

man pages section 1: User Commands

Sun Microsystems, Inc.
4150 Network Circle
Santa Clara, CA 95054
U.S.A.

Part No: 817-5441-10
February 2004

Copyright 2004 Sun Microsystems, Inc. 4150 Network Circle, Santa Clara, CA 95054 U.S.A. All rights reserved.

This product or document is protected by copyright and distributed under licenses restricting its use, copying, distribution, and decompilation. No part of this product or document may be reproduced in any form by any means without prior written authorization of Sun and its licensors, if any. Third-party software, including font technology, is copyrighted and licensed from Sun suppliers.

Parts of the product may be derived from Berkeley BSD systems, licensed from the University of California. UNIX is a registered trademark in the U.S. and other countries, exclusively licensed through X/Open Company, Ltd.

Sun, Sun Microsystems, the Sun logo, docs.sun.com, AnswerBook, AnswerBook2, and Solaris are trademarks, registered trademarks, or service marks of Sun Microsystems, Inc. in the U.S. and other countries. All SPARC trademarks are used under license and are trademarks or registered trademarks of SPARC International, Inc. in the U.S. and other countries. Products bearing SPARC trademarks are based upon an architecture developed by Sun Microsystems, Inc.

The OPEN LOOK and Sun™ Graphical User Interface was developed by Sun Microsystems, Inc. for its users and licensees. Sun acknowledges the pioneering efforts of Xerox in researching and developing the concept of visual or graphical user interfaces for the computer industry. Sun holds a non-exclusive license from Xerox to the Xerox Graphical User Interface, which license also covers Sun's licensees who implement OPEN LOOK GUIs and otherwise comply with Sun's written license agreements.

Federal Acquisitions: Commercial Software—Government Users Subject to Standard License Terms and Conditions.

DOCUMENTATION IS PROVIDED "AS IS" AND ALL EXPRESS OR IMPLIED CONDITIONS, REPRESENTATIONS AND WARRANTIES, INCLUDING ANY IMPLIED WARRANTY OF MERCHANTABILITY, FITNESS FOR A PARTICULAR PURPOSE OR NON-INFRINGEMENT, ARE DISCLAIMED, EXCEPT TO THE EXTENT THAT SUCH DISCLAIMERS ARE HELD TO BE LEGALLY INVALID.

Copyright 2004 Sun Microsystems, Inc. 4150 Network Circle, Santa Clara, CA 95054 U.S.A. Tous droits réservés.

Ce produit ou document est protégé par un copyright et distribué avec des licences qui en restreignent l'utilisation, la copie, la distribution, et la décompilation. Aucune partie de ce produit ou document ne peut être reproduite sous aucune forme, par quelque moyen que ce soit, sans l'autorisation préalable et écrite de Sun et de ses bailleurs de licence, s'il y en a. Le logiciel détenu par des tiers, et qui comprend la technologie relative aux polices de caractères, est protégé par un copyright et licencié par des fournisseurs de Sun.

Des parties de ce produit pourront être dérivées du système Berkeley BSD licenciés par l'Université de Californie. UNIX est une marque déposée aux Etats-Unis et dans d'autres pays et licenciée exclusivement par X/Open Company, Ltd.

Sun, Sun Microsystems, le logo Sun, docs.sun.com, AnswerBook, AnswerBook2, et Solaris sont des marques de fabrique ou des marques déposées, ou marques de service, de Sun Microsystems, Inc. aux Etats-Unis et dans d'autres pays. Toutes les marques SPARC sont utilisées sous licence et sont des marques de fabrique ou des marques déposées de SPARC International, Inc. aux Etats-Unis et dans d'autres pays. Les produits portant les marques SPARC sont basés sur une architecture développée par Sun Microsystems, Inc.

L'interface d'utilisation graphique OPEN LOOK et Sun™ a été développée par Sun Microsystems, Inc. pour ses utilisateurs et licenciés. Sun reconnaît les efforts de pionniers de Xerox pour la recherche et le développement du concept des interfaces d'utilisation visuelle ou graphique pour l'industrie de l'informatique. Sun détient une licence non exclusive de Xerox sur l'interface d'utilisation graphique Xerox, cette licence couvrant également les licenciés de Sun qui mettent en place l'interface d'utilisation graphique OPEN LOOK et qui en outre se conforment aux licences écrites de Sun.

CETTE PUBLICATION EST FOURNIE "EN L'ETAT" ET AUCUNE GARANTIE, EXPRESSE OU IMPLICITE, N'EST ACCORDEE, Y COMPRIS DES GARANTIES CONCERNANT LA VALEUR MARCHANDE, L'APTITUDE DE LA PUBLICATION A REpondre A UNE UTILISATION PARTICULIERE, OU LE FAIT QU'ELLE NE SOIT PAS CONTREFAISANTE DE PRODUIT DE TIERS. CE DENI DE GARANTIE NE S'APPLIQUERAIT PAS, DANS LA MESURE OU IL SERAIT TENU JURIDIQUEMENT NUL ET NON AVENU.

Index 1613

Preface

Both novice users and those familiar with the SunOS operating system can use online man pages to obtain information about the system and its features. A man page is intended to answer concisely the question “What does it do?” The man pages in general comprise a reference manual. They are not intended to be a tutorial.

Overview

The following contains a brief description of each man page section and the information it references:

- Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2.
- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character-set tables.
- Section 6 contains available games and demos.
- Section 7 describes various special files that refer to specific hardware peripherals and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.

- Section 9 provides reference information needed to write device drivers in the kernel environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver/Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer can include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the `intro` pages for more information and detail about each section, and `man(1)` for more information about man pages in general.

NAME	This section gives the names of the commands or functions documented, followed by a brief description of what they do.								
SYNOPSIS	<p>This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full path name is shown. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.</p> <p>The following special characters are used in this section:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 10px;">[]</td> <td>Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.</td> </tr> <tr> <td style="padding-right: 10px;">. . .</td> <td>Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".</td> </tr> <tr> <td style="padding-right: 10px;"> </td> <td>Separator. Only one of the arguments separated by this character can be specified at a time.</td> </tr> <tr> <td style="padding-right: 10px;">{ }</td> <td>Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.</td> </tr> </table>	[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.	. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".		Separator. Only one of the arguments separated by this character can be specified at a time.	{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.
[]	Brackets. The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument must be specified.								
. . .	Ellipses. Several values can be provided for the previous argument, or the previous argument can be specified multiple times, for example, "filename . . .".								
	Separator. Only one of the arguments separated by this character can be specified at a time.								
{ }	Braces. The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.								

PROTOCOL	This section occurs only in subsection 3R to indicate the protocol description file.
DESCRIPTION	This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, and functions are described under USAGE.
IOCTL	This section appears on pages in Section 7 only. Only the device class that supplies appropriate parameters to the <code>ioctl(2)</code> system call is called <code>ioctl</code> and generates its own heading. <code>ioctl</code> calls for a specific device are listed alphabetically (on the man page for that specific device). <code>ioctl</code> calls are used for a particular class of devices all of which have an <code>io</code> ending, such as <code>mtio(7I)</code> .
OPTIONS	This section lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.
OPERANDS	This section lists the command operands and describes how they affect the actions of the command.
OUTPUT	This section describes the output – standard output, standard error, or output files – generated by the command.
RETURN VALUES	If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared void do not return values, so they are not discussed in RETURN VALUES.
ERRORS	On failure, most functions place an error code in the global variable <code>errno</code> indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than

	one condition can cause the same error, each condition is described in a separate paragraph under the error code.
USAGE	This section lists special rules, features, and commands that require in-depth explanations. The subsections listed here are used to explain built-in functionality: Commands Modifiers Variables Expressions Input Grammar
EXAMPLES	This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command-line entry and machine response is shown. Whenever an example is given, the prompt is shown as <code>example%</code> , or if the user must be superuser, <code>example#</code> . Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS, and USAGE sections.
ENVIRONMENT VARIABLES	This section lists any environment variables that the command or function affects, followed by a brief description of the effect.
EXIT STATUS	This section lists the values the command returns to the calling program or shell and the conditions that cause these values to be returned. Usually, zero is returned for successful completion, and values other than zero for various error conditions.
FILES	This section lists all file names referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.
ATTRIBUTES	This section lists characteristics of commands, utilities, and device drivers by defining the attribute type and its corresponding value. See <code>attributes(5)</code> for more information.
SEE ALSO	This section lists references to other man pages, in-house documentation, and outside publications.

DIAGNOSTICS	This section lists diagnostic messages with a brief explanation of the condition causing the error.
WARNINGS	This section lists warnings about special conditions which could seriously affect your working conditions. This is not a list of diagnostics.
NOTES	This section lists additional information that does not belong anywhere else on the page. It takes the form of an aside to the user, covering points of special interest. Critical information is never covered here.
BUGS	This section describes known bugs and, wherever possible, suggests workarounds.

Introduction

Intro(1)

NAME	Intro – introduction to commands and application programs												
DESCRIPTION	<p>This section describes, in alphabetical order, commands available with this operating system.</p> <p>Pages of special interest are categorized as follows:</p> <table><tr><td>1B</td><td>Commands found only in the <i>SunOS/BSD Compatibility Package</i>. Refer to the <i>Source Compatibility Guide</i> for more information.</td></tr><tr><td>1C</td><td>Commands for communicating with other systems.</td></tr><tr><td>1F</td><td>Commands associated with <i>Form and Menu Language Interpreter</i> (FMLI).</td></tr><tr><td>1S</td><td>Commands specific to the SunOS system.</td></tr></table>	1B	Commands found only in the <i>SunOS/BSD Compatibility Package</i> . Refer to the <i>Source Compatibility Guide</i> for more information.	1C	Commands for communicating with other systems.	1F	Commands associated with <i>Form and Menu Language Interpreter</i> (FMLI).	1S	Commands specific to the SunOS system.				
1B	Commands found only in the <i>SunOS/BSD Compatibility Package</i> . Refer to the <i>Source Compatibility Guide</i> for more information.												
1C	Commands for communicating with other systems.												
1F	Commands associated with <i>Form and Menu Language Interpreter</i> (FMLI).												
1S	Commands specific to the SunOS system.												
OTHER SECTIONS	<p>See these sections of the <i>man pages section 1M: System Administration Commands</i> for more information.</p> <ul style="list-style-type: none">■ Section 1M in this manual for system maintenance commands.■ Section 4 of this manual for information on file formats.■ Section 5 of this manual for descriptions of publicly available files and miscellaneous information pages.■ Section 6 in this manual for computer demonstrations. <p>For tutorial information about these commands and procedures, see:</p> <ul style="list-style-type: none">■ <i>OpenWindows Advanced User's Guide</i>												
Manual Page Command Syntax	<p>Unless otherwise noted, commands described in the SYNOPSIS section of a manual page accept options and other arguments according to the following syntax and should be interpreted as explained below.</p> <p><i>name</i> [-option...] [<i>cmdarg</i>...] where:</p> <table><tr><td>[]</td><td>Surround an <i>option</i> or <i>cmdarg</i> that is not required.</td></tr><tr><td>...</td><td>Indicates multiple occurrences of the <i>option</i> or <i>cmdarg</i>.</td></tr><tr><td><i>name</i></td><td>The name of an executable file.</td></tr><tr><td>{ }</td><td>The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.</td></tr><tr><td><i>option</i></td><td>(Always preceded by a “-”.) <i>noargletter</i>... or, <i>argletter optarg</i>[, ...]</td></tr><tr><td><i>noargletter</i></td><td>A single letter representing an option without an option-argument. Note that more than one <i>noargletter</i> option can be grouped after one “-” (Rule 5, below).</td></tr></table>	[]	Surround an <i>option</i> or <i>cmdarg</i> that is not required.	...	Indicates multiple occurrences of the <i>option</i> or <i>cmdarg</i> .	<i>name</i>	The name of an executable file.	{ }	The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.	<i>option</i>	(Always preceded by a “-”.) <i>noargletter</i> ... or, <i>argletter optarg</i> [, ...]	<i>noargletter</i>	A single letter representing an option without an option-argument. Note that more than one <i>noargletter</i> option can be grouped after one “-” (Rule 5, below).
[]	Surround an <i>option</i> or <i>cmdarg</i> that is not required.												
...	Indicates multiple occurrences of the <i>option</i> or <i>cmdarg</i> .												
<i>name</i>	The name of an executable file.												
{ }	The options and/or arguments enclosed within braces are interdependent, such that everything enclosed must be treated as a unit.												
<i>option</i>	(Always preceded by a “-”.) <i>noargletter</i> ... or, <i>argletter optarg</i> [, ...]												
<i>noargletter</i>	A single letter representing an option without an option-argument. Note that more than one <i>noargletter</i> option can be grouped after one “-” (Rule 5, below).												

<i>argletter</i>	A single letter representing an option requiring an option-argument.
<i>optarg</i>	An option-argument (character string) satisfying a preceding <i>argletter</i> . Note that groups of <i>optargs</i> following an <i>argletter</i> must be separated by commas, or separated by a tab or space character and quoted (Rule 8, below).
<i>cmdarg</i>	Path name (or other command argument) <i>not</i> beginning with “-”, or “-” by itself indicating the standard input.

**Command Syntax
Standard: Rules**

These command syntax rules are not followed by all current commands, but all new commands will obey them. `getopts(1)` should be used by all shell procedures to parse positional parameters and to check for legal options. It supports Rules 3-10 below. The enforcement of the other rules must be done by the command itself.

1. Command names (*name* above) must be between two and nine characters long.
2. Command names must include only lower-case letters and digits.
3. Option names (*option* above) must be one character long.
4. All options must be preceded by “-”.
5. Options with no arguments may be grouped after a single “-”.
6. The first option-argument (*optarg* above) following an option must be preceded by a tab or space character.
7. Option-arguments cannot be optional.
8. Groups of option-arguments following an option must either be separated by commas or separated by tab or space character and quoted (`-o xxx, z, yy` or `-o "xxx z yy"`).
9. All options must precede operands (*cmdarg* above) on the command line.
10. “- -” may be used to indicate the end of the options.
11. The order of the options relative to one another should not matter.
12. The relative order of the operands (*cmdarg* above) may affect their significance in ways determined by the command with which they appear.
13. “-” preceded and followed by a space character should only be used to mean standard input.

ATTRIBUTES See `attributes(5)` for a discussion of the attributes listed in this section.

SEE ALSO `getopts(1)`, `wait(1)`, `exit(2)`, `getopt(3C)`, `wait(3UCB)`, `attributes(5)`

DIAGNOSTICS Upon termination, each command returns two bytes of status, one supplied by the system and giving the cause for termination, and (in the case of “normal” termination) one supplied by the program [see `wait(3UCB)` and `exit(2)`]. The former byte is 0 for

Intro(1)

normal termination; the latter is customarily 0 for successful execution and non-zero to indicate troubles such as erroneous parameters, or bad or inaccessible data. It is called variously "exit code", "exit status", or "return code", and is described only where special conventions are involved.

WARNINGS

Some commands produce unexpected results when processing files containing null characters. These commands often treat text input lines as strings and therefore become confused upon encountering a null character (the string terminator) within a line.

User Commands

acctcom(1)

NAME	acctcom – search and print process accounting files
SYNOPSIS	acctcom [-abfhikmqrtv] [-C <i>sec</i>] [-e <i>time</i>] [-E <i>time</i>] [-g <i>group</i>] [-H <i>factor</i>] [-I <i>chars</i>] [-l <i>line</i>] [-n <i>pattern</i>] [-o <i>output-file</i>] [-O <i>sec</i>], [-s <i>time</i>] [-S <i>time</i>] [-u <i>user</i>] [<i>filename...</i>]
DESCRIPTION	<p>The acctcom utility reads <i>filenames</i>, the standard input, or <code>/var/adm/pacct</code>, in the form described by <code>acct(3HEAD)</code> and writes selected records to standard output. Each record represents the execution of one process. The output shows the <code>COMMAND NAME</code>, <code>USER</code>, <code>TTYNAME</code>, <code>START TIME</code>, <code>END TIME</code>, <code>REAL (SEC)</code>, <code>CPU (SEC)</code>, <code>MEAN SIZE (K)</code>, and optionally, <code>F (the fork() /exec() flag: 1 for fork() without exec())</code>, <code>STAT (the system exit status)</code>, <code>HOG FACTOR</code>, <code>KCORE MIN</code>, <code>CPU FACTOR</code>, <code>CHARS TRNSFD</code>, and <code>BLOCKS READ (total blocks read and written)</code>.</p> <p>A '#' is prepended to the command name if the command was executed with super-user privileges. If a process is not associated with a known terminal, a '?' is printed in the <code>TTYNAME</code> field.</p> <p>If no <i>filename</i> is specified, and if the standard input is associated with a terminal or <code>/dev/null</code> (as is the case when using '&' in the shell), <code>/var/adm/pacct</code> is read; otherwise, the standard input is read.</p> <p>If any <i>filename</i> arguments are given, they are read in their respective order. Each file is normally read forward, that is, in chronological order by process completion time. The file <code>/var/adm/pacct</code> is usually the current file to be examined; a busy system may need several such files of which all but the current file are found in <code>/var/adm/pacctincr</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Show some average statistics about the processes selected. The statistics will be printed after the output records.-b Read backwards, showing latest commands first. This option has no effect when standard input is read.-f Print the <code>fork() /exec()</code> flag and system exit status columns in the output. The numeric output for this option will be in octal.-h Instead of mean memory size, show the fraction of total available CPU time consumed by the process during its execution. This "hog factor" is computed as (total CPU time)/(elapsed time).-i Print columns containing the I/O counts in the output.-k Instead of memory size, show total kcore-minutes.-m Show mean core size (the default).-q Do not print any output records, just print the average statistics as with the -a option.-r Show CPU factor (user-time/(system-time + user-time)).

- t Show separate system and user CPU times.
- v Exclude column headings from the output.
- C *sec* Show only processes with total CPU time (system-time + user-time) exceeding *sec* seconds.
- e *time* Select processes existing at or before *time*.
- E *time* Select processes ending at or before *time*. Using the same *time* for both -S and -E shows the processes that existed at *time*.
- g *group* Show only processes belonging to *group*. The *group* may be designated by either the group ID or group name.
- H *factor* Show only processes that exceed *factor*, where *factor* is the “hog factor” as explained in option -h above.
- I *chars* Show only processes transferring more characters than the cutoff number given by *chars*.
- l *line* Show only processes belonging to terminal */dev/term/line*.
- n *pattern* Show only commands matching *pattern* that may be a regular expression as in `regcmp(3C)`, except + means one or more occurrences.
- o *output-file* Copy selected process records in the input data format to *output-file*; suppress printing to standard output.
- O *sec* Show only processes with CPU system time exceeding *sec* seconds.
- s *time* Select processes existing at or after *time*, given in the format *hr* [*:min* [*:sec*]].
- S *time* Select processes starting at or after *time*.
- u *user* Show only processes belonging to *user*. The user may be specified by a user ID, a login name that is then converted to a user ID, '#' (which designates only those processes executed with superuser privileges), or '?' (which designates only those processes associated with unknown user IDs).

FILES

/etc/group	system group file
/etc/passwd	system password file
/var/adm/pacctincr	active processes accounting file

NOTES acctcom reports only on processes that have terminated; use ps(1) for active processes.

NAME	adb – general-purpose debugger
SYNOPSIS	adb [-k] [-w] [-I <i>dir</i>] [-P <i>prompt</i>] [-V <i>mode</i>] [<i>objectfile</i> [<i>corefile</i> [<i>swapfile</i>]]]
DESCRIPTION	The adb utility is an interactive, general-purpose debugger. It can be used to examine files and provides a controlled environment for the execution of programs.
OPTIONS	The following options are supported: <ul style="list-style-type: none"> -k Performs kernel memory mapping. Use when <i>corefile</i> is a system crash dump or <i>/dev/mem</i>, or when using a <i>swapfile</i>. -w Creates both <i>objectfile</i> and <i>corefile</i>, if necessary, and opens them for reading and writing so that they can be modified using adb. -I <i>dir</i> Specifies a colon-separated list of directories where files to be read with \$< or \$<< (see below) will be sought; the default is <i>/usr/platform/plat-name/lib/adb:/usr/lib/adb</i>, where <i>plat-name</i> is the name of the platform implementation. <i>plat-name</i> can be found using the -i option of <i>uname(1)</i>. -P <i>prompt</i> Specifies the adb prompt string.
SPARC Only	-V <i>mode</i> Specifies the disassembly and register display mode. Options are: 1 (v8), 2 (generic V9), and 4 (v9 plus Sun Ultra-SPARC specific instructions). The default mode is determined by the type of <i>corefile</i> being examined.
OPERANDS	The following operands are supported: <ul style="list-style-type: none"> <i>objectfile</i> Normally an executable program file, preferably containing a symbol table. If the file does not contain a symbol table, it can still be examined, but the symbolic features of adb cannot be used. The default for <i>objectfile</i> is <i>a.out</i>. <i>corefile</i> Assumed to be a core image file produced after executing <i>objectfile</i>. The default for <i>corefile</i> is <i>core</i>. <i>swapfile</i> The image of the swap device used. It is valid only when used with the -k option.
USAGE	The adb utility reads commands from the standard input and displays responses on the standard output. It does not supply a prompt by default. It ignores the QUIT signal. INTERRUPT invokes the next adb command. adb generally recognizes command input of the form: <pre>[<i>address</i>] [, <i>count</i>] [<i>command</i>] [;]</pre> <p><i>address</i> and <i>count</i> (if supplied) are expressions that result, respectively, in a new current location and a repetition count. <i>command</i> is composed of a verb followed by a modifier or list of modifiers.</p>

adb(1)

	The symbol <code>'.'</code> represents the current location; it is initially 0. The default <i>count</i> is 1.
Expressions	
<code>.</code>	The value of <i>dot</i> .
<code>+</code>	The value of <i>dot</i> incremented by the current increment.
<code>^</code>	The value of <i>dot</i> decremented by the current increment.
<code>&</code>	The last <i>address</i> typed. (In older versions of adb, <code>'"</code> was used.)
<i>integer</i>	A number. The prefixes <code>0o</code> and <code>0O</code> indicate octal; <code>0t</code> and <code>0T</code> , decimal; <code>0x</code> and <code>0X</code> , hexadecimal (the default).
<i>int.frac</i>	A floating-point number.
<code>'cccc'</code>	ASCII value of up to 4 characters.
<code><name</code>	The value of <i>name</i> , which is either a variable name or a register name.
<i>symbol</i>	A symbol in the symbol table.
<code>(exp)</code>	The value of <i>exp</i> .
Unary Operators	
<code>*exp</code>	The contents of location <i>exp</i> in <i>corefile</i> .
<code>%exp</code>	The contents of location <i>exp</i> in <i>objectfile</i> (In older versions of adb, <code>'@'</code> was used).
<code>-exp</code>	Integer negation.
<code>~exp</code>	Bitwise complement.
<code>#exp</code>	Logical negation.
Binary Operators	Binary operators are left associative and have lower precedence than unary operators.
<code>+</code>	Integer addition.
<code>-</code>	Integer subtraction.
<code>*</code>	Integer multiplication.
<code>%</code>	Integer division.
<code>&</code>	Bitwise conjunction ("AND").
<code> </code>	Bitwise disjunction ("OR").
<code>#</code>	<i>lhs</i> rounded up to the next multiple of <i>rhs</i> .
Variables	Named variables are set initially by adb but are not used subsequently.
<code>0</code>	The last value printed.
<code>1</code>	The last offset part of an instruction source.
<code>2</code>	The previous value of variable 1.
<code>9</code>	The count on the last <code>\$<</code> or <code>\$<<</code> command.

On entry the following are set from the system header in the *corefile* or *objectfile* as appropriate.

b	The base address of the data segment.
d	The data segment size.
e	The entry point.
m	The 'magic' number
t	The text segment size.

Commands Commands to `adb` consist of a *verb* followed by a *modifier* or list of modifiers.

<i>Verbs</i>	?	Print locations starting at <i>address</i> in <i>objectfile</i> .
	/	Print locations starting at <i>address</i> in <i>corefile</i> .
	=	Print the value of <i>address</i> itself.
	:	Manage a subprocess.
	>	Assign a value to a variable or register.
	>/ <i>modifier</i> /	Take the quantity specified by <i>modifier</i> from the address of the value and assign it to a variable or register. <i>modifier</i> can be one of the following:
	c	unsigned char quantity
	s	unsigned short quantity
	i	unsigned int quantity
	l	unsigned long quantity
	RETURN	Repeat the previous command with a <i>count</i> of 1. Increment '.'.
	!	Shell escape.

?, /, and = Modifiers

The following format modifiers apply to the commands `?`, `/`, and `=`. To specify a format, follow the command with an optional repeat count, and the desired format letter or letters. The braces (`{ }`) indicate that only one of the included commands must be specified.

```
{ ? / = } [ [ r ] f . . . ]
```

where *r* is a decimal repeat count, and *f* is one of the format letters listed below:

o	('.' increment: 2) Print 2 bytes in octal.
O	(4) Print 4 bytes in octal.
q	(2) Print in signed octal.
Q	(4) Print long signed octal.

adb(1)

g	(8) Display 8 bytes in signed octal.
G	(8) Display 8 bytes in unsigned octal.
d	(2) Print in decimal.
D	(4) Print long decimal.
e	(8) Display 8 bytes in signed decimal.
E	(8) Display 8 bytes in unsigned decimal.
x	(2) Print 2 bytes in hexadecimal.
X	(4) Print 4 bytes in hexadecimal.
J	(8) Display 8 bytes in hexadecimal.
K	(<i>n</i>) Print pointer or long in hexadecimal (displays 4 bytes for 32-bit programs and 8 bytes for 64-bit programs).
u	(2) Print as an unsigned decimal number.
U	(4) Print long unsigned decimal.
f	(4) Print a single-precision floating-point number.
F	(8) Print a double-precision floating-point number.
b	(1) Print the addressed byte in octal.
c	(1) Print the addressed character.
C	(1) Print the addressed character using ^ escape convention.
s	(<i>n</i>) Print the addressed string.
S	(<i>n</i>) Print a string using the ^ escape convention.
Y	(8) Print 8 bytes in date format.
Y	(4) Print 4 bytes in date format.
i	(4) Print as machine instructions. (SPARC)
i	(variable) Print as machine instructions. (IA)
a	(0) Print the value of ' .' in symbolic form.
p	(<i>n</i>) Print the addressed value in symbolic form.
t	(0) Tab to the next appropriate TAB stop.
r	(0) Print a SPACE.
n	(0) Print a NEWLINE.
"..."	(0) Print the enclosed string.
^	(0) Decrement ' .'.

