optional.

All characters of the string form of an XFN composite name use a single encoding. Characters with different encodings cannot exist in the same name string. This does not preclude component names of a composite name in its structural form from having different encodings. Code set mismatches that occur during the process of
converting a composite name structure to its string form are resolved in an implementation-dependent way. Strings with code sets that are determined by the implementation to be compatible are converted without loss of information into a single representation, which is also determined by the implementation. When an implementation discovers that a composite name has components with incompatible code sets, it returns the error code FN_E_INCOMPATIBLE_CODE_SETS.

Backus-Naur Form (BNF)

The following defines the standard string form of XFN composite names in Backus-Naur Form (BNF). All the characters of the string representation of one name must uniformly use the same encoding and locale information. The notations used are as shown in Table A–2:

| TABLE A–2  Backus-Naur Notation |
|------------|--------------------------------|
| Symbol     | Meaning                        |
| :=         | Is defined to be               |
| |          | Alternatively                  |
| <text>     | Nonterminal element           |
| \             | Literal expression             |
| *          | The preceding syntactic unit can appear 0 or more times. |
| +          | The preceding syntactic unit can appear 1 or more times. |
| { }        | The enclosed syntactic units are grouped as a single syntactic unit (can be nested). |

The XFN composite name syntax in BNF is shown in Table A–3:
<table>
<thead>
<tr>
<th>XFN Composite Name</th>
<th>BNF Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL ::=</td>
<td>// Empty set</td>
</tr>
</tbody>
</table>
| <PCS> ::=          | // Portable Character Set

| <CompositeName> ::= NULL  
|                   | | <Component> {<ComponentSep> <Component>}]*  

XFN Composite Names  91
Decomposing the Composite Name String

The function \texttt{fn\_composite\_name\_from\_string()} returns an XFN composite name in its structural form, \texttt{FN\_composite\_name\_t}, given the composite name's string representation. The syntax rules used by \texttt{fn\_composite\_name\_from\_string()} are as follows:

- An XFN composite name is decomposed into an ordered set of components \(<\text{Component}>\).

- Each component represents a compound name, or a single atomic name of a compound name if the compound name's syntax uses the XFN component separator (/) as a separator for its atomic parts and the compound name is not quoted.

The following are the rules for parsing a composite name.

1. Any \(<\text{Component}\text{Sep}>\) character that is neither escaped nor enclosed in quoted strings is considered to be a component separator.
2. Any string enclosed by component separators is a component \(<\text{Component}>\).
3. A composite name is parsed and decomposed into components from left to right:
   a. The first component is the string preceding the first occurrence of a component separator.
   b. Empty components are processed as follows:
      i. A leading component separator (the composite name begins with a component separator) means a leading null component.
      ii. A trailing component separator (the composite name ends with a component separator) means a trailing null component.
   c. Two consecutive component separators mean a null component.
   d. The name string that immediately follows the last component separator of the composite name is the final component.
4. A component string is evaluated from left to right and converted into its standard form according to the following rules:
   a. A component string is considered to be quoted if it is enclosed in a pair of matching unescaped quote characters (either a \(<\text{Quote1}>\) or a \(<\text{Quote2}>\) pair). The quoted string must represent the full component; that is, a begin quote must immediately be preceded by a component separator or no character, and the end quote must immediately be followed by a component separator or no character.
   b. If a component does not contain a valid begin quote (a \(<\text{Quote1}>\) or \(<\text{Quote2}>\) immediately preceded by either a component separator or no character), any occurrence of \(<\text{Quote1}>\) or \(<\text{Quote2}>\) within that component is treated just as any other \(<\text{SimpleChar}>\).
c. An unmatched begin quote (missing or misplaced end quote) fails with an 
FN_E_ILLEGAL_NAME status.
d. Quotes are considered to be escaped in quoted strings if a matching quote 
character is preceded immediately by the unescaped <EscapeChar>.
e. Quoted components are resolved by eliminating the quote characters from the 
component name and substituting possibly escaped quotes by simple quote 
characters. <MetaChar>s and the nonmatching quote characters enclosed in 
quoted strings are treated just as any other <SimpleChar>.
f. Any of the defined metacharacters (<ComponentSep> and <EscapeChar>) is 
considered to be escaped in an unquoted component name string if preceded 
immediately by the unescaped <EscapeChar> (for instance, the sequence 
<EscapeChar> <EscapeChar> <ComponentSep> denotes an escaped <EscapeChar> 
but an unescaped <ComponentSep>).
g. <Quote1> and <Quote2> are considered to be escaped in an unquoted 
component if and only if <EscapeChar> is preceded by a component separator 
(that is, sequences <ComponentSep> <EscapeChar> <Quote1> or <ComponentSep> 
<EscapeChar> <Quote2>). Other occurrences of <Quote1> and <Quote2> in an 
unquoted component are treated just as any other <SimpleChar>.
h. Any occurrence of escaped <MetaChar>, escaped <Quote1>, or escaped 
<Quote2> in unquoted components is substituted by the corresponding 
escaped character.
i. No substitution is done for <EscapeChar> <SimpleChar>. <EscapeChar> 
<SimpleChar> maps to <EscapeChar> <SimpleChar>.

