Preface

The Solaris on Sun Hardware Reference Manual Supplement contains reference manual pages (man pages) for software provided to Sun hardware customers with the Solaris 8 product. These supplement the man pages provided in the general Solaris 8 Reference Manual. This edition has bee updated to include man pages found in the Solaris 8 10/00 release.

Before you can access some of the information published in this book through the man command, you may need to install software from the Sun Microsystems Computer Systems Supplement CD for your Solaris release. In most cases, when you install a software product from the Sun Microsystems Computer Systems Supplement CD, a package containing man pages about the software will be automatically installed. For information about installing the man page software, refer to the Solaris 8 Sun Hardware Platform Guide.

How This Book Is Organized

This manual contains man pages in alphabetical order within each category: User Commands (1)
- System Administration Commands (1M)
- File Formats (4)
- Device and Network Interfaces (7)

The man pages apply to the following products:
- CD Read/Write drives: cdrw
- SunFDDI™ network adapter software: nf, nf_fddidaemon, nf_install_agents, nf_macid, nf_smtmon, nf_snmd, nf_snmd_kill, nf_stat, nf_sync, pf, pf_fddidaemon, pf_install_agents, pf_macid, pf_smtmon, pf_snmd, pf_snmd_kill, pf_stat, smt
■ SunHSI/P™ (PCI bus) network adapter software: hsip, hsip_init, hsip_loop, hsip_stat
■ SunHSI/S™ (Sbus) network adapter software: hsi, hsi_init, hsi_loop, hsi_stat, hsi_trace
■ Sun Remote System Control (RSC): rscadm
■ SunVTS™ diagnostic software: sunvts, vts_cmd, vtsk, vtsprobe, vtstty, vtsui, vtsui.ol
■ Netra™ t server environmental monitoring software: envmond, envmond.conf

NAME  cdrw – CD read and write

SYNOPSIS  cdrw -i [ -hvSCO ] [ -d device ] [ -p speed ] [ image-file ]
cdrw -a [ -hvSCO ] [ -d device ] [ -p speed ]
    [ -T audio-type ] audio-file1 [ audio-file2 ... ]
cdrw -x [ -hv ] [ -d device ] [ -T audio-type ]
    track-number out-file

cdrw -c [ -hvSC ] [ -d device ] [ -p speed ] [ -m tmp-dir ] [ -s src-device ]
cdrw -b [ -hv ] [ -d device ] all | session

cdrw -M [ -hv ] [ -d device ]
cdrw -l [ -hv ]

AVAILABILITY  SUNWcdrw

DESCRIPTION  The cdrw command provides the ability to create data and audio CDs. It also provides
the ability to extract audio tracks from an audio CD. Any MMC-compliant CD-R or
CD-RW drive can be used with cdrw. cdrw will search for a CD writer device connected to the system, unless the user
specifies a device with the -d option. If it finds a single such writer device, it will use
that as the default CD writer device for the command.
When more than one CD writer is connected to the system, use the -d option to indi-
cate which device is desired. The device name can be specified in one of the following
ways: /dev/rdsk/cNtNdNsN, cNtNdNsN, cNtNdN, or a symbolic name used by
volume manager, such as cdrom or cdrom1. The -l option will provide a list of CD
writers.

Creating Data CDs  When creating data CDs, cdrw uses the track-at-once mode of writing. With the -i
option, the user will specify a file that contains the data to write on CD media. In the
absence of such a file, cdrw will read data from standard input.
In either case, the data will typically first have been prepared by using the mknfs
(1M) command to convert the file and file information into the High Sierra format
used on CDs. See the examples that include use of this command.

Creating Audio CDs  For creating an audio CD, using the -a option, single or multiple audio files can be
specified. All of the audio files should be in the supported audio formats. Currently
approved formats are:

- sun – Sun .au files with data in Red Book CDDA form
- wav – RIFF (.wav) files with data in Red Book CDDA form
- cda – .cda files having raw CD audio data (i.e., 16 bit PCM stereo at 44.1 KHz
    sample rate in little-endian byteorder)
aur - .aur files having raw CD data in big-endian byteorder

If no audio format is specified, `cdrw` tries to understand the audio file format based on the file extension. The case of the characters in the extension is ignored. If a format is specified using `-T`, it will be assumed as the audio file type for all the files specified. Also, `cdrw` will close the session after writing the audio tracks; therefore, the tracks to be written should be specified in a single command line.

**Extracting Audio**

`cdrw` can also be used for extracting audio data from an audio CD with the `-x` option. The CD should have tracks in Red Book CDDA form. By default, the output format is based on the file extension. A user can specify a sun, wav, cda, au, or aur output format using the `-T` option.

**Copying CDs**

`cdrw` can be used to copy single session data CD-ROMs and Red Book audio CDs. For copying a CD, `cdrw` looks for a specified source device. If no source device is specified when using the `-c` option, the current CD writing device is assumed to be the source. `cdrw` will extract the track or tracks into a temporary file and will look for a blank writable CD-R/RW media in the current CD writing device. If no such media is found, the user will be asked to insert a blank writable CD media in the current CD writing device. If enough space is not available in the default temporary directory, an alternative directory can be specified using the `-m` option.

**Erasing CD-RW Media**

Users have to erase the CD-RW media before it can be re-written. With the `-b` option, currently, the following flavors of erasing are supported:

- **session** - Erase the last session
- **all** - Erase the entire media

If the **session** erasing type is used, `cdrw` will erase the last session. If there is only one session recorded on the CD-RW (e.g., a data/audio CD-RW created by this tool), then session erasing is useful as it will only erase the portion that is recorded, leaving behind a blank disc; this is faster than erasing the entire media.

The **all** erasing type should be used if it is a multisession disc, or the last session is not closed, or disc status is unknown, and the user wishes to erase the disc. With this type of erase, `cdrw` will erase the entire disc.

**Checking device-list/media-status**

The user can get a list of CD writing devices currently present in the system with the `-l` option. Also, for a particular media, the user can get the blanking status and table of contents through the `-M` option. `-M` also prints information about the last session start address and the next writable address. This information along with the `-O` option can be used to create multisession CDs. Please refer to `mkisofs(1M)` for more information.

**OPTIONS**

- **-a** Create an audio disc. At least one *audio-file* name must be specified. A CD can not have more than 99 audio tracks, so no more than 99 audio files can be specified. Also, the maximum audio data that can be written to the media by default is 74 minutes, unless `-C` is specified.

1-2 Solaris 8 modified 15 AUG 2000
User Commands

−b Blank a CD-RW media. The type of erasing must be specified by the all or session argument.

−c Copy a CD. If no other argument is specified, the default CD writing device is assumed to be the source device as well. In this case, the copying operation will read the source media into a temporary directory and will prompt the user to place a blank media into the drive for copying to proceed.

−C Use media stated capacity. Without this option, cdrw will use a default value for writable CD media, which is 74 minutes for an audio CD or 68198400 bytes for a data CD.

−d CD writing device.

−h Help, which prints usage message.

−i Image file for creating data CDs. The file size should be less than what can be written on a CD-R or CD-RW media, which is 68198400 bytes by default or the media stated capacity if the −C option is used. Also, it is better to have the file locally available instead of having it on an NFS mounted filesystem, because the CD writing process expects data to be available continuously without interruptions.

−l List all the CD writers found in the system.

−m Use an alternate temporary directory instead of system default temporary directory for storing track data while copying a CD. An alternate temporary directory might be required because the amount of data on a CD can be huge (as much as 800 Mbytes for an 80 minute audio CD) and the system default temporary directory might not have that much space.

−M Report media status. cdrw will report if the media is blank or not, its table of contents, the last session’s start address, and the next writable address if the disc is open.

−O Keep the disc open. cdrw will close the session, but it will keep the disc open so that another session can be added later on to create a multisession disc.

−p Set the CD writing speed; e.g., −p 4 will set the speed to 4X. If this option is not specified, cdrw will use the default speed of the CD writer. If this option is specified, cdrw will try to set the drive write speed to this value, but there is no guarantee of the speed actually used by the drive.

−s Source device for copying CD.

−S Simulation mode. In this mode, cdrw will do everything with the drive laser turned off, so nothing will be written to the media. This can be used to verify if the system can provide data at a rate good enough for CD writing.

−T Audio format to use extracting audio files or reading audio files for audio CD creation. The audio-type can be sun, wav, cda, au, or aur.

−v Verbose mode.

−x Extract audio data from an audio track.
EXAMPLES

Example 1: Creating a data CD.

```
cdrw -i /local/iso_image
```

Example 2: Creating a CD from the directory tree /home/foo.

```
$ mkisofs -r /home/foo 2>/dev/null | cdrw -i -p 1
```

Example 3: Extracting audio track number 1 to /home/foo/song1.wav.

```
$ cdrw -x -T wav 1 /home/foo/song1.wav
```

Example 4: Creating an audio CD from wav files on disc.

```
$ cdrw -a song1.wav song2.wav song3.wav song4.wav
```

Example 5: Erasing a CD-RW media in a CD-RW drive.

```
$ cdrw -b all
```

Example 6: Creating a data CD on a system with multiple CD-R/RW drives.

```
$ cdrw -d cl16d0s2 -i /home/foo/iso-image
```

Example 7: Checking if the system can provide data to a CD-RW drive at a rate sufficient for write operation.

```
$ cdrw -S -i /home/foo/iso-image
```

Example 8: Running cdrw at a higher priority (for root user only).

```
$ priocntl -e -p 60 cdrw -i /home/foo/iso-image
```

SEE ALSO mkisofs(1M), audioconvert(1)

NOTES

The CD writing process requires data to be supplied at a constant rate to the drive. It is advised to keep I/O activity to a minimum and shut down the related applications while writing CDs.

When making copies or extracting audio tracks, it is better to use an MMC compliant source CD-ROM drive. The CD writing device can be used for this purpose.

Before writing a CD, it is best to ensure that the media is blank by using the -M option and to test that the system can provide data at the required rate by using the -S simulation mode. In case the system is not able to provide data at the required rate, try simulation with a slower write speed set through the -p option. Users can also try to run cdrw at a higher priority using the priocntl(1) command.

The -p option is provided for users who are aware of the CD-R/RW drive and its capabilities to operate at different write speeds. Some commercially available drives handle the drive speed setting command differently, so use this option judiciously.

Most commercially available drives allow writing beyond 74 minutes as long as the media has the capacity (such as 80 minute media). However, such capability of writing beyond 74 minutes might not be supported by the drive in use. If the drive being used supports such capability, then use the -C option to indicate that the tool should rely on the capacity indicated by the media.

1-4 Solaris 8 modified 15 AUG 2000
NAME
envmond - environmental monitor daemon

SYNOPSIS
/usr/platform/SUNW,UltraSPARC-IIi-Netract/lib/envmond/sparcv9/envmond [-d] 
[ -f file ] [ -g granularity ]

AVAILABILITY
SUNWcteux

DESCRIPTION
The envmond daemon polling system environment monitoring devices to check for conditions that may require corrective action. In order to do this, the daemon reads a configuration file on startup, during the initial Solaris boot process, to find out which environmental devices will be monitored. Each configuration file entry describing an environmental device is referred to as a policy, and the supported policy entries are described in envmond.conf(4).

The envmond daemon logs appropriate messages to a system log file via syslogd(1M).

The envmond daemon will reread its configuration information file whenever it receives a hang-up signal, SIGHUP.

OPTIONS
-d Sets Debug mode option. The envmond will not run as a daemon, and will instead run in the foreground, inheriting standard input and output. Error and warning messages will be written to the standard output instead of being logged via syslogd(1M).

-f file Provides an alternate file path for the configuration file.

-g granularity Defines the finest granularity for the poll interval. The default value is 10 seconds.

FILES
/usr/platform/SUNW,UltraSPARC-IIi-Netract/lib/envmond/sparcv9/envmond
The executable daemon
/usr/platform/SUNW,UltraSPARC-IIi-Netract/lib/envmond/sparcv9/*.so
The envmond policies
/platform/SUNW,UltraSPARC-IIi-Netract/lib/envmond.conf
The envmond configuration file

SEE ALSO
syslogd(1M), envmond.conf(4)

NOTES
The envmond policies retrieve their environmental information via I2C devices in the system.

This daemon is in the PROTOTYPE stage, and is therefore subject to CHANGE WITHOUT NOTICE.
NAME
hsi_init – set high speed serial line interface operating parameters.

SYNOPSIS
/opt/SUNWconn/bin/hsi_init device [[ baud_rate ] | [ keyword=value, ... ] | [ single-word option ]]

DESCRIPTION
The hsi_init utility allows the user to modify some of the hardware operating modes common to high speed synchronous serial lines. This may be useful in troubleshooting a link, or necessary to the operation of a communications package.

If run without options, hsi_init reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.

OPTIONS
Options to hsi_init normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, "loop=" and "loopback=" are equivalent.

Recognized options are listed in the table below.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>loopback</td>
<td>no</td>
<td>Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc.</td>
</tr>
<tr>
<td></td>
<td>yes</td>
<td>Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>nrzi</td>
<td>no</td>
<td>Set the port to operate with NRZ data encoding. NRZ encoding maintains a constant voltage level when data is present (1) and does not return to a zero voltage (0) until data is absent. The data is decoded as an absolute value based on the voltage level (0 or 1).</td>
</tr>
<tr>
<td></td>
<td>yes</td>
<td>Set the port to operate with NRZI data encoding. NRZI encoding does a voltage transition when data is absent (0) and no voltage transition (no return to zero) when data is present (1). Hence, the name non-return to zero inverted. The data is decoded using relational decoding.</td>
</tr>
<tr>
<td>txc</td>
<td>txc</td>
<td>Transmit clock source will be the TxCI signal.</td>
</tr>
<tr>
<td></td>
<td>-txc</td>
<td>Transmit clock source will be the inverted TxCI signal.</td>
</tr>
<tr>
<td></td>
<td>rxc</td>
<td>Transmit clock source will be the RxCI signal.</td>
</tr>
<tr>

<td>This flag is used for inverting transmit data on serial lines. You can switch the polarity of a link by setting this flag to be negative, i.e. <code>-txd</code>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>rxd</strong></td>
<td>This flag is used for inverting receive data on serial lines. You can switch the polarity of a link by setting this flag to be negative, i.e. <code>-rxd</code>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>reset</strong></td>
<td>Resets the board. Terminates all incoming and outgoing traffic.</td>
</tr>
</tbody>
</table>

There are also several single-word options that set one or more parameters at a time:

**Keyword** | **Equivalent to Options:**
---|---
external | `txc=txc rxc=rxc loop=no`
sender | `txc=baud rxc=baud loop=no`
stop | `speed=0`

**EXAMPLES**

The following command sets the first CPU port to loop internally, use internal clocking and operate at 38400 bps:

```bash
example# hsi_init hih0 38400 loop=yes
port=hih0 speed=38309, mode=fdx, loopback=yes, nrzi=no, mtu=1600, mru=1600, txc=baud, rxc=baud, txd=txd, rxd=rxd, signal=no.
```

The following command sets the same port’s clocking, local loopback and bit rate settings to their default values:

modified 14 April 1993  Solaris 8  1M-7
example# hsi_init hih0 1536000 loop=no
port=hih0 speed=1536000, mode=fdx, loopback=no, nrzi=no, mtu=1600,
mru=1600, txc=txc, rxc=rxc, txd=txd, rxd=rxd, signal=no.

SEE ALSO  hsi_loop(1M), hsi_stat(1M), hsi_trace(1M), Intro(2), hsi(7D)

DIAGNOSTICS  device missing minor device number
   The name device does not end in a decimal number that can be used as a minor
device number.

   bad speed: arg
   The string arg that accompanied the "speed=" option could not be interpreted
   as a decimal integer.

   Bad arg: arg
   The string arg did not make sense as an option.

   ioctl failure code = errno
   An ioctl(2) system call failed. The meaning of the value of errno may be
   found in the Intro(2) manual page.

WARNINGS  hsi_init should not be used on an active serial link, unless needed to resolve an error
condition. It should not be run casually, or if the user is unsure of the consequences of
its use.
NAME
hsi_loop – high speed synchronous serial loopback test program for high speed serial interface.

SYNOPSIS
/opt/SUNWconn/bin/hsi_loop [-cdlsvt] device

DESCRIPTION
The hsi_loop command performs several loopback tests that are useful in exercising the various components of a serial communications link.