	+	(0) Increment '.'
	-	(0) Decrement '.' by 1.
? and / Modifiers	l <i>value mask</i>	Apply <i>mask</i> and compare for <i>value</i> ; move '.' to matching location.
	L <i>value mask</i>	Apply <i>mask</i> and compare for 4-byte <i>value</i> ; move '.' to matching location.
	M <i>value mask</i>	Apply <i>mask</i> and compare for 8-byte <i>value</i> ; move '.' to matching location.
	w <i>value</i>	Write the 2-byte <i>value</i> to address.
	W <i>value</i>	Write the 4-byte <i>value</i> to address.
	Z <i>value</i>	Write the 8-byte <i>value</i> to address.
	m <i>b1 e1 f1[?]</i>	Map new values for <i>b1</i> , <i>e1</i> , <i>f1</i> . If the ? or / is followed by * then the second segment (<i>b2,e2,f2</i>) of the address mapping is changed.
	v	Like <i>w</i> , but writes only one byte at a time.
: Modifiers		The optional <i>len</i> is specified in decimal; if not specified, it defaults to 1.
	b <i>commands</i>	Set instruction breakpoint; set '.' to <i>address</i> and execute <i>commands</i> when reached.
	len w <i>commands</i>	Set write watchpoint (data breakpoint); set '.' to the affected location and execute <i>commands</i> when any byte in the range [<i>address</i> , <i>address+len</i>) is written.
	len a <i>commands</i>	Set access watchpoint; set '.' to the affected location and execute <i>commands</i> when any byte in the range [<i>address</i> , <i>address+len</i>) is read or written.
	len p <i>commands</i>	Set execution watchpoint; set '.' to the affected location and execute <i>commands</i> when any instruction in the range [<i>address</i> , <i>address+len</i>) is executed.
	r	Run <i>objectfile</i> as a subprocess.
	d	Delete breakpoint at <i>address</i> or watchpoint containing <i>address</i> .
	z	Delete all breakpoints and watchpoints.
	cs	Continue the subprocess with signal <i>s</i> .
	ss	Single-step the subprocess with signal <i>s</i> .
	es	Single-step but do not step into called functions.
	i	Add the signal specified by <i>address</i> to the list of signals passed directly to the subprocess.

adb(1)

	t	Remove the signal specified by <i>address</i> from the list implicitly passed to the subprocess.
	k	Terminate (kill) the current subprocess, if any.
	A	Attach adb to an existing process ID. (For example, <code>0t1234:A</code> would attach adb to decimal process number 1234.)
	R	Release the previously attached process.
\$ Modifiers	< <i>filename</i>	Read commands from the file <i>filename</i> .
	<< <i>filename</i>	Similar to <, but can be used in a file of commands without closing the file.
	> <i>filename</i>	Append output to <i>filename</i> , which is created if it does not exist.
	l	Show the current lightweight process (LWP) ID.
	L	Show all the LWP IDs.
	P	Specify the adb prompt string.
	?	Print process ID, the signal which stopped the subprocess, and the registers.
	r	Print the names and contents of the general CPU registers, and the instruction addressed by <i>pc</i> .
	x	Print the names and contents of floating-point registers 0 through 15. (SPARC)
	X	Print the names and contents of floating-point registers 16 through 31. (SPARC)
	x or X	Print the contents of floating point registers. <i>\$x</i> and <i>\$X</i> accept a <i>count</i> which determines the precision in which the floating point registers will be printed; the default is 25. Using <i>\$X</i> will produce more verbose output than using <i>\$x</i> . (IA)
	y	Print the names and contents of floating-point registers 32 through 47. (SPARC)
	Y	Print the names and contents of floating-point registers 48 through 63. (SPARC)
	b	Print all breakpoints and watchpoints and their associated counts, types, lengths, and commands.
	c	C stack backtrace. On SPARC based systems, it is impossible for adb to determine how many parameters were passed to a function. The default that adb chooses in a <i>\$c</i> command is to show the six parameter

	registers. This can be overridden by appending a hexadecimal number to the <code>\$c</code> command, specifying how many parameters to display. For example, the <code>\$cf</code> command will print 15 parameters for each function in the stack trace.
C	Same as <code>\$c</code> , but in addition it displays the frame pointer values.
d	Set the default radix to <i>address</i> and report the new value. Note: <i>address</i> is interpreted in the (old) current radix. Thus <code>'10\$d'</code> never changes the default radix.
e	Print the names and values of external variables.
w	Set the page width for output to <i>address</i> (default 80).
s	Set the limit for symbol matches to <i>address</i> (default 255).
o	All integers input are regarded as octal.
q	Exit from adb.
v	Print all non-zero variables in octal.
m	Print the address map.
f	Print a list of known source filenames.
p	(<i>Kernel debugging</i>) Change the current kernel memory mapping to map the designated user structure to the address given by <i>u</i> ; this is the address of the user's proc structure.
i	Show which signals are passed to the subprocess with the minimum of adb interference.
V	Change the current disassembly and register display mode. Options are: 1 (v8), 2 (generic V9), and 4 (v9 plus Sun Ultra-SPARC specific instructions). Omitting the numeric parameter prints information on the current disassembly mode. (SPARC)
W	Reopen <i>objectfile</i> and <i>corefile</i> for writing, as though the <code>-w</code> command-line argument had been given.

See `largefile(5)` for the description of the behavior of adb when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Starting adb on the running kernel

To start adb on the running kernel, use (as root):

```
example# adb -k /dev/ksyms /dev/mem
```

adb(1)

EXAMPLE 1 Starting adb on the running kernel (Continued)

`/dev/ksyms` is a special driver that provides an image of the kernel's symbol table. This can be used to examine kernel state and debug device drivers. Refer to the Debugging chapter in *Writing Device Drivers* for more information.

EXIT STATUS The following exit values are returned:

0 Successful completion.
non-zero The last command either failed or returned a non-zero status.

FILES

`/usr/lib/adb`
`/usr/platform/platform-name/lib/adb`
Default directories in which files are to be read with `$<` and `$<<`. *platform-name* is the name of the platform implementation and can be found using `uname -i` (see `uname(1)`).

`/usr/lib/adb/sparcv9`
`/usr/platform/platform-name/lib/adb/sparcv9`
Default directories in which files for 64-bit SPARC V9 are to be read with `$<` and `$<<`. *platform-name* is the name of the platform implementation and can be found using `uname -i` (see `uname(1)`).

`a.out`
Default name for *objectfile* operand.

`core`
Default name for *corefile* operand.

`/dev/ksyms`
Special driver to provide an image of the kernel's symbolic table.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu (32-bit) SUNWcsxu (64-bit)

SEE ALSO `mdb(1)`, `uname(1)`, `a.out(4)`, `core(4)`, `proc(4)`, `attributes(5)`, `largefile(5)`, `ksyms(7D)`

Writing Device Drivers

DIAGNOSTICS When there is no current command or format, adb comments about inaccessible files, syntax errors, abnormal termination of commands, and so forth.

NOTES The adb utility may be implemented as a link to the new mdb(1) utility in versions of Solaris after Solaris 8. The adb and mdb utilities are both low-level debuggers that can be used to examine user processes as well as the live operating system or operating system crash dumps. The new mdb utility provides complete backwards compatibility with the existing syntax and features of adb, including support for processing adb macro files. The mdb(1) man page describes more fully the features of the new debugger, including its adb compatibility mode. This mode will be activated by default if the adb link is present and is executed.

The adb utility is platform and release dependent. Kernel core dumps should be examined on the same platform they were created on.

BUGS Since no shell is invoked to interpret the arguments of the :r command, the customary wild-card and variable expansions cannot occur.

Since there is little type-checking on addresses, using a sourcefile address in an inappropriate context may lead to unexpected results.

The `$cparameter-count` command is a work-around.

addbib(1)

NAME	addbib – create or extend a bibliographic database																																
SYNOPSIS	addbib [-a] [-p <i>promptfile</i>] <i>database</i>																																
DESCRIPTION	When <code>addbib</code> starts up, answering <code>y</code> to the initial <code>Instructions?</code> prompt yields directions; typing <code>n</code> or <code>RETURN</code>) skips them. <code>addbib</code> then prompts for various bibliographic fields, reads responses from the terminal, and sends output records to <i>database</i> . A null response (just <code>RETURN</code>) means to leave out that field. A <code>'-</code> (minus sign) means to go back to the previous field. A trailing backslash allows a field to be continued on the next line. The repeating <code>Continue?</code> prompt allows the user either to resume by typing <code>y</code> or <code>RETURN</code>), to quit the current session by typing <code>n</code> or <code>q</code> , or to edit <i>database</i> with any system editor (see <code>vi(1)</code> , <code>ex(1)</code> , <code>ed(1)</code>).																																
OPTIONS	<p><code>-a</code> Suppress prompting for an abstract; asking for an abstract is the default. Abstracts are ended with a <code>CTRL-D</code>.</p> <p><code>-p <i>promptfile</i></code> Use a new prompting skeleton, defined in <i>promptfile</i>. This file should contain prompt strings, a <code>TAB</code>, and the key-letters to be written to the <i>database</i>.</p>																																
USAGE																																	
Bibliography Key Letters	<p>The most common key-letters and their meanings are given below. <code>addbib</code> insulates you from these key-letters, since it gives you prompts in English, but if you edit the bibliography file later on, you will need to know this information.</p> <table><tr><td><code>%A</code></td><td>Author's name</td></tr><tr><td><code>%B</code></td><td>Book containing article referenced</td></tr><tr><td><code>%C</code></td><td>City (place of publication)</td></tr><tr><td><code>%D</code></td><td>Date of publication</td></tr><tr><td><code>%E</code></td><td>Editor of book containing article referenced</td></tr><tr><td><code>%F</code></td><td>Footnote number or label (supplied by <code>refer</code>)</td></tr><tr><td><code>%G</code></td><td>Government order number</td></tr><tr><td><code>%H</code></td><td>Header commentary, printed before reference</td></tr><tr><td><code>%I</code></td><td>Issuer (publisher)</td></tr><tr><td><code>%J</code></td><td>Journal containing article</td></tr><tr><td><code>%K</code></td><td>Keywords to use in locating reference</td></tr><tr><td><code>%L</code></td><td>Label field used by <code>-k</code> option of <code>refer</code></td></tr><tr><td><code>%M</code></td><td>Bell Labs Memorandum (undefined)</td></tr><tr><td><code>%N</code></td><td>Number within volume</td></tr><tr><td><code>%O</code></td><td>Other commentary, printed at end of reference</td></tr><tr><td><code>%P</code></td><td>Page number(s)</td></tr></table>	<code>%A</code>	Author's name	<code>%B</code>	Book containing article referenced	<code>%C</code>	City (place of publication)	<code>%D</code>	Date of publication	<code>%E</code>	Editor of book containing article referenced	<code>%F</code>	Footnote number or label (supplied by <code>refer</code>)	<code>%G</code>	Government order number	<code>%H</code>	Header commentary, printed before reference	<code>%I</code>	Issuer (publisher)	<code>%J</code>	Journal containing article	<code>%K</code>	Keywords to use in locating reference	<code>%L</code>	Label field used by <code>-k</code> option of <code>refer</code>	<code>%M</code>	Bell Labs Memorandum (undefined)	<code>%N</code>	Number within volume	<code>%O</code>	Other commentary, printed at end of reference	<code>%P</code>	Page number(s)
<code>%A</code>	Author's name																																
<code>%B</code>	Book containing article referenced																																
<code>%C</code>	City (place of publication)																																
<code>%D</code>	Date of publication																																
<code>%E</code>	Editor of book containing article referenced																																
<code>%F</code>	Footnote number or label (supplied by <code>refer</code>)																																
<code>%G</code>	Government order number																																
<code>%H</code>	Header commentary, printed before reference																																
<code>%I</code>	Issuer (publisher)																																
<code>%J</code>	Journal containing article																																
<code>%K</code>	Keywords to use in locating reference																																
<code>%L</code>	Label field used by <code>-k</code> option of <code>refer</code>																																
<code>%M</code>	Bell Labs Memorandum (undefined)																																
<code>%N</code>	Number within volume																																
<code>%O</code>	Other commentary, printed at end of reference																																
<code>%P</code>	Page number(s)																																

%Q Corporate or Foreign Author (unreversed)
 %R Report, paper, or thesis (unpublished)
 %S Series title
 %T Title of article or book
 %V Volume number
 %X Abstract — used by roffbib, not by refer
 %Y, Z Ignored by refer

EXAMPLES **EXAMPLE 1** Editing the bibliography file

Except for A, each field should be given just once. Only relevant fields should be supplied.

```
%A Mark Twain
%T Life on the Mississippi
%I Penguin Books
%C New York
%D 1978
```

alias(1)

NAME	alias, unalias – create or remove a pseudonym or shorthand for a command or series of commands
SYNOPSIS	<pre> /usr/bin/alias [alias-name [= string...]] /usr/bin/unalias alias-name... /usr/bin/unalias -a </pre>
csh	<pre> alias [name [def]] unalias pattern </pre>
ksh	<pre> alias [-tx] [name [= value]...] unalias name... </pre>
DESCRIPTION	<p>The <code>alias</code> and <code>unalias</code> utilities create or remove a pseudonym or shorthand term for a command or series of commands, with different functionality in the C-shell and Korn shell environments.</p>
/usr/bin/alias	<p>The <code>alias</code> utility creates or redefines alias definitions or writes the values of existing alias definitions to standard output. An alias definition provides a string value that replaces a command name when it is encountered.</p> <p>An alias definition affects the current shell execution environment and the execution environments of the subshells of the current shell. When used as specified by this document, the alias definition will not affect the parent process of the current shell nor any utility environment invoked by the shell.</p>
/usr/bin/unalias	<p>The <code>unalias</code> utility removes the definition for each alias name specified. The aliases are removed from the current shell execution environment.</p>
csh	<p><code>alias</code> assigns <i>def</i> to the alias <i>name</i>. <i>def</i> is a list of words that may contain escaped history-substitution metasyntax. <i>name</i> is not allowed to be <code>alias</code> or <code>unalias</code>. If <i>def</i> is omitted, the alias <i>name</i> is displayed along with its current definition. If both <i>name</i> and <i>def</i> are omitted, all aliases are displayed.</p> <p>Because of implementation restrictions, an alias definition must have been entered on a previous command line before it can be used.</p> <p><code>unalias</code> discards aliases that match (filename substitution) <i>pattern</i>. All aliases may be removed by <code>'unalias *'</code>.</p>
ksh	<p><code>alias</code> with no arguments prints the list of aliases in the form <i>name=value</i> on standard output. An alias is defined for each name whose <i>value</i> is given. A trailing space in <i>value</i> causes the next word to be checked for alias substitution. The <code>-t</code> flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given <i>name</i>. The value becomes undefined when the value of <code>PATH</code> is reset but the aliases remained tracked. Without the <code>-t</code> flag, for each <i>name</i> in</p>

the argument list for which no *value* is given, the name and value of the alias is printed. The `-x` flag is used to set or print *exported aliases*. An exported alias is defined for scripts invoked by *name*. The exit status is non-zero if a *name* is given, but no value, and no alias has been defined for the *name*.

The aliases given by the list of *names* may be removed from the `alias` list with `unalias`.

OPTIONS The following option is supported by `unalias`:

`-a` Removes all alias definitions from the current shell execution environment.

ksh The following options are supported by `alias`:

`-t` Sets and lists tracked aliases.

`-x` Sets or prints *exported aliases*. An exported alias is defined for scripts invoked by *name*.

OPERANDS The following operands are supported:

alias *alias-name* Write the alias definition to standard output.

unalias *alias-name* The name of an alias to be removed.

alias-name=string Assign the value of *string* to the alias *alias-name*.

If no operands are given, all alias definitions will be written to standard output.

OUTPUT The format for displaying aliases (when no operands or only *name* operands are specified) is:

```
"%s=%s\n" name, value
```

The *value* string will be written with appropriate quoting so that it is suitable for reinput to the shell.

EXAMPLES **EXAMPLE 1** Change `ls` to give a columnated, more annotated output:

```
alias ls="ls -CF"
```

EXAMPLE 2 Create a simple “redo” command to repeat previous entries in the command history file:

```
alias r='fc -s'
```

EXAMPLE 3 Use 1K units for `du`:

```
alias du=du -k
```

EXAMPLE 4 Set up `nohup` so that it can deal with an argument that is itself an alias name:

```
alias nohup="nohup "
```

alias(1)

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `alias` and `unalias`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.

alias >0 One of the *alias-name* operands specified did not have an alias definition, or an error occurred.

unalias >0 One of the *alias-name* operands specified did not represent a valid alias definition, or an error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	answerbook2 – online documentation system				
SYNOPSIS	<code>/usr/dt/bin/answerbook2 [-h]</code>				
DESCRIPTION	<p>The <code>answerbook2</code> utility brings up the default web browser and shows any online documentation installed in the default AnswerBook2 server. If an AnswerBook2 server has not been defined, <code>answerbook2</code> checks if there is one running on the user's machine. If so, it displays that server's information.</p> <p>To define a default AnswerBook2 server, use the environment variable, <code>AB2_DEFAULTSERVER</code>.</p> <p>This functionality is also accessible through the AnswerBook2 option on the CDE front panel Help menu.</p>				
OPTIONS	<p>The following option is supported:</p> <p><code>-h</code> Displays a usage statement.</p>				
USAGE	<p>At startup time, <code>answerbook2</code> starts up the default web browser (for example, HotJava or Netscape) and displays the URL specified for the default AnswerBook2 server. If no default AnswerBook2 server is defined, it looks for <code>http://localhost:8888</code>.</p>				
ENVIRONMENT VARIABLES	<p><code>AB2_DEFAULTSERVER</code> Fully-qualified URL that identifies the default AnswerBook2 server to use. For example: <code>http://imaserver.eng.sun.com:8888/</code></p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWab2m</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWab2m
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWab2m				
SEE ALSO	<code>ab2admin(1M)</code> , <code>ab2cd(1M)</code> , <code>attributes(5)</code>				
NOTES	Use the online Help system to find out more about the AnswerBook2 product, once the web browser is opened and the AnswerBook2 library can be viewed.				

appcert(1)

NAME	appcert – examine application-level products for unstable use of Solaris interfaces
SYNOPSIS	appcert [-h] [-n] [-f <i>infile</i>] [-w <i>working_dir</i>] [-B] [-L] [-S] { <i>obj</i> <i>dir...</i> }
DESCRIPTION	<p>The <code>appcert</code> utility examines an application's conformance to the Solaris Application Binary Interface (ABI). The Solaris ABI defines the runtime library interfaces in Solaris that are safe and stable for application use. More specifically, <code>appcert</code> identifies any dependencies on unstable runtime interfaces, as well as certain other risks that could cause the product to fail to work on a subsequent release of Solaris.</p> <p><code>appcert</code> checks for:</p> <ul style="list-style-type: none">■ <i>Private symbol usage in Solaris libraries.</i> These are private symbols, that is, functions or data, that are not intended for developer consumption. They are interfaces that Solaris libraries use to call one another. These symbols might change their semantic behavior or even disappear altogether (so-called "demoted" symbols), so it is a good practice to make sure your application does not depend upon any of them.■ <i>Static linking.</i> In particular, this refers to static linking of archives <code>libc.a</code>, <code>libsocket.a</code>, and <code>libnsl.a</code>, that is, instead of dynamically linking the corresponding shared object <code>.so</code>'s. Because the semantics of private symbol calls from one Solaris library to another can change from one release to another, it is not a good practice to "hardwire" library code into your binary objects.■ <i>Unbound symbols.</i> These are library symbols (that is, functions or data) that the dynamic linker could not resolve when <code>appcert</code> was run. This might be an environment problem (for example, <code>LD_LIBRARY_PATH</code>) or a build problem (for example, not specifying <code>-llib</code> and/or <code>-z defs</code> with compiling). They are flagged to point these problems out and in case a more serious problem is indicated. <p>An entire product can be readily examined by <code>appcert</code> (that is, if the product is a collection of many programs and supporting shared objects) by referring <code>appcert</code> to the directories where the product is installed.</p> <p>To perform its task, <code>appcert</code> constructs a profile of interface dependencies for each object file within the product (whether an executable object or shared object), to determine all the Solaris system interfaces that are depended upon. (Notice that <code>appcert</code> uses the Solaris runtime linker to make this determination.) These dependency profiles are then compared to a definition of the Solaris ABI to identify any interfaces that are Private (unsafe and unstable for application-level use).</p> <p><code>appcert</code> generates a simple roll-up report that indicates which of the product's components, if any, had liabilities and what those liabilities were. The report aids developers who are examining their product's release-to-release stability.</p> <p>Notice that <code>appcert</code> produces complete interface dependency information, both the Public (safe and stable) Solaris interfaces and the Private (non-ABI) interfaces. This information can also be examined for each product component, if you want.</p> <p>IMPORTANT: <code>appcert</code> must run in the same environment in which the application being checked runs. See NOTES.</p>

OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -B If <code>appcert</code> is run in "batch" mode, the output report will contain one line per binary, beginning with <code>PASS</code> if no problems were detected for the binary, <code>FAIL</code> if any problems were found, or <code>INC</code> if the binary could not be completely checked. Do not interpret these labels too literally. For example, <code>PASS</code> just means that none of the <code>appcert</code> warnings were triggered. These strings are flush left and so can be selected via <code>grep ^FAIL . . .</code>, and so forth. -f <i>infile</i> Specifies the file <i>infile</i> that contains a list of files (one per line) to check. This list is appended to the list determined from the command line operands (see OPERANDS below). -h Prints out the usage information. -L <code>appcert</code> examines your product for the presence of shared objects. If it finds some, it appends the directories they reside in to <code>LD_LIBRARY_PATH</code>. Use this flag to prevent <code>appcert</code> from doing this. -n When searching directories for binaries to check, this option does not follow symbolic links. See <code>find(1)</code>. -S Appends Solaris library directories (that is, <code>/usr/openwin/lib:/usr/dt/lib</code>) to <code>LD_LIBRARY_PATH</code>. -w <i>working_dir</i> Identifies the directory in which to run the library components and create temporary files (default is <code>/tmp</code>).
OPERANDS	<p>The following operands are supported:</p> <p>{ <i>obj</i> <i>dir</i> } ... A complete list of objects and/or directories that contain the objects constituting the product to be checked. <code>appcert</code> recursively searches directories looking for object files; non-object files are ignored.</p>
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 <code>appcert</code> ran successfully and found no potential binary stability problems. 1 <code>appcert</code> failed to run successfully. 2 Some of the objects checked have potential binary stability problems. 3 No binary objects were located that could be checked.
LIMITATIONS	<p>If the object file to be examined depends on libraries, those dependencies must be recorded in it (by using the compiler's <code>-l</code> switch).</p> <p>If the object file to be examined depends on other shared libraries, those libraries must be accessible via <code>LD_LIBRARY_PATH</code> or <code>RPATH</code> when <code>appcert</code> is run.</p>

appcert(1)

To check 64-bit applications, the machine must be running the 64-bit Solaris kernel. See `isalist(1)`. Also, the checks for static linking are currently not done on 64-bit applications.

appcert cannot examine:

- Object files that are completely or partially statically linked.

Completely statically linked objects are reported as unstable.

- Executable files that do not have execute permission set.

These are skipped. Shared objects without execute permission are not skipped.

- Object files that are setuid root.

Due to limitations in `ldd(1)`, these are skipped. Copy and/or change the permissions to check them.

- Non-ELF file executables such as shell scripts.
- Non-C language interfaces to Solaris; for example, C++ and Java.

The code itself need not be in C as long as the calls to Solaris libraries are in C.

OUTPUT FILES

appcert records its findings in the following files in the working directory (`/tmp/appcert.????` by default):

Index	A mapping between checked binaries and the subdirectory in the working directory in which the output specific to that binary can be found.
Report	A copy of the rollup report that was displayed on stdout when appcert was run.
Skipped	A list of binaries that appcert was asked to check but had to skip, along with a brief reason why each was skipped.

In addition, there is per-object information in the subdirectories under `appcert.????/objects/`, in the following files:

`check.demoted_symbols`

A list of symbols suspected to be demoted Solaris symbols.

`check.dynamic.private`

A list of private Solaris symbols to which the object makes direct bindings.

`check.dynamic.public`

A list of public Solaris symbols to which the object makes direct bindings.

`check.dynamic.unbound`

A list of symbols not bound by the dynamic linker when `ldd -r` was run. For convenience, `ldd` output lines containing "file not found" are also included.

`summary.dynamic`

A pretty-printed summary of dynamic bindings for the objects examined, including tables of Public and Private symbols used from each Solaris library.

Other files are temporary files used internally by `appcert`.

OUTPUT MESSAGES

Private Symbol Use

Private symbols are functions or data variables in a Solaris library that are not intended for developer or external use. These symbols are interfaces that the Solaris libraries use to call and communicate with one another. They are marked in `pvs(1)` output with the symbol version name "SUNWprivate".

Private symbols can change their semantic behavior or even disappear altogether ("demoted" or "deprecated" symbols), so your application should not depend upon any of them.

Demoted Symbols

Demoted symbols are functions or data variables in a Solaris library that were once private to that library and have been removed (or possibly scoped local to the library) in a later Solaris release. If your application directly calls one of these demoted symbols, it will fail to run (relocation error) on the release in which the symbol was removed and releases thereafter.

In some rare cases, a demoted symbol will return in a later release, but nevertheless there are still some releases on which the application will not run.

Sun Microsystems Inc. performed most of the library scoping in the transition from Solaris 2.5.1 to 2.6. This action was done to increase binary stability. By making these completely internal interfaces invisible (that is, they cannot be dynamically linked against), a developer cannot accidentally or intentionally call these interfaces. For more information, see the *Linker and Libraries Guide*, in particular the chapter on versioning. This document may be found online at <http://docs.sun.com>.