Composing the Composite Name String
The function fn_string_from_composite_name() returns the string 
representation of an XFN composite name given its structural form 
(FN_composite_name_t). The following are the rules used by 
fn_string_from_composite_name().
1. The components are added to the composite name string in left to right order 
(that is, rightmost is the tail).
2. Successive components are separated by the component separator 
(ComponentSep).
3. Empty components are handled in the following way:
   a. A leading empty component is represented by a leading <ComponentSep>.
   b. A trailing empty component is represented by a trailing <ComponentSep>.
   c. An empty component occurring within a composite name is represented by 
two consecutive <ComponentSep>s.
4. A composite name denoting a single non-empty component does not contain any 
escaped component separator.
5. Any occurrence of <ComponentSep> in a component is escaped by inserting 
<EscapeChar> immediately preceding <ComponentSep>.
6. If the first character of a component is either \textit{<Quote1>} or \textit{<Quote2>}, it will be escaped by inserting \textit{<EscapeChar>} immediately preceding the quote.

7. Any occurrence of \textit{<EscapeChar>} before \textit{<ComponentSep>} in a component is escaped by inserting \textit{<EscapeChar>} immediately preceding the \textit{<EscapeChar>}

8. Any occurrence of \textit{<EscapeChar>} as the first character of a component with \textit{<Quote1>} or \textit{<Quote2>} as the second character in a component is escaped by inserting \textit{<EscapeChar>} immediately preceding the \textit{<EscapeChar>}. Subsequent \textit{<EscapeChar>} occurring before any matching quote character is also escaped by inserting \textit{<EscapeChar>} immediately preceding the \textit{<EscapeChar>}.
This appendix provides supplemental information about XFN composite name syntax.

### XFN Composite Name Encoding

All XFN implementations are required to support the ISO 646 portable representation (same encoding as ASCII) for XFN composite names. All other representations are optional.

All characters of the string form of an XFN composite name use a single encoding. There cannot be characters with different encodings in the same name string. This does not preclude component names of a composite name in its structural form from having different encodings. Code set mismatches that occur during the process of converting a composite name structure to its string form are resolved in an implementation-dependent way. Strings with code sets that are determined by the implementation to be compatible are converted without loss of information into a single representation, which is also determined by the implementation. When an implementation discovers that a composite name has components with incompatible code sets, it returns the error code FN_E_INCOMPATIBLE_CODE_SETS.
XFN Backus-Naur Form (BNF)

The following defines the standard string form of XFN composite names in Backus-Naur Form (BNF). All the characters of the string representation of one name must uniformly use the same encoding and locale information. The notations used are shown in Table B–1:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>::=</td>
<td>Is defined to be</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>&lt;text&gt;</td>
<td>Nonterminal element</td>
</tr>
<tr>
<td>* *</td>
<td>Literal expression</td>
</tr>
<tr>
<td>*</td>
<td>The preceding syntactic unit can appear 0 or more times.</td>
</tr>
<tr>
<td>+</td>
<td>The preceding syntactic unit can appear 1 or more times.</td>
</tr>
<tr>
<td>()</td>
<td>The enclosed syntactic units are grouped as a single syntactic unit (can be nested).</td>
</tr>
</tbody>
</table>

The XFN composite name syntax in BNF is shown in Table B–2:

<table>
<thead>
<tr>
<th>XFN Composite Name</th>
<th>BNF Syntax</th>
</tr>
</thead>
<tbody>
<tr>
<td>NULL ::=</td>
<td>// Empty set</td>
</tr>
<tr>
<td>&lt;PCS&gt; ::=</td>
<td>// Portable Character Set.</td>
</tr>
</tbody>
</table>

The set consists of the glyphs:
// thirteen glyphs: 
// !*#$%&'()++",.\0123456789:;<=>?
// @ABCDEFghijklmnopqrstuvwxyz[^~]
// abcdefghijklmnopqrstuvwxyz[^~]
XFN Decomposing the Composite Name String

The function `fn_composite_name_from_string()` returns an XFN composite name in its structural form, `FN_composite_name_t`, given the composite name’s string representation. The syntax rules used by `fn_composite_name_from_string()` are as follows:
An XFN composite name is decomposed into an ordered set of components
\(<Component>\).