Before running a test, hsi_loop opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the device argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, hsi_loop proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

In the second phase, called the "first-packet" phase, hsi_loop attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an error message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.

The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.

After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:

<table>
<thead>
<tr>
<th>Port</th>
<th>CRC errors</th>
<th>Aborts</th>
<th>Overruns</th>
<th>Underruns</th>
<th>In</th>
<th>&lt;-Drops-&gt;</th>
<th>Out</th>
</tr>
</thead>
<tbody>
<tr>
<td>hih0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them. This is a very rough approximation and should not be used in benchmarking, because elapsed time includes time to print to the display.

modified 14 April 1992

Solaris 8

1M-9
The options for hsi_loop are described in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>packet_count</td>
<td>100</td>
<td>Specifies the number of packets to be sent in the multiple-packet phase.</td>
</tr>
<tr>
<td>-d</td>
<td>hex_data_byte</td>
<td>random</td>
<td>Specifies that each packet will be filled with bytes with the value of hex_data_byte.</td>
</tr>
<tr>
<td>-l</td>
<td>packet_length</td>
<td>100</td>
<td>Specifies the length of each packet in bytes.</td>
</tr>
<tr>
<td>-s</td>
<td>line_speed</td>
<td>9600</td>
<td>Bit rate in bytes per second.</td>
</tr>
<tr>
<td>-v</td>
<td></td>
<td></td>
<td>Sets verbose mode. If data errors occur, the expected and received data is displayed.</td>
</tr>
<tr>
<td>-t</td>
<td>test_type</td>
<td>none</td>
<td>A number, from 1 to 4, that specifies which test to perform. The values for test_type are as follows:</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>1 Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator).</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2 External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>3 External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem, the remote modem, or the remote system (not a Sun) be set in a loopback configuration.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>4 Test using predefined parameters. User defines hardware configuration and may select port parameters using the hsi_init(1M) command.</td>
</tr>
</tbody>
</table>

All numeric options except -d are entered as decimal numbers (for example, -s 19200). If you do not provide the -t test_type option, hsi_loop prompts for it.

The following command causes hsi_loop to use a packet length of 512 bytes over the first CPU port:

```bash
example# hsi_loop -l 512 hih0
```

In response to the above command, hsi_loop prompts you for the test option you want.

The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56Kbps:

```bash
example# hsi_loop -l 512 100 hih0
```
example# hsi_loop -t 1 -s 56000 -c 5000 hih0

DIAGNOSTICS  device missing minor device number
              The name device does not end in a decimal number that can be used as a minor
device number.

invalid packet length: nnn
              The packet length was specified to be less than zero or greater than 1600.

poll: nothing to read
poll: nothing to read or write.
              The poll(2) system call indicates that there is no input pending and/or that
output would be blocked if attempted.

len xxx should be yyy
              The packet that was sent had a length of yyy, but was received with a length of
xxx.

nnn packets lost in outbound queueing
nnn packets lost in inbound queueing
              A discrepancy has been found between the number of packets sent by hsi_loop
and the number of packets the driver counted as transmitted, or between the
number counted as received and the number read by the program.

WARNINGS  To allow its tests to run properly, as well as prevent disturbance of normal operations,
hsi_loop should only be run on a port that is not being used for any other purpose at
that time.
NAME
hsi_stat – report driver statistics from a high speed synchronous serial link port.

SYNOPSIS
/opt/SUNWconn/bin/hsi_stat [-f] -a num_of_ports
/opt/SUNWconn/bin/hsi_stat -c [-f] -a num_of_ports
/opt/SUNWconn/bin/hsi_stat [-f] device [period]
/opt/SUNWconn/bin/hsi_stat -c [-f] device

DESCRIPTION
The hsi_stat command reports the event statistics maintained by a high speed synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes.

Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system when one of the driver’s entry points is first called.

The device argument is the name of the high speed serial device as it appears in the /dev directory. For example, hih0 specifies the first on-board high speed serial device.

As an alternative, you can display or clear the statistics for multiple physical channels using num_of_ports argument. The hsi_stat program will then display statistics accumulated from device hih0 to hih(num_of_ports - 1). Additionally, statistics for all ports can be displayed or cleared by the use of the -a option. In this case, the command will be issued for all the ports on the system. This option is not available for sampling purposes.

The following is a breakdown of hsi_stat output:
speed
The line speed the device has been set to operate at. It is the user’s responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.
ipkts
The total number of input packets.
opkts
The total number of output packets.
undrun
The number of transmitter underrun errors.
ovrrun
The number of receiver overrun errors.
abort
The number of aborted received frames.
crc
The number of received frames with CRC errors.
isize
The average size (in bytes) of input packets.
osize
The average size (in bytes) of output packets.
iutil
Reports the input line utilization expressed as a percentage.
outil
Reports the output line utilization expressed as a percentage.

Additional fields for the ‘f’ flag are listed below.

ierror
Reports the input error count. Errors can be incomplete frames, empty frames, or receive clock (RxC) problems.
inactiv  Reports the number of input packets received when receive is inactive.

ishort  Reports the number of short input packets. This is the number of input packets with lengths less than the number of CRC bytes.

ilong  Reports the number of long input packets. This is the number of input packets with lengths larger than the MRU.

oerror  Reports the output error count. Errors that can be lost are clear to send (CTS) signals or transmit clock (TxC) problems.

olong  Reports the number of long output packets. This is the number of output packets with lengths larger than the MTU.

ohung  Reports the number of times the transmitter hangs, which is usually due to a missing clock.

**OPTIONS**

- `f`  Select full set of accumulated statistics for the device specified. This is useful while debugging the hsi driver.

- `c`  Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.

**num_of_ports**  Specify the number of devices that you want to dump the statistics.

- `a`  Specify all of the ports in the system, regardless of the number of HSI boards.

**interval**  Cause hsi_stat to sample the statistics every `interval` seconds and report incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the baud rate, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.

**EXAMPLES**

```
example# hsi_stat hih0
speed ipkts opkts undrun ovrrun abort crc isize
9600 15716 17121 0 0 1 3 98
```

```
example# hsi_stat 5
speed ipkts opkts undrun ovrrun abort crc isize
hih0 9600 15716 10100 0 0 1 3
hih1 9600 15234 20100 0 0 1 3
hih2 9600 15123 18254 0 0 1 3
hih3 9600 15378 18234 0 0 1 3
```

```
example# hsi_stat -a
speed ipkts opkts undrun ovrrun abort crc isize osize
```

DIAGNOSTICS  

device missing minor device number

The name device does not end in a decimal number that can be used as a minor device number.

hsi_stat: Can't sample multiple ports simultaneously.

Sampling is only available with one specified port, i.e. hsi_stat hih0 10.

WARNINGS

Underrun, overrun, frame-abort and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the interval option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.

1M-14  Solaris 8  modified 14 April 1993
**NAME**

hsi_trace – Dump and Parse the HSI/S driver trace buffer. This is a development/field support only diagnostic utility.

**SYNOPSIS**

/opt/SUNWconn/bin/hsi_trace

**DESCRIPTION**

hsi_trace utility id for support and field personnel only. This utility prints out the trace of the incoming and outgoing packets at the hsi driver level.

There are two levels of traces that can be captured. This is controlled by setting a variable in the driver in the /etc/system file.

set HSI:hsi_trace=1

The driver maintains an internal circular buffer to store 24K frames (both in and out).

Then run hsi_trace on the driver to collect the trace data.

# hsi_trace > hsi_trace.log

This trace is useful when the problem occurs rarely (typically a week or so) and we do not have enough file system space.

This trace collects the last 24K of frame data.

Then there is another trace ‘strace’ which can be used to collect all the data from the driver. This can be enabled by setting ‘hsi_trace’ as

set HSI:hsi_trace=2

Then run

#strace 18515 all all > hsi_trace.log

This collects all the data from the driver. This trace is useful when we know that the problem occurs within a short time.

The trace output is as follows

In the first case (‘hsi_trace’ utility )

13:26:38 0000004f hih9 len=0100 R: 31323334 35363738 fm: I-FR P/F=1 Nr=1 Ns=1

The fields are as follows

1 st field: Time stamp
2 nd field: time difference in microsecs between the last frame and current frame.
3 rd field: port
4 th field: length of the frame.
5 th field: R: received data T: transmitted data
6 th and 7 th field: First 8 bytes of the data transmitted or received.
7 th field: The frame type (SABM, TEST, XID, RR, RNR....)
Some of the frame types are described below.

<table>

DIAGNOSTICS

modified 02 September 1998
Solaris 8

1M-17
NAME  
hsip_init – set high speed serial line interface operating parameters.

SYNOPSIS  
/opt/SUNWconn/bin/hsip_init device [[ baud_rate ] | [ keyword=value, ... ] | [ single-word option ]]

DESCRIPTION  
The hsip_init utility allows the user to modify some of the hardware operating modes common to high speed synchronous serial lines. This may be useful in troubleshooting a link, or necessary to the operation of a communications package.

If run without options, hsip_init reports the options as presently set on the port. If options are specified, the new settings are reported after they have been made.

OPTIONS  
Options to hsip_init normally take the form of a keyword, followed by an equal sign and a value. The exception is that a baud rate may be specified as a decimal integer by itself. Keywords must begin with the value shown in the options table, but may contain additional letters up to the equal sign. For example, "loop=" and "loopback=" are equivalent.

Recognized options are listed in the table below.

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Value</th>
<th>Effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>loopback</td>
<td>yes</td>
<td>Set the port to operate in internal loopback mode. The receiver is electrically disconnected from the DCE receive data input and tied to the outgoing transmit data line. Transmit data is available to the DCE. If no other clocking options have been specified, perform the equivalent of txc=baud and rxc=baud.</td>
</tr>
<tr>
<td></td>
<td>no</td>
<td>Disable internal loopback mode. If no other clocking options have been specified, perform the equivalent of txc=txc and rxc=rxc.</td>
</tr>
<tr>
<td>echo</td>
<td>Set the port to operate in auto-echo mode. The port will echo incoming receive data on the transmit data pin. When the loopback is set for echo and no clocking option is given the clocking is set txc=txc and rxc=rxc. Other clocking options can be used but line errors may occur due to the loopback=echo implementation.</td>
<td></td>
</tr>
<tr>
<td>nrzi</td>
<td>no</td>
<td>Set the port to operate with NRZ data encoding. NRZ encoding maintains a constant voltage level when data is present (1) and does not not return to a zero voltage (0) until data is absent. The data is decoded as an absolute value based on the voltage level (0 or 1).</td>
</tr>
</tbody>
</table>
yes  Set the port to operate with NRZI data encoding. NRZI encoding does a voltage transition when data is absent (0) and no voltage transition (no return to zero) when data is present (1). Hence, the name non-return to zero inverted. The data is decoded using relational decoding.

**txc**
- **txc** Transmit clock source will be the TxCI signal.
- **rxc** Transmit clock source will be the RxC signal.
- **baud** Transmit clock source will be the internal baud rate generator.
- **pll** Transmit clock source will be the output of the DPLL circuit. This can only be set with NRZI data encoding.
- **-txc** Transmit clock source will be the inverted TxCI signal.

**rxc**
- **rxc** Receive clock source will be the RxC signal.
- **txc** Receive clock source will be the TxCI signal. This can only be used with transmit clock option txc=txc.
- **baud** Receive clock source will be the internal baud rate generator.
- **-rxc** Receive clock source will be the inverted RxC signal.

**txd**
- **txd** Transmit data is not inverted.
- **-txd** Transmit data is inverted.

**rxd**
- **rxd** Receive data is not inverted.
- **-rxd** Receive data is inverted.

**mode**
- **fdx** HDLC Full Duplex mode (Default mode).
- **ibm-fdx** IBM Full Duplex mode (SDLC).
- **ibm-hdx** IBM Half Duplex mode (SDLC).
- **ibm-mpt** IBM Multipoint mode (SDLC).

**signal**
- **yes** Notify application of modem signal (RTS and CTS) changes.
- **no** Do not notify application of modem signal (RTS and CTS) changes.

**mtu**
- **integer** Set the maximum transmit unit to integer bytes with 2064 bytes maximum.

**mru**
- **integer** Set the maximum receive unit to integer bytes with 2064 bytes maximum.

**speed**
- **integer** Set the baud rate to integer bits per second with a minimum rate of 9600 bps and a maximum of 2048000 bps. Zero is also valid when txc is set to txc or -txc.
There are also several single-word options that set one or more parameters at a time:

<table>
<thead>
<tr>
<th>Keyword</th>
<th>Equivalent to Options:</th>
</tr>
</thead>
<tbody>
<tr>
<td>external</td>
<td>txc=txc rxc=rxc loop=no</td>
</tr>
<tr>
<td>sender</td>
<td>txc=baud rxc=rxc loop=no</td>
</tr>
<tr>
<td>internal</td>
<td>txc=pll rxc=pll loop=no</td>
</tr>
<tr>
<td>stop</td>
<td>speed=0</td>
</tr>
</tbody>
</table>

**EXAMPLES**

The following command sets the first port to loop internally, use internal clocking and operate at 38400 baud:

```
example# hsip_init hihp0 38400 loop=yes
```

port=hihp0
speed=38400,
mode=fdx, signal=no, loopback=yes, nrzi=no, mtu=2064, mru=2064,
txc=baud, rxc=baud, txd=txd, rxd=rxd

The following command sets the same port’s clocking, local loopback and baud rate settings to their default values:

```
example# hsip_init hihp0 speed=1536000 loopback=no txc=txc rxc=rxc
```

port=hihp0
speed=1536000,
mode=fdx, signal=no, loopback=no, nrzi=no, mtu=2064, mru=2064,
txc=txc, rxc=rxc, txd=txd, rxd=rxd

**SEE ALSO**

hsip_loop(1M), hsip_stat(1M), Intro(2), hsip(7D)

**DIAGNOSTICS**

device missing minor device number

The name `device` does not end in a decimal number that can be used as a minor device number.

bad speed: arg

The string `arg` that accompanied the "speed=" option could not be interpreted as a decimal integer.

Bad arg: arg

The string `arg` did not make sense as an option.

ioctl failure code = errno

An ioctl(2) system called failed. The meaning of the value of `errno` may be found in the Intro(2) manual page.

**WARNINGS**

`hsip_init` should not be used on an active serial link, unless needed to resolve an error condition. It should not be run casually, or if the user is unsure of the consequences of its use.
NAME    
.hsip_loop – high speed synchronous serial loopback test program for high speed serial interface.

SYNOPSIS
/opt/SUNWconn/bin/hsip_loop [-cdlsvt] device

DESCRIPTION
The hsip_loop command performs several loopback tests that are useful in exercising the various components of a serial communications link.

Before running a test, hsip_loop opens the designated port and configures it according to command line options and the specified test type. It announces the names of the devices being used to control the hardware channel, the channel number (ppa) corresponding to the device argument, and the parameters it has set for that channel. It then runs the loopback test in three phases.

The first phase is to listen on the port for any activity. If no activity is seen for at least four seconds, hsip_loop proceeds to the next phase. Otherwise, the user is informed that the line is active and that the test cannot proceed, and the program exits.

In the second phase, called the "first-packet" phase, hsip_loop attempts to send and receive one packet. The program will wait for up to four seconds for the returned packet. If no packets are seen after five attempts, the test fails with an error message. If a packet is returned, the result is compared with the original. If the length and content do not match exactly, the test fails.

The final phase, known as the "multiple-packet" phase, attempts to send many packets through the loop. Because the program has verified the integrity of the link in the first-packet phase, the test will not fail after a particular number of timeouts. If a packet is not seen after four seconds, a message is displayed. Otherwise, a count of the number of packets received is updated on the display once per second. If it becomes obvious that the test is not receiving packets during this phase, the user may wish to stop the program manually. The number and size of the packets sent during this phase is determined by default values, or by command line options. Each returned packet is compared with its original for length and content. If a mismatch is detected, the test fails. The test completes when the required number of packets have been sent, regardless of errors.