Unbound Symbols

Unbound symbols are library symbols (that is, functions or data) referenced by the application that the dynamic linker could not resolve when `appcert` was run. *Note:* `appcert` does not actually run your application, so some aspect of the environment that affects dynamic linking might not be set properly.

Unbound symbols do not necessarily indicate a potential binary stability problem. They only mean that when `appcert` was run, the runtime dynamic linker could not resolve these symbols.

Unbound symbols might be due to `LD_LIBRARY_PATH` not being correctly set. Make sure it is set, so that all of your binary objects can find all of the libraries they depend on (either your product's own libraries, Solaris libraries, or those of a third party). Then re-run `appcert`.

appcert(1)

You might find it useful to write a shell script that sets up the environment correctly and then runs `appcert` on the binaries you want to check.

Another common cause for unbound symbols is when a shared object under test has not recorded its dynamic dependencies, that is, at build time the `-l` switch was *not* supplied to the compiler and `ld(1)`. So the shared object requires that the *executables* that link against it have the correct dependencies recorded.

Notice that such a shared object can either be linked in the standard way (that is, specified at an executable's build time) or dynamically opened (for example, an executable calls `dlopen(3DL)` on the shared object sometimes when running). Either case can give rise to unbound symbols when `appcert` is run. The former can usually be resolved by setting `LD_LIBRARY_PATH` appropriately before running `appcert`. The latter (`dlopen`) is usually difficult to resolve. Under some circumstances, you might be able to set `LD_PRELOAD` appropriately to preload the needed libraries, but this procedure does not always work.

How do you know if the environment has been set up correctly so that there will be no unbound symbols? It must be set up so that running `ldd -r` on the binary yields no "file not found" or "symbol not found" errors. See `ld.so.1(1)` and `ldd(1)` for more information on dynamic linking.

In any event, `appcert` flags unbound symbols as a warning in case they might indicate a more serious problem. Unbound symbols can be an indicator of dependencies on demoted symbols (symbols that have been removed from a library or scoped local to it). Dependencies on demoted symbols will lead to serious binary stability problems.

However, setting up the environment properly should remove most unbound symbols. In general, it is good practice to record library dependencies at build time whenever possible because it helps make the binary object better defined and self-contained. Also recommended is using the `-z defs` flag when building shared objects, to force the resolution of all symbols during compilation. See `ld(1)` for more information.

No Bindings Found

`appcert` runs `/bin/ldd -r` on each binary object to be tested. It sets the environment variable `LD_DEBUG="files,bindings"`. (See `ldd(1)` and `ld.so.1(1)` for more information). If that command fails for some reason, `appcert` will have no dynamic symbol binding information and will find "no bindings".

`appcert` can fail if any of the following is true:

- The binary object does not have read permission.
- The binary object is SUID or SGID and the user does not have sufficient privileges.
- The binary object is an executable without the execute permission bit set.
- The binary object is a 64-bit application, but the kernel running on the current machine supports only 32-bit applications.
- The binary object is completely statically linked.

- The binary object has no library dependency information recorded.

Other cases exist as well (for example, out of memory). In general, this flag means that `appcert` could not completely examine the object due to permissions or environment. Try to modify the permissions or environment so that the dynamic bindings can be recorded.

Obsolete Library	An obsolete library is one whose use is deprecated and that might, in some future release, be removed from Solaris altogether. <code>appcert</code> flags these because applications depending on them might not run in future releases of Solaris. All interfaces, including Private ones, in an obsolete library are frozen and will not change.
Use of <code>sys_errlist</code>/<code>sys_nerr</code>	Direct use of the symbols <code>sys_errlist</code> or <code>sys_nerr</code> presents a risk in which reference might be made past the end of the <code>sys_errlist</code> array. These symbols are deprecated in 32-bit versions of Solaris and are absent altogether in 64-bit versions. Use <code>strerror(3C)</code> instead.
Use of Strong vs. Weak Symbols	The “strong” symbols (for example, <code>_socket</code>) associated with “weak” symbols (for example, <code>socket</code>) are reserved as private (their behavior could change in the future). Your application should only directly reference the weak symbol (usually the strong symbols begin with “_”).

Note: Under certain build environments, the strong/private symbol dependency gets recorded into your binary instead of the weak/public one, even though the source code doesn’t appear to reference the private symbol. Nevertheless, steps should be taken to trace down why this is occurring and fix the dependency.

- NOTES** `appcert` needs to run in the same environment in which the application being checked runs. Otherwise it might not be able to resolve references correctly to interfaces in the Solaris libraries. Take the following steps:
1. Make sure that `LD_LIBRARY_PATH` and any other aspects of the environment are set to whatever settings are used when the application is run. Also make sure that it contains the directories containing any non-Solaris shared objects that are part of the product, so that they can be found when referenced.
 2. Make sure that all the binaries to be checked:
 - Are dynamically linked ELF objects
 - Have execute permission set on executables (this is not necessary for shared objects)
 - Are not SUID root (otherwise you will have to be root to check them; make non-SUID copies and check those if necessary).

You might find it useful to write a shell script that sets up the environment correctly and then runs `appcert`.

Some potential problems that can be encountered are:

- `appcert` reports unbound symbols that appear to be part of Solaris libraries.

appcert(1)

This is probably caused when the application uses `dlopen(3DL)` to access a shared object that does not have its Solaris dependencies recorded. `appcert` cannot resolve symbol use in such cases, since the dynamic linker is never invoked on the shared object, and there is no other dependency information that could be used to resolve the Solaris symbol bindings. This can also occur with non-Solaris symbols.

To avoid this problem, make sure that when a shared object is built, its dependencies on Solaris libraries are explicitly recorded by using the `-llib` option on the compile line (see `cc(1)` and `ld(1)`).

- `appcert` reports that the application uses a Solaris private symbol that is not referenced in the application's source code.

This problem is most likely due to static linking of a Solaris library that references that symbol. Since `appcert` uses the dynamic linker to resolve symbols, statically linked libraries appear to `appcert` to be part of the application code (which, in a sense, they are). This can also sometimes happen as a result of macro substitution in a Solaris header file.

To avoid this problem, whenever possible do not statically link Solaris library archives into your application.

- `appcert` does not recognize a library as part of Solaris.

Some obsolete Solaris libraries are so old that they were obsoleted before their symbols could be versioned. Consequently, `appcert` cannot recognize them as being part of Solaris.

BUGS The use of the terms "public" and "private" as equivalent to "stable" and "unstable" is unfortunately somewhat confusing. In particular, experimental or evolving interfaces are public in the sense that they are documented and their use is encouraged. But they are unstable, because an application built with them might not run on subsequent releases. Thus, they are classified as private for `appcert`'s purposes until they are no longer evolving. Conversely, obsolete interfaces will eventually disappear, and so are unstable, even though they have been public and stable in the past and are still treated as public by `appcert`. Fortunately, these two situations are rare.

Linker and Libraries Guide

NAME	apptrace – trace application function calls to Solaris shared libraries
SYNOPSIS	apptrace [-f] [-F [!] <i>tracefromlist</i>] [-T [!] <i>tracetolist</i>] [-o <i>outputfile</i>] [[-tv] [!] <i>syscall</i> ,...] <i>command</i> [<i>command arguments</i>]
DESCRIPTION	<p>The <code>apptrace</code> utility runs the executable program specified by <code>command</code> and traces all calls that the program <i>command</i> makes to the Solaris shared libraries. Tracing means that for each call the program makes, <code>apptrace</code> reports the name of the library interface called, the values of the arguments passed, and the return value.</p> <p>By default, <code>apptrace</code> traces calls directly from the executable object to any of the shared objects it depends on. Indirect calls (that is, calls made between shared objects that the executable depends upon) are not reported by default.</p> <p>Calls from or to additional shared objects may be traced using the <code>-F</code> or <code>-T</code> options (see below).</p> <p>The default reporting format is a single line per call, with no formatted printing of arguments passed by reference or of data structures.</p> <p>Formatted printing providing additional argument details is obtained using the <code>-v</code> option (see below).</p> <p>By default, every interface provided by a shared object is traced if called. However, the set of interfaces traced may be restricted, using a regular expression that matches the interface names to be traced, and is given to either the <code>-t</code> or <code>-v</code> option.</p> <p>Since it is generally possible to trace calls between any of the dynamic objects linked at runtime (the executable object and any of the shared objects depended upon), the report of each traced call gives the name of the object from which the call was made.</p> <p><code>apptrace</code> traces all of the procedure calls that occur between dynamic objects via the procedure linkage table, so only those procedure calls which are bound via the table will be traced. See the <i>Linker and Libraries Guide</i>.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-F [!] <i>tracefromlist</i></code> Traces calls from a comma-separated list of shared objects. Only calls from these shared objects will be traced. The default is to trace calls from the main executable only. Only the basename of the shared object is required. For example, <i>libc</i> will match <i>/usr/lib/libc.so.1</i>. Additionally, shell style wildcard characters are supported as described in <code>fnmatch(5)</code>. A list preceded by a “!” defines a list of objects from which calls are to be excluded from the trace. If the tracing of calls from <i>command</i> is required, then <i>command</i> must be a member of <i>tracefromlist</i>.</p> <p><code>-T [!] <i>tracetolist</i></code> Traces calls to a comma-separated list of shared objects. The default is to trace calls to all shared objects. As</p>

appttrace(1)

	above, the basename is all that is required and wildcarding is allowed. A list preceded by a "!" denotes a list of objects to which calls are to be excluded from the trace.
-o <i>outputfile</i>	appttrace output will be directed to the <i>outputfile</i> . By default, appttrace output is placed on stderr.
-f	Follows all children created by <code>fork(2)</code> and also print <code>truss(1)</code> output on each. This option will also cause a 'pid' to be output on each <code>truss(1)</code> output line.
-t [!] <i>call</i> , ...	Traces or excludes function calls. Those calls specified in the comma-separated list <i>call</i> are traced. If the list begins with a !, the specified function calls are excluded from the trace output. The default is <code>-t all</code> . The use of shell style wildcards is allowed.
-v [!] <i>call</i> , ...	Provides verbose, formatted output of the arguments and return values of the function calls specified (as above in the <code>-t</code> option). Unlike <code>truss(1)</code> , calls named by the <code>-v</code> option do not have to be named by the <code>-t</code> option. For example, <code>appttrace -v open</code> is equivalent to <code>truss -t open -v open</code> .

EXAMPLES

EXAMPLE 1 Tracing the date command

```
% appttrace date
date → libc.so.1:atexit(func = 0xff3ba1c8) = 0x0
date → libc.so.1:atexit(func = 0x117e4) = 0x0
date → libc.so.1:setlocale(category = 0x6, locale = "") = "C"
date → libc.so.1:textdomain(domainname =
      "SUNW_OST_OSCMD") = "SUNW_OST_OSCMD"
date → libc.so.1:getopt(argc = 0x1, argv = 0xffbeed5c,
      optstring = "a:u") = 0xffffffff errno = No error
date → libc.so.1:time(tloc = 0x21ecc) = 0x371397c3
date → libc.so.1:nl_langinfo(item = 0x3a) = "%a %b %e %T %Z %Y"
date → libc.so.1:localtime(clock = 0x21ecc) = 0xff03c928
date → libc_psr.so.1:memcpy(0xffbeecc, 0xff03c928, 0x24)
date → libc.so.1:strftime(s = "Tue Apr 13 15:15:15 ",
      maxsize = 0x400, format = "%a %b %e %T %Z %Y",
      timeptr = 0xffbeecc) = 0x1c
date → libc.so.1:puts(Tue Apr 13 15:15:15 EDT 1999
      s = "Tue Apr 13 15:15:15 ") = 0x1d
date → libc.so.1:exit(status = 0)
```

EXAMPLE 2 Tracing a specific set of interfaces with verbosity set

```
% appttrace -v '*gid*' id -a
id → libc.so.1:getgid() = 0xa
      return = (gid_t) 10 (0xa)
id → libc.so.1:getegid() = 0xa
      return = (gid_t) 10 (0xa)
id → libc.so.1:getgrgid(gid = 0xa) = 0x2238c
```

EXAMPLE 2 Tracing a specific set of interfaces with verbosity set (Continued)

```

gid = (gid_t) 10          (0xa)
return = (struct group *) 0x2238c (struct group) {
  gr_name:  (char *) 0x223a0 "staff"
  gr_passwd: (char *) 0x223a6 ""
  gr_gid:   (gid_t) 10 (0xa)
  gr_mem:   (char **) 0x2239c
}

id  → libc.so.1:getgrgid(gid = 0xa) = 0x2238c
gid = (gid_t) 10          (0xa)
return = (struct group *) 0x2238c (struct group) {
  gr_name:  (char *) 0x223a0 "staff"
  gr_passwd: (char *) 0x223a6 ""
  gr_gid:   (gid_t) 10 (0xa)
  gr_mem:   (char **) 0x2239c
}

id  → libc.so.1:getgrgid(gid = 0x3) = 0x2238c
gid = (gid_t) 3          (0x3)
return = (struct group *) 0x2238c (struct group) {
  gr_name:  (char *) 0x223b4 "sys"
  gr_passwd: (char *) 0x223b8 ""
  gr_gid:   (gid_t) 3  (0x3)
  gr_mem:   (char **) 0x2239c
}

id  → libc.so.1:getgrgid(gid = 0x29) = 0x2238c
gid = (gid_t) 41         (0x29)
return = (struct group *) 0x2238c (struct group) {
  gr_name:  (char *) 0x223a4 "opcom"
  gr_passwd: (char *) 0x223aa ""
  gr_gid:   (gid_t) 41 (0x29)
  gr_mem:   (char **) 0x2239c
}

id  → libc.so.1:getgrgid(gid = 0xe) = 0x2238c
gid = (gid_t) 14         (0xe)
return = (struct group *) 0x2238c (struct group) {
  gr_name:  (char *) 0x223a0 "sysadmin"
  gr_passwd: (char *) 0x223a9 ""
  gr_gid:   (gid_t) 14 (0xe)
  gr_mem:   (char **) 0x2239c
}

id  → libc.so.1:getgrgid(gid = 0xd3) = 0x2238c
gid = (gid_t) 211        (0xd3)
return = (struct group *) 0x2238c (struct group) {
  gr_name:  (char *) 0x223a8 "test"
  gr_passwd: (char *) 0x223ad ""
  gr_gid:   (gid_t) 211 (0xd3)
  gr_mem:   (char **) 0x2239c
}

uid=44013(georgn) gid=10(staff) groups=10(staff),3(sys),

```

apptrace(1)

EXAMPLE 2 Tracing a specific set of interfaces with verbosity set *(Continued)*

```
41 (opcom) , 14 (sysadmin) , 211 (test)
```

FILES Basic runtime support for `apptrace` is provided by the link auditing feature of the Solaris runtime linker (`ld.so.1(1)`) and the `apptrace` command's use of this facility relies on an auditing object (`apptrace.so.1`) kept in `/usr/lib/abi`.

In order to perform formatted printing of arguments when tracing calls (as selected by the `-v` option), `apptrace` needs to know the number and data types of the arguments supplied to the called interface. Special runtime support shared objects are provided which `apptrace` relies upon to perform formatted printing. A runtime support object is provided for each Solaris shared library, which contains an "interceptor" function for each interface within the shared library. These supporting shared objects are kept in `/usr/lib/abi`. `apptrace` has a simple algorithm to map from the name of a library interface to the name of an interceptor function in the library's supporting verbose-tracing shared object. In the case that an interceptor is not found in the library's supporting tracing shared object, `apptrace` cannot determine either the number or data types of the arguments for that interface. In this case, `apptrace` uses a default output for the call-tracing report (simply hex-formatted printing of the first three arguments).

LIMITATIONS In general, `apptrace` cannot trace calls to functions accepting variable argument lists. There has been some clever coding in several specific cases to work around this limitation, most notably in the `printf` family.

Functions that attempt to probe the stack or otherwise extract information about the caller cannot be traced. Some examples are `[gs]etcontext()`, `getsp()`, `[sig]longjmp()`, `[sig]setjmp()`, and `vfork()`.

Functions such as `exit(2)` that do not return may also produce strange output.

NAME	apropos – locate commands by keyword lookup						
SYNOPSIS	apropos <i>keyword...</i>						
DESCRIPTION	<p>The <code>apropos</code> utility displays the man page name, section number, and a short description for each man page whose <code>NAME</code> line contains <i>keyword</i>. This information is contained in the <code>/usr/share/man/windex</code> database created by <code>catman(1M)</code>. If <code>catman(1M)</code> was not run, or was run with the <code>-n</code> option, <code>apropos</code> fails. Each word is considered separately and the case of letters is ignored. Words which are part of other words are considered; for example, when looking for ‘<code>compile</code>’, <code>apropos</code> finds all instances of ‘<code>compiler</code>’ also.</p> <p><code>apropos</code> is actually just the <code>-k</code> option to the <code>man(1)</code> command.</p>						
EXAMPLES	<p>EXAMPLE 1 To find a man page whose <code>NAME</code> line contains a keyword</p> <p>Try</p> <pre>example% apropos password</pre> <p>and</p> <pre>example% apropos editor</pre> <p>If the line starts ‘<code>filename(section) . . .</code>’ you can run</p> <pre>man -s <i>section filename</i></pre> <p>to display the man page for <i>filename</i>.</p> <p>EXAMPLE 2 To find the man page for the subroutine <code>printf()</code></p> <p>Try</p> <pre>example% apropos format</pre> <p>and then</p> <pre>example% man -s 3s printf</pre> <p>to get the manual page on the subroutine <code>printf()</code>.</p>						
FILES	<code>/usr/share/man/windex</code> table of contents and keyword database

apropos(1)

DIAGNOSTICS

/usr/share/man/windex: No such file or directory
This database does not exist. catman(1M) must be run to create it.

NAME	ar – maintain portable archive or library
SYNOPSIS	<pre> /usr/ccs/bin/ar -d [-Vv] archive file... /usr/ccs/bin/ar -m [-abiVv] [posname] archive file... /usr/ccs/bin/ar -p [-sVv] archive [file...] /usr/ccs/bin/ar -q [-cVv] archive file... /usr/ccs/bin/ar -r [-abciuVv] [posname] archive file... /usr/ccs/bin/ar -t [-sVv] archive [file...] /usr/ccs/bin/ar -x [-CsTVv] archive [file...] /usr/xpg4/bin/ar -d [-Vv] archive file... /usr/xpg4/bin/ar -m [-abiVv] [posname] archive file... /usr/xpg4/bin/ar -p [-sVv] archive [file...] /usr/xpg4/bin/ar -q [-cVv] archive file... /usr/xpg4/bin/ar -r [-abciuVv] [posname] archive file... /usr/xpg4/bin/ar -t [-sVv] archive [file...] /usr/xpg4/bin/ar -x [-CsTVv] archive [file...] </pre>
DESCRIPTION	<p>The <code>ar</code> utility maintains groups of files combined into a single archive file. Its main use is to create and update library files. However, it can be used for any similar purpose. The magic string and the file headers used by <code>ar</code> consist of printable ASCII characters. If an archive is composed of printable files, the entire archive is printable.</p> <p>When <code>ar</code> creates an archive, it creates headers in a format that is portable across all machines. The portable archive format and structure are described in detail in <code>ar(3HEAD)</code>. The archive symbol table (described in <code>ar(3HEAD)</code>) is used by the link editor <code>ld</code> to effect multiple passes over libraries of object files in an efficient manner. An archive symbol table is only created and maintained by <code>ar</code> when there is at least one object file in the archive. The archive symbol table is in a specially named file that is always the first file in the archive. This file is never mentioned or accessible to the user. Whenever the <code>ar</code> command is used to create or update the contents of such an archive, the symbol table is rebuilt. The <code>s</code> option described below will force the symbol table to be rebuilt.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Positions new files in <i>archive</i> after the file named by the <i>posname</i> operand. -b Positions new files in <i>archive</i> before the file named by the <i>posname</i> operand. -c Suppresses the diagnostic message that is written to standard error by default when <i>archive</i> is created.

ar(1)

-C	Prevents extracted files from replacing like-named files in the file system. This option is useful when -T is also used to prevent truncated file names from replacing files with the same prefix.
-d	Deletes one or more <i>files</i> from <i>archive</i> .
-i	Positions new <i>files</i> in <i>archive</i> before the file named by the <i>posname</i> operand (equivalent to -b).
-m	Moves <i>files</i> . If -a, -b, or -i with the <i>posname</i> operand are specified, moves <i>files</i> to the new position; otherwise, moves <i>files</i> to the end of <i>archive</i> .
-p	Prints the contents of <i>files</i> in <i>archive</i> to standard output. If no <i>files</i> are specified, the contents of all files in <i>archive</i> will be written in the order of the archive.
-q	Quickly appends <i>files</i> to the end of <i>archive</i> . Positioning options -a, -b, and -i are invalid. The command does not check whether the added <i>files</i> are already in <i>archive</i> . This option is useful to avoid quadratic behavior when creating a large archive piece-by-piece.
-r	Replaces or adds <i>files</i> in <i>archive</i> . If <i>archive</i> does not exist, a new archive file will be created and a diagnostic message will be written to standard error (unless the -c option is specified). If no <i>files</i> are specified and the <i>archive</i> exists, the results are undefined. Files that replace existing files will not change the order of the archive. If the -u option is used with the -r option, then only those files with dates of modification later than the archive files are replaced. If the -a, -b, or -i option is used, then the <i>posname</i> argument must be present and specifies that new files are to be placed after (-a) or before (-b or -i) <i>posname</i> ; otherwise the new files are placed at the end.
-s	Forces the regeneration of the archive symbol table even if ar is not invoked with a option which will modify the archive contents. This command is useful to restore the archive symbol table after the strip(1) command has been used on the archive.
-t	Prints a table of contents of <i>archive</i> . The files specified by the <i>file</i> operands will be included in the written list. If no <i>file</i> operands are specified, all files in <i>archive</i> will be included in the order of the archive.
-T	Allows file name truncation of extracted files whose archive names are longer than the file system can support. By default, extracting a file with a name that is too long is an error; a diagnostic message will be written and the file will not be extracted.
-u	Updates older files. When used with the -r option, files within <i>archive</i> will be replaced only if the corresponding <i>file</i> has a modification time that is at least as new as the modification time of the file within <i>archive</i> .
-V	Prints its version number on standard error.
/usr/bin/ar -v	Gives verbose output. When used with the option characters -d, -r, or -x, writes a detailed file-by-file description of the archive creation and the

		constituent <i>files</i> , and maintenance activity. When used with <i>-p</i> , writes the name of the file to the standard output before writing the file itself to the standard output. When used with <i>-t</i> , includes a long listing of information about the files within the archive. When used with <i>-x</i> , prints the filename preceding each extraction. When writing to an archive, a message is written to the standard error.				
/usr/xpg4/bin/ar	<i>-v</i>	Same as <i>/usr/bin/ar</i> version, except when writing to an archive, no message is written to the standard error.				
	<i>-x</i>	Extracts the files named by the <i>file</i> operands from <i>archive</i> . The contents of <i>archive</i> will not be changed. If no <i>file</i> operands are given, all files in <i>archive</i> will be extracted. If the file name of a file extracted from <i>archive</i> is longer than that supported in the directory to which it is being extracted, the results are undefined. The modification time of each <i>file</i> extracted will be set to the time <i>file</i> is extracted from <i>archive</i> .				
OPERANDS	The following operands are supported:					
	<i>archive</i>	A path name of the archive file.				
	<i>file</i>	A path name. Only the last component will be used when comparing against the names of files in the archive. If two or more <i>file</i> operands have the same last path name component (<i>basename(1)</i>), the results are unspecified. The implementation's archive format will not truncate valid file names of files added to or replaced in the archive.				
	<i>posname</i>	The name of a file in the archive file, used for relative positioning; see options <i>-m</i> and <i>-r</i> .				
ENVIRONMENT VARIABLES	See <i>environ(5)</i> for descriptions of the following environment variables that affect the execution of <i>ar</i> : <i>LC_CTYPE</i> , <i>LC_MESSAGES</i> , and <i>NLSPATH</i> .					
EXIT STATUS	The following exit values are returned:					
	0	Successful completion.				
	>0	An error occurred.				
ATTRIBUTES	See <i>attributes(5)</i> for descriptions of the following attributes:					
/usr/bin/ar	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWbtool</td> </tr> </tbody> </table>		ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWbtool

NOTES | If the same file is mentioned twice in an argument list, it may be put in the archive
twice.

By convention, archives are suffixed with the characters .a.

NAME	arch – display the architecture of the current host				
SYNOPSIS	arch [-k <i>archname</i>]				
DESCRIPTION	<p>arch displays the application architecture of the current host system. Due to extensive historical use of this command without any options, all SunOS 5.x SPARC based systems will return "sun4" as their application architecture. Use of this command is discouraged; see NOTES section below.</p> <p>Systems can be broadly classified by their <i>architectures</i>, which define what executables will run on which machines. A distinction can be made between <i>kernel architecture</i> and <i>application architecture</i> (or, commonly, just “architecture”). Machines that run different kernels due to underlying hardware differences may be able to run the same application programs.</p>				
OPTIONS	<p>-k Display the kernel architecture, such as sun4m, sun4c, and so forth. This defines which specific SunOS kernel will run on the machine, and has implications only for programs that depend on the kernel explicitly (for example, ps(1)).</p>				
OPERANDS	<p>The following operand is supported:</p> <p><i>archname</i> Use <i>archname</i> to determine whether the application binaries for this application architecture can run on the current host system. The <i>archname</i> must be a valid application architecture, such as sun4, i86pc, and so forth.</p> <p> If <i>application</i> binaries for <i>archname</i> can run on the current host system, TRUE (0) is returned; otherwise, FALSE (1) is returned.</p>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>>0 An error occurred.</p>				
ATTRIBUTES	<p>See attributes(5) for descriptions of the following attributes:</p> <table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	mach(1), ps(1), uname(1), attributes(5)				
NOTES	<p>This command is provided for compatibility with previous releases and its use is discouraged. Instead, the uname command is recommended. See uname(1) for usage information.</p>				

as(1)

NAME	as – assembler
SYNOPSIS	
Sparc	as [-b] [-K PIC] [-L] [-m] [-n] [-o <i>outfile</i>] [-P] [-Dname] [-Dname= <i>def</i>] [-I <i>path</i>] [-U <i>name...</i>] [-q] [-Qy <i>n</i>] [-s] [-S [<i>a</i> <i>b</i> <i>c</i> <i>l</i> <i>A</i> <i>B</i> <i>C</i> <i>L</i>]] [-T] [-V] [-xarch=v7 -xarch=v8 -xarch=v8a -xarch=v8plus -xarch=v8plusa -xarc [-xF] <i>filename...</i>
IA	as [-b] [-K PIC] [-L] [-m] [-n] [-o <i>outfile</i>] [-P] [-Dname] [-Dname= <i>def</i>] [-I <i>path</i>] [-U <i>name...</i>] [-Qy <i>n</i>] [-s] [-S [<i>a</i> <i>b</i> <i>c</i> <i>l</i> <i>A</i> <i>B</i> <i>C</i> <i>L</i>]] [-T] [-V] <i>filename...</i>
DESCRIPTION	The as command creates object files from assembly language source files.
OPTIONS	
Common Options	The following flags are common to both SPARC and IA. They may be specified in any order:
-b	Generates extra symbol table information for the Sun SourceBrowser.
-K PIC	Generates position-independent code.
-L	Saves all symbols, including temporary labels that are normally discarded to save space, in the ELF symbol table.
-m	Runs the m4(1) macro processor on the input to the assembler.
-n	Suppresses all the warnings while assembling.
-o <i>outfile</i>	Puts the output of the assembly in <i>outfile</i> . By default, the output file name is formed by removing the <i>.s</i> suffix, if there is one, from the input file name and appending a <i>.o</i> suffix.
-P	Runs cpp(1) , the C preprocessor, on the files being assembled. The preprocessor is run separately on each input file, not on their concatenation. The preprocessor output is passed to the assembler.
-D <i>name</i> -D <i>name=def</i>	When the -P option is in effect, these options are passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, they are ignored.