Each component represents a compound name, or a single atomic name of a
compound name if the compound name's syntax uses the XFN component
separator (/) as a separator for its atomic parts and the compound name is not
quoted.

The following are the rules for parsing a composite name:

1. Any \(<ComponentSep>\) character that is neither escaped nor enclosed in quoted
   strings is considered to be a component separator.
2. Any string enclosed by component separators is a component \(<Component>\).
3. A composite name is parsed and decomposed into components from left to right:
   a. The first component is the string preceding the first occurrence of a component
      separator.
   b. Empty components are processed as follows:
      i. A leading component separator (the composite name begins with a
         component separator) means a leading null component.
      ii. A trailing component separator (the composite name ends with a
          component separator) means a trailing null component.
   c. Two consecutive component separators mean a null component.
   d. The name string that immediately follows the last component separator of the
      composite name is the final component.
4. A component string is evaluated from left to right and converted into its standard
   form, according to the following rules:
   a. A component string is considered to be quoted if it is enclosed in a pair of
      matching unescaped quote characters (either a \(<Quote1>\) or a \(<Quote2>\) pair).
      The quoted string must represent the full component; that is, a begin quote
      must immediately be preceded by a component separator or no character, and
      the end quote must immediately be followed by a component separator or no
      character.
   b. If a component does not contain a valid begin quote (a \(<Quote1>\) or \(<Quote2>\)
      immediately preceded by either a component separator or no character), any
      occurrence of \(<Quote1>\) or \(<Quote2>\) within that component is treated just as
      any other \(<SimpleChar>\).
   c. An unmatched begin quote (missing or misplaced end quote) fails with an
      FN_E_ILLEGAL_NAME status.
   d. Quotes are considered to be escaped in quoted strings if a matching quote
      character is preceded immediately by the unescaped \(<EscapeChar>\).
   e. Quoted components are resolved by eliminating the quote characters from the
      component name and substituting possibly escaped quotes by simple quote

---

Federated Naming Service Programming Guide ♦ February 2000
characters. <MetaChar>s and the nonmatching quote characters enclosed in quoted strings are treated just as any other <SimpleChar>.

f. Any of the defined metacharacters (<ComponentSep> and <EscapeChar>) is considered to be escaped in an unquoted component name string if preceded immediately by the unescaped <EscapeChar> (for instance, the sequence <EscapeChar> EscapeChar>ComponentSep> denotes an escaped <EscapeChar> but an unescaped <ComponentSep>.

g. <Quote1> and <Quote2> are considered to be escaped in an unquoted component if and only if <EscapeChar> is preceded by a component separator (that is, sequences <ComponentSep> <EscapeChar> <Quote1> or <ComponentSep> <EscapeChar> <Quote2>). Other occurrences of <Quote1> and <Quote2> in an unquoted component are treated just as any other <SimpleChar>.

h. Any occurrence of escaped <MetaChar>, escaped <Quote1>, or escaped <Quote2> in unquoted components is substituted by the corresponding unescaped character.

i. No substitution is done for <EscapeChar> SimpleChar>. <EscapeChar> SimpleChar> maps to <EscapeChar> <SimpleChar>.

XFN Composing the Composite Name String

The function fn_string_from_composite_name() returns the string representation of an XFN composite name given its structural form (FN_composite_name_t). The following are the rules used by fn_string_from_composite_name().

1. The components are added to the composite name string in left to right order (that is, rightmost is the tail).

2. Successive components are separated by the component separator (<ComponentSep>).

3. Empty components are handled in the following way:
   a. A leading empty component is represented by a leading <ComponentSep>.
   b. A trailing empty component is represented by a trailing <ComponentSep>.
   c. An empty component occurring within a composite name is represented by two consecutive <ComponentSep>s.

4. A composite name denoting a single non-empty component does not contain any unescaped component separator.

5. Any occurrence of <ComponentSep> in a component is escaped by inserting <EscapeChar> immediately preceding <ComponentSep>.
6. If the first character of a component is either \:<Quote1> or \:<Quote2>, it will be escaped by inserting \:<EscapeChar> immediately preceding the quote.