After the multiple-packet phase has completed, the program displays a summary of the hardware event statistics for the channel that was tested. The display takes the following form:

<table>
<thead>
<tr>
<th>Port</th>
<th>CRC errors</th>
<th>Aborts</th>
<th>Overruns</th>
<th>Underruns</th>
<th>In</th>
<th>&lt;-Drops-&gt;</th>
<th>Out</th>
</tr>
</thead>
<tbody>
<tr>
<td>hihp0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
</tr>
</tbody>
</table>

This is followed by an estimated line speed, which is an approximation of the bit rate of the line, based on the number of bytes sent and the actual time that it took to send them. This is a very rough approximation and should not be used in benchmarking, because elapsed time includes time to print to the display.
hsip_loop (1M) Maintenance Commands

OPTIONS

The options for hsip_loop are described in the following table:

<table>
<thead>
<tr>
<th>Option</th>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-c</td>
<td>packet_count</td>
<td>100</td>
<td>Specifies the number of packets to be sent in the multiple-packet phase.</td>
</tr>
<tr>
<td>-d</td>
<td>hex_data_byte</td>
<td>random</td>
<td>Specifies that each packet will be filled with bytes with the value of hex_data_byte.</td>
</tr>
<tr>
<td>-l</td>
<td>packet_length</td>
<td>100</td>
<td>Specifies the length of each packet in bytes with a maximum of 2064 bytes.</td>
</tr>
<tr>
<td>-s</td>
<td>line_speed</td>
<td>9600</td>
<td>Bit rate in bits per second, minimum of 9600 bps and a maximum of 2048000 bps.</td>
</tr>
<tr>
<td>-v</td>
<td></td>
<td></td>
<td>Sets verbose mode. If data errors occur, the expected and received data is displayed.</td>
</tr>
<tr>
<td>-t</td>
<td>test_type</td>
<td>none</td>
<td>A number, from 1 to 4, that specifies which test to perform. The values for test_type are as follows:</td>
</tr>
</tbody>
</table>

1. Internal loopback test. Port loopback is on. Transmit and receive clock sources are internal (baud rate generator).
2. External loopback test. Port loopback is off. Transmit and receive clock sources are internal. Requires a loopback plug suitable to the port under test.
3. External loopback test. Port loopback is off. Transmit and receive clock sources are external (modem). Requires that one of the local modem or the remote modem be set in a loopback configuration.
4. Test using predefined parameters. User defines hardware configuration and may select port parameters using the \texttt{hsip_init(1M)} command.

All numeric options except \(-d\) are entered as decimal numbers (for example, \(-s 19200\)). If you do not provide the \(-t test\_type\) option, hsip_loop prompts for it.

EXAMPLES

The following command causes hsip_loop to use a packet length of 512 bytes over the first CPU port:

\texttt{example# hsip_loop \(-l 512\) hihp0}

In response to the above command, hsip_loop prompts you for the test option you want.
The following command performs an internal loopback test on the first CPU port, using 5000 packets and a bit rate of 56000 bps:

```
example# hsip_loop -t 1 -s 56000 -c 5000 hihp0
```

**DIAGNOSTICS**

- **device missing minor device number**
  The name `device` does not end in a decimal number that can be used as a minor device number.

- **invalid packet length: nnn**
  The packet length was specified to be less than zero or greater than 2064.

- **poll: nothing to read**
- **poll: nothing to read or write.**
  The `poll(2)` system call indicates that there is no input pending and/or that output would be blocked if attempted.

- **len xxx should be yyy**
  The packet that was sent had a length of `yyy`, but was received with a length of `xxx`.

- **nnn packets lost in outbound queueing**
- **nnn packets lost in inbound queueing**
  A discrepancy has been found between the number of packets sent by `hsip_loop` and the number of packets the driver counted as transmitted, or between the number counted as received and the number read by the program.

**WARNINGS**
To allow its tests to run properly, as well as prevent disturbance of normal operations, `hsip_loop` should only be run on a port that is not being used for any other purpose at that time.

NAME
hsip_stat – report driver statistics from a high speed synchronous serial link port.

SYNOPSIS
/opt/SUNWconn/bin/hsip_stat [-f] -a | num_of_ports
/opt/SUNWconn/bin/hsip_stat [-f] device [period]
/opt/SUNWconn/bin/hsip_stat -c [-f] -a | num_of_ports
/opt/SUNWconn/bin/hsip_stat -c [-f] device

DESCRIPTION
The hsip_stat command reports the event statistics maintained by a high speed synchronous serial device driver. The report may be a single snapshot of the accumulated totals, or a series of samples showing incremental changes.

Event statistics are maintained by a driver for each physical channel that it supports. They are initialized to zero at the time the driver module is loaded into the system when one of the driver’s entry points is first called.

The device argument is the name of the high speed serial device as it appears in the /dev directory. For example, hihp0 specifies the first on-board high speed serial device.

As an alternative, you can display or clear the statistics for multiple physical channels using num_of_ports argument. The hsip_stat program will then display statistics accumulated for the first n number of ports, where n is num_of_ports.

The following is a breakdown of hsip_stat output:

- **speed**: The line speed the device has been set to operate at. It is the user’s responsibility to make this value correspond to the modem clocking speed when clocking is provided by the modem.
- **ipkts**: The total number of input packets.
- **opkts**: The total number of output packets.
- **undrun**: The number of transmitter underrun errors.
- **ovrrun**: The number of receiver overrun errors.
- **abort**: The number of aborted received frames.
- **crc**: The number of received frames with CRC errors.
- **isize**: The average size (in bytes) of input packets.
- **osize**: The average size (in bytes) of output packets.
- **ierror**: Input error count (errors: Incomplete Frame, Empty frame, Glitch on RxC).
- **oerror**: Output error count (errors: CTS lost, Glitch on TxC).
- **iutil**: Input line utilization expressed as a percentage.
- **outil**: Output line utilization expressed as a percentage.
OPTIONS

- f
  Select a complete set of accumulated statistics for the device specified. This is useful while debugging the hsip driver.

- a
  Select all devices.

- c
  Clear the accumulated statistics for the device specified. This may be useful when it is not desirable to unload a particular driver, or when the driver is not capable of being unloaded.

num_of_ports
  Specify the number of devices that you want to dump the statistics.

period
  Cause hsip_stat to sample the statistics every period seconds and report incremental changes. The output reports line utilization for input and output in place of average packet sizes. These are the relationships between bytes transferred and the speed, expressed as percentages. The loop repeats indefinitely, with a column heading printed every twenty lines for convenience.

DIAGNOSTICS
bad interval: arg
The argument arg is expected to be an interval and could not be understood.
device missing minor device number
The name *device* does not end in a decimal number that can be used as a minor device number.

**WARNINGS**

Underrun, overrun, frame-abort and CRC errors have a variety of causes. Communication protocols are typically able to handle such errors and initiate recovery of the transmission in which the error occurred. Small numbers of such errors are not a significant problem for most protocols. However, because the overhead involved in recovering from a link error can be much greater than that of normal operation, high error rates can greatly degrade overall link throughput. High error rates are often caused by problems in the link hardware, such as cables, connectors, interface electronics or telephone lines. They may also be related to excessive load on the link or the supporting system.

The percentages for input and output line utilization reported when using the *interval* option may occasionally be reported as slightly greater than 100% because of inexact sampling times and differences in the accuracy between the system clock and the modem clock. If the percentage of use greatly exceeds 100%, or never exceeds 50%, then the baud rate set for the device probably does not reflect the speed of the modem.
**NAME**  
nf_fddidaemon – start/stop the NF FDDI SMT/SNM daemon and its associated processes.

**SYNOPSIS**  
nf_fddidaemon start | stop

**AVAILABILITY**  
This command is available with the SunFDDI product.

**DESCRIPTION**  
The nf_fddidaemon script starts/stops the SNM daemon and its associated processes.

**OPTIONS**  
- **start**  
  Starts the SNM daemon
- **stop**  
  Stops the SNM daemon

You must be root to run this command.

nf_snmd (1M)
NAME       nf_install_agents – install SunNet Manager agents for SunFDDI

SYNOPSIS   nf_install_agents

AVAILABILITY  This command is available with the SunFDDI product.

DESCRIPTION  The nf_install_agents script copies the FDDI schema files to the directory in which the
              standard agents are installed and updates the configuration files for SunNet Manager.
              The nf_install_agents command takes no arguments.
              You must be root to run this command.

SEE ALSO    nf_snmd (1M)
## NAME

nf_macid – obtain MAC address from specified nf (SunFDDI) interface.

## SYNOPSIS

nf_macid interface

## AVAILABILITY

This command is available only with the SunFDDI product.

## DESCRIPTION

This command queries the IDPROM on the SunFDDI SBus card associated with a nf interface to obtain the MAC address resident there. This address is a globally unique, 48-bit address that is drawn from the same pool from which Ethernet addresses are taken.

The nf_macid command does not allow you to set a MAC address, either on the SBus card or for an interface. Use ifconfig with the ether argument to assign the MAC address you obtain with nf_macid to an SunFDDI interface.

Normally, you use the host-resident MAC address for all network interfaces on a machine. You would only use the MAC address obtained with nf_macid under unusual circumstances.

You can be normal user (not root) to run this command.

## OPTIONS

**interface** Specifies the FDDI interface (nf<num>). The default (which you can omit) is nf0.

## EXAMPLE

Obtain the MAC address for nf0:

```plaintext
% nf_macid
8:0:20:3e:da:5
```

Set the nf0 interface to have the MAC address in the SBus card IDPROM:

```plaintext
# ifconfig nf0 ether ‘nf_macid’
```

You would follow the preceding command with an ifconfig command to assign an IP address to nf0 and bring up that interface. Normally, such ifconfig commands would be run from a startup file.

## SEE ALSO

ifconfig (1M)
NAME nf_smtmon – the SMT monitor.

SYNOPSIS nf_smtmon [ -i interface ] [ -x ] [ -h ] [ frametype ]

AVAILABILITY This command is available with the SunFDDI product.

DESCRIPTION nf_smtmon is used to display received SMT frames. You should run this command on the FDDI proxy system if the Console does not receive a response from a request for SMT MIB information.

You must be root to run this command.

OPTIONS

- i interface Specifies the FDDI interface (nfnum for SunFDDI). If this option is not specified, frames for all FDDI interfaces are displayed.

-x Displays the received frames in hex.

-h Displays the usage of this command.

frametype Specifies one or more types of SMT frames to be displayed. If this option is not specified, all types of frames are displayed. You can specify the following types of frames to be displayed:

ecf Echo Frame. Request and response frames are used for SMT-to-SMT loopback testing on an FDDI ring.

esf Extended Service Frame. Request, response, and announcement frames are used to extend new SMT services.

nif Neighborhood Information Frame. Request, response, and announcement frames are used to communicate station addresses and descriptions.

pmf_get Parameter Management Frame (PMF) Get Request. Request and response frames are used to retrieve SMT Management Information Base (MIB) attribute values.

rdf Request Denied Frame (response only). Sent in response to an unsupported or unknown request.

sifconfig Status Information Frame (SIF) Configuration. Request and response frames are used to retrieve configuration parameters for one or more stations on the ring.

sifoperation Status Information Frame (SIF) Operation. Request and response frames are used to retrieve operation information for one or more stations on the ring.

srf Status Report Frame. Announcement frame used to report Station Status. The current version of the SMT.
daemon does not send out SRFs; however, any received SRFs are passed on to SNM as traps.

EXAMPLES

nf_smtmon -i nf0 nif sifconfig
displays the NIF and SIF configuration frames received in non-hex format on the nf0 (SunFDDI) interface.

nf_smtmon -i nf1 -x ecf
displays, in hex, ECF frames received on the nf1 (SunFDDI) interface.

smtd (1M)
NAME nf_snmd – start the station management (SMT) to SunNet Manager daemon.

SYNOPSIS nf_snmd [-d] [-v5]

AVAILABILITY This command is available with the SunFDDI product.

DESCRIPTION Upon invocation, the SNM daemon starts up station management processes that allow the station to communicate with other stations using the SMT protocol, and collect and return FDDI statistics to a SunNet Manager (SNM) Console. The daemon also receives SMT requests and SMT responses. The daemon also sends out SMT requests to other stations on the ring on behalf of SNM. The SMT daemon also forwards received Status Report Frames (SRFs) to the SNM management station in the form of traps.

The processes started by the SNM daemon include two SNM agents: a local agent (fddi) and a proxy agent (fddismt). Like other SNM agents, the local agent and proxy agent communicate with the SNM management station using RPC. The local agent responds to SNM requests with FDDI statistics gathered on the local machine. These statistics are equivalent to those displayed with the nf_stat and nf_stat -m commands.

The proxy agent can return two types of SMT information to the SNM Console: actual SMT frames (ECF, ESF, NIF, SIF Configuration, or SIF Operation), and attribute values for selected SMT MIB groups. The proxy agent gathers information from target stations by issuing SMT request frames and receiving SMT response frames. The proxy uses PMF Get request and response frames to retrieve MIB attribute values from the target station.

If the target station does not support PMF Get frames, it returns an RDF response to the proxy system. If a Console request for MIB attributes values is not successful, run the SMT monitor on the proxy system to see if an RDF frame has been received from the target station. If PMF Get frames are not supported by the target station, you may be able to use NIF, SIF Configuration or SIF Operation frames to return the desired attribute values.

The SMT MIB attributes groups MAC, PATH, and PORT contain index parameters. If you send a Quick Dump request from the Console for attribute values from one of these groups, only the values associated with the first index are returned (from the Console’s point of view, the key value associated with the request is 1). If you want to see attribute values associated with other indexes, you must send a Data Report request with the Key field in the request set to the desired index.

If you make any changes to the /etc/opt/snm/snm.conf file on the station (for example, you add an additional hostname to the na.fddi.trap-rendez entry), you must kill the SNM daemon with nf_snmd_kill and then restart it in order for the change(s) to take effect.

You must be root to run this command.
OPTIONS -d  (debug mode) Displays a one-line entry in the window where nf_snmd is started for each frame that the station sends or receives. If this option is not specified, you are returned to the system prompt and there is no display. Use of this option is not recommended if the nf_snmd command is included in /etc/rc2.d/S98nf_fddidaemon.

SEE ALSO nf_snmd_kill (1M), nf_stat (1M)
NAME nf_snmd_kill – kill the station management (SMT) to SunNet Manager daemon and its associated processes.

SYNOPSIS nf_snmd_kill

AVAILABILITY This command is available with the SunFDDI product.

DESCRIPTION The nf_snmd_kill script kills the SNM daemon and its associated processes. This command also kills the two SNM agents which are started by the SNM daemon: the local agent (fdidi) and the proxy agent (fddismt). This command should not be used if the SNM daemon is not already running.

The nf_snmd_kill command takes no arguments.

You must be root to run this command.

SEE ALSO nf_snmd (1M)
NAME  nf_stat – display SunFDDI interface statistics.

SYNOPSIS  nf_stat [ -m ] [ interface ] [ interval ] [ count ]

AVAILABILITY  This command is available with the SunFDDI product.

DESCRIPTION  The nf_stat utility displays statistics for the SunFDDI interface. Some statistics relate to the SunFDDI implementation of the ANSI FDDI Connection Management standard (CMT), while others contain packet throughput, or station neighbor information.

This utility can report, on a periodic basis, packet throughput statistics, reconfiguration events, and interface exceptions. It also reports the identity of neighboring stations, information on its PHYs, and some FORMAC error counters. Several of the counters and status variables are periodically passed to the host from the hardware during the heartbeat signal. These statistics are available when invoking the command without the -m option. Issuing the command without an interval value displays the accumulated statistics; issuing the command with an interval value displays any differences between values since the previous display.

OPTIONS  -m  Dumps the current nearest neighbor information and FDDI/S timer settings (described below). The interval and count arguments have no effect when used with this option. Note that you must be root to invoke nf_stat with the -m option.

interface  Specifies which SunFDDI interface, nfname.

interval  Specifies the interval in seconds at which to display the statistics.

count  Specifies the number of times to display the statistics. If no count is provided, the utility runs forever. It can be terminated by typing ‘C (Control-C).

USAGE  You invoke nf_stat with the -m option to display information about neighboring stations. It generates a columnar display containing the following categories of data:

PhyA  On a machine running SunFDDI Dual, shows the PHY type of the neighboring station that is connected to PHYA. Values are A, B, S, M, and None (if no connection). This column does not appear on a machine running SunFDDI SAS - Single Attached Station. (See Chapter 9 of the document ANSI/FDDI Station Management (SMT) Rev7.2 (25 June 1992)).