-I <i>path</i>	When the -P option is in effect, this option is passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, it is ignored.
-U <i>name</i>	When the -P option is in effect, this option is passed to the cpp(1) preprocessor without interpretation by the as command; otherwise, it is ignored.
-Q <i>y n</i>	If <i>n</i> is specified, this option produces the "assembler version" information in the comment section of the output object file. If <i>y</i> is specified, the information is suppressed.
-s	Places all stabs in the .stabs section. By default, stabs are placed in stabs.exc1 sections, which are stripped out by the static linker, ld(1), during final execution. When the -s option is used, stabs remain in the final executable because .stab sections are not stripped by the static linker.
-S[<i>a b c l A B C L</i>]	Produces a disassembly of the emitted code to the standard output. Adding each of the following characters to the -S option produces: <ul style="list-style-type: none"> <i>a</i> disassembling with address <i>b</i> disassembling with ".bof" <i>c</i> disassembling with comments <i>l</i> disassembling with line numbers <p>Capital letters turn the switch off for the corresponding option.</p>
-T	This is a migration option for 4.x assembly files to be assembled on 5.x systems. With this option, the symbol names in 4.x assembly files will be interpreted as 5.x symbol names.
-V	Writes the version number of the assembler being run on the standard error output.
-xF	Generates additional information for performance analysis of the executable using Sun WorkShop analyzer. If the input file does not contain any stabs (debugging directives), then the assembler will generate some default stabs which are needed by the Sun WorkShop analyzer. Also see the dbx manual page available with Sun Workshop.
-q	Performs a quick assembly. When the -q option is used, many error checks are not performed. Note :

**Options for
SPARC only**

as(1)

	This option disables many error checks. Use of this option to assemble handwritten assembly language is not recommended.
-xarch=v7	This option instructs the assembler to accept instructions defined in the SPARC version 7 (V7) architecture. The resulting object code is in ELF format.
-xarch=v8	This option instructs the assembler to accept instructions defined in the SPARC-V8 architecture, less the quad-precision floating-point instructions. The resulting object code is in ELF format.
-xarch=v8a	This option instructs the assembler to accept instructions defined in the SPARC-V8 architecture, less the quad-precision floating-point instructions and less the <i>fsmuld</i> instruction. The resulting object code is in ELF format. This is the default choice of the <i>-xarch=options</i> .
-xarch=v8plus	This option instructs the assembler to accept instructions defined in the SPARC-V9 architecture, less the quad-precision floating-point instructions. The resulting object code is in ELF format. It will not execute on a Solaris V8 system (a machine with a V8 processor). It will execute on a Solaris V8+ system. This combination is a SPARC 64-bit processor and a 32-bit OS.
-xarch=v8plusa	This option instructs the assembler to accept instructions defined in the SPARC-V9 architecture, less the quad-precision floating-point instructions, plus the instructions in the Visual Instruction Set (VIS). The resulting object code is in V8+ ELF format. It will not execute on a Solaris V8 system (a machine with a V8 processor). It will execute on a Solaris V8+ system
-xarch=v9	This option limits the instruction set to the SPARC-V9 architecture. The resulting .o object files are in 64-bit ELF format and can only be linked with other object files in the same format. The resulting executable can only be run on a 64-bit SPARC processor running 64-bit Solaris with the 64-bit kernel.
-xarch=v9a	This option limits the instruction set to the SPARC-V9 architecture, adding the Visual Instruction Set (VIS) and extensions specific to UltraSPARC processors. The resulting .o object files are in 64-bit ELF format and can only be linked with other object files in the same format. The resulting executable can only be run on a

as(1)

64-bit SPARC processor running 64-bit Solaris with the 64-bit kernel.

- OPERANDS** The following operand is supported:
- filename* Assembly language source file
- ENVIRONMENT VARIABLES** TMPDIR The `as` command normally creates temporary files in the directory `/tmp`. Another directory may be specified by setting the environment variable `TMPDIR` to the chosen directory. (If `TMPDIR` is not a valid directory, then `as` will use `/tmp`).
- FILES** By default, `as` creates its temporary files in `/tmp`.
- ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

SEE ALSO `cc(1B)`, `cpp(1)`, `ld(1)`, `m4(1)`, `nm(1)`, `strip(1)`, `tmpnam(3C)`, `a.out(4)`, `attributes(5)`

dbx manual page available with Sun Workshop

NOTES If the `-m` option, which invokes the `m4(1)` macro processor, is used, keywords for `m4` cannot be used as symbols (variables, functions, labels) in the input file, since `m4` cannot determine which keywords are assembler symbols and which keywords are real `m4` macros.

Whenever possible, access the assembler through a compilation system interface program such as `cc(1B)`.

All undefined symbols are treated as global.

asa(1)

NAME	asa – convert FORTRAN carriage-control output to printable form								
SYNOPSIS	asa [- <i>ε</i>] [<i>file...</i>]								
DESCRIPTION	<p>The <i>asa</i> utility will write its input files to standard output, mapping carriage-control characters from the text files to line-printer control sequences.</p> <p>The first character of every line will be removed from the input, and the following actions will be performed.</p> <p>If the character removed is:</p> <table><tr><td>SPACE</td><td>The rest of the line will be output without change.</td></tr><tr><td>0</td><td>It is replaced by a newline control sequence followed by the rest of the input line.</td></tr><tr><td>1</td><td>It is replaced by a newpage control sequence followed by the rest of the input line.</td></tr><tr><td>+</td><td>It is replaced by a control sequence that causes printing to return to the first column of the previous line, where the rest of the input line is printed.</td></tr></table> <p>For any other character in the first column of an input line, <i>asa</i> skips the character and prints the rest of the line unchanged.</p> <p>If <i>asa</i> is called without providing a <i>filename</i>, the standard input is used.</p>	SPACE	The rest of the line will be output without change.	0	It is replaced by a newline control sequence followed by the rest of the input line.	1	It is replaced by a newpage control sequence followed by the rest of the input line.	+	It is replaced by a control sequence that causes printing to return to the first column of the previous line, where the rest of the input line is printed.
SPACE	The rest of the line will be output without change.								
0	It is replaced by a newline control sequence followed by the rest of the input line.								
1	It is replaced by a newpage control sequence followed by the rest of the input line.								
+	It is replaced by a control sequence that causes printing to return to the first column of the previous line, where the rest of the input line is printed.								
OPTIONS	<p>The following option is supported:</p> <table><tr><td>-f</td><td>Start each file on a new page.</td></tr></table>	-f	Start each file on a new page.						
-f	Start each file on a new page.								
OPERANDS	<p>The following operand is supported:</p> <table><tr><td>file</td><td>A pathname of a text file used for input. If no <i>file</i> operands are specified, or ' - ' is specified, then the standard input will be used.</td></tr></table>	file	A pathname of a text file used for input. If no <i>file</i> operands are specified, or ' - ' is specified, then the standard input will be used.						
file	A pathname of a text file used for input. If no <i>file</i> operands are specified, or ' - ' is specified, then the standard input will be used.								
EXAMPLES	<p>EXAMPLE 1 Examples of the <i>asa</i> command.</p> <p>The command</p> <pre>a.out asa lp</pre> <p>converts output from <i>a.out</i> to conform with conventional printers and directs it through a pipe to the printer.</p> <p>The command</p> <pre>asa output</pre> <p>shows the contents of file <i>output</i> on a terminal as it would appear on a printer.</p> <p>The following program is used in the next two examples:</p>								

EXAMPLE 1 Examples of the asa command. (Continued)

```
write(*,'(" Blank"')
write(*,'("0Zero ")')
write(*,'("+      Plus "')')
write(*,'("1One  ")')
end
```

Example 1. With actual files:

```
a.out > MyOutputFile
asa < MyOutputFile | lp
```

Example 2. With only pipes:

```
a.out | asa | lp
```

Both of the above examples produce two pages of output:

Page 1:

Blank

ZeroPlus

Page 2:

One

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `asa`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 All input files were output successfully.

>0 An error occurred.

ATTRIBUTES

at(1)

NAME	at, batch – execute commands at a later time						
SYNOPSIS	at [-c -k -s] [-m] [-f <i>file</i>] [-p <i>project</i>] [-q <i>queue</i>] -t <i>time</i> at [-c -k -s] [-m] [-f <i>file</i>] [-p <i>project</i>] [-q <i>queue</i>] <i>timespec...</i> at -l [-p <i>project</i>] [-q <i>queue</i>] [<i>at_job_id.</i> ..] at -r <i>at_job_id.</i> .. batch [-p <i>project</i>]						
DESCRIPTION	<p>at The at utility reads commands from standard input and groups them together as an <i>at-job</i>, to be executed at a later time.</p> <p>The <i>at-job</i> will be executed in a separate invocation of the shell, running in a separate process group with no controlling terminal, except that the environment variables, current working directory, file creation mask (see <code>umask(1)</code>), and system resource limits (for <code>sh</code> and <code>ksh</code> only, see <code>ulimit(1)</code>) in effect when the at utility is executed will be retained and used when the <i>at-job</i> is executed.</p> <p>When the <i>at-job</i> is submitted, the <i>at_job_id</i> and scheduled time are written to standard error. The <i>at_job_id</i> is an identifier that will be a string consisting solely of alphanumeric characters and the period character. The <i>at_job_id</i> is assigned by the system when the job is scheduled such that it uniquely identifies a particular job.</p> <p>User notification and the processing of the job's standard output and standard error are described under the <code>-m</code> option.</p> <p>Users are permitted to use at and batch (see below) if their name appears in the file <code>/usr/lib/cron/at.allow</code>. If that file does not exist, the file <code>/usr/lib/cron/at.deny</code> is checked to determine if the user should be denied access to at. If neither file exists, only a user with the <code>solaris.jobs.user</code> authorization is allowed to submit a job. If only <code>at.deny</code> exists and is empty, global usage is permitted. The <code>at.allow</code> and <code>at.deny</code> files consist of one user name per line.</p>						
batch	<p>The batch utility reads commands to be executed at a later time. It is the equivalent of the command:</p> <pre>at -q b -m now</pre> <p>where <code>queue b</code> is a special at queue, specifically for batch jobs. Batch jobs will be submitted to the batch queue for immediate execution.</p>						
OPTIONS	<p>The following options are supported. If the <code>-c</code>, <code>-k</code>, or <code>-s</code> options are not specified, the <code>SHELL</code> environment variable by default determines which shell to use.</p> <table><tr><td>-c</td><td>C shell. <code>csh(1)</code> is used to execute the <i>at-job</i>.</td></tr><tr><td>-k</td><td>Korn shell. <code>ksh(1)</code> is used to execute the <i>at-job</i>.</td></tr><tr><td>-s</td><td>Bourne shell. <code>sh(1)</code> is used to execute the <i>at-job</i>.</td></tr></table>	-c	C shell. <code>csh(1)</code> is used to execute the <i>at-job</i> .	-k	Korn shell. <code>ksh(1)</code> is used to execute the <i>at-job</i> .	-s	Bourne shell. <code>sh(1)</code> is used to execute the <i>at-job</i> .
-c	C shell. <code>csh(1)</code> is used to execute the <i>at-job</i> .						
-k	Korn shell. <code>ksh(1)</code> is used to execute the <i>at-job</i> .						
-s	Bourne shell. <code>sh(1)</code> is used to execute the <i>at-job</i> .						

<code>-f file</code>	Specifies the path of a file to be used as the source of the at-job, instead of standard input.
<code>-l</code>	(The letter ell.) Reports all jobs scheduled for the invoking user if no <i>at_job_id</i> operands are specified. If <i>at_job_ids</i> are specified, reports only information for these jobs.
<code>-m</code>	Sends mail to the invoking user after the at-job has run, announcing its completion. Standard output and standard error produced by the at-job will be mailed to the user as well, unless redirected elsewhere. Mail will be sent even if the job produces no output. If <code>-m</code> is not used, the job's standard output and standard error will be provided to the user by means of mail, unless they are redirected elsewhere; if there is no such output to provide, the user is not notified of the job's completion.
<code>-p project</code>	Specifies under which project the at or batch job will be run. When used with the <code>-l</code> option, limits the search to that particular project. Values for <i>project</i> will be interpreted first as a project name, and then as a possible project ID, if entirely numeric. By default, the user's current project is used.
<code>-q queue_name</code>	Specifies in which queue to schedule a job for submission. When used with the <code>-l</code> option, limits the search to that particular queue. Values for <i>queue_name</i> are limited to the lower case letters a through z. By default, at-jobs will be scheduled in queue a. In contrast, queue b is reserved for batch jobs. Since queue c is reserved for cron jobs, it can not be used with the <code>-q</code> option.
<code>-r at_job_id</code>	Removes the jobs with the specified <i>at_job_id</i> operands that were previously scheduled by the at utility.
<code>-t time</code>	Submits the job to be run at the time specified by the <i>time</i> option-argument, which must have the format as specified by the touch(1) utility.

OPERANDS The following operands are supported:

<i>at_job_id</i>	The name reported by a previous invocation of the at utility at the time the job was scheduled.
<i>timespec</i>	Submit the job to be run at the date and time specified. All of the <i>timespec</i> operands are interpreted as if they were separated by space characters and concatenated. The date and time are interpreted as being in the timezone of the user (as determined by the TZ variable), unless a timezone name appears as part of <i>time</i> below.

at(1)

In the "C" locale, the following describes the three parts of the time specification string. All of the values from the LC_TIME categories in the "C" locale are recognized in a case-insensitive manner.

time The *time* can be specified as one, two or four digits. One- and two-digit numbers are taken to be hours, four-digit numbers to be hours and minutes. The time can alternatively be specified as two numbers separated by a colon, meaning *hour : minute*. An AM/PM indication (one of the values from the *am_pm* keywords in the LC_TIME locale category) can follow the time; otherwise, a 24-hour clock time is understood. A timezone name of GMT, UCT, or ZULU (case insensitive) can follow to specify that the time is in Coordinated Universal Time. Other timezones can be specified using the TZ environment variable. The *time* field can also be one of the following tokens in the "C" locale:

midnight Indicates the time 12:00 am (00:00).

noon Indicates the time 12:00 pm.

now Indicate the current day and time. Invoking *at now* will submit an at-job for potentially immediate execution (that is, subject only to unspecified scheduling delays).

date An optional *date* can be specified as either a month name (one of the values from the *mon* or *abmon* keywords in the LC_TIME locale category) followed by a day number (and possibly year number preceded by a comma) or a day of the week (one of the values from the *day* or *abday* keywords in the LC_TIME locale category). Two special days are recognized in the "C" locale:

today Indicates the current day.

tomorrow Indicates the day following the current day.

If no *date* is given, *today* is assumed if the given time is greater than the current time, and *tomorrow* is assumed if it is less. If the given month is less than the current month (and no year is given), next year is assumed.

increment

The optional *increment* is a number preceded by a plus sign (+) and suffixed by one of the following: *minutes*, *hours*, *days*, *weeks*, *months*, or *years*. (The singular forms will be also accepted.) The keyword *next* is equivalent to an increment number of + 1. For example, the following are equivalent commands:

```
at 2pm + 1 week
at 2pm next week
```

USAGE The format of the `at` command line shown here is guaranteed only for the "C" locale. Other locales are not supported for *midnight*, *noon*, *now*, *mon*, *abmon*, *day*, *abday*, *today*, *tomorrow*, *minutes*, *hours*, *days*, *weeks*, *months*, *years*, and *next*.

Since the commands run in a separate shell invocation, running in a separate process group with no controlling terminal, open file descriptors, traps and priority inherited from the invoking environment are lost.

EXAMPLES

at **EXAMPLE 1** Typical sequence at a terminal

This sequence can be used at a terminal:

```
$ at -m 0730 tomorrow
sort < file >outfile
<EOT>
```

EXAMPLE 2 Redirecting output

This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
$ at now + 1 hour <<!
diff file1 file2 2>&1 >outfile | mailx mygroup
```

EXAMPLE 3 Self-rescheduling a job

To have a job reschedule itself, `at` can be invoked from within the `at`-job. For example, this "daily-processing" script named `my.daily` will run every day (although `crontab` is a more appropriate vehicle for such work):

```
# my.daily runs every day
at now tomorrow < my.daily
daily-processing
```

at(1)

EXAMPLE 3 Self-rescheduling a job (Continued)

EXAMPLE 4 Various time and operand presentations

The spacing of the three portions of the "C" locale *timespec* is quite flexible as long as there are no ambiguities. Examples of various times and operand presentations include:

```
at 0815am Jan 24
at 8 :15amjan24
at now "+ 1day"
at 5 pm FRIday
at '17
    utc+
    30minutes'
```

batch **EXAMPLE 5** Typical sequence at a terminal

This sequence can be used at a terminal:

```
$ batch
sort <file >outfile
<EOT>
```

EXAMPLE 6 Redirecting output

This sequence, which demonstrates redirecting standard error to a pipe, is useful in a command procedure (the sequence of output redirection specifications is significant):

```
$ batch <<!
diff file1 file2 2>&1 >outfile | mailx mygroup
!
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `at` and `batch`: `LC_CTYPE`, `LC_MESSAGES`, `NLSPATH`, and `LC_TIME`.

SHELL	Determine a name of a command interpreter to be used to invoke the <code>at</code> -job. If the variable is unset or <code>NULL</code> , <code>sh</code> will be used. If it is set to a value other than <code>sh</code> , the implementation will use that shell; a warning diagnostic will be printed telling which shell will be used.
TZ	Determine the timezone. The job will be submitted for execution at the time specified by <i>timespec</i> or <code>-t time</code> relative to the timezone specified by the <code>TZ</code> variable. If <i>timespec</i> specifies a timezone, it will override <code>TZ</code> . If <i>timespec</i> does not specify a timezone and <code>TZ</code> is unset or <code>NULL</code> , an unspecified default timezone will be used.
DATEMSK	If the environment variable <code>DATEMSK</code> is set, <code>at</code> will use its value as the full path name of a template file containing format strings. The strings consist of format specifiers and text characters that are used to provide a richer set of allowable date formats in different

languages by appropriate settings of the environment variable LANG or LC_TIME. The list of allowable format specifiers is located in the `getdate(3C)` manual page. The formats described in the OPERANDS section for the *time* and *date* arguments, the special names *noon*, *midnight*, *now*, *next*, *today*, *tomorrow*, and the *increment* argument are not recognized when DATEMSK is set.

EXIT STATUS The following exit values are returned:

- 0 The at utility successfully submitted, removed or listed a job or jobs.
 >0 An error occurred, and the job will not be scheduled.

FILES

<code>/usr/lib/cron/at.allow</code>	names of users, one per line, who are authorized access to the at and batch utilities
<code>/usr/lib/cron/at.deny</code>	names of users, one per line, who are denied access to the at and batch utilities

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

at	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWcsu
	CSI	Not enabled

batch	ATTRIBUTE TYPE	ATTRIBUTE VALUE
	Availability	SUNWesu
	CSI	Enabled

SEE ALSO `auths(1)`, `crontab(1)`, `csh(1)`, `date(1)`, `ksh(1)`, `sh(1)`, `touch(1)`, `ulimit(1)`, `umask(1)`, `cron(1M)`, `getdate(3C)`, `auth_attr(4)`, `attributes(5)`, `environ(5)`

NOTES Regardless of queue used, `cron(1M)` has a limit of 100 jobs in execution at any time.

There can be delays in `cron` at job execution. In some cases, these delays can compound to the point that `cron` job processing appears to be hung. All jobs will be executed eventually. When the delays are excessive, the only workaround is to kill and restart `cron`.

atq(1)

NAME	atq – display the jobs queued to run at specified times				
SYNOPSIS	atq [-c] [-n] [<i>username...</i>]				
DESCRIPTION	<p>The <code>atq</code> utility displays the <code>at</code> jobs queued up for the current user. <code>at(1)</code> is a utility that allows users to execute commands at a later date. If invoked by a user with the <code>solaris.jobs.admin</code> authorization, <code>atq</code> will display all jobs in the queue.</p> <p>If no options are given, the jobs are displayed in chronological order of execution.</p> <p>When an authorized user invokes <code>atq</code> without specifying <i>username</i>, the entire queue is displayed; when a <i>username</i> is specified, only those jobs belonging to the named user are displayed.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-c Displays the queued jobs in the order they were created (that is, the time that the <code>at</code> command was given).-n Displays only the total number of jobs currently in the queue.				
FILES	<code>/var/spool/cron/atjobs</code> spool area for <code>at</code> jobs.

NAME	atrm – remove jobs spooled by at or batch				
SYNOPSIS	atrm [-afi] [[job #] [user...]]				
DESCRIPTION	<p>The atrm utility removes delayed-execution jobs that were created with the at(1) command, but have not yet executed. The list of these jobs and associated job numbers can be displayed by using atq(1).</p> <p>atrm removes each job-number you specify, and/or all jobs belonging to the user you specify, provided that you own the indicated jobs.</p> <p>You can only remove jobs belonging to other users if you have solaris.jobs.admin privileges.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a All. Removes all unexecuted jobs that were created by the current user. If invoked by the privileged user, the entire queue will be flushed. -f Force. All information regarding the removal of the specified jobs is suppressed. -i Interactive. atrm asks if a job should be removed. If you respond with a y, the job will be removed. 				
FILES	/var/spool/cron/atjobs spool area for at jobs

audioconvert(1)

NAME	audioconvert – convert audio file formats
SYNOPSIS	audioconvert [-pF] [-f <i>outfmt</i>] [-o <i>outfile</i>] [[-i <i>infmt</i>] [<i>file...</i>]] ...
DESCRIPTION	<p>audioconvert converts audio data between a set of supported audio encodings and file formats. It can be used to compress and decompress audio data, to add audio file headers to raw audio data files, and to convert between standard data encodings, such as -law and linear PCM.</p> <p>If no filenames are present, audioconvert reads the data from the standard input stream and writes an audio file to the standard output. Otherwise, input files are processed in order, concatenated, and written to the output file.</p> <p>Input files are expected to contain audio file headers that identify the audio data format. If the audio data does not contain a recognizable header, the format must be specified with the -i option, using the <i>rate</i>, <i>encoding</i>, and <i>channels</i> keywords to identify the input data format.</p> <p>The output file format is derived by updating the format of the first input file with the format options in the -f specification. If -p is not specified, all subsequent input files are converted to this resulting format and concatenated together. The output file will contain an audio file header, unless <i>format=raw</i> is specified in the output format options.</p> <p>Input files may be converted in place by using the -p option. When -p is in effect, the format of each input file is modified according to the -f option to determine the output format. The existing files are then overwritten with the converted data.</p> <p>The <i>file(1)</i> command decodes and prints the audio data format of Sun audio files.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-p <i>In Place</i>: The input files are individually converted to the format specified by the -f option and rewritten. If a target file is a symbolic link, the underlying file will be rewritten. The -o option may not be specified with -p.-F <i>Force</i>: This option forces audioconvert to ignore any file header for input files whose format is specified by the -i option. If -F is not specified, audioconvert ignores the -i option for input files that contain valid audio file headers.-f <i>outfmt</i> <i>Output Format</i>: This option is used to specify the file format and data encoding of the output file. Defaults for unspecified fields are derived from the input file format. Valid keywords and values are listed in the next section.-o <i>outfile</i> <i>Output File</i>: All input files are concatenated, converted to the output format, and written to the named output file. If -o and -p are not specified, the concatenated output is written to the standard output. The -p option may not be specified with -o.

audioconvert(1)

	used for telephone quality speech in Europe.
<code>linear8, linear16, linear32</code>	Linear Pulse Code Modulation (PCM) encoding. The name identifies the number of bits of precision. <code>linear16</code> is typically used for high quality audio data.
<code>pcm</code>	Same as <code>linear16</code> .
<code>g721</code>	CCITT G.721 compression format. This encoding uses Adaptive Delta Pulse Code Modulation (ADPCM) with 4-bit precision. It is primarily used for compressing -law voice data (achieving a 2:1 compression ratio).
<code>g723</code>	CCITT G.723 compression format. This encoding uses Adaptive Delta Pulse Code Modulation (ADPCM) with 3-bit precision. It is primarily used for compressing -law voice data (achieving an 8:3 compression ratio). The audio quality is similar to G.721, but may result in lower quality when used for non-speech data.