7. Any occurrence of \:<EscapeChar> before \:<ComponentSep> in a component is escaped by inserting \:<EscapeChar> immediately preceding the \:<EscapeChar>.

8. Any occurrence of \:<EscapeChar> as the first character of a component with \:<Quote1> or \:<Quote2> as the second character in a component is escaped by inserting \:<EscapeChar> immediately preceding the \:<EscapeChar>. Subsequent \:<EscapeChar> occurring before any matching quote character is also escaped by inserting \:<EscapeChar> immediately preceding the \:<EscapeChar>. 
## Glossary

| **application-level name service** | Application-level name services are incorporated in applications offering services such as files, mail, and printing. Application-level name services are bound below enterprise-level name services. The enterprise-level name services provide contexts in which contexts of application-level name services can be bound. |
| **atomic name** | An indivisible component of a name as defined by the naming convention. |
| **attribute** | Each named object is associated with a set of zero or more attributes. Each attribute in the set has a unique attribute identifier, an attribute syntax, and a set of zero or more distinct attribute values. |
| **binding** | The association of an atomic name with an object reference. For simplicity, an object reference and the object it refers to are used interchangeably in this guide. |
| **BNF** | Backus-Naur Form. |
| **composite name** | A name that spans multiple naming systems. It consists of an ordered list of zero or more components. Each component is a name from the namespace of a single naming system. Composite name resolution is the process of resolving a name that spans multiple naming systems. |
| **compound name** | A sequence of atomic names composed according to the naming convention of a naming system. |
| **context** | An object whose state is a set of bindings with distinct atomic names. Every context has an associated naming convention. A context provides a lookup (resolution) operation, which returns the reference, and may provide operations such as binding names, unbinding names, and listing bound names. |
DNS  
Domain Name System. A system that provides the naming policy and mechanisms for mapping domain and machine names to addresses on the Internet.

enterprise-level name service  
A name service that names objects within an enterprise. The types of objects named are organizational units, sites, users, hosts, and files. Enterprise-level name services are bound below global name services. Global name services provide contexts in which the root contexts of enterprise-level naming systems can be bound.

enterprise root  
The root context of an enterprise. A context for naming objects found at the root of the enterprise namespace.

federated naming service  
The service offered by a federated naming system.

federated naming system  
An aggregation of autonomous naming systems that cooperate to support name resolution of composite names through a standard interface. Each member of a federation has autonomy in its choice of operations other than name resolution.

federated namespace  
The set of all possible names generated according to the policies that govern the relationships among member naming systems and their respective namespaces.

generic context  
A context for binding names used in applications.

global context  
A context for naming objects that have global names (currently, DNS and X.500 are the only global naming systems specified by XFN).

global name service  
A name service that has worldwide scope, such as Internet DNS and X.500. The types of entities named at this global level are typically countries, states, provinces, cities, companies, universities, institutions, and government departments and ministries. Each of these entities can be an enterprise.

host context  
A context for naming objects related to a computer.

implicit naming system pointer  
An unnamed reference that points to a context in another naming system.

initial context  
Every XFN name is interpreted relative to some context, and every XFN naming operation is performed on a context object. The XFN interface provides a function that allows the client to obtain an initial context object that provides a starting point for resolution of composite names.

<tr>
<td>parent context</td>
<td>A context in which this context and its siblings are bound.</td>
</tr>
<tr>
<td>reference</td>
<td>The thing bound to a name. It contains addresses identifying the communication endpoints of the object.</td>
</tr>
<tr>
<td>root context</td>
<td>A context for naming the objects found in the root of the namespace.</td>
</tr>
<tr>
<td>service context</td>
<td>A context for naming objects that provide services.</td>
</tr>
<tr>
<td>site context</td>
<td>A context for naming objects related to a physical site.</td>
</tr>
<tr>
<td>strong separation</td>
<td>The case where the XFN context treats the XFN component separator as the naming system boundary.</td>
</tr>
<tr>
<td>subcontext</td>
<td>A context bound within another context.</td>
</tr>
</tbody>
</table>
user context  A context for naming objects related to a human user.

weak separation  The case where the XFN context does not treat the XFN component separator as the naming system boundary.

XFN link  A special form of reference that has a composite name as an address. Like any other type of reference, an XFN link is bound to an atomic name in a context.

X.500  A global-level directory service defined by an Open Systems Interconnection (OSI) standard. The X.500 directory service is not supported in a 64-bit application.