PhyB  On a machine running SunFDDI Dual, shows the PHY type of the neighboring station that is connected to PHYB. Values are A, B, S, M, and None (if no connection). This column does not appear on a machine running SunFDDI SAS. (See Chapter 7 of the document ANSI/FDDI Station Management (SMT) Rev7.2 (25 June 1992)).

PhyS  On a machine running SunFDDI SAS, shows the PHY type of the neighboring station that is connected to PHYS. Values are A, B, S, M, and None (if no connection). If connected to a concentrator, this will be M. This column
Frame
FDDI MAC standard counter, frames received.

Error
FDDI MAC standard counter, frame with the E bit first detected at this station.

Lost
Frames whose reception is aborted.

SA
MAC address; the unique 48-bit address of the SunFDDI interface. Where an IP hostname exists, it is displayed; otherwise, the 48-bit MAC address is used.

UNA
The address of this station’s upstream neighbor, using the SMT NIF protocol.

DNA
The address of this station’s downstream neighbor, using the SMT NIF protocol.

Display status information: You invoke `nf_stat` without the `-m` option, or with values for `interface` or `interval`, to display status information. Issuing the command without an `interval` value displays the accumulated statistics; issuing the command with an `interval` value displays any differences between values since the previous display.

One use of `nf_stat` without the `-m` option is to monitor the `Ring_OP` (Ring Operational) column; if it indicates more than one ring_op per second, there are media problems that must be fixed.

When invoked without the `-m` option, `nf_stat` generates a columnar display containing the following categories of data:

**Ring**
Indicates whether the ring is up or down (that is, the Claim has succeeded).

**Note:** The following five fields use terms described in the SMT document, Chapter 9.

**ECM**
(ec_state). Shows the current state of the ECM state machine. Valid values are: `Out`, `In`, `Trace`, `Leave`, `Path_Test`, `Insert`, `Check`, and `Deinsert`.

**RMT**
(rmt_state). Shows the current state of the RMT state machine. Valid values are: `Isolated`, `Non_Op`, `Ring_Op`, `Detect`, `Non_Op_Dup`, `Ring_Op_Dup`, `Directed`, and `Rm_TRACE`.

**PCMA/PCMB** (for SunFDDI Dual) **PCMS** (for SunFDDI SAS)
(pc_state). Is a variable from PCM to other management entities containing the current state of the PCM state machine. Current valid values are: `Off` (O), `Break` (B), `Reject` (R), `Connect` (C), `Next` (N), `Signal` (S), `Join` (J), `Verify` (V), `Active` (A), and `Maint` (M).

**Ring_OP** (Ring Operational). Indicates the number of times the ring has come up (and therefore implies the number of times the ring has gone down).

**XmitP** The number of packets transmitted.

**RecvP** The number of packets received.

NF_SYNC (1M) Maintenance Commands

NAME   nf_sync – configure SunFDDI interface to operate in synchronous mode.

SYNOPSIS     nf_sync nf<inst> [ tsync sap ]

AVAILABILITY   This command is available with the SunFDDI product.

DESCRIPTION  The nf_sync utility is used to configure SunFDDI interfaces to operate in synchronous mode. By default, the SunFDDI interface configure to carry asynchronous traffic only.

OPTIONS

  nf<inst>          Specifies the FDDI interface,

  tsync             Specifies synchronous timer in nanoseconds, 400000 nanoseconds minimum,

  sap               Specifies the service access point (SAP) for synchronous operation.

USAGE  Running nf_sync without specifying values for tsync and sap returns current configuration of the interface.

To reconfigure SAP for asynchronous operations, specify tsync=0

EXAMPLES   nf_sync nf0
            displays current configuration on the nf0 (SunFDDI) interface.

            nf_sync nf0 1000000 800
            configures SAP 800 for synchronous operation with a clock rate 1000000 nanoseconds (1ms)
NAME     pf_fddidaemon – start/stop the PF FDDI SMT/SNM daemon and its associated processes.

SYNOPSIS  pf_fddidaemon start | stop

AVAILABILITY This command is available with the SunFDDI product.

DESCRIPTION The pf_fddidaemon script starts/stops the SNM daemon and its associated processes.

OPTIONS

  start    Starts the SNM daemon
  stop     Stops the SNM daemon

You must be root to run this command.

pf_macid – obtain MAC address from specified pf (SunFDDI/P) interface.

**SYNOPSIS**

pf_macid interface

**AVAILABILITY**

This command is available only with the SunFDDI product.

**DESCRIPTION**

This command queries the IDPROM on the SunFDDI card associated with a pf interface to obtain the MAC address resident there. This address is a globally unique, 48-bit address that is drawn from the same pool from which Ethernet addresses are taken.

The pf_macid command does not allow you to set a MAC address, either on the PCI card or for an interface. Use ifconfig with the ether argument to assign the MAC address you obtain with pf_macid to an SunFDDI interface.

Normally, you use the host-resident MAC address for all network interfaces on a machine. You would only use the MAC address obtained with pf_macid under unusual circumstances.

You can be normal user (not root) to run this command.

**OPTIONS**

*interface* Specifies the FDDI interface (pf<num>). The default (which you can omit) is pf0.

**EXAMPLE**

Obtain the MAC address for pf0:

```
% pf_macid
8:0:20:3e:da:5
```

Set the pf0 interface to have the MAC address in the PCI card IDPROM:

```
# ifconfig pf0 ether 'pf_macid'
```

You would follow the preceding command with an ifconfig command to assign an IP address to pf0 and bring up that interface. Normally, such ifconfig commands would be run from a startup file.

NAME  pf_smtmon – the SMT monitor.

SYNOPSIS  pf_smtmon [ -i interface ] [ -x ] [ -h ] [ frametype ]

AVAILABILITY  This command is available with the SunFDDI/P product.

DESCRIPTION  pf_smtmon is used to display received SMT frames. You should run this command on the FDDI proxy system if the Console does not receive a response from a request for SMT MIB information.

You must be root to run this command.

OPTIONS  

- i interface  Specifies the FDDI interface (pfnum for SunFDDI/P). If this option is not specified, frames for all FDDI interfaces are displayed.

- x  Displays the received frames in hex.

- h  Displays the usage of this command.

frametype  Specifies one or more types of SMT frames to be displayed. If this option is not specified, all types of frames are displayed. You can specify the following types of frames to be displayed:

  ecf  Echo Frame. Request and response frames are used for SMT-to-SMT loopback testing on an FDDI ring.

  esf  Extended Service Frame. Request, response, and announcement frames are used to extend new SMT services.

  nif  Neighborhood Information Frame. Request, response, and announcement frames are used to communicate station addresses and descriptions.

  pmf_get  Parameter Management Frame (PMF) Get Request. Request and response frames are used to retrieve SMT Management Information Base (MIB) attribute values.

  rdf  Request Denied Frame (response only). Sent in response to an unsupported or unknown request.

  sifconfig  Status Information Frame (SIF) Configuration. Request and response frames are used to retrieve configuration parameters for one or more stations on the ring.

  sifoperation  Status Information Frame (SIF) Operation. Request and response frames are used to retrieve operation information for one or more stations on the ring.

  srf  Status Report Frame. Announcement frame used to report Station Status. The current version of the SMT
daemon does not send out SRFs; however, any received SRFs are passed on to SNM as traps.

**EXAMPLES**

```
pf_smtmon -i pf0 nif sifconfig
```

displays the NIF and SIF configuration frames received in non-hex format on the pf0 (SunFDDI/P) interface.

```
pf_smtmon -i pf1 -x ecf
```

displays, in hex, ECF frames received on the pf1 (SunFDDI/P) interface.

NAME

pf_snmd – start the station management (SMT) to SunNet Manager daemon.

SYNOPSIS

pf_snmd [-d] [-v5]

AVAILABILITY

This command is available with the SunFDDI/P product.

DESCRIPTION

Upon invocation, the SNM daemon starts up station management processes that allow the station to communicate with other stations using the SMT protocol, and collect and return FDDI statistics to a SunNet Manager (SNM) Console. The daemon also receives SMT requests and SMT responses. The daemon also sends out SMT requests to other stations on the ring on behalf of SNM. The SMT daemon also forwards received Status Report Frames (SRFs) to the SNM management station in the form of traps.

The processes started by the SNM daemon include two SNM agents: a local agent (fddi) and a proxy agent (fddismt). Like other SNM agents, the local agent and proxy agent communicate with the SNM management station using RPC. The local agent responds to SNM requests with FDDI statistics gathered on the local machine. These statistics are equivalent to those displayed with the pf_stat and pf_stat -m commands.

The proxy agent can return two types of SMT information to the SNM Console: actual SMT frames (ECF, ESF, NIF, SIF Configuration, or SIF Operation), and attribute values for selected SMT MIB groups. The proxy agent gathers information from target stations by issuing SMT request frames and receiving SMT response frames. The proxy uses PMF Get request and response frames to retrieve MIB attribute values from the target station.

If the target station does not support PMF Get frames, it returns an RDF response to the proxy system. If a Console request for MIB attributes values is not successful, run the SMT monitor on the proxy system to see if an RDF frame has been received from the target station. If PMF Get frames are not supported by the target station, you may be able to use NIF, SIF Configuration or SIF Operation frames to return the desired attribute values.

The SMT MIB attributes groups MAC, PATH, and PORT contain index parameters. If you send a Quick Dump request from the Console for attribute values from one of these groups, only the values associated with the first index are returned (from the Console’s point of view, the key value associated with the request is 1). If you want to see attribute values associated with other indexes, you must send a Data Report request with the Key field in the request set to the desired index.

If you make any changes to the /etc/opt/snm/snm.conf file on the station (for example, you add an additional hostname to the na.fddi.trap-rendez entry), you must kill the SNM daemon with pf_snmd kill and then restart it in order for the change(s) to take effect.

You must be root to run this command.
| OPTIONS | -d  | (debug mode) Displays a one-line entry in the window where `pf_snmd` is started for each frame that the station sends or receives. If this option is not specified, you are returned to the system prompt and there is no display. Use of this option is not recommended if the `pf_snmd` command is included in `/etc/rc2.d/S98pf_fddidaemon`.

SEE ALSO | `pf_snmd_kill` (1M), `pf_stat` (1M) |
**NAME**

pf_snmd_kill – kill the station management (SMT) to SunNet Manager daemon and its associated processes.

**SYNOPSIS**

pf_snmd_kill

**AVAILABILITY**

This command is available with the SunFDDI/P product.

**DESCRIPTION**

The `pf_snmd_kill` script kills the SNM daemon and its associated processes. This command also kills the two SNM agents which are started by the SNM daemon: the local agent (fddi) and the proxy agent (fdismt). This command should not be used if the SNM daemon is not already running.

The `pf_snmd_kill` command takes no arguments.

You must be root to run this command.

**AVAILABILITY**

This command is available with the SunFDDI/P product.

**DESCRIPTION**

The pf_stat utility displays statistics for the SunFDDI/P interface. Some statistics relate to the SunFDDI/P implementation of the ANSI FDDI Connection Management standard (CMT), while others contain packet throughput, or station neighbor information.

This utility can report, on a periodic basis, packet throughput statistics, reconfiguration events, and interface exceptions. It also reports the identity of neighboring stations, information on its PHYs, and some FORMAC error counters. Several of the counters and status variables are periodically passed to the host from the hardware during the heartbeat signal. These statistics are available when invoking the command without the -m option. Issuing the command without an interval value displays the accumulated statistics; issuing the command with an interval value displays any differences between values since the previous display.

**OPTIONS**

- **-m** Dumps the current nearest neighbor information and FDDI/S timer settings (described below). The interval and count arguments have no effect when used with this option. Note that you must be root to invoke pf_stat with the -m option.

  **interface** Specifies which SunFDDI/P interface, pfnum.

  **interval** Specifies the interval in seconds at which to display the statistics.

  **count** Specifies the number of times to display the statistics. If no count is provided, the utility runs forever. It can be terminated by typing ‘C (Control-C).

**USAGE**

You invoke pf_stat with the -m option to display information about neighboring stations. It generates a columnar display containing the following categories of data:

- **PhyA** On a machine running SunFDDI/P Dual, shows the PHY type of the neighboring station that is connected to PHYA. Values are A, B, S, M, and None (if no connection). This column does not appear on a machine running SunFDDI/P SAS - Single Attached Station. (See Chapter 9 of the document ANSI/FDDI Station Management (SMT) Rev7.2 (25 June 1992)).

- **PhyB** On a machine running SunFDDI/P Dual, shows the PHY type of the neighboring station that is connected to PHYB. Values are A, B, S, M, and None (if no connection). This column does not appear on a machine running SunFDDI/P SAS. (See Chapter 7 of the document ANSI/FDDI Station Management (SMT) Rev7.2 (25 June 1992)).

- **PhyS** On a machine running SunFDDI/P SAS, shows the PHY type of the neighboring station that is connected to PHYS. Values are A, B, S, M, and None.

modified 14 January 1997

Solaris 8

1M-47
(if no connection). If connected to a concentrator, this will be M. This column does not appear on a machine running SunFDDI/P Dual.

**Frame**
FDDI MAC standard counter, frames received.

**Error**
FDDI MAC standard counter, frame with the E bit first detected at this station.

**Lost**
Frames whose reception is aborted.

**SA**
MAC address; the unique 48-bit address of the SunFDDI/P interface. Where an IP hostname exists, it is displayed; otherwise, the 48-bit MAC address is used.

**UNA**
The address of this station’s upstream neighbor, using the SMT NIF protocol.

**DNA**
The address of this station’s downstream neighbor, using the SMT NIF protocol.

**Display status information**
You invoke `pf_stat` without the `-m` option, or with values for `interface` or `interval`, to display status information. Issuing the command without an `interval` value displays the accumulated statistics; issuing the command with an `interval` value displays any differences between values since the previous display.

One use of `pf_stat` without the `-m` option is to monitor the **Ring OP** (Ring Operational) column; if it indicates more than one ring_op per second, there are media problems that must be fixed.

When invoked without the `-m` option, `pf_stat` generates a columnar display containing the following categories of data:

**Ring**
Indicates whether the ring is up or down (that is, the Claim has succeeded).

**Note:** The following five fields use terms described in the SMT document, Chapter 9.

**ECM**
(ec_state). Shows the current state of the ECM state machine. Valid values are: Out, In, Trace, Leave, Path_Test, Insert, Check, and Deinsert.

**RMT**
(rmt_state). Shows the current state of the RMT state machine. Valid values are: Isolated, Non_Op, Ring_Op, Detect, Non_Op_Dup, Ring_Op_Dup, Directed, and Rm_Trace.

**PCMA/PCMB** (for SunFDDI/P Dual) **PCMS** (for SunFDDI/P SAS)

**Ring_OP** (Ring Operational). Indicates the number of times the ring has come up (and therefore implies the number of times the ring has gone down).

**XmitP**
The number of packets transmitted.

**RecvP**
The number of packets received.
rscadm (1M)  

NAME
rscadm – administer SUN(tm) Remote System Control (RSC)

SYNOPSIS
rscadm help
rscadm resetrsc [-s]
rscadm set variable value
rscadm download [boot] file
rscadm show [variable]
rscadm date [-s]  [[mmdd]HHMM | mmddHHMM[cc]yy][.SS]
rscadm send_event [-c] message
rscadm modem_setup
rscadm useradd username
rscadm userdel username
rscadm usershow [username]
rscadm userpassword username
rscadm userperm username [cuar]

DESCRIPTION
rscadm administers the SUN(tm) Remote System Console (RSC). It allows the host server to interact with the RSC. The following operations are supported:

rscadm help
Displays a usage screen.

rscadm resetrsc
Reset the RSC. There are two types of reset allowed, a "hard" reset and a "soft" reset. The hard reset is done by default. The soft reset can be selected by using the -s option.

rscadm set
Set RSC configuration variables. Examples of RSC configuration variables include RSC IP address and RSC hostname. See the RSC documentation for a complete list of RSC configuration variables.

rscadm download
Program the RSC’s firmware. There are two parts to the firmware, the boot monitor and the main image. By default, rscadm download programs the main firmware image. The boot option selects programming of the boot monitor.

rscadm show
View the current RSC configuration variable settings. If no variable is specified, rscadm shows all variable settings.

rscadm date
Show or set RSC’s time and date. The -s options can be used to set RSC’s time and date to the hosts time and date.

rscadm send_event
Send a text based event to RSC. RSC may forward the event based on its event configuration.
rscadm modem_setup
   Direct connection to the RSC modem. This allows the user to enter AT
   commands to configure the modem. "." returns to prompt.

rscadm useradd
   Add user account to RSC. RSC can support up to four separate users.

rscadm userdel
   Delete a user account from RSC.

rscadm usershow
   Show details on the specified user account. If a username is not specified,
   all user accounts will be shown.

rscadm userpassword
   Set a password for the user account specified. This password overrides any
   existing password currently set. There is no verification of the old pass-
   word before setting the new password. See the RSC documentation on
   valid password formats.

rscadm userperm
   Set the authorization profile for the user. See the userperm options section
   in this man page for more detail.