The following encoding values are also accepted as shorthand to set the sample rate, channels, and encoding:

`voice` Equivalent to
 `encoding=ulaw, rate=8k, channels=mono.`

<code>cd</code>	Equivalent to <code>encoding=linear16,rate=44.1k,channels=stereo.</code>
<code>dat</code>	Equivalent to <code>encoding=linear16,rate=48k,channels=stereo.</code>
<code>format</code>	This option specifies the audio file format. Valid formats are:
<code>sun</code>	Sun compatible file format (the default).
<code>raw</code>	Use this format when reading or writing raw audio data (with no audio header), or in conjunction with an <code>offset</code> to import a foreign audio file format.
<code>offset</code>	(<i>-i only</i>) Specify a byte offset to locate the start of the audio data. This option may be used to import audio data that contains an unrecognized file header.

USAGE See `largefile(5)` for the description of the behavior of `audioconvert` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Examples of the `audioconvert` command.

Record voice data and compress it before storing it to a file:

```
example% audiorecord | audioconvert -f g721 > mydata.au
```

Concatenate two Sun format audio files, regardless of their data format, and output an 8-bit -law, 16 kHz, mono file:

```
example% audioconvert -f ulaw,rate=16k,mono -o outfile.au infile1 infile2
```

Convert a directory containing raw voice data files, in place, to Sun format (adds a file header to each file):

```
example% audioconvert -p -i voice -f sun *.au
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWaudio

SEE ALSO `audioplay(1)`, `audiorecord(1)`, `file(1)`, `attributes(5)`, `largefile(5)`

NOTES The algorithm used for converting multi-channel data to mono is implemented by simply summing the channels together. If the input data is perfectly in phase (as would be the case if a mono file is converted to stereo and back to mono), the resulting data may contain some distortion.

audioplay(1)

NAME	audioplay – play audio files
SYNOPSIS	audioplay [-iV] [-v <i>vol</i>] [-b <i>bal</i>] [-p <i>speaker</i> <i>headphone</i> <i>line</i>] [-d <i>dev</i>] [<i>file...</i>]
DESCRIPTION	<p>The <code>audioplay</code> utility copies the named audio files (or the standard input if no filenames are present) to the audio device. If no input file is specified and standard input is a tty, the port, volume, and balance settings specified on the command line will be applied and the program will exit.</p> <p>The input files must contain a valid audio file header. The encoding information in this header is matched against the capabilities of the audio device and, if the data formats are incompatible, an error message is printed and the file is skipped. Compressed ADPCM (G.721) monaural audio data is automatically uncompressed before playing.</p> <p>Minor deviations in sampling frequency (that is, less than 1%) are ordinarily ignored. This allows, for instance, data sampled at 8012 Hz to be played on an audio device that only supports 8000 Hz. If the <code>-v</code> option is present, such deviations are flagged with warning messages.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-i <i>Immediate</i>: If the audio device is unavailable (that is, another process currently has write access), <code>audioplay</code> ordinarily waits until it can obtain access to the device. When the <code>-i</code> option is present, <code>audioplay</code> prints an error message and exits immediately if the device is busy.-V <i>Verbose</i>: Prints messages on the standard error when waiting for access to the audio device or when sample rate deviations are detected.-v <i>vol</i> <i>Volume</i>: The output volume is set to the specified value before playing begins, and is reset to its previous level when <code>audioplay</code> exits. The <i>vol</i> argument is an integer value between 0 and 100, inclusive. If this argument is not specified, the output volume remains at the level most recently set by any process.-b <i>bal</i> <i>Balance</i>: The output balance is set to the specified value before playing begins, and is reset to its previous level when <code>audioplay</code> exits. The <i>bal</i> argument is an integer value between -100 and 100, inclusive. A value of -100 indicates left balance, 0 middle, and 100 right. If this argument is not specified, the output balance remains at the level most recently set by any process.-p <i>speaker</i> <i>headphone</i> <i>line</i> <i>Output Port</i>: Selects the built-in <i>speaker</i> (the default), <i>headphone</i> jack, or <i>line</i> out as the destination of the audio output signal. If this argument is not specified, the output port will remain unchanged. <i>Please note</i>: Not all audio adapters support all of the output ports. If the named port does not exist, an appropriate substitute will be used.

`-d dev`

Device: The *dev* argument specifies an alternate audio device to which output should be directed. If the `-d` option is not specified, the `AUDIODEV` environment variable is consulted (see below). Otherwise, `/dev/audio` is used as the default audio device.

`-\?`

Help: Prints a command line usage message.

OPERANDS *file* *File Specification:* Audio files named on the command line are played sequentially. If no filenames are present, the standard input stream (if it is not a tty) is played (it, too, must contain an audio file header). The special filename `'-'` may be used to read the standard input stream instead of a file. If a relative path name is supplied, the `AUDIOPATH` environment variable is consulted (see below).

USAGE See `largefile(5)` for the description of the behavior of `audioplay` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES

`AUDIODEV` The full path name of the audio device to write to, if no `-d` argument is supplied. If the `AUDIODEV` variable is not set, `/dev/audio` is used.

`AUDIOPATH` A colon-separated list of directories in which to search for audio files whose names are given by relative pathnames. The current directory (`."`) may be specified explicitly in the search path. If the `AUDIOPATH` variable is not set, only the current directory will be searched.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	SPARC, IA
Availability	SUNWauda
Interface Stability	Evolving

SEE ALSO `audioconvert(1)`, `audiorecord(1)`, `mixerctl(1)`, `attributes(5)`, `largefile(5)`, `usb_ac(7D)`, `audio(7I)`, `mixer(7I)`

BUGS `audioplay` currently supports a limited set of audio format conversions. If the audio file is not in a format supported by the audio device, it must first be converted. For example, to convert to voice format on the fly, use the command:

```
example% audioconvert -f voice myfile | audioplay
```

The format conversion will not always be able to keep up with the audio output. If this is the case, you should convert to a temporary file before playing the data.

audiorecord(1)

NAME	audiorecord – record an audio file
SYNOPSIS	audiorecord [-af] [-v <i>vol</i>] [-b <i>bal</i>] [-m <i>monvol</i>] [-p mic line internal-cd] [-c <i>channels</i>] [-s <i>rate</i>] [-e <i>encoding</i>] [-t <i>time</i>] [-i <i>info</i>] [-d <i>dev</i>] [<i>file</i>]
DESCRIPTION	<p>The <code>audiorecord</code> utility copies audio data from the audio device to a named audio file (or the standard output if no filename is present). If no output file is specified and standard output is a tty, the volume, balance, monitor volume, port, and audio format settings specified on the command line will be applied and the program will exit.</p> <p>By default, monaural audio data is recorded at 8 kHz and encoded in -law format. If the audio device supports additional configurations, the -c, -s, and -e options may be used to specify the data format. The output file is prefixed by an audio file header that identifies the format of the data encoded in the file.</p> <p>Recording begins immediately and continues until a SIGINT signal (for example, Ctrl-C) is received. If the -t option is specified, <code>audiorecord</code> stops when the specified quantity of data has been recorded.</p> <p>If the audio device is unavailable (that is, another process currently has read access), <code>audiorecord</code> prints an error message and exits immediately.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a <i>Append</i>: Appends the data on the end of the named audio file. The audio device must support the audio data format of the existing file.-f <i>Force</i>: When the -a flag is specified, the sample rate of the audio device must match the sample rate at which the original file was recorded. If the -f flag is also specified, sample rate differences are ignored, with a warning message printed on the standard error.-v <i>vol</i> <i>Volume</i>: The recording gain is set to the specified value before recording begins, and is reset to its previous level when <code>audiorecord</code> exits. The <i>vol</i> argument is an integer value between 0 and 100, inclusive. If this argument is not specified, the input volume will remain at the level most recently set by any process.-b <i>bal</i> <i>Balance</i>: The recording balance is set to the specified value before recording begins, and is reset to its previous level when <code>audiorecord</code> exits. The <i>bal</i> argument is an integer value between -100 and 100, inclusive. A value of -100 indicates left balance, 0 middle, and 100 right. If this argument is not specified, the input balance will remain at the level most recently set by any process.-m <i>monvol</i> <i>Monitor Volume</i>: The input monitor volume is set to the specified value before recording begins, and is reset to its previous level when <code>audiorecord</code> exits. The <i>monval</i> argument is an integer value between 0 and 100, inclusive. A non-zero value

allows a directly connected input source to be heard on the output speaker while recording is in-progress. If this argument is not specified, the monitor volume will remain at the level most recently set by any process.

-p *mic | line | internal-cd*

Input Port: Selects the *mic*, *line*, or *internal-cd* input as the source of the audio output signal. If this argument is not specified, the input port will remain unchanged. *Please note:* Some systems will not support all possible input ports. If the named port does not exist, this option is ignored.

-c *channels*

Channels: Specifies the number of audio channels (1 or 2). The value may be specified as an integer or as the string *mono* or *stereo*. The default value is *mono*.

-s *rate*

Sample Rate: Specifies the sample rate, in samples per second. If a number is followed by the letter *k*, it is multiplied by 1000 (for example, *44.1k* = 44100). The default sample rate is 8 kHz.

-e *encoding*

Encoding: Specifies the audio data encoding. This value may be one of *ulaw*, *alaw*, or *linear*. The default encoding is *ulaw*.

-t *time*

Time: The *time* argument specifies the maximum length of time to record. Time can be specified as a floating-point value, indicating the number of seconds, or in the form: *hh:mm:ss.dd*, where the hour and minute specifications are optional.

-i *info*

Information: The 'information' field of the output file header is set to the string specified by the *info* argument. This option cannot be specified in conjunction with the *-a* argument.

-d *dev*

Device: The *dev* argument specifies an alternate audio device from which input should be taken. If the *-d* option is not specified, the `AUDIODEV` environment variable is consulted (see below). Otherwise, `/dev/audio` is used as the default audio device.

-\?

Help: Prints a command line usage message.

OPERANDS

file *File Specification:* The named audio file is rewritten (or appended). If no filename is present (and standard output is not a tty), or if the special filename *'-'* is specified, output is directed to the the standard output.

USAGE

See `largefile(5)` for the description of the behavior of `audiorecord` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES

`AUDIODEV` The full path name of the audio device to record from, if no *-d* argument is supplied. If the `AUDIODEV` variable is not set, `/dev/audio` is used.

NAME	auths – print authorizations granted to a user				
SYNOPSIS	auths [<i>user</i> ...]				
DESCRIPTION	<p>The auths command prints on standard output the authorizations that you or the optionally-specified user or role have been granted. Authorizations are rights that are checked by certain privileged programs to determine whether a user may execute restricted functionality.</p> <p>Each user may have zero or more authorizations. Authorizations are represented by fully-qualified names, which identify the organization that created the authorization and the functionality that it controls. Following the Java convention, the hierarchical components of an authorization are separated by dots (.), starting with the reverse order Internet domain name of the creating organization, and ending with the specific function within a class of authorizations.</p> <p>An asterisk (*) indicates all authorizations in a class.</p> <p>A user's authorizations are looked up in <code>user_attr(4)</code>. Authorizations may be specified directly in <code>user_attr(4)</code> or indirectly through <code>prof_attr(4)</code>.</p>				
EXAMPLES	<p>EXAMPLE 1 Sample output</p> <p>The auths output has the following form:</p> <pre>example% auths tester01 tester02 tester01 : com.sun.system.date, com.sun.jobs.admin tester02 : com.sun.system.* example%</pre>				
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>1 An error occurred.</p>				
FILES	<p>/etc/user_attr</p> <p>/etc/security/auth_attr</p> <p>/etc/security/prof_attr</p>

awk(1)

NAME	awk – pattern scanning and processing language
SYNOPSIS	<pre> /usr/bin/awk [-f <i>progfile</i>] [-F <i>c</i>] [<i>' prog '</i>] [<i>parameters</i>] [<i>filename...</i>] /usr/xpg4/bin/awk [-F <i>ERE</i>] [-v <i>assignment...</i>] '<i>program</i>' -f <i>progfile...</i> [<i>argument...</i>] </pre>
DESCRIPTION	<p>The /usr/xpg4/bin/awk utility is described on the nawk(1) manual page.</p> <p>The /usr/bin/awk utility scans each input <i>filename</i> for lines that match any of a set of patterns specified in <i>prog</i>. The <i>prog</i> string must be enclosed in single quotes (<code>'</code>) to protect it from the shell. For each pattern in <i>prog</i> there may be an associated action performed when a line of a <i>filename</i> matches the pattern. The set of pattern-action statements may appear literally as <i>prog</i> or in a file specified with the <code>-f progfile</code> option. Input files are read in order; if there are no files, the standard input is read. The file name <code>'-'</code> means the standard input.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-f progfile</code> awk uses the set of patterns it reads from <i>progfile</i>. <code>-Fc</code> Uses the character <i>c</i> as the field separator (FS) character. See the discussion of FS below.
USAGE	
Input Lines	<p>Each input line is matched against the pattern portion of every pattern-action statement; the associated action is performed for each matched pattern. Any <i>filename</i> of the form <i>var=value</i> is treated as an assignment, not a filename, and is executed at the time it would have been opened if it were a filename. <i>Variables</i> assigned in this manner are not available inside a BEGIN rule, and are assigned after previously specified files have been read.</p> <p>An input line is normally made up of fields separated by white spaces. (This default can be changed by using the FS built-in variable or the <code>-Fc</code> option.) The default is to ignore leading blanks and to separate fields by blanks and/or tab characters. However, if FS is assigned a value that does not include any of the white spaces, then leading blanks are not ignored. The fields are denoted \$1, \$2, . . . ; \$0 refers to the entire line.</p>
Pattern-action Statements	<p>A pattern-action statement has the form:</p> <pre> <i>pattern</i> { <i>action</i> } </pre> <p>Either pattern or action may be omitted. If there is no action, the matching line is printed. If there is no pattern, the action is performed on every input line. Pattern-action statements are separated by newlines or semicolons.</p> <p>Patterns are arbitrary Boolean combinations (<code>!</code>, <code> </code>, <code>&&</code>, and parentheses) of relational expressions and regular expressions. A relational expression is one of the following:</p>

```
expression relop expression
expression matchop regular_expression
```

where a *relop* is any of the six relational operators in C, and a *matchop* is either ~ (contains) or !~ (does not contain). An *expression* is an arithmetic expression, a relational expression, the special expression

```
var in array
```

or a Boolean combination of these.

Regular expressions are as in `egrep(1)`. In patterns they must be surrounded by slashes. Isolated regular expressions in a pattern apply to the entire line. Regular expressions may also occur in relational expressions. A pattern may consist of two patterns separated by a comma; in this case, the action is performed for all lines between the occurrence of the first pattern to the occurrence of the second pattern.

The special patterns BEGIN and END may be used to capture control before the first input line has been read and after the last input line has been read respectively. These keywords do not combine with any other patterns.

Built-in Variables

Built-in variables include:

FILENAME	name of the current input file
FS	input field separator regular expression (default blank and tab)
NF	number of fields in the current record
NR	ordinal number of the current record
OFMT	output format for numbers (default % . 6g)
OFS	output field separator (default blank)
ORS	output record separator (default new-line)
RS	input record separator (default new-line)

An action is a sequence of statements. A statement may be one of the following:

```
if ( expression ) statement [ else statement ]
while ( expression ) statement
do statement while ( expression )
for ( expression ; expression ; expression ) statement
for ( var in array ) statement
break
continue
{ [ statement ] . . . }
expression      # commonly variable = expression
print [ expression-list ] [ >expression ]
printf format [ ,expression-list ] [ >expression ]
next           # skip remaining patterns on this input line
exit [expr]    # skip the rest of the input; exit status is expr
```

awk(1)

Statements are terminated by semicolons, newlines, or right braces. An empty expression-list stands for the whole input line. Expressions take on string or numeric values as appropriate, and are built using the operators `+`, `-`, `*`, `/`, `%`, `^` and concatenation (indicated by a blank). The operators `++`, `--`, `+=`, `-=`, `*=`, `/=`, `%=`, `^=`, `>`, `>=`, `<`, `<=`, `==`, `!=`, and `?:` are also available in expressions. Variables may be scalars, array elements (denoted `x[i]`), or fields. Variables are initialized to the null string or zero. Array subscripts may be any string, not necessarily numeric; this allows for a form of associative memory. String constants are quoted ("`"`), with the usual C escapes recognized within.

The `print` statement prints its arguments on the standard output, or on a file if `>expression` is present, or on a pipe if `|cmd'` is present. The output resulted from the `print` statement is terminated by the output record separator with each argument separated by the current output field separator. The `printf` statement formats its expression list according to the format (see `printf(3C)`).

Built-in Functions

The arithmetic functions are as follows:

<code>cos(x)</code>	Return cosine of x , where x is in radians.
<code>sin(x)</code>	Return sine of x , where x is in radians.
<code>exp(x)</code>	Return the exponential function of x .
<code>log(x)</code>	Return the natural logarithm of x .
<code>sqrt(x)</code>	Return the square root of x .
<code>int(x)</code>	Truncate its argument to an integer. It will be truncated toward 0 when $x > 0$.

The string functions are as follows:

<code>index(s, t)</code>	Return the position in string s where string t first occurs, or 0 if it does not occur at all.
<code>int(s)</code>	truncates s to an integer value. If s is not specified, <code>\$0</code> is used.
<code>length(s)</code>	Return the length of its argument taken as a string, or of the whole line if there is no argument.
<code>match(s, re)</code>	Return the position in string s where the regular expression re occurs, or 0 if it does not occur at all.
<code>split(s, a, fs)</code>	Split the string s into array elements $a[1]$, $a[2]$, \dots , $a[n]$, and returns n . The separation is done with the regular expression fs or with the field separator <code>FS</code> if fs is not given.

```
sprintf(fmt, expr, expr, ...)
```

Format the expressions according to the printf(3C) format given by *fmt* and returns the resulting string.

```
substr(s, m, n)
```

returns the *n*-character substring of *s* that begins at position *m*.

The input/output function is as follows:

```
getline          Set $0 to the next input record from the current input file.
                 getline returns 1 for successful input, 0 for end of file, and -1
                 for an error.
```

Large File Behavior

See largefile(5) for the description of the behavior of awk when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

EXAMPLES

EXAMPLE 1 Print lines longer than 72 characters:

```
length > 72
```

EXAMPLE 2 Print first two fields in opposite order:

```
{ print $2, $1 }
```

EXAMPLE 3 Same, with input fields separated by comma and/or blanks and tabs:

```
BEGIN { FS = ", [ \t]*| [ \t]+" }
       { print $2, $1 }
```

EXAMPLE 4 Add up first column, print sum and average:

```
       { s += $1 }
END   { print "sum is", s, " average is", s/NR }
```

EXAMPLE 5 Printing fields in reverse order

```
{ for (i = NF; i > 0; --i) print $i }
```

EXAMPLE 6 Print all lines between start/stop pairs:

```
/start/, /stop/
```

EXAMPLE 7 Print all lines whose first field is different from the previous one:

```
$1 != prev { print; prev = $1 }
```

EXAMPLE 8 Print a file, filling in page numbers starting at 5:

```
/Page/    { $2 = n++; }
          { print }
```

awk(1)

EXAMPLE 8 Print a file, filling in page numbers starting at 5: (Continued)

EXAMPLE 9 Print a file and number its pages starting at 5:

Assuming this program is in a file named `prog`, the following command line prints the file `input` numbering its pages starting at 5:

```
awk f prog n=5 input
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `awk`: `LC_CTYPE` and `LC_MESSAGES`.

`LC_NUMERIC` Determine the radix character used when interpreting numeric input, performing conversions between numeric and string values and formatting numeric output. Regardless of locale, the period character (the decimal-point character of the POSIX locale) is the decimal-point character recognized in processing `awk` programs (including assignments in command-line arguments).

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/awk`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled

`/usr/xpg4/bin/awk`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled

SEE ALSO

`egrep(1)`, `grep(1)`, `nawk(1)`, `sed(1)`, `printf(3C)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `XPG4(5)`

NOTES

Input white space is not preserved on output if fields are involved.

There are no explicit conversions between numbers and strings. To force an expression to be treated as a number add 0 to it; to force it to be treated as a string concatenate the null string (" ") to it.

banner(1)

NAME banner – make posters

SYNOPSIS **banner** *strings*

DESCRIPTION banner prints its arguments (each up to 10 characters long) in large letters on the standard output.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO `echo(1)`, `attributes(5)`

basename(1)

NAME basename, dirname – deliver portions of path names

SYNOPSIS /usr/bin/basename *string* [*suffix*]
 /usr/xpg4/bin/basename *string* [*suffix*]
dirname *string*

DESCRIPTION The basename utility deletes any prefix ending in / and the *suffix* (if present in *string*) from *string*, and prints the result on the standard output. It is normally used inside substitution marks (` `) within shell procedures.

/usr/bin/basename The *suffix* is a pattern defined on the expr(1) manual page.

/usr/xpg4/bin/basename The *suffix* is a string with no special significance attached to any of the characters it contains.

The **dirname** utility delivers all but the last level of the path name in *string*.

EXAMPLES **EXAMPLE 1** Examples of the basename command.

The following example, invoked with the argument /home/sms/personal/mail sets the environment variable NAME to the file named mail and the environment variable MYMAILPATH to the string /home/sms/personal:

```
example% NAME=`basename $HOME/personal/mail`
example% MYMAILPATH=`dirname $HOME/personal/mail`
```

This shell procedure, invoked with the argument /usr/src/bin/cat.c, compiles the named file and moves the output to cat in the current directory:

```
example% cc $1
example% mv a.out `basename $1 .c`
```

ENVIRONMENT VARIABLES See environ(5) for descriptions of the following environment variables that affect the execution of basename and dirname: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

/usr/bin/basename

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

basename(1)

/usr/xpg4/bin/basename

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4

SEE ALSO `expr(1)`, `attributes(5)`, `environ(5)`, `XPG4(5)`

basename(1B)

NAME | basename – display portions of pathnames

SYNOPSIS | `/usr/ucb/basename string [suffix]`

DESCRIPTION | The basename utility deletes any prefix ending in '/' and the *suffix*, if present in *string*. It directs the result to the standard output, and is normally used inside substitution marks (` `) within shell procedures. The *suffix* is a string with no special significance attached to any of the characters it contains.

EXAMPLES | **EXAMPLE 1** Using the basename command.

This shell procedure invoked with the argument `/usr/src/bin/cat.c` compiles the named file and moves the output to `cat` in the current directory:

```
example% cc $1
example% mv a.out `basename $1 .c`
```

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO | sh(1), attributes(5)

NAME	bc – arbitrary precision arithmetic language
SYNOPSIS	bc [-c] [-l] [file...]
DESCRIPTION	The bc utility implements an arbitrary precision calculator. It takes input from any files given, then reads from the standard input. If the standard input and standard output to bc are attached to a terminal, the invocation of bc is <i>interactive</i> , causing behavioral constraints described in the following sections. bc processes a language that resembles C and is a preprocessor for the desk calculator program dc , which it invokes automatically unless the -c option is specified. In this case the dc input is sent to the standard output instead.
USAGE	The syntax for bc programs is as follows: <i>L</i> means a letter a–z, <i>E</i> means an expression: a (mathematical or logical) value, an operand that takes a value, or a combination of operands and operators that evaluates to a value, <i>S</i> means a statement.
Comments	Enclosed in /* and */ .
Names (Operands)	Simple variables: <i>L</i> . Array elements: <i>L [E]</i> (up to BC_DIM_MAX dimensions). The words ibase , obase (limited to BC_BASE_MAX), and scale (limited to BC_SCALE_MAX).
Other Operands	Arbitrarily long numbers with optional sign and decimal point. Strings of fewer than BC_STRING_MAX characters, between double quotes ("). (<i>E</i>) sqrt (<i>E</i>) Square root length (<i>E</i>) Number of significant decimal digits. scale (<i>E</i>) Number of digits right of decimal point. <i>L</i> (<i>E</i> , ... , <i>E</i>)
Operators	+ - * / % ^ (% is remainder; ^ is power) ++ -- (prefix and postfix; apply to names) == <= >= != < > = += -= *= /= %= ^=
Statements	<i>E</i> { <i>S</i> ; ... ; <i>S</i> } if (<i>E</i>) <i>S</i>

bc(1)

	<pre>while (E) S for (E ; E ; E) S null statement break quit .string</pre>
Function Definitions	<pre>define L (L , ... , L) { auto L , ... , L S ; ... S return (E) }</pre>
Functions in -1 Math Library	<pre>s (x) sine c (x) cosine e (x) exponential l (x) log a (x) arctangent j (n , x) Bessel function</pre>
	<p>All function arguments are passed by value.</p> <p>The value of a statement that is an expression is printed unless the main operator is an assignment. Either semicolons or new-lines may separate statements. Assignment to <code>scale</code> influences the number of digits to be retained on arithmetic operations in the manner of <code>dc</code>. Assignments to <code>ibase</code> or <code>obase</code> set the input and output number radix respectively.</p> <p>The same letter may be used as an array, a function, and a simple variable simultaneously. All variables are global to the program. <code>auto</code> variables are stacked during function calls. When using arrays as function arguments or defining them as automatic variables, empty square brackets must follow the array name.</p>
OPTIONS	<p>The following operands are supported:</p> <ul style="list-style-type: none">-c Compile only. The output is <code>dc</code> commands that are sent to the standard output.-1 Define the math functions and initialize <code>scale</code> to 20, instead of the default zero.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"><i>file</i> A pathname of a text file containing <code>bc</code> program statements. After all cases of <i>file</i> have been read, <code>bc</code> will read the standard input.

EXAMPLES | **EXAMPLE 1** Setting the precision of a variable

In the shell, the following assigns an approximation of the first ten digits of n to the variable x :

```
x=$(printf "%s\n" 'scale = 10; 104348/33215' | bc)
```

EXAMPLE 2 Defining a computing function

Defines a function to compute an approximate value of the exponential function:

```
scale = 20
define e(x){
    auto a, b, c, i, s
    a = 1
    b = 1
    s = 1
    for(i=1; 1==1; i++){
        a = a*x
        b = b*i
        c = a/b
        if(c == 0) return(s)
        s = s+c
    }
}
```

EXAMPLE 3 Printing the approximate values of the function

Prints approximate values of the exponential function of the first ten integers:

```
for(i=1; i<=10; i++) e(i)
```

or

```
for (i = 1; i <= 10; ++i) {          e(i) }
```

**ENVIRONMENT
VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `bc`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0	All input files were processed successfully.
unspecified	An error occurred.