OPTIONS
   The following options are supported for rscadm:

rscadm resetrsc
   [-s] Perform a "soft" reset instead of a "hard" reset. A hard reset physically
   resets the RSC hardware. The RSC software jumps to the boot firmware,
   simulating a reset, for a soft reset.

rscadm download
   [boot] Program the boot monitor portion of the flash. The main portion of the
   flash is usually programmed.

rscadm show
   [variable] Show the value of that particular variable.

rscadm date
   [-s] Set the date to the hosts time and date.
   [mmdm][HHMM | mmdmHHMM[cc][yy][.SS]
          the date.
   mm  - month
   dd  - day
   HH  - hour
   MM  - minute
   cc  - the first two digits of the four digit year
   yy  - last 2 digits of the year number
   SS  - seconds
rscadm send_event

[-c]  Send a critical event. Without the -c, send_event sends a warning. Warnings are only logged in the RSC event log and not forwarded further.

rscadm usershow

[username]  RSC account name to display info on. If no username is given, all accounts will be displayed.

rscadm userperm

[cuar]  Set permissions for RSC account. If no permissions are specified, all four permissions will be disabled. The options are to; allow user to connect to (c)onsole, allow user to use the (u)ser commands to modify RSC accounts, allow user to (a)dminister/change the RSC configuration variables, allow the user to (r)eset RSC and to power on/off the host.

OPERANDS  The following operands are supported for rscadm:

rscadm set

variable  RSC configuration variable to set. See the RSC documentation for a list of configuration variables.

value  Value to set RSC configuration variable to. See the RSC documentation for a list of valid values.

rscadm download

file  Firmware file to download. The file should contain the RSC boot monitor image or RSC main image.

rscadm send_event

message  Text message to describe event. Should be enclosed in quotes.

rscadm useradd

username  Username for new RSC account.

rscadm userdel

username  RSC account to be removed.

rscadm userpassword

username  RSC account to have password set.

rscadm userperm

username  RSC account to have permissions changed.

EXIT STATUS  = 0  on success

!= 0  on failure (with status message)

EXAMPLES  # rscadm date
# rscadm date -s
# rscadm date 050113101998
# rscadm set hostname rsc15
# rscadm show
# rscadm show hostname
# rscadm send_event -c "The UPS signaled a loss in power!"
# rscadm send_event "The disk is close to full capacity"
# rscadm useradd rscroot
# rscadm userdel olduser
# rscadm usershow
# rscadm usershow rscroot
# rscadm userperm rscroot cuar
# rscadm userperm newuser c
# rscadm userperm newuser

NOTES  rscadm modem_setup - "~" will only work after a new line.
       rscadm MUST be run as root.

BUGS   None known.
NAME sunvts - Invokes the SunVTS kernel and its user interface

SYNOPSIS sunvts [-lepqstv] [-o option_file] [-f log_dir] [-h hostname]

AVAILABILITY SUNWvts

DESCRIPTION The sunvts command is used to invoke the SunVTS user interface and kernel on the same system. It could be used to start the user interface on the local system and connect to the SunVTS kernel on the remote system. By default, it displays CDE Motif graphic interface for CDE environment, OpenLook graphic interface for OpenWindows environment, or TTY interface for non-windowing system.

OPTIONS
-1 Displays SunVTS OpenLook graphic interface.
-e Disables the security checking feature.
-f log_dir
   Specifies an alternative log_file directory. The default log_file directory is /var/opt/SUNWvts/logs.
-h hostname
   Starts the SunVTS user interface on the local system, which connects to or invokes the SunVTS kernel on the specified host after security checking succeeds.
-o option_file
   Starts the SunVTS kernel with the test options loaded from the specified option_file, which by default is located in /var/opt/SUNWvts/options.
-p Starts the SunVTS kernel vtsk (1M) such that it does not probe the test system’s devices.
-q Automatically quits both the SunVTS kernel and the user interface when testing stops.
-s Automatically starts testing from a selected group of tests. The flag must be used with the -o option_file flag.
-t Starts vtstty (1M), a TTY based interface, instead of CDE or OpenLook interface.
-v Displays version information from vtsui(1M) and vtsk(1M).

NOTES If vtsk (1M) is already running on the test system, the sunvts command ignores the -e, -o, -f, -q, -p, and -s options.

SEE ALSO vtsk(1M), vtstty(1M), vtsui(1M), vtsui.ol(1M), vtsprobe(1M)
NAME
vts_cmd – Send a command to the SunVTS kernel (vtsk)

SYNOPSIS
vts_cmd [ command ] [ argument ]

AVAILABILITY
SUNWvts

DESCRIPTION
vts_cmd is a UNIX shell application that allows you to send a single command to the
SunVTS kernel (vtsk). The test machine’s SunVTS kernel will send the response to the
standard output.

The SunVTS application programming interface (API) is character based, which means
that a string of characters (in the form of a command) can be sent to the SunVTS ker-
nel, which then returns a reply back in the form of a string of characters.

vts_cmd(1M) allows the user to send commands and receive replies from a UNIX
command line.

OPTIONS
vts_cmd uses the commands listed below. In all cases, the commands (and any of the
command’s arguments) must follow vts_cmd. See the EXAMPLES section for refer-
ence.

Some of the command descriptions listed below refer to a testnode. In the SunVTS
API, there is a hierarchy of testnodes, with the system being on the top, the test groups
below the system, and the tests themselves at the bottom. In the commands below,
use a slash ”/” to refer to the system. A test group can be one of the following:
Processor(s), Memory, Network, SCSI-Devices(esp0), Comm.Ports, Graphics, OtherDev-
ices, or any user specified group. When referring to a test, you must mention the dev-
vice name and the test name [for example, sound0(audio)].

list testnode
Displays all the testnodes under the specified testnode.

config testnode
Displays the configuration information of the testnode.

status [ testnode ] [-r]
Displays the testing status information of the system. If a testnode is specified,
status will display the status information of that testnode. If you use the -r
argument, the status information of all of testnodes recursive to the testnode
will be displayed.

option [ testnode ] [-l] [-h|n|s|t|a]
Either displays all the options associated with the specified testnode, or sets a
specific option in a testnode.

To display a testnode’s options, type option followed by the testnode and one
of the categories:
-h Threshold
-n Notify category
-s Scheduling category

modified 11 May 2000
Solaris 8
1M-55
-t Test execution category
-a Advanced category

vts_cmd will print all options, as well as the setting of each option. Use the -l option to display the options in long form. In long form, the options will be displayed with all their settings.

option [ testnode ] [ test_option ] [ -g | s | x | y | z ]

-g is used to pass all of the current option settings, for a given instance of a given test, to all of the same instances and tests that are in the same group (will not affect the same tests that are in different groups).

-s is used to pass all of the current option settings for a given instance of a given test, to all of the same instances for all of the same tests on the system (rather than for a group, as with -g).

-x is used to pass all of the current option settings for a given instance of a given test, to all the instances of that test.

-y is used to pass all of the current option settings for a given instance of a given test, to all the instances of all the same tests in a particular group.

-z is used to pass all of the current option settings for a given instance of a given test, to all the instances of all the same tests in the whole system.

To set an option, you must state the testnode immediately followed by the option and the new setting. You must use this format when setting an option:

vts_cmd option testnode[option:setting]

Once the option has been successfully changed, vts_cmd will display the word "DONE".

select testnode

Selects a testnode. If a testnode is selected, all the tests associated with the testnode will be enabled and run when testing begins.
For example, if you select the Graphics testnode, all the tests in Graphics will be enabled for testing. If you select just the "fpu(fputest)" test, then you will only enable this test.

deselect testnode

Deselects a testnode. If a testnode is deselected, all the tests associated with the testnode will be disabled and will not be run when testing begins.

For example, if you deselect the OtherDevices testnode, all the tests in the OtherDevices will be disabled. If you select just the "cgsix0(cg6)" test, then you will only enable this test.

start

Starts all enabled (selected) SunVTS tests.

stop

Stops all running SunVTS tests.

suspend

Suspends (or pauses) all running SunVTS tests. When you are ready to resume testing, type "resume".

resume

Resumes any suspended tests.

reset

Resets all the SunVTS pass and error counts to zero.

probe

Probes all the devices on the test machine and updates the SunVTS kernel's device list.

If a device is listed in the device list, but it is not found during the probe, it will be removed from the list. Conversely, if a device does not exist in a previous device list and is found during the probe, it will be added to the list.

load option_file

Loads an option file. Once loaded, the system and test options will be changed to reflect the settings listed in the option file.

Option files are stored in the /var/opt/SUNWvts/options directory.

store option_file

Creates an option file, listing all the system and test options, and save it in the /var/opt/SUNWvts/options directory.
quit
Terminates the SunVTS kernel (vtsk).

invokes
Starts the deterministic scheduler.

quitds
Terminates the deterministic scheduler.

loadseq sequence_file
Loads a sequence file. Once loaded, the deterministic scheduler UI will reflect the tasks in the loaded sequence file.

storeseq sequence_file
Creates sequence_file, listing all the tasks in the directory /var/opt/SUNWvts/sequences.

statusseq
Returns a string containing the status information of the currently running sequence. The string consists of four fields separated by commas (","). The fields are: current status of SunVTS, current loop count of the sequence, total loop count of the sequence, and currently running task's position.

startseq
Starts the execution of the deterministic scheduler.

stopseq
Stops the execution of the currently running task in the sequence file. Upon starting again, the execution will start from the task that was stopped.

resumeseq
Restarts the execution of the sequence file. Execution will start at the point where the sequence was stopped, unless the sequence was reset, in which case it would start at the beginning of the sequence file.

resetseq
Sets the starting point of the execution to the start of the sequence file. Will also reset the passes and error count.

suspendseq
Suspends the execution of the currently running task in the sequence file.

removeseq sequence_file
Removes sequence_file from the list of sequence files in the directory /var/opt/SUNWvts/sequences.

listtask
Lists the tasks that are present in the currently loaded
addtask task_name [i]
   Adds task_name at the ith position in the sequence file. If no index is passed then the task would be added to the end of the list.

deletetask [i]
   Removes the task at the specified index from the selected sequence.

loadtask task_name
   Loads a task file. Once loaded, the system and test options will be changed to reflect the settings listed in the task file.

setloopcount count
   Sets the number of loops to run in the current sequence to count.

getvtmode
   Gets the current mode of SunVTS kernel.

EXAMPLES
   To list out the configuration information of the test machine, you would use the config command:

   sample% vts_cmd config /[/Hostname:sample,Model:SPARCstation-10,SunVTS version:1.0]:idle

   To load an option file, you would use the load command:

   sample% ls /var/adm/sunvtslog/options
   CPU_options   sample   options
   sbus_standard
   sample% vts_cmd load sbus_standard
   DONE

   To print all the system options in the Comm.Ports testnode, you would use the option command and pipe the output to your local printer:

   sample% vts_cmd option Comm.Ports -l | lp
   request id is printer-213 (standard input)

ENVIRONMENT
VTS_CMD_HOST=hostname
   The hostname of the test machine running the SunVTS kernel (vtksk). If this environment variable is not set, vts_cmd will attempt to send the commands to

modified 11 May 2000
the local machine’s SunVTS kernel.

SEE ALSO SunVTS User’s Guide
NAME
vtsk – SunVTS diagnostic kernel

SYNOPSIS
vtsk [ -epqsv ] [ -o options_file ] [ -f logfile_directory ]

AVAILABILITY
SUNWvts

DESCRIPTION
The `vtsk` command starts up the SunVTS diagnostic kernel as a background process. There can only be one copy of `vtsk` running at a time. Only the superuser can execute this command.

Normally, `vtsk` is automatically started up by the `sunvts (1M)` command if it is not already running. `vtsk` will also be invoked by `inetd (1M)` when there is a connection request from `vtsui` or `vtsui.ol`. In that case, the security file, `.sunvts_sec`, will be checked for the permission before running `vtsk` on the target host specified by `vtsui(1M)` or `vtsui.ol(1M)`.

OPTIONS

- `-e` Enables the security checking for all connection requests.
- `-p` Starts SunVTS diagnostic kernel, but does not probe system configuration.
- `-q` Quits both the SunVTS diagnostic kernel and the attached User Interfaces when the testing is completed.
- `-s` Runs enabled tests immediately after started.
- `-v` Display SunVTS diagnostic kernel’s version information only.

- `-o options_file`
  Starts the SunVTS diagnostic kernel and sets the test options according to the option file named `options_file`.

- `-f logfile_directory`
  Specifies an alternative logfile directory, other than the default.

EXIT STATUS
The following exit values are returned:

0  Successful completion.
1  An error occurred.

FILES
/var/opt/SUNWvts/options  default option file directory.
/var/opt/SUNWvts/logs    default log file directory.

NAME  vtsprobe – prints the device probe information from the SunVTS kernel

SYNOPSIS  vtsprobe [ -m ] [ -h hostname ]

AVAILABILITY  SUNWvts

DESCRIPTION  vtsprobe is a utility that displays the device and configuration information contained in the SunVTS kernel. The output includes the SunVTS assigned group for the device, the device name, the device instance, the testname attached to this device, and the configuration information obtained from the device-specific test probe.

OPTIONS
    -m  Specifies manufacturing mode, which displays the probe information in a format that is easy to read using script files.

    -h hostname
        Specifies the hostname to connect to and get the device and configuration information. If not specified, the current host will be used.

USAGE  After the SunVTS kernel is up and running, you may type vtsprobe at the shell prompt to get the probe output. (See the sunvts (1M) man page for more information on how to start up SunVTS.

EXAMPLE  Running vtsprobe on a sun4m SPARCclassic produces the following output:

    Processor(s)
        system(systest)
            System Configuration=sun4m SPARCclassic
            System clock frequency=50 MHz
            SBUS clock frequency=25 MHz
        fpu(fputest)
            Architecture=sparc
            Type=TI TMS390S10 or TMS390S15 microSPARC chip

    Memory
        kmem(vmem)

modified 15 Mar 1996  Solaris 8  1M-63

**Calls**

\[ spd0(spdtest) \]

**Logical name:** spd0

**NOTES**

The output of **vtsprobe** is highly dependent on the device being correctly configured into the system (so that a SunVTS probe for the device can be run successfully on it) and on the availability of a device-specific test probe.

If the device is improperly configured or if there is no probing function associated with this device, **vtsprobe** cannot print any information associated with it.

**SEE ALSO**  

sunvts(1M), vtsk(1M), vtsui(1M), vtsui.ol(1M), vtstty(1M)
NAME    vtstty – TTY interface for SunVTS

SYNOPSIS    vtstty [ −qv ] [ −h hostname ]

AVAILABILITY    SUNWvts

DESCRIPTION    vtstty is the default interface for SunVTS in the absence of a windowing environment. It can be used in a non-windowing environment such as a terminal connected to the serial port of the system. However, its use is not restricted to this; vtstty can also be used from shell window.

OPTIONS
−q    The "auto-quit" option automatically quits when the conditions for SunVTS to quit are met.
−v    Prints the vtstty version. The interface is not started when you include this option.
−h hostname    Connects to the SunVTS kernel running on the host identified by hostname.

USAGE    The vtstty screen consists of four panels: main control, status, test groups, and console. The panels are used to display choices that the user can select to perform some function and/or to display information. A panel is said to be "in focus" or in a "selected" state when it is surrounded by asterisks and the current item is highlighted. In order to choose from the items in a panel, the focus should be shifted to that panel first.

The following are the different types of selection items that can be present in a panel:
Text string    Describes a choice that, when selected, either pops up another panel or performs a function. For example, "stop" will stop the SunVTS testing.
Data entry field    To enter or edit numeric or textual data.
Checkbox    Represented as "[ ]". Checkboxes are associated with items and indicate whether the associated item is selected or not. A checkbox can be in one of the following two states: Deselected [ ] or Selected [*].

The key assignments given below describe the keys for shifting focus, making a selection, and performing other functions:
TAB or <CTRL>W    Shift focus to another panel
RETURN    Select current item
Spacebar    Toggle checkbox
Up arrow or <CTRL>U    Move up one item
Down arrow or <CTRL>N    Move down one item

Right arrow or <CTRL>R
  Move right one item
Backspace
  Delete text in a data entry field
ESC
  Dismiss a pop-up
<CTRL>F
  Scroll forward in a scrollable panel
<CTRL>B
  Scroll backward in a scrollable panel
<CTRL>X
  Quit vtstty but leave the SunVTS kernel running
<CTRL>L
  Refresh the vtstty screen

NOTES
1. To run vtstty from a telnet session, carry out the following steps:
   a. Before telnet-ing, determine the values for "rows and "columns". (See stty(1)).
   b. Set term to the appropriate type after telnet-ing(for example, set term=vt100).
   c. Set the values of columns and rows to the value noted above. (See stty(1)).
2. Before running vtstty ensure that the environment variable describing the terminal type is set correctly.

NAME       vtsui – SunVTS Graphic User Interface (CDE)

SYNOPSIS   vtsui [ −qv ] [ −h hostname ]

AVAILABILITY      SUNWvts

DESCRIPTION The vtsui command starts up the CDE Motif version of SunVTS graphic user interface. There can be multiple instances of vtsui running at the same time, all connected to one SunVTS diagnostic kernel, vtsk(1M). The name of the host machine running the diagnostic kernel, vtsk(1M), will be displayed in the title bar of the graphical user interface window.

vtsui is automatically started up by the sunvts (1M) command. vtsui can be also used to start vtsk (1M) if inetd (1M) is in operation. In that case, the security file, sunvts_sec, will be checked for the permission before running vtsk on the target host. See the "SunVTS User’s Guide" for a complete description on using the graphical user interface.

OPTIONS

−q          Quits the SunVTS graphic user interface when testing has terminated.

−v          Displays graphic user interface version information only.

−h hostname Starts the SunVTS graphic user interface and connects to the SunVTS diagnostic kernel running on hostname, or invokes the kernel if not running, after security checking succeeds. If hostname not specified, the local host is assumed.

EXIT STATUS The following exit values are returned:

0       Successful completion.

1       An error occurred.

vtsui.ol (1M)  Maintenance Commands

NAME  vtsui.ol – SunVTS Graphic User Interface (OpenLook)

SYNOPSIS  vtsui.ol [ -qv ] [ -h hostname ]

AVAILABILITY  SUNWvts

DESCRIPTION  The vtsui.ol command starts up the OpenLook version of SunVTS graphic user interface. There can be multiple instances of vtsui.ol running at the same time, all connected to one SunVTS diagnostic kernel, vtsk(1M). The name of the host machine running the diagnostic kernel, vtsk(1M), will be displayed in the title bar of the graphic user interface window.

vtsui.ol can be used to start vtsk(1M) if inetd(1M) is in operation. In that case, the security file, .sunvts_sec, will be checked for the permission before running vtsk on the target host. vtsui.ol is also automatically started up by the sunvts(1M) command. See the "SunVTS User’s Guide" for a complete description on using the graphic user interface.

OPTIONS  -q  Quits the SunVTS graphic user interface when testing has terminated.
- v  Displays graphic user interface version information only.
- h hostname  Starts the SunVTS graphic user interface and connects to the SunVTS diagnostic kernel running on hostname, or invokes the kernel if not running, after security checking succeeds. If hostname not specified, the local host is assumed.

EXIT STATUS  The following exit values are returned:
0  Successful completion.
1  An error occurred.

NAME
envmond.conf - configuration file for environment monitor daemon

SYNOPSIS
/usr/platform/SUNW,UltraSPARC-IIi-Netract/envmond.conf

DESCRIPTION
The envmond.conf file is the configuration file for envmond(1M), the system environment monitor daemon. The daemon monitors environmental devices to check for conditions that may require some action. The envmond (1M) daemon logs appropriate messages to a system log file via syslogd(1M).

Each configuration file entry provides the daemon information about a shared object library, referred to as a policy, which has the knowledge to monitor a device. Each policy entry describes an interface between the envmond daemon and the policy. The policy entry in the envmond.conf file can contain configurable parameters in the policy-args field.

All policy entries have the same format:

poll-interval policy-name policy-args

The three fields shown above are separated by whitespace. Use the backslash (/) at the end of a line to continue policy-args to the line following.

The fields in the envmond.conf file are described as follows:

poll-interval
Given in seconds as a decimal number, specifies how often to invoke the policy check function. If poll-interval is 0, the policy check function will never be called.

policy-name
The file name, with optional path, of the file implementing the policy. The default location for the policy files is /usr/platform/SUNW,UltraSPARC-IIi-Netract/lib/envmond/sparcv9

policy-args
An optional list of whitespace-separated arguments to be passed to the policy during initialization. The number and format of these arguments is policy-dependent.

The following sections describe policies shipped with the implementation of envmond(1M).

fancpu Policy
The fancpu policy polls I2C slave devices every poll-interval seconds to get the current CPU temperature and the fantray status. If the CPU temperature reaches a warning temperature threshold, a warning message is printed on the system console and to the system log file specified in syslog.conf(4). If the CPU temperature reaches the shutdown temperature, a critical error message is printed on the system console by syslogd(1M). The system is then halted by the shutdown(1M) command. The fan status will be reflected by the corresponding LEDs on the System Status Board, and with log messages sent to syslogd.

modified 16 JUN 2000

Solaris 8 4-69
powersupply Policy
The powersupply policy sets and clears the power supply LEDs on the System Status Board to reflect power supply status. The policy also handles an interrupt event if a power supply fails.

csb Policy
The System Controller and Status Board Policy is primarily to configure the scsb driver for cPCI Slot Status LED control. The default \texttt{scsb\_led\_crtl} setting is false, meaning that the scsb driver controls the cPCI slot LEDs. If \texttt{scsb\_led\_crtl} is set to true, then some application is responsible for slot LED updates.

EXAMPLES
Example 1: Sample Entries
The first entry, below, invokes the powersupply shared library every 60 seconds. The second entry specifies that the scsb policy controls the cPCI Slot Status LED.

\begin{verbatim}
60 powersupply.so
scsb.so scsb\_led\_crtl=false
\end{verbatim}

FILES
\texttt{/usr/platform/SUNW,UltraSPARC-Ii-Netract/}
Installation directory.
The following relative pathnames are all beneath the directory named above.

\texttt{lib/envmond/sparcv9/envmond}
Executable for the environmental daemon.

\texttt{lib/envmond/sparcv9/fancpu.so}
Policy for CPU temperature and fan speed control.

\texttt{lib/envmond/sparcv9/powersupply.so}
Policy for power supply monitoring.

NAME  ge – GEM Gigabit-Ethernet device driver

SYNOPSIS  /dev/ge

DESCRIPTION  The ge Sun Gigabit-Ethernet driver is a multi-threaded, loadable, clonable, STREAMS hardware driver supporting the connectionless Data Link Provider Interface, dlpi(7P), over GEM SBus and PCI Gigabit-Ethernet add-in Adapters. Multiple GEM based adapters installed within the system are supported by the driver. The ge driver provides basic support for the GEM based Ethernet hardware and it is used to handle the SUNW,sbus-gem (SBus GEM) and pci108e,2bad (PCI GEM) devices. Functions include chip initialization, frame transmit and receive, multicast and promiscuous support, and error recovery and reporting. The GEM device provides 1000BASE-SX networking interfaces using the GEM ASIC, external SERDES and Fiber optical Transceiver. The GEM ASIC provides the appropriate bus interface, MAC functions and the Physical code sub-layer (PCS) functions. The external SERDES connects to a fiber transceiver and provides the physical connection.

The 1000Base-SX standard specifies an “auto-negotiation” protocol to automatically select the mode of operation. In addition to to the duplex mode of the operation, the GEM ASIC can auto-negotiate for IEEE 802.3x Frame Based Flow Control capabilities. The GEM PCS is capable of doing “auto-negotiation” with the remote-end of the link (Link Partner) and receives the capabilities of the remote end. It selects the Highest Common Denominator mode of operation based on the priorities. It also supports forced-mode of operation where the driver can select the mode of operation.

APPLICATION PROGRAMMING INTERFACE  ge and DLPI

The cloning character-special device /dev/ge is used to access all ge controllers installed within the system.

The ge driver is a “style 2” Data Link Service provider. All M PROTO and M_PCPROTO type messages are interpreted as DLPI primitives. Valid DLPI primitives are defined in <sys/dlpi.h>. Refer to dlpi(7P) for more information. An explicit DL_ATTACH_REQ message by the user is required to associate the opened stream with a particular device (ppa). The ppa ID is interpreted as an unsigned long data type and indicates the corresponding device instance (unit) number. An error (DL_ERROR_ACK) is returned by the driver if the ppa field value does not correspond to a valid device instance number for this system. The device is initialized on first attach and de-initialized (stopped) at last detach.

The values returned by the driver in the DL_INFO_ACK primitive in response to the DL_INFO_REQ from the user are as follows:

- The maximum SDU is 1500 (ETHERMTU - defined in <sys/ethernet.h>).
- The minimum SDU is 0.
- The dlsap address length is 8.
- The MAC type is DL Ether.
- The sap length values is –2 meaning the physical address component is followed immediately by a 2 byte sap component within the DLSAP address.

modified 01 Sep 1998  Solaris 8  7-71
• The service mode is **DL_CLDLS**.
• No optional quality of service (QOS) support is included at present so the QOS fields are 0.
• The provider style is **DL_STYLE2**.
• The version is **DL_VERSION_2**.
• The broadcast address value is Ethernet/IEEE broadcast address (0xFFFFFFFF).

Once in the **DL_ATTACHED** state, the user must send a **DL_BIND_REQ** to associate a particular SAP (Service Access Pointer) with the stream. The ge driver interprets the **sap** field within the **DL_BIND_REQ** as an Ethernet “type” therefore valid values for the **sap** field are in the [0-0xFFFFFFFF] range. Only one Ethernet type can be bound to the stream at any time.

If the user selects a **sap** with a value of 0, the receiver will be in “802.3 mode”. All frames received from the media having a “type” field in the range [0-1500] are assumed to be 802.3 frames and are routed up all open Streams which are bound to **sap** value 0. If more than one Stream is in “802.3 mode” then the frame will be duplicated and routed up multiple Streams as **DL_UNITDATA_IND** messages.

In transmission, the driver checks the **sap** field of the **DL_BIND_REQ** if the **sap** value is 0, and if the destination type field is in the range [0-1500]. If either is true, the driver computes the length of the message, not including initial **M_PROTO** mblk (message block), of all subsequent **DL_UNITDATA_REQ** messages and transmits 802.3 frames that have this value in the MAC frame header length field.

The ge driver **DLSAP** address format consists of the 6 byte physical (Ethernet) address component followed immediately by the 2 byte **sap** (type) component producing an 8 byte **DLSAP** address. Applications should not hard code to this particular implementation-specific **DLSAP** address format but use information returned in the **DL_INFO_ACK** primitive to compose and decompose **DLSAP** addresses. The **sap** length, full **DLSAP** length, and **sap**/physical ordering are included within the **DL_INFO_ACK**. The physical address length can be computed by subtracting the **sap** length from the full **DLSAP** address length or by issuing the **DL_PHYS_ADDR_REQ** to obtain the current physical address associated with the stream.

Once in the **DL_BOUND** state, the user may transmit frames on the Ethernet by sending **DL_UNITDATA_REQ** messages to the ge driver. The ge driver will route received Ethernet frames up all those open and bound streams having a **sap** which matches the Ethernet type as **DL_UNITDATA_IND** messages. Received Ethernet frames are duplicated and routed up multiple open streams if necessary. The **DLSAP** address contained within the **DL_UNITDATA_REQ** and **DL_UNITDATA_IND** messages consists of both the **sap** (type) and physical (Ethernet) components.

In addition to the mandatory connectionless **DLPI** message set the driver additionally supports the following primitives.

**ge Primitives**

The **DL_ENABMULTI_REQ** and **DL_DISABMULTI_REQ** primitives enable/disable reception of individual multicast group addresses. A set of multicast addresses may be iteratively created and modified on a per-stream basis using these primitives. These
primitives are accepted by the driver in any state following DL_ATTACHED.

The DL_PROMICON_REQ and DL_PROMISCOFF_REQ primitives with the DL_PROMISC_PHYS flag set in the dl_level field enables/disables reception of all ("promiscuous mode") frames on the media including frames generated by the local host.

When used with the DL_PROMISC_SAP flag set this enables/disables reception of all sap (Ethernet type) values. When used with the DL_PROMISC_MULTI flag set this enables/disables reception of all multicast group addresses. The effect of each is always on a per-stream basis and independent of the other sap and physical level configurations on this stream or other streams.

The DL_PHYS_ADDR_REQ primitive returns the 6 octet Ethernet address currently associated (attached) to the stream in the DL_PHYS_ADDR_ACK primitive. This primitive is valid only in states following a successful DL_ATTACH_REQ.

The DL_SET_PHYS_ADDR_REQ primitive changes the 6 octet Ethernet address currently associated (attached) to this stream. The credentials of the process which originally opened this stream must be superuser. Otherwise EPERM is returned in the DL_ERROR_ACK. This primitive is destructive in that it affects all other current and future streams attached to this device. An M_ERROR is sent up all other streams attached to this device when this primitive is successful on this stream. Once changed, all streams subsequently opened and attached to this device will obtain this new physical address. Once changed, the physical address will remain until this primitive is used to change the physical address again or the system is rebooted, whichever comes first.

ge DRIVER By default, the ge driver performs “auto-negotiation” to select the mode and flow control capabilities of the link.

The link can be in one of the 4 following modes:
- 1000 Mbps, full-duplex
- 1000 Mbps, half-duplex
- Symmetric Pause
- Asymmetric Pause

These speeds and modes are described in the 1000Base-TX standard.

The auto-negotiation protocol automatically selects:
- Operation mode (half-duplex or full-duplex)
- Flow Control Capability (Symmetric and/or Asymmetric)

The auto-negotiation protocol does the following:
- Gets all the modes of operation supported by the Link Partner
- Advertises its capabilities to the Link Partner
- Selects the highest common denominator mode of operation based on the priorities

The GEM Hardware is capable of all of the operating modes listed above, when by default, auto-negotiation is used to bring up the link and select the common mode of operation with the Link Partner. The PCS also supports forced-mode of operation in
which the driver can select the mode of operation and the flow control capabilities, using the \textit{ndd} utility.

The \textbf{GEM} device also supports programmable “\textit{IPG}” (Inter-Packet Gap) parameters \texttt{ipg1} and \texttt{ipg2}. By default, the driver sets \texttt{ipg1} to 8 byte-times and \texttt{ipg2} to 4 byte-times (which are the standard values). Sometimes, the user may want to alter these values from the standard 1000 Mbps \textit{IPG} set to 0.096 microseconds.

\textbf{ge Parameter List}

The ge driver provides for setting and getting various parameters for the \textbf{GEM} device. The parameter list includes \textit{current transceiver status}, \textit{current link status}, \textit{inter-packet gap}, \textit{PCS capabilities} and \textit{link partner capabilities}.

The PCS has two sets of capabilities: one set reflects the capabilities of the \textbf{hardware}, which are \textbf{read-only (RO)} parameters and the second set reflects the values chosen by the user and is used in \textit{speed selection}. There are \textbf{read/write (RW)} capabilities. At boot time, these two sets of capabilities will be the same. The Link Partner capabilities are also read only parameters because the current default value of these parameters can only be read and cannot be modified.

NAME  
hsi – S-Bus based high speed serial line interface.

SYNOPSIS  
#include <fcntl.h>
open(/dev/hih, mode);
open(/dev/hih, mode);

DESCRIPTION  
The hsi module is a loadable and unloadable STREAMS driver that implements the sending and receiving of data packets such as HDLC frames over synchronous serial lines. The hsi driver is a standalone driver that supports HSI/S S-Bus based serial interface hardware and provides physical level data transfer services for upper data link layer protocols (e.g. HDLC or SDLC).