FILES

<code>/usr/lib/lib.b</code>	mathematical library
<code>/usr/include/limits.h</code>	to define <code>BC_</code> parameters

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

bc(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO dc(1), awk(1), attributes(5)

NOTES The bc command does not recognize the logical operators && and | |.
The for statement must have all three expressions (*E*'s).

NAME	bdiff – big diff						
SYNOPSIS	bdiff <i>filename1 filename2</i> [<i>n</i>] [-s]						
DESCRIPTION	<p>bdiff is used in a manner analogous to diff to find which lines in <i>filename1</i> and <i>filename2</i> must be changed to bring the files into agreement. Its purpose is to allow processing of files too large for diff. If <i>filename1</i> (<i>filename2</i>) is -, the standard input is read.</p> <p>bdiff ignores lines common to the beginning of both files, splits the remainder of each file into <i>n</i>-line segments, and invokes diff on corresponding segments. If both optional arguments are specified, they must appear in the order indicated above.</p> <p>The output of bdiff is exactly that of diff, with line numbers adjusted to account for the segmenting of the files (that is, to make it look as if the files had been processed whole). Note: Because of the segmenting of the files, bdiff does not necessarily find a smallest sufficient set of file differences.</p>						
OPTIONS	<p><i>n</i> The number of line segments. The value of <i>n</i> is 3500 by default. If the optional third argument is given and it is numeric, it is used as the value for <i>n</i>. This is useful in those cases in which 3500-line segments are too large for diff, causing it to fail.</p> <p>-s Specifies that no diagnostics are to be printed by bdiff (silent option). Note: However, this does not suppress possible diagnostic messages from diff, which bdiff calls.</p>						
USAGE	See largefile(5) for the description of the behavior of bdiff when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).

bfs(1)

NAME	bfs – big file scanner
SYNOPSIS	<code>/usr/bin/bfs [-] filename</code>
DESCRIPTION	<p>The <code>bfs</code> command is (almost) like <code>ed(1)</code> except that it is read-only and processes much larger files. Files can be up to 1024K bytes and 32K lines, with up to 512 characters, including new-line, per line (255 for 16-bit machines). <code>bfs</code> is usually more efficient than <code>ed(1)</code> for scanning a file, since the file is not copied to a buffer. It is most useful for identifying sections of a large file where <code>csplit(1)</code> can be used to divide it into more manageable pieces for editing.</p> <p>Normally, the size of the file being scanned is printed, as is the size of any file written with the <code>w</code> (write) command. The optional <code>-</code> suppresses printing of sizes. Input is prompted with <code>*</code> if <code>P</code> and a carriage return are typed, as in <code>ed(1)</code>. Prompting can be turned off again by inputting another <code>P</code> and carriage return. Note that messages are given in response to errors if prompting is turned on.</p> <p>All address expressions described under <code>ed(1)</code> are supported. In addition, regular expressions may be surrounded with two symbols besides <code>/</code> and <code>?</code>:</p> <ul style="list-style-type: none"><code>></code> indicates downward search without wrap-around, and<code><</code> indicates upward search without wrap-around. <p>There is a slight difference in mark names; that is, only the letters <code>a</code> through <code>z</code> may be used, and all 26 marks are remembered.</p>
bfs Commands	<p>The <code>e</code>, <code>g</code>, <code>v</code>, <code>k</code>, <code>p</code>, <code>q</code>, <code>w</code>, <code>=</code>, <code>!</code>, and null commands operate as described under <code>ed(1)</code>. Commands such as <code>—</code>, <code>+++</code>, <code>+++</code>, <code>-12</code>, and <code>+4p</code> are accepted. Note that <code>1, 10p</code> and <code>1, 10</code> will both print the first ten lines. The <code>f</code> command only prints the name of the file being scanned; there is no <i>remembered</i> file name. The <code>w</code> command is independent of output diversion, truncation, or crunching (see the <code>xo</code>, <code>xt</code>, and <code>xc</code> commands, below). The following additional commands are available:</p> <p><code>xf file</code> Further commands are taken from the named <code>file</code>. When an end-of-file is reached, an interrupt signal is received or an error occurs, reading resumes with the file containing the <code>xf</code>. The <code>xf</code> commands may be nested to a depth of 10.</p> <p><code>xn</code> List the marks currently in use (marks are set by the <code>k</code> command).</p> <p><code>xo [file]</code> Further output from the <code>p</code> and null commands is diverted to the named <code>file</code>, which, if necessary, is created mode 666 (readable and writable by everyone), unless your <code>umask</code> setting (see <code>umask(1)</code>) dictates otherwise. If <code>file</code> is missing, output is diverted to the standard output. Note that each diversion causes truncation or creation of the file.</p>

`: label`

This positions a *label* in a command file. The *label* is terminated by new-line, and blanks between the `:` (colon) and the start of the *label* are ignored. This command may also be used to insert comments into a command file, since labels need not be referenced.

`(, , .)xb/regular expression/label`

A jump (either upward or downward) is made to *label* if the command succeeds. It fails under any of the following conditions:

1. Either address is not between 1 and \$.
2. The second address is less than the first.
3. The regular expression does not match at least one line in the specified range, including the first and last lines.

On success, `.` (dot) is set to the line matched and a jump is made to *label*. This command is the only one that does not issue an error message on bad addresses, so it may be used to test whether addresses are bad before other commands are executed. Note that the command, `xb/^/label`, is an unconditional jump.

The `xb` command is allowed only if it is read from someplace other than a terminal. If it is read from a pipe, only a downward jump is possible.

`x t number`

Output from the `p` and null commands is truncated to, at most, *number* characters. The initial number is 255.

`xv[digit] [spaces] [value]`

The variable name is the specified *digit* following the `xv`. The commands `xv5100` or `xv5 100` both assign the value 100 to the variable 5. The command `xv61,100p` assigns the value 1,100p to the variable 6. To reference a variable, put a `%` in front of the variable name. For example, using the above assignments for variables 5 and 6:

```
1,%5p
1,%5
%6
```

will all print the first 100 lines.

```
g/%5/p
```

would globally search for the characters 100 and print each line containing a match. To escape the special meaning of `%`, a `\` must precede it.

```
g/".*\%[cds]/p
```

bfs(1)

could be used to match and list %c, %d, or %s formats (for example, "printf"-like statements) of characters, decimal integers, or strings. Another feature of the xv command is that the first line of output from a UNIX system command can be stored into a variable. The only requirement is that the first character of *value* be an !. For example:

```
.w junk
xv5!cat junk
!rm junk
!echo "%5"
xv6!expr %6 + 1
```

would put the current line into variable 35, print it, and increment the variable 36 by one. To escape the special meaning of ! as the first character of *value*, precede it with a \.

```
xv7\!date
```

stores the value !date into variable 7.

xbz label

xbn label

These two commands will test the last saved *return code* from the execution of a UNIX system command (!command) or nonzero value, respectively, to the specified label. The two examples below both search for the next five lines containing the string *size*:

Example 1:

```
xv55
: 1
/size/
xv5!expr %5 - 1
!if 0%5 != 0 exit 2
xbn 1
```

Example 2:

```
xv45
: 1
/size/
xv4!expr %4 - 1
!if 0%4 = 0 exit 2
xbz 1
```

xc [switch]

If *switch* is 1, output from the p and null commands is crunched; if *switch* is 0, it is not. Without an argument, *xc* reverses *switch*. Initially, *switch* is set for no crunching. Crunched output has strings of tabs and blanks reduced to one blank and blank lines suppressed.

OPERANDS The following operand is supported:

bfs(1)

filename Any file up to 1024K bytes and 32K lines, with up to 512 characters, including new-line, per line (255 for 16-bit machines). *filename* can be a section of a larger file which has been divided into more manageable sections for editing by the use of `csplit(1)`.

EXIT STATUS The following exit values are returned:

0 Successful completion without any file or command errors.
>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO `csplit(1)`, `ed(1)`, `umask(1)`, `attributes(5)`

DIAGNOSTICS Message is ? for errors in commands, if prompting is turned off. Self-explanatory error messages are displayed when prompting is on.

biff(1B)

NAME | biff – give notice of incoming mail messages

SYNOPSIS | `/usr/ucb/biff [y | n]`

DESCRIPTION | biff turns mail notification on or off for the terminal session. With no arguments, biff displays the current notification status for the terminal.

| If notification is allowed, the terminal rings the bell and displays the header and the first few lines of each arriving mail message. biff operates asynchronously. For synchronized notices, use the MAIL variable of sh(1) or the mail variable of csh(1).

| A 'biff y' command can be included in your ~/.login or ~/.profile file for execution when you log in.

OPTIONS | y Allow mail notification for the terminal.

| n Disable notification for the terminal.

FILES | ~/.login User's login file

| ~/.profile User's profile file

ATTRIBUTES | See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO | csh(1), mail(1), sh(1), attributes(5)

NAME	break, continue – shell built-in functions to escape from or advance within a controlling while, for, foreach, or until loop
SYNOPSIS	
sh	break [<i>n</i>] continue [<i>n</i>]
csh	break continue
ksh	*break [<i>n</i>] *continue [<i>n</i>]
DESCRIPTION	
sh	break exits from the enclosing <code>for</code> or <code>while</code> loop, if any. If <i>n</i> is specified, break <i>n</i> levels. <code>continue</code> resumes the next iteration of the enclosing <code>for</code> or <code>while</code> loop. If <i>n</i> is specified, resume at the <i>n</i> -th enclosing loop.
csh	break resumes execution after the end of the nearest enclosing <code>foreach</code> or <code>while</code> loop. The remaining commands on the current line are executed. This allows multilevel breaks to be written as a list of <code>break</code> commands, all on one line. <code>continue</code> continues execution of the next iteration of the nearest enclosing <code>while</code> or <code>foreach</code> loop.
ksh	break exits from the enclosed <code>for</code> , <code>while</code> , <code>until</code> , or <code>select</code> loop, if any. If <i>n</i> is specified then break <i>n</i> levels. <code>continue</code> resumes the next iteration of the enclosed <code>for</code> , <code>while</code> , <code>until</code> , or <code>select</code> loop. If <i>n</i> is specified then resume at the <i>n</i> -th enclosed loop. On this man page, <code>ksh(1)</code> commands that are preceded by one or two * (asterisks) are treated specially in the following ways: 1. Variable assignment lists preceding the command remain in effect when the command completes. 2. I/O redirections are processed after variable assignments. 3. Errors cause a script that contains them to abort. 4. Words, following a command preceded by ** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

NAME	cal – display a calendar
SYNOPSIS	cal [[<i>month</i>] <i>year</i>]
DESCRIPTION	The <code>cal</code> utility writes a Gregorian calendar to standard output. If the <i>year</i> operand is specified, a calendar for that year is written. If no operands are specified, a calendar for the current month is written.
OPERANDS	The following operands are supported: <i>month</i> Specify the month to be displayed, represented as a decimal integer from 1 (January) to 12 (December). The default is the current month. <i>year</i> Specify the year for which the calendar is displayed, represented as a decimal integer from 1 to 9999. The default is the current year.
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>cal</code> : <code>LC_TIME</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

SEE ALSO `calendar(1)`, `attributes(5)`, `environ(5)`

NOTES An unusual calendar is printed for September 1752. That is the month 11 days were skipped to make up for lack of leap year adjustments. To see this calendar, type:

```
cal 9 1752
```

The command `cal 83` refers to the year 83, not 1983.

The year is always considered to start in January.

calendar(1)

NAME	calendar – reminder service						
SYNOPSIS	calendar [-]						
DESCRIPTION	<p>The <code>calendar</code> utility consults the file <code>calendar</code> in the current directory and writes lines that contain today's or tomorrow's date anywhere in the line to standard output. Most reasonable month-day dates such as Aug. 24, august 24, 8/24, and so forth, are recognized, but not 24 August or 24/8. On Fridays and weekends "tomorrow" extends through Monday. <code>calendar</code> can be invoked regularly by using the <code>crontab(1)</code> or <code>at(1)</code> commands.</p> <p>When the optional argument <code>-</code> is present, <code>calendar</code> does its job for every user who has a file <code>calendar</code> in his or her login directory and sends them any positive results by <code>mail(1)</code>. Normally this is done daily by facilities in the UNIX operating system (<code>secron(1M)</code>).</p> <p>If the environment variable <code>DATMSK</code> is set, <code>calendar</code> will use its value as the full path name of a template file containing format strings. The strings consist of conversion specifications and text characters and are used to provide a richer set of allowable date formats in different languages by appropriate settings of the environment variable <code>LANG</code> or <code>LC_TIME</code>; see <code>environ(5)</code>. See <code>strftime(3C)</code> for the list of allowable conversion specifications.</p>						
EXAMPLES	<p>EXAMPLE 1 Possible contents of a template.</p> <p>The following example shows the possible contents of a template:</p> <pre>%B %eth of the year %Y</pre> <p><code>%B</code> represents the full month name, <code>%e</code> the day of month and <code>%Y</code> the year (4 digits).</p> <p>If <code>DATMSK</code> is set to this template, the following <code>calendar</code> file would be valid:</p> <pre>March 7th of the year 1989 <Reminder></pre>						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>calendar</code> : <code>LC_CTYPE</code> , <code>LC_TIME</code> , <code>LC_MESSAGES</code> , <code>NLSPATH</code> , and <code>TZ</code> .						
EXIT STATUS	0 Successful completion. >0 An error occurred.						
FILES	<table><tr><td><code>/etc/passwd</code></td><td>system password file</td></tr><tr><td><code>/tmp/cal*</code></td><td>temporary files used by <code>calendar</code></td></tr><tr><td><code>/usr/lib/calprog</code></td><td>program used to determine dates for today and tomorrow</td></tr></table>	<code>/etc/passwd</code>	system password file	<code>/tmp/cal*</code>	temporary files used by <code>calendar</code>	<code>/usr/lib/calprog</code>	program used to determine dates for today and tomorrow

ATTRIBUTE TYPE	ATTRIBUTE VALUE						

Availability	SUNWesu
--------------	---------

SEE ALSO at(1), crontab(1), mail(1), cron(1M), ypbind(1M), strftime(3C), attributes(5), environ(5)

NOTES Appropriate lines beginning with white space will not be printed.

Your calendar must be public information for you to get reminder service.

calendar's extended idea of "tomorrow" does not account for holidays.

The - argument works only on calendar files that are local to the machine; calendar is intended not to work on calendar files that are mounted remotely with NFS. Thus, 'calendar -' should be run only on diskful machines where home directories exist; running it on a diskless client has no effect.

calendar is no longer in the default root crontab. Because of the network burden 'calendar -' can induce, it is inadvisable in an environment running ypbind(1M) with a large passwd.byname map. If, however, the usefulness of calendar outweighs the network impact, the super-user may run 'crontab -e' to edit the root crontab. Otherwise, individual users may wish to use 'crontab -e' to edit their own crontabs to have cron invoke calendar without the - argument, piping output to mail addressed to themselves.

cancel(1)

NAME	cancel – cancel print request
SYNOPSIS	cancel [<i>request-ID</i> ...] [<i>destination</i> ...] cancel -u <i>user</i> ... [<i>destination</i> ...]
DESCRIPTION	<p>The <code>cancel</code> utility cancels print requests. There are two forms of the <code>cancel</code> command.</p> <p>The first form of <code>cancel</code> has two optional arguments: print requests (<i>request-ID</i>) and destinations (<i>destination</i>). Specifying <i>request-ID</i> with <i>destination</i> cancels <i>request-ID</i> on <i>destination</i>. Specifying only the destination cancels the current print request on <i>destination</i>. If <i>destination</i> is not specified, <code>cancel</code> cancels the requested print request on all destinations.</p> <p>The second form of <code>cancel</code> cancels a user's print requests on specific destinations.</p> <p>Users can only cancel print requests associated with their username. By default, users can only cancel print requests on the host from which the print request was submitted. If a super-user has set <code>user-equivalence=true</code> in <code>/etc/printers.conf</code> on the print server, users can cancel print requests associated with their username on any host. Super-users can cancel print requests on the host from which the print request was submitted. Super-users can also cancel print requests from the print server.</p> <p>The print client commands locate destination information in a very specific order. See <code>printers.conf(4)</code> and <code>printers(4)</code> for details.</p>
OPTIONS	<p>The following options are supported:</p> <p>-u <i>user</i> The name of the user for which print requests are to be cancelled. Specify <i>user</i> as a username.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>destination</i> The destination on which the print requests are to be canceled. <i>destination</i> is the name of a printer or class of printers (see <code>lpadmin(1M)</code>). If <i>destination</i> is not specified, <code>cancel</code> cancels the requested print request on all destinations. Specify <i>destination</i> using atomic, POSIX-style (<i>server:destination</i>), or Federated Naming Service (FNS) (<code>./service/printer/. . .</code>) names. See NOTES for information regarding using POSIX-style destination names with <code>cancel</code>. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic and FNS names, and <code>standards(5)</code> for information regarding POSIX.</p> <p><i>request-ID</i> The print request to be canceled. Specify <i>request-ID</i> using LP-style request IDs (<i>destination-number</i>).</p> <p><i>user</i> The name of the user for which the print requests are to be cancelled. Specify <i>user</i> as a username.</p>
EXIT STATUS	The following exit values are returned:

cancel(1)

0 Successful completion.
non-zero An error occurred.

FILES /var/spool/print/* LP print queue.
\$HOME/.printers User-configurable printer database.
/etc/printers.conf System printer configuration database.
printers.conf.byname NIS version of /etc/printers.conf.
fns.ctx_dir.domain NIS+ version of /etc/printers.conf.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpcu

SEE ALSO lp(1), lpq(1B), lpr(1B), lprm(1B), lpstat(1), lpadmin(1M), printers(4), printers.conf(4), attributes(5), standards(5)

NOTES POSIX-style destination names (*server:destination*) are treated as print requests if *destination* has the same format as an LP-style *request-ID*. See standards(5).

case(1)

NAME	case, switch, select – shell built-in functions to choose from among a list of actions
SYNOPSIS	<pre> sh case <i>word</i> in [<i>pattern</i> [<i>pattern</i>]) <i>actions</i> ; ;...] esac csh switch (<i>expression</i>) case <i>comparison1</i> : <i>actions</i> breaksw case <i>comparison2</i> : <i>actions</i> breaksw ... default : endsw ksh case <i>word</i> in [<i>pattern</i> [<i>pattern</i>]) <i>actions</i> ; ;...] esac select <i>identifier</i> [<i>in word...</i>] ; do <i>list</i> ; done </pre>
DESCRIPTION	<p>sh A <i>case</i> command executes the <i>actions</i> associated with the first <i>pattern</i> that matches <i>word</i>. The form of the patterns is the same as that used for file-name generation except that a slash, a leading dot, or a dot immediately following a slash need not be matched explicitly.</p> <p>csh The c-shell uses the <i>switch</i> statement, in which each <i>comparison</i> is successively matched, against the specified <i>expression</i>, which is first command and filename expanded. The file metacharacters *, ? and [...] may be used in the case comparison, which are variable expanded. If none of the comparisons match before a "default" comparison is found, execution begins after the default comparison. Each <i>case</i> statement and the <i>default</i> statement must appear at the beginning of a line. The command <i>breaksw</i> continues execution after the <i>endsw</i>. Otherwise control falls through subsequent <i>case</i> and <i>default</i> statements as with C. If no comparison matches and there is no default, execution continues after the <i>endsw</i>.</p> <p><i>case comparison</i> : A compared-expression in a <i>switch</i> statement.</p> <p><i>default</i> : If none of the preceding <i>comparisons</i> match <i>expression</i>, then this is the default case in a <i>switch</i> statement. The default should come after all <i>case</i> comparisons. Any remaining commands on the command line are first executed.</p> <p><i>breaksw</i> exits from a <i>switch</i>, resuming after the <i>endsw</i>.</p> <p>ksh A <i>case</i> command executes the <i>actions</i> associated with the first <i>pattern</i> that matches <i>word</i>. The form of the patterns is the same as that used for file-name generation (see File Name Generation in <i>ksh</i>(1)).</p> <p>A <i>select</i> command prints to standard error (file descriptor 2), the set of <i>words</i>, each preceded by a number. If <i>in word . . .</i> is omitted, then the positional parameters are used instead. The PS3 prompt is printed and a line is read from the standard input. If</p>

this line consists of the number of one of the listed *words*, then the value of the variable *identifier* is set to the *word* corresponding to this number. If this line is empty the selection list is printed again. Otherwise the value of the variable *identifier* is set to NULL. The contents of the line read from standard input is saved in the shell variable REPLY. The *list* is executed for each selection until a *break* or *end-of-file* is encountered. If the REPLY variable is set to NULL by the execution of *list*, then the selection list is printed before displaying the PS3 prompt for the next selection.

EXAMPLES

sh

```
STOPLIGHT=green
case $STOPLIGHT in
    red)    echo "STOP" ;;
    orange) echo "Go with caution; prepare to stop" ;;
    green)  echo "you may GO" ;;
    blue|brown) echo "invalid stoplight colors" ;;
esac
```

csh In the C-shell, you must add NEWLINE characters as below.

```
set STOPLIGHT = green
switch ($STOPLIGHT)
    case red:
        echo "STOP"
        breaksw
    case orange:
        echo "Go with caution; prepare to stop"
        breaksw
    case green:
        echo "you may GO"
        endsw
endsw
```

ksh

```
STOPLIGHT=green
case $STOPLIGHT in
    red)    echo "STOP" ;;
    orange) echo "Go with caution; prepare to stop" ;;
    green)  echo "you may GO" ;;
    blue|brown) echo "invalid stoplight colors" ;;
esac
```

cat(1)

NAME	cat – concatenate and display files
SYNOPSIS	cat [-nbsuvet] [<i>file</i> ...]
DESCRIPTION	<p>The <i>cat</i> utility reads each <i>file</i> in sequence and writes it on the standard output. Thus:</p> <pre>example% cat file</pre> <p>prints <i>file</i> on your terminal, and:</p> <pre>example% cat file1 file2 >file3</pre> <p>concatenates <i>file1</i> and <i>file2</i>, and writes the results in <i>file3</i>. If no input file is given, <i>cat</i> reads from the standard input file.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-n Precede each line output with its line number.-b Number the lines, as -n, but omit the line numbers from blank lines.-u The output is not buffered. (The default is buffered output.)-s <i>cat</i> is silent about non-existent files.-v Non-printing characters (with the exception of tabs, new-lines and form-feeds) are printed visibly. ASCII control characters (octal 000 – 037) are printed as ^<i>n</i>, where <i>n</i> is the corresponding ASCII character in the range octal 100 – 137 (@, A, B, C, . . . , X, Y, Z, [, \,], ^, and _); the DEL character (octal 0177) is printed ^?. Other non-printable characters are printed as M-<i>x</i>, where <i>x</i> is the ASCII character specified by the low-order seven bits. <p>When used with the -v option, the following options may be used:</p> <ul style="list-style-type: none">-e A \$ character will be printed at the end of each line (prior to the new-line).-t Tabs will be printed as ^I's and formfeeds to be printed as ^L's. <p>The -e and -t options are ignored if the -v option is not specified.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>file</i> A path name of an input file. If no <i>file</i> is specified, the standard input is used. If <i>file</i> is ' - ', <i>cat</i> will read from the standard input at that point in the sequence. <i>cat</i> will not close and reopen standard input when it is referenced in this way, but will accept multiple occurrences of ' - ' as <i>file</i>.</p>
USAGE	See <i>largefile</i> (5) for the description of the behavior of <i>cat</i> when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
EXAMPLES	<p>EXAMPLE 1 Concatenating a file</p> <p>The following command:</p> <pre>example% cat myfile</pre>

EXAMPLE 1 Concatenating a file *(Continued)*

writes the contents of the file `myfile` to standard output.

EXAMPLE 2 Concatenating two files into one

The following command:

```
example% cat doc1 doc2 > doc.all
```

concatenates the files `doc1` and `doc2` and writes the result to `doc.all`.

EXAMPLE 3 Concatenating two arbitrary pieces of input with a single invocation

The command:

```
example% cat start - middle - end > file
```

when standard input is a terminal, gets two arbitrary pieces of input from the terminal with a single invocation of `cat`. Note, however, that if standard input is a regular file, this would be equivalent to the command:

```
cat start - middle /dev/null end > file
```

because the entire contents of the file would be consumed by `cat` the first time `' - '` was used as a *file* operand and an end-of-file condition would be detected immediately when `' - '` was referenced the second time.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cat`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 All input files were output successfully.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

SEE ALSO

`touch(1)`, `environ(5)`, `attributes(5)`, `largefile(5)`

NOTES

Redirecting the output of `cat` onto one of the files being read will cause the loss of the data originally in the file being read. For example,

```
example% cat filename1 filename2 >filename1
```

causes the original data in `filename1` to be lost.

cc(1B)

NAME	cc – C compiler
SYNOPSIS	<code>/usr/ucb/cc</code> [<i>options</i>]
DESCRIPTION	<code>/usr/ucb/cc</code> is the interface to the BSD Compatibility Package C compiler. It is a script that looks for the link <code>/usr/ccs/bin/ucbcc</code> to the C compiler. The <code>/usr/ccs/bin/ucbcc</code> link is available only with the SPROcc package, whose default location is <code>/opt/SUNWspro</code> . The <code>/usr/ucb/cc</code> interface is identical to <code>/usr/ccs/bin/ucbcc</code> , except that BSD headers are used and BSD libraries are linked <i>before</i> base libraries. The <code>/opt/SUNWspro/man/man1/acc.1</code> man page is available only with the SPROcc package.
OPTIONS	The <code>/usr/ucb/cc</code> interface accepts the same options as <code>/usr/ccs/bin/ucbcc</code> , with the following exceptions: -I <i>dir</i> Search <i>dir</i> for included files whose names do not begin with a slash (/) prior to searching the usual directories. The directories for multiple -I options are searched in the order specified. The preprocessor first searches for #include files in the directory containing <i>sourcefile</i> , and then in directories named with -I options (if any), then <code>/usr/ucbinclude</code> , and finally, in <code>/usr/include</code> . -L <i>dir</i> Add <i>dir</i> to the list of directories searched for libraries by <code>/usr/ccs/bin/ld</code> and <code>/usr/lib</code> . Directories specified with this option are searched before <code>/usr/ucb/lib</code> and <code>/usr/lib</code> . -Y <i>P, dir</i> Change the default directory used for finding libraries.
EXIT STATUS	The following exit values are returned: 0 Successful compilation or link edit. >0 An error occurred.
FILES	<code>/usr/ccs/bin/ld</code> link editor <code>/usr/lib/libc</code> C library <code>/usr/ucbinclude</code> BSD Compatibility directory for header files <code>/usr/ucb/lib</code> BSD Compatibility directory for libraries <code>/usr/ucb/lib/libucb</code> BSD Compatibility C library <code>/usr/lib/libsocket</code> library containing socket routines <code>/usr/lib/libnsl</code> library containing network functions <code>/usr/lib/libelf</code> library containing routines to process ELF object files <code>/usr/lib/libaio</code> library containing asynchronous I/O routines

NOTES The `-Y P, dir` option may have unexpected results and should not be used.

cd(1)

NAME	cd, chdir, pushd, popd, dirs – change working directory
SYNOPSIS	<code>/usr/bin/cd</code> [<i>directory</i>]
sh	<code>cd</code> [<i>argument</i>] <code>chdir</code> [<i>argument</i>]
csh	<code>cd</code> [<i>dir</i>] <code>chdir</code> [<i>dir</i>] <code>pushd</code> [<i>+n</i> <i>dir</i>] <code>popd</code> [<i>+n</i>] <code>dirs</code> [<i>-1</i>]
ksh	<code>cd</code> [<i>arg</i>] <code>cd</code> <i>old new</i>
DESCRIPTION	
<code>/usr/bin/cd</code>	The <code>cd</code> utility will change the working directory of the current shell execution environment. When invoked with no operands, and the <code>HOME</code> environment variable is set to a non-empty value, the directory named in the <code>HOME</code> environment variable will become the new working directory.
sh	The Bourne shell built-in <code>cd</code> changes the current directory to <i>argument</i> . The shell parameter <code>HOME</code> is the default <i>argument</i> . The shell parameter <code>CDPATH</code> defines the search path for the directory containing <i>argument</i> . Alternative directory names are separated by a colon (:). The default path is <code><null></code> (specifying the current directory). Note: The current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If <i>argument</i> begins with <code>'/'</code> , <code>'.'</code> , or <code>'..'</code> , the search path is not used. Otherwise, each directory in the path is searched for <i>argument</i> . <code>cd</code> must have execute (search) permission in <i>argument</i> . Because a new process is created to execute each command, <code>cd</code> would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the shell. (See <code>pwd(1)</code> , <code>sh(1)</code> , and <code>chdir(2)</code>).
	<code>chdir</code> is just another way to call <code>cd</code> .
csh	If <i>dir</i> is not specified, the C shell built-in <code>cd</code> uses the value of shell parameter <code>HOME</code> as the new working directory. If <i>dir</i> specifies a complete path starting with <code>'/'</code> , <code>'.'</code> , or <code>'..'</code> , <i>dir</i> becomes the new working directory. If neither case applies, <code>cd</code> tries to find the designated directory relative to one of the paths specified by the <code>CDPATH</code> shell variable. <code>CDPATH</code> has the same syntax as, and similar semantics to, the <code>PATH</code> shell variable. <code>cd</code> must have execute (search) permission in <i>dir</i> . Because a new process is created to execute each command, <code>cd</code> would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the C-shell. (See <code>pwd(1)</code> , <code>sh(1)</code> , and <code>chdir(2)</code>).

`chdir` changes the shell's working directory to directory *dir*. If no argument is given, change to the home directory of the user. If *dir* is a relative pathname not found in the current directory, check for it in those directories listed in the `cdpath` variable. If *dir* is the name of a shell variable whose value starts with a `/`, change to the directory named by that value.

`pushd` will push a directory onto the directory stack. With no arguments, exchange the top two elements.

`+n` Rotate the *n*'th entry to the top of the stack and `cd` to it.

dir Push the current working directory onto the stack and change to *dir*.

`popd` pops the directory stack and `cd` to the new top directory. The elements of the directory stack are numbered from 0 starting at the top.

`+n` Discard the *n*'th entry in the stack.

`dirs` will print the directory stack, most recent to the left; the first directory shown is the current directory. With the `-l` argument, produce an unabbreviated printout; use of the `~` notation is suppressed.

ksh The Korn shell built-in `cd` command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is `-` the directory is changed to the previous directory. The shell variable `HOME` is the default *arg*. The variable `PWD` is set to the current directory. The shell variable `CDPATH` defines the search path for the directory containing *arg*. Alternative directory names are separated by a colon (`:`). The default path is `<null>` (specifying the current directory). Note that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a `' / '`, `. '`, or `' . . '`, then the search path is not used. Otherwise, each directory in the path is searched for *arg*.

The second form of `cd` substitutes the string *new* for the string *old* in the current directory name, `PWD` and tries to change to this new directory.

The `cd` command may not be executed by `rksh`. Because a new process is created to execute each command, `cd` would be ineffective if it were written as a normal command; therefore, it is recognized by and is internal to the Korn shell. (See `pwd(1)`, `sh(1)`, and `chdir(2)`).

OPERANDS The following operands are supported:

directory An absolute or relative pathname of the directory that becomes the new working directory. The interpretation of a relative pathname by `cd` depends on the `CDPATH` environment variable.

OUTPUT If a non-empty directory name from `CDPATH` is used, an absolute pathname of the new working directory will be written to the standard output as follows:

`"%s\n", <new directory>`

cd(1)

Otherwise, there will be no output.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cd`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

CDPATH A colon-separated list of pathnames that refer to directories. If the *directory* operand does not begin with a slash (/) character, and the first component is not dot or dot-dot, `cd` will search for *directory* relative to each directory named in the `CDPATH` variable, in the order listed. The new working directory will be set to the first matching directory found. An empty string in place of a directory pathname represents the current directory. If `CDPATH` is not set, it will be treated as if it were an empty string.

HOME The name of the home directory, used when no *directory* operand is specified.

PWD A pathname of the current working directory, set by `cd` after it has changed to that directory.

EXIT STATUS

The following exit values are returned by `cd`:

0 The directory was successfully changed.

>0 An error occurred.

NAME	checknr – check nroff and troff input files; report possible errors				
SYNOPSIS	checknr [-fs] [-a .x1 .y1 .x2 .y2xn .yn] [-c .x1 .x2 .x3xn] [filename...]				
DESCRIPTION	<p>checknr checks a list of nroff(1) or troff(1) input files for certain kinds of errors involving mismatched opening and closing delimiters and unknown commands. If no files are specified, checknr checks the standard input. Delimiters checked are:</p> <ul style="list-style-type: none"> ■ Font changes using \fx ... \fP. ■ Size changes using \sx ... \s0. ■ Macros that come in open ... close forms, for example, the .TS and .TE macros which must always come in pairs. <p>checknr knows about the ms(5) and me(5) macro packages.</p> <p>checknr is intended to be used on documents that are prepared with checknr in mind. It expects a certain document writing style for \f and \s commands, in that each \fx must be terminated with \fP and each \sx must be terminated with \s0. While it will work to directly go into the next font or explicitly specify the original font or point size, and many existing documents actually do this, such a practice will produce complaints from checknr. Since it is probably better to use the \fP and \s0 forms anyway, you should think of this as a contribution to your document preparation style.</p>				
OPTIONS	<p>-f Ignore \f font changes.</p> <p>-s Ignore \s size changes.</p> <p>-a .x1 .y1 ... Add pairs of macros to the list. The pairs of macros are assumed to be those (such as .DS and .DE) that should be checked for balance. The -a option must be followed by groups of six characters, each group defining a pair of macros. The six characters are a period, the first macro name, another period, and the second macro name. For example, to define a pair .BS and .ES, use '-a.BS.ES'</p> <p>-c .x1 ... Define commands which checknr would otherwise complain about as undefined.</p>

BUGS	There is no way to define a one-character macro name using the -a option.				

chgrp(1)

NAME	chgrp – change file group ownership
SYNOPSIS	chgrp [-fhR] <i>group file...</i>
DESCRIPTION	<p>The <code>chgrp</code> utility will set the group ID of the file named by each <i>file</i> operand to the group ID specified by the <i>group</i> operand.</p> <p>For each <i>file</i> operand, it will perform actions equivalent to the <code>chown(2)</code> function, called with the following arguments:</p> <ul style="list-style-type: none">■ The <i>file</i> operand will be used as the <i>path</i> argument.■ The user ID of the file will be used as the <i>owner</i> argument.■ The specified group ID will be used as the <i>group</i> argument. <p>Unless <code>chgrp</code> is invoked by a process with appropriate privileges, the set-user-ID and set-group-ID bits of a regular file will be cleared upon successful completion; the set-user-ID and set-group-ID bits of other file types may be cleared.</p> <p>The operating system has a configuration option <code>_POSIX_CHOWN_RESTRICTED</code>, to restrict ownership changes. When this option is in effect, the owner of the file may change the group of the file only to a group to which the owner belongs. Only the super-user can arbitrarily change owner IDs, whether or not this option is in effect. To set this configuration option, include the following line in <code>/etc/system</code>:</p> <pre>set rstchown = 1</pre> <p>To disable this option, include the following line in <code>/etc/system</code>:</p> <pre>set rstchown = 0</pre> <p><code>_POSIX_CHOWN_RESTRICTED</code> is enabled by default. See <code>system(4)</code> and <code>fpathconf(2)</code>.</p>
OPTIONS	<p>-f Force. Do not report errors.</p> <p>-h If the file is a symbolic link, change the group of the symbolic link. Without this option, the group of the file referenced by the symbolic link is changed.</p> <p>-R Recursive. <code>chgrp</code> descends through the directory, and any subdirectories, setting the specified group ID as it proceeds. When a symbolic link is encountered, the group of the target file is changed (unless the <code>-h</code> option is specified), but no recursion takes place.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>group</i> A group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file named by one of the <i>file</i> operands. If a numeric <i>group</i> operand exists in the group database as a group name, the group ID number associated with that group name is used as the group ID.</p> <p><i>file</i> A path name of a file whose group ID is to be modified.</p>

USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>chgrp</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).						
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>chgrp</code> : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .						
EXIT STATUS	The following exit values are returned: 0 The utility executed successfully and all requested changes were made. >0 An error occurred.						
FILES	<code>/etc/group</code> group file						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:						
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> <tr> <td>CSI</td> <td>Enabled (see NOTES)</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu	CSI	Enabled (see NOTES)

chkey(1)

NAME	chkey – change user’s secure RPC key pair										
SYNOPSIS	chkey [-p] [-s nisplus nis files] [-m <mechanism>]										
DESCRIPTION	<p>chkey is used to change a user’s secure RPC public key and secret key pair. chkey prompts for the old secure-rpc password and verifies that it is correct by decrypting the secret key. If the user has not already used keylogin(1) to decrypt and store the secret key with keyserver(1M), chkey registers the secret key with the local keyserver(1M) daemon. If the secure-rpc password does not match the login password, chkey prompts for the login password. chkey uses the login password to encrypt the user’s secret Diffie-Hellman (192 bit) cryptographic key. chkey can also encrypt other Diffie-Hellman keys for authentication mechanisms configured using nisauthconf(1M).</p> <p>chkey ensures that the login password and the secure-rpc password(s) are kept the same, thus enabling password shadowing. See shadow(4).</p> <p>The key pair can be stored in the /etc/publickey file (see publickey(4)), the NIS publickey map, or the NIS+ cred.org_dir table. If a new secret key is generated, it will be registered with the local keyserver(1M) daemon. However, only NIS+ can store Diffie-Hellman keys other than 192-bits.</p> <p>Keys for specific mechanisms can be changed or reencrypted using the -m option followed by the authentication mechanism name. Multiple -m options can be used to change one or more keys. However, only mechanisms configured using nisauthconf(1M) can be changed with chkey.</p> <p>If the source of the publickey is not specified with the -s option, chkey consults the publickey entry in the name service switch configuration file. See nsswitch.conf(4). If the publickey entry specifies one and only one source, then chkey will change the key in the specified name service. However, if multiple name services are listed, chkey can not decide which source to update and will display an error message. The user should specify the source explicitly with the -s option.</p> <p>Non root users are not allowed to change their key pair in the files database.</p>										
OPTIONS	<p>The following options are supported:</p> <table><tr><td>-p</td><td>Re-encrypt the existing secret key with the user’s login password.</td></tr><tr><td>-s nisplus</td><td>Update the NIS+ database.</td></tr><tr><td>-s nis</td><td>Update the NIS database.</td></tr><tr><td>-s files</td><td>Update the files database.</td></tr><tr><td>-m <mechanism></td><td>Changes or re-encrypt the secret key for the specified mechanism.</td></tr></table>	-p	Re-encrypt the existing secret key with the user’s login password.	-s nisplus	Update the NIS+ database.	-s nis	Update the NIS database.	-s files	Update the files database.	-m <mechanism>	Changes or re-encrypt the secret key for the specified mechanism.
-p	Re-encrypt the existing secret key with the user’s login password.										
-s nisplus	Update the NIS+ database.										
-s nis	Update the NIS database.										
-s files	Update the files database.										
-m <mechanism>	Changes or re-encrypt the secret key for the specified mechanism.										
FILES	<p>/etc/nsswitch.conf</p> <p>/etc/publickey</p>

chmod(1)

NAME	chmod – change the permissions mode of a file
SYNOPSIS	chmod [-fR] <absolute-mode> file... chmod [-fR] <symbolic-mode-list> file...
DESCRIPTION	chmod changes or assigns the mode of a file. The mode of a file specifies its permissions and other attributes. The mode may be absolute or symbolic.
Absolute mode	An absolute <i>mode</i> is specified using octal numbers: chmod <i>nnnn</i> file . . .where: <i>n</i> a number from 0 to 7. An absolute mode is constructed from the OR of any of the following modes: 4000 Set user ID on execution. 20#0 Set group ID on execution if # is 7, 5, 3, or 1. Enable mandatory locking if # is 6, 4, 2, or 0. For directories, files are created with BSD semantics for propagation of the group ID. With this option, files and subdirectories created in the directory inherit the group ID of the directory, rather than of the current process. It may be cleared only by using symbolic mode. 1000 Turn on sticky bit. See chmod(2). 0400 Allow read by owner. 0200 Allow write by owner. 0100 Allow execute (search in directory) by owner. 0700 Allow read, write, and execute (search) by owner. 0040 Allow read by group. 0020 Allow write by group. 0010 Allow execute (search in directory) by group. 0070 Allow read, write, and execute (search) by group. 0004 Allow read by others. 0002 Allow write by others. 0001 Allow execute (search in directory) by others. 0007 Allow read, write, and execute (search) by others. Note that the <code>setgid</code> bit cannot be set (or cleared) in absolute mode; it must be set (or cleared) in symbolic mode using <code>g+s</code> (or <code>g-s</code>).

Symbolic mode | A symbolic *mode* specification has the following format:

`chmod <symbolic-mode-list> file . . .` where: *<symbolic-mode-list>* is a comma-separated list (with no intervening whitespace) of symbolic mode expressions of the form:

`[who] operator [permissions]`

Operations are performed in the order given. Multiple *permissions* letters following a single operator cause the corresponding operations to be performed simultaneously.

who zero or more of the characters *u*, *g*, *o*, and *a* specifying whose permissions are to be changed or assigned:

u user's permissions

g group's permissions

o others' permissions

a all permissions (user, group, and other)

If *who* is omitted, it defaults to *a*, but the setting of the file mode creation mask (see `umask` in `sh(1)` or `csh(1)` for more information) is taken into account. When *who* is omitted, `chmod` will not override the restrictions of your user mask.

operator either `+`, `-`, or `=`, signifying how permissions are to be changed:

`+` Add permissions.

If *permissions* is omitted, nothing is added.

If *who* is omitted, add the file mode bits represented by *permissions*, *except* for the those with corresponding bits in the file mode creation mask.

If *who* is present, add the file mode bits represented by the *permissions*.

`-` Take away permissions.

If *permissions* is omitted, do nothing.

If *who* is omitted, clear the file mode bits represented by *permissions*, *except* for those with corresponding bits in the file mode creation mask.

If *who* is present, clear the file mode bits represented by *permissions*.

`=` Assign permissions absolutely.

chmod(1)

If *who* is omitted, clear all file mode bits; if *who* is present, clear the file mode bits represented by *who*.

If *permissions* is omitted, do nothing else.

If *who* is omitted, add the file mode bits represented by *permissions*, *except* for the those with corresponding bits in the file mode creation mask.

If *who* is present, add the file mode bits represented by *permissions*.

Unlike other symbolic operations, = has an absolute effect in that it resets all other bits represented by *who*. Omitting *permissions* is useful only with = to take away all permissions.

permission

any compatible combination of the following letters:

r	read permission
w	write permission
x	execute permission
l	mandatory locking
s	user or group set-ID
t	sticky bit
u,g,o	indicate that <i>permission</i> is to be taken from the current user, group or other mode respectively.

Permissions to a file may vary depending on your user identification number (UID) or group identification number (GID). Permissions are described in three sequences each having three characters:

User	Group	Other
rwX	rwX	rwX

This example (user, group, and others all have permission to read, write, and execute a given file) demonstrates two categories for granting permissions: the access class and the permissions themselves.

The letter *s* is only meaningful with *u* or *g*, and *t* only works with *u*.

Mandatory file and record locking (1) refers to a file's ability to have its reading or writing permissions locked while a program is accessing that file.

In a directory which has the set-group-ID bit set (reflected as either `-----s---` or `-----l---` in the output of `'ls -ld'`), files and subdirectories are created with the group-ID of the parent directory—not that of current process.

It is not possible to permit group execution and enable a file to be locked on execution at the same time. In addition, it is not possible to turn on the set-group-ID bit and enable a file to be locked on execution at the same time. The following examples, therefore, are invalid and elicit error messages:

```
chmod g+x,+l file
```

```
chmod g+s,+l file
```

Only the owner of a file or directory (or the super-user) may change that file's or directory's mode. Only the super-user may set the sticky bit on a non-directory file. If you are not super-user, `chmod` will mask the sticky-bit but will not return an error. In order to turn on a file's set-group-ID bit, your own group ID must correspond to the file's and group execution must be set.

OPTIONS The following options are supported:

- f Force. `chmod` will not complain if it fails to change the mode of a file.
- R Recursively descend through directory arguments, setting the mode for each file as described above. When symbolic links are encountered, the mode of the target file is changed, but no recursion takes place.

OPERANDS The following operands are supported:

mode Represents the change to be made to the file mode bits of each file named by one of the *file* operands; see the DESCRIPTION section for more information.

file A path name of a file whose file mode bits are to be modified.

USAGE See `largefile(5)` for the description of the behavior of `chmod` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Deny execute permission to everyone:

```
example% chmod a-x file
```

EXAMPLE 2 Allow only read permission to everyone:

```
example% chmod 444 file
```

chmod(1)

EXAMPLE 2 Allow only read permission to everyone: (Continued)

EXAMPLE 3 Make a file readable and writable by the group and others:

```
example% chmod go+rw file
example% chmod 066 file
```

EXAMPLE 4 Cause a file to be locked during access:

```
example% chmod +l file
```

EXAMPLE 5 Allow everyone to read, write, and execute the file and turn on the set group-ID.

```
example% chmod a=rwx,g+s file
example% chmod 2777 file
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `chmod`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

```
0          Successful completion.
>0        An error occurred.
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

SEE ALSO

`ls(1)`, `chmod(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `getfacl(1)`, `setfacl(1)`

NOTES

Absolute changes don't work for the set-group-ID bit of a directory. You must use `g+s` or `g-s`.

`chmod` permits you to produce useless modes so long as they are not illegal (for instance, making a text file executable). `chmod` does not check the file type to see if mandatory locking is meaningful.

If the filesystem is mounted with the `nosuid` option, `setuid` execution is not allowed.

If you use `chmod` to change the file group owner permissions on a file with ACL entries, both the file group owner permissions and the ACL mask are changed to the new permissions. Be aware that the new ACL mask permissions may change the effective permissions for additional users and groups who have ACL entries on the file. Use the `getfacl(1)` command to make sure the appropriate permissions are set for all ACL entries.

chown(1)

NAME	chown – change file ownership
SYNOPSIS	chown [-fhR] <i>owner</i> [: <i>group</i>] <i>file</i> ...
DESCRIPTION	<p>The chown utility will set the user ID of the file named by each <i>file</i> to the user ID specified by <i>owner</i>, and, optionally, will set the group ID to that specified by <i>group</i>.</p> <p>If chown is invoked by other than the super-user, the set-user-ID bit is cleared.</p> <p>Only the owner of a file (or the super-user) may change the owner of that file.</p> <p>The operating system has a configuration option <code>{_POSIX_CHOWN_RESTRICTED}</code>, to restrict ownership changes. When this option is in effect the owner of the file is prevented from changing the owner ID of the file. Only the super-user can arbitrarily change owner IDs whether or not this option is in effect. To set this configuration option, include the following line in <code>/etc/system</code>:</p> <pre>set rstchown = 1</pre> <p>To disable this option, include the following line in <code>/etc/system</code>:</p> <pre>set rstchown = 0</pre> <p><code>{_POSIX_CHOWN_RESTRICTED}</code> is enabled by default. See <code>system(4)</code> and <code>fpathconf(2)</code>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-f Do not report errors.-h If the file is a symbolic link, change the owner of the symbolic link. Without this option, the owner of the file referenced by the symbolic link is changed.-R Recursive. chown descends through the directory, and any subdirectories, setting the ownership ID as it proceeds. When a symbolic link is encountered, the owner of the target file is changed (unless the -h option is specified), but no recursion takes place.
OPERANDS	<p>The following operands are supported:</p> <p><i>owner</i>[: <i>group</i>]</p> <p>A user ID and optional group ID to be assigned to <i>file</i>. The <i>owner</i> portion of this operand must be a user name from the user database or a numeric user ID. Either specifies a user ID to be given to each file named by <i>file</i>. If a numeric <i>owner</i> exists in the user database as a user name, the user ID number associated with that user name will be used as the user ID. Similarly, if the <i>group</i> portion of this operand is present, it must be a group name from the group database or a numeric group ID. Either specifies a group ID to be given to each file. If a numeric group operand exists in the</p>

group database as a group name, the group ID number associated with that group name will be used as the group ID.

file A path name of a file whose user ID is to be modified.

USAGE See `largefile(5)` for the description of the behavior of `chown` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Changing ownership of all files in the hierarchy

To change ownership of all files in the hierarchy, including symbolic links, but not the targets of the links:

```
example% chown -R -h owner[:group] file...
```

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `chown`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 The utility executed successfully and all requested changes were made.

>0 An error occurred.

FILES `/etc/passwd` system password file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled (see NOTES)

SEE ALSO `chgrp(1)`, `chmod(1)`, `chown(2)`, `fpathconf(2)`, `passwd(4)`, `system(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`

NOTES `chown` is CSI-enabled except for the *owner* and *group* names.

chown(1B)

NAME | chown – change owner

SYNOPSIS | `/usr/ucb/chown [-fR] owner [.group] filename...`

DESCRIPTION | chown changes the owner of the *filenames* to *owner*. The owner may be either a decimal user ID (UID) or a login name found in the password file. An optional *group* may also be specified. The group may be either a decimal group ID (GID) or a group name found in the GID file.

Only the super-user can change owner, in order to simplify accounting procedures.

OPTIONS | -f Do not report errors.
 -R Recursively descend into directories setting the ownership of all files in each directory encountered. When symbolic links are encountered, their ownership is changed, but they are not traversed.

USAGE | See `largefile(5)` for the description of the behavior of `chown` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES | `/etc/passwd` password file

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO | `chgrp(1)`, `chown(2)`, `group(4)`, `passwd(4)`, `attributes(5)`, `largefile(5)`

NAME	ckdate, errdate, helpdate, valdate – prompts for and validates a date
SYNOPSIS	<pre>ckdate [-Q] [-W width] [-f format] [-d default] [-h help] [-e error] [-p prompt] [-k pid [-s signal]] /usr/sadm/bin/errdate [-W width] [-e error] [-f format] /usr/sadm/bin/helpdate [-W width] [-h help] [-f format] /usr/sadm/bin/valdate [-f format] input</pre>
DESCRIPTION	<p>The <code>ckdate</code> utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a date, text for help and error messages, and a default value (which will be returned if the user responds with a RETURN). The user response must match the defined format for a date.</p> <p>All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The <code>-w</code> option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.</p> <p>Three visual tool modules are linked to the <code>ckdate</code> command. They are <code>errdate</code> (which formats and displays an error message), <code>helpdate</code> (which formats and displays a help message), and <code>valdate</code> (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When <code>format</code> is defined in the <code>errdate</code> and <code>helpdate</code> modules, the messages will describe the expected format.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-d default</code> Defines the default value as <i>default</i>. The default does not have to meet the format criteria. <code>-e error</code> Defines the error message as <i>error</i>. <code>-f format</code> Specifies the format against which the input will be verified. Possible formats and their definitions are: <ul style="list-style-type: none"> <code>%b =</code> abbreviated month name (jan, feb, mar) <code>%B =</code> full month name <code>%d =</code> day of month (01 - 31) <code>%D =</code> date as %m/%d/%y (the default format) <code>%e =</code> day of month (1 - 31; single digits are preceded by a blank) <code>%h =</code> abbreviated month name, identical to <code>%b</code> <code>%m =</code> month number (01 - 12)

ckdate(1)

	%y =	year within century (for instance, 89)
	%Y =	year as CCYY (for instance, 1989)
-h <i>help</i>		Defines the help messages as <i>help</i> .
-k <i>pid</i>		Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.
-p <i>prompt</i>		Defines the prompt message as <i>prompt</i> .
-Q		Specifies that quit will not be allowed as a valid response.
-s <i>signal</i>		Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-w <i>width</i>		Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .

OPERANDS The following operand is supported:

input Input to be verified against format criteria.

EXIT STATUS The following exit values are returned:

0	Successful execution.
1	EOF on input, or negative width on -W option, or usage error.
3	User termination (quit).
4	Garbled format argument.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`

NOTES The default prompt for `ckdate` is:

Enter the date [?,q]:

The default error message is:

ERROR - Please enter a date. Format is <format>.