The hih devices provide what is known as a data path which supports the transfer of data via read(2) and write(2) system calls, as well as ioctl(2) calls. Data path opens are exclusive in order to protect against injection or diversion of data by another process.

The hih device provides a separate control path for use by programs that need to configure or monitor a connection independent of any exclusive access restrictions imposed by data path opens. Up to three control paths may be active on a particular serial channel at any one time. Control path accesses are restricted to ioctl(2) calls only; no data transfer is possible.

When used in synchronous modes, the Z16C35 ISCC supports several options for clock sourcing and data encoding. Both the transmit and receive clock sources can be set to be the external receive clock (RTxC) and the internal baud rate generator (BRG). Additionally, the transmit clock source can be set to the external transmit clock (TRxC).

The baud rate generator is a programmable divisor that derives a clock frequency from the PCLK input signal to the ISCC. A programmed baud rate is translated into a 16-bit time constant that is stored in the ISCC. When using the BRG as a clock source the driver may answer a query of its current speed with a value different from the one specified. This is because baud rates translate into time constants in discrete steps, and reverse translation shows the change. If an exact baud rate is required that cannot be obtained with the BRG, an external clock source must be selected.

A local loopback mode is available, primarily for use by the hsi_loop(1M) utility for testing purposes, and should not be confused with SDLC loop mode, which is not supported on this interface. This option should be selected casually, or left in use when not needed.

The hsi driver keeps running totals of various hardware generated events for each channel. These include numbers of packets and characters sent and received, abort conditions detected by the receiver, receive CRC errors, transmit underruns, receive overruns, input errors and output errors, and message block allocation failures. Input errors are logged whenever an incoming message must be discarded, such as when an abort or CRC error is detected, a receive overrun occurs, or when no message block is available to store incoming data. Output errors are logged when the data must be discarded due to underruns, CTS drops during transmission, CTS timeouts, or excessive watchdog timeouts caused by a cable break.

modified 14 April 1993    Solaris 8  7-75
IOCTLS

The hsi driver supports several ioctl() commands, including:

S_IOCGETMODE    Return a struct scc_mode containing parameters currently in use. These include the transmit and receive clock sources, boolean loopback and NRZI mode flags and the integer baudrate.

S_IOCSETMODE    The argument is a struct scc_mode from which the ISCC channel will be programmed.

S_IOCGETSTATS   Return a struct hs_stats containing the current totals of hardware-generated events. These include numbers of packets and characters sent and received by the driver, aborts and CRC errors detected, transmit underruns, and receive overruns.

S_IOCCLRSTATS   Clear the hardware statistics for this channel.

S_IOCGETSPEED   Returns the currently set baudrate as an integer. This may not reflect the actual data transfer rate if external clocks are used.

S_IOCGETMCTL    Returns the current state of the CTS and DCD incoming modem interface signals as an integer.

The following structures are used with hsi ioctl() commands:

struct scc_mode {
    char sm_txclock; /* transmit clock sources */
    char sm_rxclock; /* receive clock sources */
    char sm_iflags; /* data and clock inversion flags (non-zsh) */
    u_char sm_config; /* boolean configuration options */
    int sm_baudrate; /* real baud rate */
    int sm_retval; /* reason codes for ioctl failures */
};

struct hs_stats {
    unsigned int ipack; /* input packets */
    unsigned int opack; /* output packets */
    unsigned int ichar; /* input bytes */
    unsigned int ochar; /* output bytes */
    int abort; /* abort received */
    int crc; /* CRC error */
    int cts; /* CTS timeouts */
    int dcd; /* Carrier drops */
    int overrun; /* receive overrun */
    int underrun; /* transmit underrun */
    int ierror; /* input error */
    int oerror; /* output error */
    int nobuffers; /* rcv side memory allocation failure */
    int ishort; /* input packet too short (< CRC-bytes+1) */
    int ilong; /* input packet too long (> mru) */
    int inactive; /* input packet rcvd when rcv is inactive */
    int idma; /* receive dma error */
}
Devices

```c
int olong; /* output packet too long (> mtu) */
int ohung; /* transmit hung (usually missing clock) */
int odma; /* transmit dma error */

};
```

**ERRORS**

An `open()` will fail if a STREAMS message block cannot be allocated, or:

- **ENXIO** The unit being opened does not exist.
- **EBUSY** The device is in use by another serial protocol.

An `ioctl()` will fail if:

- **EINVAL** An attempt was made to select an invalid clocking source.
- **EINVAL** The baud rate specified for use with the baud rate generator would translate to a null time constant in the ISCC’s registers.

**FILES**

`/dev/hih[0-n]`, `/dev/hih`

Character-special devices.

`/usr/include/sys/ser_sync.h`

Header file specifying synchronous serial communication definitions.

**DIAGNOSTICS**

- **hih data open failed, no memory, rq=nnn**
  
  A kernel memory allocation failed for one of the private data structures. The value of `nnn` is the address of the read queue passed to `open(2)`.

- **hih clone open failed, no memory, rq=nnn**
  
  The open could not proceed because an initial STREAMS message block could not be made available for incoming data.

- **hih: clone device d must be attached before use!**
  
  An operation was attempted through a control path before that path had been attached to a particular serial channel.

- **hihn: invalid operation for clone dev.**
  
  An inappropriate STREAMS message type was passed through a control path. Only `M_IOCTL` and `MPROTO` message types are permitted.

- **hihn: not initialized, can’t send message**
  
  An `M_DATA` message was passed to the driver for a channel that had not been programmed at least once since the driver was loaded. The ISCC’s registers were in an unknown state. The `S_IOCSETMODE ioctl` command performs the programming operation.

- **hihn: transmit hung**
  
  The transmitter was not successfully restarted after the watchdog timer

modified 14 April 1993

7-77
expired.

**hihN: Bad PPA = N.**
SunHSI/S driver received a DL_ATTACH_REQ, which has an out-of-range PPA number N, from upper layers.

**hihN: port N not installed.**
The SunHSI/S port N, which is referenced by the PPA number in a received DL_ATTACH_REQ message, is not installed in the system.

**hihN: out of STREAMS mblocks.**
Running out of streams mblocks for SunHSI/S port N.

**hihN: xmit hung.**
Transmission hung on SunHSI/S port N. This usually happens because of cabling problems or due to missing clocks from the CSU/DSU or modem.

**hihN: <hih_rxsoft> no buffers - rxbad.**
Running out of streams mblocks for SunHSI/S port N in hih_rxsoft() routine.

**WARNING: hih init: changed baudrate from 100000 to 99512.**
The baud rate specified was rounded to a value the SunHSI/S hardware can support.
NAME  
hsip – PCI-Bus based high speed serial line interface.

SYNOPSIS
#include <fcntl.h>
#include <usr/include/sys/ser_sync.h>
open(/dev/hihp, mode);
open(/dev/hihp, mode);

DESCRIPTION
The hsip module is a loadable and unloadable STREAMS driver that implements the sending and receiving of data packets such as HDLC frames over synchronous serial lines. The hsip driver is a standalone driver that supports HSI/P PCI-Bus based serial interface hardware and provides phsipcal level data transfer services for upper data link layer protocols (e.g. HDLC or SDLC).

The hihp devices provide what is known as a data path which supports the transfer of data via read(2) and write(2) system calls, as well as ioctl(2) calls. Data path opens are exclusive in order to protect against injection or diversion of data by another process.

The hihp device provides a separate control path for use by programs that need to configure or monitor a connection independent of any exclusive access restrictions imposed by data path opens. Up to three control paths may be active on a particular serial channel at any one time. Control path accesses are restricted to ioctl(2) calls only; no data transfer is possible.

The HSIP ports support several options for clock sourcing and data encoding. Both the transmit and receive clock sources can be set to be the external transmit clock (TxC), external receive clock (RxC), the internal baud rate generator (BRG), or the output of the SCC’s Digital Phase-Lock Loop (DPLL).

The baud rate generator is a programmable divisor that derives a clock frequency from the PCLK input signal to the SCC. A programmed baud rate is translated into a 16-bit time constant that is stored in the SCC. When using the BRG as a clock source the driver may answer a query of its current speed with a value different from the one specified. This is because baud rates translate into time constants in discrete steps, and reverse translation shows the change. If an exact baud rate is required that cannot be obtained with the BRG, an external clock source must be selected.

Use of the DPLL option requires the selection of NRZI data encoding and the setting of a non-zero value for the baud rate, because the DPLL uses the BRG as its reference clock source.

A local loopback mode is available, primarily for use by the hsip_loop(1m) utility for testing purposes, and should not be confused with SDLC loop mode, which is not supported on this interface. Also, an auto-echo feature may be selected that causes all incoming data to be routed to the transmit data line, allowing the port to act as the remote end of a digital loop. Neither of these options should be selected casually, or left in use when not needed.
The hsip driver keeps running totals of various hardware generated events for each channel. These include numbers of packets and characters sent and received, abort conditions detected by the receiver, receive CRC errors, transmit underruns, receive overruns, input errors and output errors. Input errors are logged whenever an incoming message must be discarded, such as when an abort or CRC error is detected, a receive overrun occurs, or when no message block is available to store incoming data. Output errors are logged when the data must be discarded due to underruns, CTS drops during transmission, CTS timeouts, or excessive watchdog timeouts caused by a cable break.

IOCTS

The hsip driver supports several ioctl() commands, including:

S_IOCGETMODE Return a struct scc_mode containing parameters currently in use. These include the transmit and receive clock sources, boolean loopback and NRZI mode flags and the integer baudrate.

S_IOCSETMODE The argument is a struct scc_mode from which the SCC channel will be programmed.

S_IOCGETSTATS Return a struct sl_stats containing the current totals of hardware-generated events. These include numbers of packets and characters sent and received by the driver, aborts and CRC errors detected, transmit underruns, and receive overruns.

S_IOCCLRSTATS Clear the hardware statistics for this channel.

S_IOCGETSPEED Returns the currently set baudrate as an integer. This may not reflect the actual data transfer rate if external clocks are used.

S_IOCGETMCTL Returns the current state of the CTS and DCD incoming modem interface signals as an integer.

The following structures are used with hsip ioctl() commands:

```c
struct scc_mode {
    char sm_txclock; /* transmit clock sources */
    char sm_rxclock; /* receive clock sources */
    char sm_iflags; /* data and clock inversion flags (non-zsh) */
    u_char sm_config; /* boolean configuration options */
    int sm_baudrate; /* real baud rate */
    int sm_retval; /* reason codes for ioctl failures */
};

struct sl_stats {
    int ipack; /* input packets */
    int opack; /* output packets */

ERRORS
An open() will fail if a STREAMS message block cannot be allocated, or:
ENXIO The unit being opened does not exist.
EBUSY The device is in use by another serial protocol.

An ioctl() will fail if:
EINVAL An attempt was made to select an invalid clocking source.
EINVAL The baud rate speciﬁed for use with the baud rate generator would
translate to a null time constant in the SCC’s registers.

DIAGNOSTICS
hihp data open failed, no memory, rq=nnn
hihp clone open failed, no memory, rq=nnn A kernel memory allocation
failed for one of the private data structures. The value of nnn is the address of
the read queue passed to open(2).

hihp_open: can't alloc message block
The open could not proceed because an initial STREAMS message block could
not be made available for incoming data.

hihp: clone device d must be attached before use!
An operation was attempted through a control path before that path had been
attached to a particular serial channel.

hihp: invalid operation for clone dev.
An inappropriate STREAMS message type was passed through a control path.
Only M_IOCTL and M_PROTO message types are permitted.

hihp: not initialized, can't send message
An M_DATA message was passed to the driver for a channel that had not been
programmed at least once since the driver was loaded. The S_IOCSETMODE
ioctl command performs the programming operation.

modified 14 April 1997 Solaris 8 7-81
**hihp**: transmit hung

The transmitter was not successfully restarted after the watchdog timer expired.
**NAME**
nf – FDDI device driver

**SYNOPSIS**
```c
#include <sys/nf.h>
#include <sys/dlpi.h>
```

**DESCRIPTION**

nf is a multi-threaded, loadable, clonable, STREAMS hardware device driver supporting the connectionless Data Link Provider Interface, dlpi(7), over DP83265A (BSI-2) FDDI controller in the SBus card. There is no fixed limitation on the number of FDDI cards supported by the driver. The nf driver provides basic support for the BSI-2, BMAC and PLAYER+ hardware. Functions include chip initialization, frame transmit and receive, multicast and promiscuous support, and error recovery and reporting.

The cloning character-special device /dev/nf is used to access BSI-2 controller installed within the system.

**nf and DLPI**

The nf driver is a “style 2” Data Link Service provider. All M_PROTO and M_PCPROTO type msgs are interpreted as DLPI primitives. An explicit DL_ATTACH_REQ message by the user is required to associate the opened stream with a particular device (ppa). The ppa ID is interpreted as an unsigned long and indicates the corresponding device instance (unit) number. An error (DL_ERROR_ACK) is returned by the driver if the ppa field value does not correspond to a valid device instance number for this system. The device is initialized on first attach and de-initialized (stopped) on last detach.

The values returned by the driver in the DL_INFO_ACK primitive in response to the DL_INFO_REQ from the user are as follows:

- The max SDU is 4352 (FDDIMTU).
- The min SDU is 0.
- The dl sap address length is 8.
- The MAC type is DL_FDDI.
- The sap length value is –2 meaning the physical address component is followed immediately by a 2 byte sap component within the DLSAP address.
- The service mode is DL_CLDLS.
- No optional quality of service (QOS) support is included at present so the QOS fields are 0.
- The provider style is DL_STYLE2.
- The version is DL_VERSION_2.
- The broadcast address value is Ethernet/IEEE broadcast address (0xFFFFFFF).

modified 17 May 1996 Solaris 8 7-83
Once in the DL_ATTACHED state, the user must send a DL_BIND_REQ to associate a particular SAP (Service Access Pointer) with the stream. The nf driver interprets the sap field within the DL_BIND_REQ as an Ethernet “type” therefore valid values for the sap field are in the [0-0xFFFF] range. Only one Ethernet type can be bound to the stream at any time.

In addition to Ethernet V2 service, an “802.3 mode” is provided by the driver and works as follows. sap value 0 is treated as equivalent and represent a desire by the user for “802.3 mode”. If the value of the sap field of the DL_BIND_REQ is 0, then the driver computes the length of the message, not including initial M_PROTO mblk, of all subsequent DL_UNITDATA_REQ messages and transmits 802.3 frames having this value in the MAC frame header length field and a value of 0xaaaa030000 in the snap header. All frames received from the media having a “type” field in the range [0-1500] are assumed to be 802.3 frames and are routed up all open streams which are bound to sap value 0. If more than one stream is in “802.3 mode” then the frame will be duplicated and routed up multiple streams as DL_UNITDATA_IND messages.

The nf driver DLSAP address format consists of the 6 byte physical (FDDI) address component followed immediately by the 2 byte sap (type) component producing an 8 byte DLSAP address. Applications should not hardcode to this particular implementation-specific DLSAP address format but use information returned in the DL_INFO_ACK primitive to compose and decompose DLSAP addresses. The sap length, full DLSAP length, and sap/physical ordering are included within the DL_INFO_ACK. The physical address length can be computed by subtracting the sap length from the full DLSAP address length or by issuing the DL_PHYS_ADDR_REQ to obtain the current physical address associated with the stream.

Once in the DL_BOUND state, the user may transmit frames on the FDDI ring by sending DL_UNITDATA_REQ messages to the nf driver. The nf driver will route received FDDI frames up all those open and bound streams having a sap which matches the type as DL_UNITDATA_IND messages. Received FDDI frames are duplicated and routed up multiple open streams if necessary. The DLSAP address contained within the DL_UNITDATA_REQ and DL_UNITDATA_IND messages consists of both the sap (type) and physical (FDDI) components.

**nf Primitives**

In addition to the mandatory connectionless DLPI message set the driver additionally supports the following primitives.

The DL_ENABMULTI_REQ and DL_DISABMULTI_REQ primitives enable/disable reception of individual multicast group addresses. A set of multicast addresses may be iteratively created and modified on a per-stream basis using these primitives. These primitives are accepted by the driver in any state following DL_ATTACHED.

The DL_PROMISCON_REQ and DL_PROMISCOFF_REQ primitives with the DL_PROMISC_PHYS flag set in the dl_level field enables/disables reception of all (“promiscuous mode”) frames on the media including frames generated by the local host. When used with the DL_PROMISC_SAP flag set this enables/disables reception of all sap (Ethernet type) values. When used with the DL_PROMISC_MULTI flag set this enables/disables reception of all multicast group addresses. The effect of each is
always on a per-stream basis and independent of the other sap and physical level configurations on this stream or other streams.

The DL_PHYS_ADDR_REQ primitive return the 6 octet MAC address currently associated (attached) to the stream in the DL_PHYS_ADDR_ACK primitive. This primitive is valid only in states following a successful DL_ATTACH_REQ.

The DL_SET_PHYS_ADDR_REQ primitive changes the 6 octet MAC address currently associated (attached) to this stream. The credentials of the process which originally opened this stream must be superuser or EPERM is returned in the DL_ERROR_ACK. This primitive is destructive in that it affects all other current and future streams attached to this device. An M_ERROR is sent up all other streams attached to this device when this primitive on this stream is successful. Once changed, all streams subsequently opened and attached to this device will obtain this new physical address. Once changed, the physical address will remain so until this primitive is used to change the physical address again or the system is rebooted, whichever comes first.

By default the first interface will use the systems MAC address but subsequent interfaces will use the FDDI local address.

NAME

pf – FDDI device driver

SYNOPSIS

#include <sys/pf.h> #include <sys/dlpi.h>

DESCRIPTION

pf is a multi-threaded, loadable, clonable, STREAMS hardware device driver supporting the connectionless Data Link Provider Interface, dlpi(7), over PBS FDDI controller in the PCI card. The driver also provides support for Applications to get statistics and status of Station Management. There is no fixed limitation on the number of FDDI cards supported by the driver. The pf driver provides basic support for the PBS, BMAC and PLAYER+ hardware. Functions include chip initialization, LLC/SMT frame transmit and receive, multicast and promiscuous support, and error recovery and reporting.

The cloning character-special device /dev/pf is used to access PBS controller installed within the system.

pf and DLPI

The pf driver is a “style 2” Data Link Service provider. All M_PROTO and M_PCPROTO type msgs are interpreted as DLPI primitives. An explicit DL_ATTACH_REQ message by the user is required to associate the opened stream with a particular device (ppa). The ppa ID is interpreted as an unsigned long and indicates the corresponding device instance (unit) number. An error (DL_ERROR_ACK) is returned by the driver if the ppa field value does not correspond to a valid device instance number for this system. The device is initialized on first attach and de-initialized (stopped) on last detach.

The values returned by the driver in the DL_INFO_ACK primitive in response to the DL_INFO_REQ from the user are as follows:

- The max SDU is 4352 (FDDIMTU).
- The min SDU is 0.
- The dlsap address length is 8.
- The MAC type is DL_FDDI.
- The sap length value is –2 meaning the physical address component is followed immediately by a 2 byte sap component within the DLSAP address.
- The service mode is DL_CLDLS.
- No optional quality of service (QOS) support is included at present so the QOS fields are 0.
- The provider style is DL_STYLE2.
- The version is DL_VERSION_2.
- The broadcast address value is Ethernet/IEEE broadcast address (0xFFFFFFFF).
Once in the DL_ATTACHED state, the user must send a DL_BIND_REQ to associate a particular SAP (Service Access Pointer) with the stream. The pf driver interprets the sap field within the DL_BIND_REQ as an Ethernet “type” therefore valid values for the sap field are in the [0-0xFFFF] range. Only one Ethernet type can be bound to the stream at any time.

In addition to Ethernet V2 service, an “802.3 mode” is provided by the driver and works as follows. sap value 0 is treated as equivalent and represent a desire by the user for “802.3 mode”. If the value of the sap field of the DL_BIND_REQ is 0, then the driver computes the length of the message, not including initial M_PROTO mblk, of all subsequent DL_UNITDATA_REQ messages and transmits 802.3 frames having this value in the MAC frame header length field and a value of 0xaada030000 in the snap header. All frames received from the media having a “type” field in the range [0-1500] are assumed to be 802.3 frames and are routed up all open streams which are bound to sap value 0. If more than one stream is in “802.3 mode” then the frame will be duplicated and routed up multiple streams as DL_UNITDATA_IND messages.

The pf driver DLSAP address format consists of the 6 byte physical (FDDI) address component followed immediately by the 2 byte sap (type) component producing an 8 byte DLSAP address. Applications should not hardcode to this particular implementation-specific DLSAP address format but use information returned in the DL_INFO_ACK primitive to compose and decompose DLSAP addresses. The sap length, full DLSAP length, and sap/physical ordering are included within the DL_INFO_ACK. The physical address length can be computed by subtracting the sap length from the full DLSAP address length or by issuing the DL_PHYS_ADDR_REQ to obtain the current physical address associated with the stream.

Once in the DL_BOUND state, the user may transmit frames on the FDDI ring by sending DL_UNITDATA_REQ messages to the pf driver. The pf driver will route received FDDI frames up all those open and bound streams having a sap which matches the type as DL_UNITDATA_IND messages. Received FDDI frames are duplicated and routed up multiple open streams if necessary. The DLSAP address contained within the DL_UNITDATA_REQ and DL_UNITDATA_IND messages consists of both the sap (type) and physical (FDDI) components.

**pf Primitives**

In addition to the mandatory connectionless DLPI message set the driver additionally supports the following primitives.

The DL_ENABMULTI_REQ and DL_DISABMULTI_REQ primitives enable/disable reception of individual multicast group addresses. A set of multicast addresses may be iteratively created and modified on a per-stream basis using these primitives. These primitives are accepted by the driver in any state following DL_ATTACHED.

The DL_PROMISCON_REQ and DL_PROMISCOFF_REQ primitives with the DL_PROMISC_PHYS flag set in the dl_level field enables/disables reception of all (“promiscuous mode”) frames on the media including frames generated by the local host. When used with the DL_PROMISC_SAP flag set this enables/disables reception of all sap (Ethernet type) values. When used with the DL_PROMISC_MULTI flag set this enables/disables reception of all multicast group addresses. The effect of each is

modified 14 January 1997  Solaris 8  7-87
always on a per-stream basis and independent of the other sap and physical level configurations on this stream or other streams.

The DL_PHYS_ADDR_REQ primitive return the 6 octet MAC address currently associated (attached) to the stream in the DL_PHYS_ADDR_ACK primitive. This primitive is valid only in states following a successful DL_ATTACH_REQ.

The DL_SET_PHYS_ADDR_REQ primitive changes the 6 octet MAC address currently associated (attached) to this stream. The credentials of the process which originally opened this stream must be superuser or EPERM is returned in the DL_ERROR_ACK. This primitive is destructive in that it affects all other current and future streams attached to this device. An M_ERROR is sent up all other streams attached to this device when this primitive on this stream is successful. Once changed, all streams subsequently opened and attached to this device will obtain this new physical address.

Once changed, the physical address will remain so until this primitive is used to change the physical address again or the system is rebooted, whichever comes first.

By default the first interface will use the systems MAC address but subsequent interfaces will use the FDDI local address.

pf and SMT

The driver provides information on its PHYs and some FORMAC error counters.

The user has to include these two lines in the program before the line '#include <pfsmt.h>'

#define SMT7_2 0
#define CFG_YES 1

The cloning character special device /dev/pf is used to access the driver. An explicit DL_ATTACH_REQ message by the user is required to associate the opened stream with a particular device(ppa) where ppa corresponds to the interface instance number.

Once in the DL_ATTACHED state, the user need not send a DL_BIND_REQ. The user can interact with the driver with ioctl(2) calls. The arguments for the ioctl are

ioctl (int fd, int request, SMTCB *smtp)

The request is smt driver specific and can be SMT_GET or SMT_ACT. SMTCB is defined as follows in the header file pfsmt.h

typedef struct {
    int command;
    int sub_command;
    int param1;
    int param2;
    int param3;
    char *where;
    int length;
} SMTCB;

SMT_GET:
SMT_GET provides a variety of functions such as to read the HPC registers and to get the smt status. The command field of smtp should be initialized to one of the following values:

- **HPC_BMAC1_REGS**: To read the BMAC registers
- **HPC_READ**: To read the HPC registers
- **HPC_PORT1_REGS**: To read RMT port1
- **HPC_PORT2_REGS**: To read RMT port2 registers

Some of the commands provide sub commands. The field sub_command should be initialized to these sub commands.

1. **HPC_BMAC1_REGS**
   
   HPC_BMAC1_REGS enables the user to read the BMAC registers. HPC_BMAC1_REGS provides two sub commands GET_COUNTER_GROUP and GET_NEIGHBOR_ADDR. GET_COUNTER_GROUP is used to get various SMT counter values.

   ```
   GET_COUNTER_GROUP needs the SMTCB *smtp to be initialized as follows:
   
   COUNTER_GROUP ct;
   smtp->command = HPC_BMAC1_REGS;
   smtp->sub_command = GET_COUNTER_GROUP;
   smtp->where = (char *) &ct;
   smtp->length = sizeof (ct);
   ```

   GET_NEIGHBOR_ADDR enables the user to get the MAC address of the Neighbour station. GET_NEIGHBOR_ADDR needs the SMTCB *smtp to be initialized as follows:

   ```
   char addr_buf[12];
   smtp->command = HPC_BMAC1_REGS;
   smtp->sub_command = GET_NEIGHBOR_ADDR;
   smtp->where = addr_buf;
   smtp->length = 12;
   ```

2. **HPC_READ**
   
   HPC_READ enables the user to read the HPC registers. HPC_READ does not provide any sub commands. HPC_READ needs the SMTCB *smtp to be initialized as follows:

   ```
   smtp->command = HPC_READ;
   smtp->param1 = HPC_READ | HPC_SIZE_BYTE
                 | <HPC_reg_offset>;
   smtp->where = (char *) smtp;
   ```

   where HPC_reg_offset is set of register space provided by the HPC. For the set of register offsets refer to the file pfsmth.h

3. **HPC_PORT1_REGS and HPC_PORT2_REGS**
   
   HPC_PORT1_REGS enables the user to get the status of the Connection Management. HPC_PORT2_REGS is for the second port if the interface is a DAS. The sub command for HPC_PORT1_REGS is GET_PORT_GROUP. HPC_PORT1_REGS needs the SMTCB *smtp to be initialized as follows:

   ```
   mkdir 14 January 1997 Solaris 8 7-89
The two important status returned in the structure port are port.ecm_state and port.pcm_state. port.ecm_state corresponds to the current state of the ECM state machine. The valid values are OUT, IN, TRACE, PATHTEST, INSERT, CHECK and DEINSERT. The value returned in port.ecm_state is the index into the list of the ECM States. port.pcm_state corresponds to the current state of the PCM state machine. The valid values are OFF, BREAK, TRACE, CONNECT, NEXT, SIGNAL, JOIN, VERIFY, ACTIVE, MAINT. The value returned in port.pcm_state is an index into the list of PCM States.

SMT_ACT:

SMT_ACT is supported to set the state of the smt driver. The command field should always be set to SMT_CTL. SMT_ACT provides two sub commands SMT_ACCEPT_FRAME and SMT_CLOSE. SMT_ACCEPT_FRAME needs to be used when any SMT API client is active.

smtp->command = SMT_CTL;
smtp->sub_command = SMT_ACCEPT_FRAME;

SMT_CLOSE needs to be used when the API client exits.

smtp->command = SMT_CTL;
smtp->sub_command = SMT_CLOSE;

To transmit SMT NSA frames the user should bind to FDDI_NSA sap. To transmit other SMT frames the user may bind to FDDI_SMTINFO sap.

NAME  
smt – FDDI SMT Apps Interface device driver

SYNOPSIS  
#include <sys/nfsmt.h>

DESCRIPTION  
smt is a multi-threaded, loadable, clonable, STREAMS device driver supporting Data Link Provider Interface, dlpi(7), for Application programs to get the statistics and status of the Station Management. smt driver provides packet throughput statistics, reconfiguration events and interface exceptions. It also provides the information on its PHYs and some FORMAC error counters.

The user has to include these two lines in the program before the line ‘#include <nfsmt.h>’

#define SMT7 2 0
#define CFG_YES 1

The cloning character special device /dev/smt is used to access the driver. An explicit DL_ATTACH_REQ message by the user is required to associate the opened stream with a particular device(ppa) where ppa corresponds to the interface instance number.

Once in the DL_ATTACHED state, the user need not send a DL_BIND_REQ. The user can interact with the driver with ioctl(2) calls. The arguments for the ioctl are

ioctl (int fd, int request, SMTCB *smtp)

The request is smt driver specific and can be SMT_GET or SMT_ACT. SMTCB is defined as follows in the header file nfsmt.h

typedef struct {
  int command;
  int sub_command;
  int param1;
  int param2;
  int param3;
  char *where;
  int length;
} SMTCB;

SMT_GET:

SMT_GET provides a variety of functions such as to read the HPC registers and to get the smt status. command field of smtp should be initialized to one of the following values

  HPC_BMAC1_REGS : To read the BMAC registers
  HPC_READ : To read the HPC registers
  HPC_PORT1_REGS : To read RMT port1
  HPC_PORT2_REGS and port2 registers

Some of the commands provide sub commands. The field sub_command should be initialized to these sub commands.
1. HPC_BMAC1_REGS

HPC_BMAC1_REGS enables the user to read the BMAC registers. HPC_BMAC1_REGS provides two sub commands GET_COUNTER_GROUP and GET_NEIGHBOR_ADDR. GET_COUNTER_GROUP is used to get various SMT counter values.

GET_COUNTER_GROUP needs the SMTCB *smtp to be initialized as follows

```c
COUNTER_GROUP ct;
smtp->command = HPC_BMAC1_REGS;
smtp->sub_command = GET_COUNTER_GROUP;
smtp->where = (char *) &ct;
smtp->length = sizeof (ct);
```

GET_NEIGHBOR_ADDR enables the user to get the MAC address of the Neighbour station. GET_NEIGHBOR_ADDR needs the SMTCB *smtp to be initialized as follows

```c
char addr_buf[12];
smtp->command = HPC_BMAC1_REGS;
smtp->sub_command = GET_NEIGHBOR_ADDR;
smtp->where = addr_buf;
smtp->length = 12;
```

2. HPC_READ

HPC_READ enables the user to read the HPC registers. HPC_READ does not provide any sub commands. HPC_READ needs the SMTCB *smtp to be initialized as follows

```c
smtp->command = HPC_READ;
smtp->param1 = HPC_READ | HPC_SIZE_BYTE
| <HPC_reg_offset>;
smtp->where = (char *) smtp;
```

where HPC_register_offset is set of register space provided by the HPC. For the set of register offsets refer to the file nfsmt.h

3. HPC_PORT1_REGS and HPC_PORT2_REGS

HPC_PORT1_REGS enables the user to get the status of the Connection Management. HPC_PORT2_REGS is for the second port if the interface is a DAS. The sub command for HPC_PORT1_REGS is GET_PORT_GROUP. HPC_PORT1_REGS needs the SMTCB *smtp to be initialized as follows

```c
FDDI_PORT_GROUP port;
smtp->command = HPC_PORT1_REGS;
smtp->sub_command = GET_PORT_GROUP;
smtp->where = (char *) &port;
smtp->length = sizeof (port);
```

The two important status returned in the structure port are port.ecm_state and port.pcm_state. port.ecm_state corresponds to the current state of the ECM state machine. The valid values are OUT, IN, TRACE, PATHTEST, INSERT, CHECK and DEINSERT. The value returned in port.ecm_state is the index into the list of the ECM
States. port.pcm_state corresponds to the current state of the PCM state machine. The Valid values are OFF, BREAK, TRACE, CONNECT, NEXT, SIGNAL, JOIN, VERIFY, ACTIVE, MAINT. The value returned in port.pcm_state in an index into the list of PCM States.

SMT_ACT:
SMT_ACT is supported to set the state of the smt driver. The command field should always be set to SMT_CTL. SMT_ACT provides two sub commands SMT_ACCEPT_FRAME and SMT_CLOSE. SMT_ACCEPT_FRAME needs to be used when any SMT API client is active.

```c
smtp->command = SMT_CTL;
smtp->sub_command = SMT_ACCEPT_FRAME;
```

SMT_CLOSE needs to be used when the API client exits.

```c
smtp->command = SMT_CTL;
smtp->sub_command = SMT_CLOSE;
```