The default help message is:

Please enter a date. Format is <format>.

ckdate(1)

When the quit option is chosen (and allowed), `q` is returned along with the return code 3. The `validate` module will not produce any output. It returns zero for success and non-zero for failure.

ckgid(1)

NAME	ckgid, errgid, helpgid, valgid – prompts for and validates a group id																
SYNOPSIS	<pre>ckgid [-Q] [-W <i>width</i>] [-m] [-d <i>default</i>] [-h <i>help</i>] [-e <i>error</i>] [-p <i>prompt</i>] [-k <i>pid</i> [-s <i>signal</i>]] /usr/sadm/bin/errgid [-W <i>width</i>] [-e <i>error</i>] /usr/sadm/bin/helpgid [-W <i>width</i>] [-m] [-h <i>help</i>] /usr/sadm/bin/valgid <i>input</i></pre>																
DESCRIPTION	<p>ckgid prompts a user and validates the response. It defines, among other things, a prompt message whose response should be an existing group ID, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).</p> <p>All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -W option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.</p> <p>Three visual tool modules are linked to the ckgid command. They are errgid (which formats and displays an error message), helpgid (which formats and displays a help message), and valgid (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt.</p>																
OPTIONS	<p>The following options are supported:</p> <table><tr><td>-d <i>default</i></td><td>Defines the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria.</td></tr><tr><td>-e <i>error</i></td><td>Defines the error message as <i>error</i>.</td></tr><tr><td>-h <i>help</i></td><td>Defines the help messages as <i>help</i>.</td></tr><tr><td>-k <i>pid</i></td><td>Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.</td></tr><tr><td>-m</td><td>Displays a list of all groups when help is requested or when the user makes an error.</td></tr><tr><td>-p <i>prompt</i></td><td>Defines the prompt message as <i>prompt</i>.</td></tr><tr><td>-Q</td><td>Specifies that quit will not be allowed as a valid response.</td></tr><tr><td>-s <i>signal</i></td><td>Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.</td></tr></table>	-d <i>default</i>	Defines the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.	-e <i>error</i>	Defines the error message as <i>error</i> .	-h <i>help</i>	Defines the help messages as <i>help</i> .	-k <i>pid</i>	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.	-m	Displays a list of all groups when help is requested or when the user makes an error.	-p <i>prompt</i>	Defines the prompt message as <i>prompt</i> .	-Q	Specifies that quit will not be allowed as a valid response.	-s <i>signal</i>	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-d <i>default</i>	Defines the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.																
-e <i>error</i>	Defines the error message as <i>error</i> .																
-h <i>help</i>	Defines the help messages as <i>help</i> .																
-k <i>pid</i>	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.																
-m	Displays a list of all groups when help is requested or when the user makes an error.																
-p <i>prompt</i>	Defines the prompt message as <i>prompt</i> .																
-Q	Specifies that quit will not be allowed as a valid response.																
-s <i>signal</i>	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.																

-w width Specifies that prompt, help and error messages will be formatted to a line length of *width*.

OPERANDS The following operand is supported:

input Input to be verified against */etc/group*.

EXIT STATUS The following exit values are returned:

0 Successful execution.
 1 EOF on input, or negative width on *-W* option, or usage error.
 3 User termination (quit).

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO *attributes(5)*

NOTES The default prompt for *ckgid* is:

Enter the name of an existing group [?,q]:

The default error message is:

ERROR: Please enter one of the following group names: *[List]*

If the *-m* option of *ckgid* is used, a list of valid groups is displayed here.

The default help message is:

ERROR: Please enter one of the following group names: *[List]*

If the *-m* option of *ckgid* is used, a list of valid groups is displayed here.

When the quit option is chosen (and allowed), *q* is returned along with the return code 3. The *valgid* module will not produce any output. It returns 0 for success and non-zero for failure.

ckint(1)

NAME	ckint, errint, helpint, valint – display a prompt; verify and return an integer value
SYNOPSIS	<pre> ckint [-Q] [-W <i>width</i>] [-b <i>base</i>] [-d <i>default</i>] [-h <i>help</i>] [-e <i>error</i>] [-p <i>prompt</i>] [-k <i>pid</i> [-s <i>signal</i>]] /usr/sadm/bin/errint [-W <i>width</i>] [-b <i>base</i>] [-e <i>error</i>] /usr/sadm/bin/helpint [-W <i>width</i>] [-b <i>base</i>] [-h <i>help</i>] /usr/sadm/bin/valint [-b <i>base</i>] <i>input</i> </pre>
DESCRIPTION	<p>The <code>ckint</code> utility prompts a user, then validates the response. It defines, among other things, a prompt message whose response should be an integer, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).</p> <p>All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The <code>-W</code> option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under <code>NOTES</code>) will be displayed.</p> <p>Three visual tool modules are linked to the <code>ckint</code> command. They are <code>errint</code> (which formats and displays an error message), <code>helpint</code> (which formats and displays a help message), and <code>valint</code> (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When <code>base</code> is defined in the <code>errint</code> and <code>helpint</code> modules, the messages will include the expected base of the input.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-b <i>base</i></code> Defines the base for input. Must be 2 to 36, default is 10. <code>-d <i>default</i></code> Defines the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria. <code>-e <i>error</i></code> Defines the error message as <i>error</i>. <code>-h <i>help</i></code> Defines the help messages as <i>help</i>. <code>-k <i>pid</i></code> Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort. <code>-p <i>prompt</i></code> Defines the prompt message as <i>prompt</i>. <code>-Q</code> Specifies that quit will not be allowed as a valid response. <code>-s <i>signal</i></code> Specifies that the process ID <i>pid</i> defined with the <code>-k</code> option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, <code>SIGTERM</code> is used.

ckint(1)

-w width Specifies that prompt, help and error messages will be formatted to a line length of *width*.

OPERANDS The following operand is supported:

input Input to be verified against *base* criterion.

EXIT STATUS The following exit values are returned:

0 Successful execution.

1 EOF on input, or negative width on *-W* option, or usage error.

3 User termination (quit).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`

NOTES The default base 10 prompt for `ckint` is:

Enter an integer [?,q]:

The default base 10 error message is:

ERROR - Please enter an integer.

The default base 10 help message is:

Please enter an integer.

The messages are changed from "integer" to "base *base* integer" if the base is set to a number other than 10.

When the quit option is chosen (and allowed), `q` is returned along with the return code 3. The `valint` module will not produce any output. It returns 0 for success and non-zero for failure.

ckitem(1)

NAME	ckitem, erritem, helpitem – build a menu; prompt for and return a menu item										
SYNOPSIS	<pre>ckitem [-Q] [-W <i>width</i>] [-uno] [-f <i>filename</i>] [-l <i>label</i>] [[-i <i>invis</i>] [,...]] [-m <i>max</i>] [-d <i>default</i>] [-h <i>help</i>] [-e <i>error</i>] [-p <i>prompt</i>] [-k <i>pid</i> [-s <i>signal</i>]] [<i>choice</i> [...]] /usr/sadm/bin/erritem [-W <i>width</i>] [-e <i>error</i>] [<i>choice</i> [...]] /usr/sadm/bin/helpitem [-W <i>width</i>] [-h <i>help</i>] [<i>choice</i> [...]]</pre>										
DESCRIPTION	<p>The <code>ckitem</code> utility builds a menu and prompts the user to choose one item from a menu of items. It then verifies the response. Options for this command define, among other things, a prompt message whose response will be a menu item, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return).</p> <p>By default, the menu is formatted so that each item is prepended by a number and is printed in columns across the terminal. Column length is determined by the longest choice. Items are alphabetized.</p> <p>All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The <code>-W</code> option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under <code>NOTES</code>) will be displayed.</p> <p>Two visual tool modules are linked to the <code>ckitem</code> command. They are <code>erritem</code> (which formats and displays an error message) and <code>helpitem</code> (which formats and displays a help message). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When <code>choice</code> is defined in these modules, the messages will describe the available menu choice (or choices).</p>										
OPTIONS	<p>The following options are supported:</p> <table><tr><td><code>-d <i>default</i></code></td><td>Define the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria.</td></tr><tr><td><code>-e <i>error</i></code></td><td>Define the error message as <i>error</i>.</td></tr><tr><td><code>-f <i>filename</i></code></td><td>Define a file, <i>filename</i>, which contains a list of menu items to be displayed. (The format of this file is: <code>token<tab>description</code>. Lines beginning with a pound sign (#) are designated as comments and ignored.)</td></tr><tr><td><code>-h <i>help</i></code></td><td>Define the help messages as <i>help</i>.</td></tr><tr><td><code>-i <i>invis</i></code></td><td>Define invisible menu choices (those which will not be printed in the menu). (For example, “all” used as an invisible choice would mean it is a legal option but does not appear in the menu. Any</td></tr></table>	<code>-d <i>default</i></code>	Define the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.	<code>-e <i>error</i></code>	Define the error message as <i>error</i> .	<code>-f <i>filename</i></code>	Define a file, <i>filename</i> , which contains a list of menu items to be displayed. (The format of this file is: <code>token<tab>description</code> . Lines beginning with a pound sign (#) are designated as comments and ignored.)	<code>-h <i>help</i></code>	Define the help messages as <i>help</i> .	<code>-i <i>invis</i></code>	Define invisible menu choices (those which will not be printed in the menu). (For example, “all” used as an invisible choice would mean it is a legal option but does not appear in the menu. Any
<code>-d <i>default</i></code>	Define the default value as <i>default</i> . The default is not validated and so does not have to meet any criteria.										
<code>-e <i>error</i></code>	Define the error message as <i>error</i> .										
<code>-f <i>filename</i></code>	Define a file, <i>filename</i> , which contains a list of menu items to be displayed. (The format of this file is: <code>token<tab>description</code> . Lines beginning with a pound sign (#) are designated as comments and ignored.)										
<code>-h <i>help</i></code>	Define the help messages as <i>help</i> .										
<code>-i <i>invis</i></code>	Define invisible menu choices (those which will not be printed in the menu). (For example, “all” used as an invisible choice would mean it is a legal option but does not appear in the menu. Any										

	number of invisible choices may be defined.) Invisible choices should be made known to a user either in the prompt or in a help message.
-k <i>pid</i>	Specify that the process ID <i>pid</i> is to be sent a signal if the user chooses to abort.
-l <i>label</i>	Define a label, <i>label</i> , to print above the menu.
-m <i>max</i>	Define the maximum number of menu choices that the user can choose. The default is 1.
-n	Specify that menu items should not be displayed in alphabetical order.
-o	Specify that only one menu token will be returned.
-p <i>prompt</i>	Define the prompt message as <i>prompt</i> .
-Q	Specify that quit will not be allowed as a valid response.
-s <i>signal</i>	Specify that process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-u	Specify that menu items should be displayed as an unnumbered list.
-W <i>width</i>	Specify that prompt, help and error messages will be formatted to a line length of <i>width</i> .

OPERANDS The following operand is supported:

<i>choice</i>	Define menu items. Items should be separated by white space or newline.
---------------	-------------------------------------------------------------------------

EXIT STATUS The following exit values are returned:

0	Successful execution.
1	EOF on input, or negative width on -W option, or inability to open file on -f option, or usage error.
3	User termination (quit).
4	No choices from which to choose.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`

ckitem(1)

NOTES | The user may input the number of the menu item if choices are numbered or as much of the string required for a unique identification of the item. Long menus are paged with 10 items per page.

When menu entries are defined both in a file (by using the `-f` option) and also on the command line, they are usually combined alphabetically. However, if the `-n` option is used to suppress alphabetical ordering, then the entries defined in the file are shown first, followed by the options defined on the command line.

The default prompt for `ckitem` is:

```
Enter selection [?,??,q]:
```

One question mark will give a help message and then redisplay the prompt. Two question marks will give a help message and then redisplay the menu label, the menu and the prompt.

The default error message if you typed a number is:

```
ERROR: Bad numeric choice specification
```

The default error message if you typed a string is:

```
ERROR: Entry does not match available menu selection. Enter the number of the menu item you wish to select, the token which is associated with the menu item, or a partial string which uniquely identifies the token for the menu item. Enter ?? to reprint the menu.
```

The default help message is:

```
Enter the number of the menu item you wish to select, the token which is associated with the menu item, or a partial string which uniquely identifies the token for the menu item. Enter ? to reprint the menu.
```

When the quit option is chosen (and allowed), `q` is returned along with the return code 3.

NAME	ckkeywd – prompts for and validates a keyword
SYNOPSIS	ckkeywd [-Q] [-W <i>width</i>] [-d <i>default</i>] [-h <i>help</i>] [-e <i>error</i>] [-p <i>prompt</i>] [-k <i>pid</i> [-s <i>signal</i>]] <i>keyword</i> [...]
DESCRIPTION	<p>ckkeywd prompts a user and validates the response. It defines, among other things, a prompt message whose response should be one of a list of keywords, text for help and error messages, and a default value (which will be returned if the user responds with a carriage return). The answer returned from this command must match one of the defined list of keywords.</p> <p>All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -w option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under NOTES) will be displayed.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -d <i>default</i> Defines the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria. -e <i>error</i> Defines the error message as <i>error</i>. -h <i>help</i> Defines the help messages as <i>help</i>. -k <i>pid</i> Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort. -p <i>prompt</i> Defines the prompt message as <i>prompt</i>. -Q Specifies that quit will not be allowed as a valid response. -s <i>signal</i> Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used. -w <i>width</i> Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i>.
OPERANDS	<p>The following operand is supported:</p> <ul style="list-style-type: none"> <i>keyword</i> Defines the keyword, or list of keywords, against which the answer will be verified.
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 Successful execution. 1 EOF on input, or negative width on -w option, or no keywords from which to choose, or usage error.

ckkeywd(1)

3 User termination (quit).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`

NOTES The default prompt for `ckkeywd` is:

Enter appropriate value [*keyword*, [. . .],?,q]:

The default error message is:

ERROR: Please enter one of the following keywords: *keyword*, [. . .],q

The default help message is:

keyword, [. . .],q

When the quit option is chosen (and allowed), `q` is returned along with the return code 3.

NAME	ckpath, errpath, helppath, valpath – display a prompt; verify and return a pathname
SYNOPSIS	<pre> ckpath [-Q] [-W <i>width</i>] [-a l] [-b c f y] [-n [o z]] [-rtwx] [-d <i>default</i>] [-h <i>help</i>] [-e <i>error</i>] [-p <i>prompt</i>] [-k <i>pid</i>] [-s <i>signal</i>]] /usr/sadm/bin/errpath [-W <i>width</i>] [-a l] [-b c f y] [-n [o z]] [-rtwx] [-e <i>error</i>] /usr/sadm/bin/helppath [-W <i>width</i>] [-a l] [-b c f y] [-n [o z]] [-rtwx] [-h <i>help</i>] /usr/sadm/bin/valpath [-a l] [-b c f y] [-n [o z]] [-rtwx] <i>input</i> </pre>
DESCRIPTION	<p>The <code>ckpath</code> utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a pathname, text for help and error messages, and a default value (which is returned if the user responds with a RETURN).</p> <p>The pathname must obey the criteria specified by the first group of options. If no criteria is defined, the pathname must be for a normal file that does not yet exist. If neither <code>-a</code> (absolute) or <code>-l</code> (relative) is given, then either is assumed to be valid.</p> <p>All messages are limited in length to 79 characters and are formatted automatically. Tabs and newlines are removed after a single white space character in a message definition, but spaces are not removed. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under <code>EXAMPLES</code>) is displayed.</p> <p>Three visual tool modules are linked to the <code>ckpath</code> command. They are <code>errpath</code> (which formats and displays an error message on the standard output), <code>helppath</code> (which formats and displays a help message on the standard output), and <code>valpath</code> (which validates a response). These modules should be used in conjunction with Framed Access Command Environment (FACE) objects. In this instance, the FACE object defines the prompt.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Pathname must be an absolute path. -b Pathname must be a block special file. -c Pathname must be a character special file. -d <i>default</i> Defines the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria. -e <i>error</i> Defines the error message as <i>error</i>. -f Pathname must be a regular file.

ckpath(1)

-h <i>help</i>	Defines the help message as <i>help</i> .
-k <i>pid</i>	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit.
-l	Pathname must be a relative path.
-n	Pathname must not exist (must be new).
-o	Pathname must exist (must be old).
-p <i>prompt</i>	Defines the prompt message as <i>prompt</i> .
-Q	Specify that quit is not allowed as a valid response.
-r	Pathname must be readable.
-s <i>signal</i>	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-t	Pathname must be creatable (touchable). Pathname will be created if it does not already exist.
-w	Pathname must be writable.
-W <i>width</i>	Specify that prompt, help and error messages be formatted to a line length of <i>width</i> .
-x	Pathname must be executable.
-y	Pathname must be a directory.
-z	Pathname must have a file having a size greater than zero bytes.

OPERANDS The following operand is supported:

input Input to be verified against validation options.

EXAMPLES The text of the default messages for `ckpath` depends upon the criteria options that have been used.

EXAMPLE 1 Default prompt

An example default prompt for `ckpath` (using the `-a` option) is:

```
example% ckpath -a
Enter an absolute pathname [?,q]
```

EXAMPLE 2 Default error message

An example default error message (using the `-a` option) is:

```
example% /usr/sadm/bin/errpath -a
ERROR: A pathname is a filename, optionally preceded by parent directories.
The pathname you enter: - must begin with a slash (/)
```

EXAMPLE 2 Default error message (Continued)

EXAMPLE 3 Default help message

An example default help message (using the `-a` option) is:

```
example% /usr/sadm/bin/helppath -a
A pathname is a filename, optionally preceded by parent directories.
The pathname you enter: - must begin with a slash (/)
```

EXAMPLE 4 The quit option

When the quit option is chosen (and allowed), `q` is returned along with the return code 3. Quit input gets a trailing newline.

EXAMPLE 5 Using the `valpath` module

The `valpath` module will produce a usage message on `stderr`. It returns 0 for success and non-zero for failure.

```
example% /usr/sadm/bin/valpath
usage: valpath [-[a|l] [b|c|f|y] [n] [o|z]]rtwx] input
.
.
.
```

EXIT STATUS The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on `-w` option, or usage error.
- 2 Mutually exclusive options.
- 3 User termination (quit).
- 4 Mutually exclusive options.

ckrange(1)

NAME	ckrange, errange, helprange, valrange – prompts for and validates an integer
SYNOPSIS	ckrange [-Q] [-W <i>width</i>] [-l <i>lower</i>] [-u <i>upper</i>] [-b <i>base</i>] [-d <i>default</i>] [-h <i>help</i>] [-e <i>error</i>] [-p <i>prompt</i>] [-k <i>pid</i>] [-s <i>signal</i>] /usr/sadm/bin/errange [-W <i>width</i>] [-e <i>error</i>] [-l <i>lower</i>] [-u <i>upper</i>] [-b <i>base</i>] /usr/sadm/bin/helprange [-W <i>width</i>] [-h <i>help</i>] [-l <i>lower</i>] [-u <i>upper</i>] [-b <i>base</i>] /usr/sadm/bin/valrange [-l <i>lower</i>] [-u <i>upper</i>] [-b <i>base</i>] <i>input</i>
DESCRIPTION	<p>The <code>ckrange</code> utility prompts a user for an integer between a specified range and determines whether this response is valid. It defines, among other things, a prompt message whose response should be an integer in the range specified, text for help and error messages, and a default value (which is returned if the user responds with a RETURN).</p> <p>This command also defines a range for valid input. If either the lower or upper limit is left undefined, then the range is bounded on only one end.</p> <p>All messages are limited in length to 79 characters and are formatted automatically. Tabs and newlines are removed after a single whitespace character in a message definition, but spaces are not removed. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under <code>EXAMPLES</code>) is displayed.</p> <p>Three visual tool modules are linked to the <code>ckrange</code> command. They are <code>errange</code> (which formats and displays an error message on the standard output), <code>helprange</code> (which formats and displays a help message on the standard output), and <code>valrange</code> (which validates a response). These modules should be used in conjunction with Framed Access Command Environment (FACE) objects. In this instance, the FACE object defines the prompt.</p> <p>Note: Negative "input" arguments confuse <code>getopt</code> in <code>valrange</code>. By inserting a "-" before the argument, <code>getopt</code> processing will stop. See <code>getopt(1)</code> and <code>intro(1)</code> about <code>getopt</code> parameter handling. <code>getopt</code> is used to parse positional parameters and to check for legal options.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-b <i>base</i> Defines the base for input. Must be 2 to 36, default is 10. Base conversion uses <code>strtol(3C)</code>. Output is always base 10.-d <i>default</i> Defines the default value as <i>default</i>. <i>default</i> is converted using <code>strtol(3C)</code> in the desired base. Any characters invalid in the specified base will terminate the <code>strtol</code> conversion without error.

-e <i>error</i>	Defines the error message as <i>error</i> .
-h <i>help</i>	Defines the help message as <i>help</i> .
-k <i>pid</i>	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit.
-l <i>lower</i>	Defines the lower limit of the range as <i>lower</i> . Default is the machine's largest negative long.
-p <i>prompt</i>	Defines the prompt message as <i>prompt</i> .
-Q	Specifies that quit will not be allowed as a valid response.
-s <i>signal</i>	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-u <i>upper</i>	Defines the upper limit of the range as <i>upper</i> . Default is the machine's largest positive long.
-w <i>width</i>	Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .

OPERANDS The following operand is supported:

input Input to be verified against upper and lower limits and base.

EXAMPLES **EXAMPLE 1** Default base 10 prompt

The default base 10 prompt for `ckrange` is:

```
example% ckrange
Enter an integer between lower_bound and
upper_bound [lower_bound-upper_bound, ?, q] :
```

EXAMPLE 2 Default base 10 error message

The default base 10 error message is:

```
example% /usr/sadm/bin/errrange
ERROR: Please enter an integer between lower_bound and upper_bound.
```

EXAMPLE 3 Default base 10 help message

The default base 10 help message is:

```
example% /usr/sadm/bin/helprange
Please enter an integer between lower_bound and upper_bound.
```

EXAMPLE 4 Changing messages for a base other than 10

The messages are changed from "integer" to "base *base* integer" if the base is set to a number other than 10. For example,

ckrange(1)

EXAMPLE 4 Changing messages for a base other than 10 *(Continued)*

```
example% /usr/sadm/bin/helprange -b 36
```

EXAMPLE 5 Using the quit option

When the quit option is chosen (and allowed), `q` is returned along with the return code 3. Quit input gets a trailing newline.

EXAMPLE 6 Using the valrange module

The `valrange` module will produce a usage message on `stderr`. It returns 0 for success and non-zero for failure.

```
example% /usr/sadm/bin/valrange
usage: valrange [-l lower] [-u upper] [-b base] input
```

EXIT STATUS The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on `-w` option, or usage error.
- 2 Usage error.
- 3 User termination (quit).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `intro(1)`, `face(1)`, `getopt(1)`, `strtol(3C)`, `attributes(5)`, `signal(3HEAD)`

NAME	ckstr, errstr, helpstr, valstr – display a prompt; verify and return a string answer
SYNOPSIS	<pre>ckstr [-Q] [-W width] [[-r regexp] [...]] [-l length] [-d default] [-h help] [-e error] [-p prompt] [-k pid [- s signal]] /usr/sadm/bin/errstr [-W width] [-e error] [-l length] [[-r regexp] [...]] /usr/sadm/bin/helpstr [-W width] [-h help] [-l length] [[-r regexp] [...]] /usr/sadm/bin/valstr [-l length] [[-r regexp] [...]] input</pre>
DESCRIPTION	<p>The <code>ckstr</code> utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a string, text for help and error messages, and a default value (which are returned if the user responds with a RETURN).</p> <p>The answer returned from this command must match the defined regular expression and be no longer than the length specified. If no regular expression is given, valid input must be a string with a length less than or equal to the length defined with no internal, leading or trailing white space. If no length is defined, the length is not checked.</p> <p>All messages are limited in length to 79 characters and are formatted automatically. Tabs and newlines are removed after a single white space character in a message definition, but spaces are not removed. When a tilde is placed at the beginning or end of a message definition, the default text will be inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under <code>EXAMPLES</code>) is displayed.</p> <p>Three visual tool modules are linked to the <code>ckstr</code> command. They are <code>errstr</code> (which formats and displays an error message on the standard output), <code>helpstr</code> (which formats and displays a help message on the standard output), and <code>valstr</code> (which validates a response). These modules should be used in conjunction with Framed Access Command Environment (FACE) objects. In this instance, the FACE object defines the prompt.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -d <i>default</i> Defines the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria. -e <i>error</i> Defines the error message as <i>error</i>. -h <i>help</i> Defines the help message as <i>help</i>. -k <i>pid</i> Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to quit. -l <i>length</i> Specifies the maximum length of the input.

ckstr(1)

<code>-p <i>prompt</i></code>	Defines the prompt message as <i>prompt</i> .
<code>-Q</code>	Specifies that quit will not be allowed as a valid response.
<code>-r <i>regexp</i></code>	Specifies a regular expression, <i>regexp</i> , against which the input should be validated. May include white space. If multiple expressions are defined, the answer need match only one of them.
<code>-s <i>signal</i></code>	Specifies that the process ID <i>pid</i> defined with the <code>-k</code> option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
<code>-W <i>width</i></code>	Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .

OPERANDS The following operand is supported:

<code><i>input</i></code>	Input to be verified against format length and/or regular expression criteria.
---------------------------	--------------------------------------------------------------------------------

EXAMPLES

EXAMPLE 1 Default prompt

The default prompt for `ckstr` is:

```
example% ckstr
Enter an appropriate value [?,q]:
```

EXAMPLE 2

Default error message

The default error message is dependent upon the type of validation involved. The user will be told either that the length or the pattern matching failed. The default error message is:

```
example% /usr/sadm/bin/errstr
ERROR: Please enter a string which contains no embedded,
leading or trailing spaces or tabs.
```

EXAMPLE 3

Default help message

The default help message is also dependent upon the type of validation involved. If a regular expression has been defined, the message is:

```
example% /usr/sadm/bin/helpstr -r regexp
Please enter a string which matches the following pattern:
regexp
```

Other messages define the length requirement and the definition of a string.

EXAMPLE 4

Using the quit option

When the quit option is chosen (and allowed), `q` is returned along with the return code 3. Quit input gets a trailing newline.

EXAMPLE 5 Using the valstr module

The `valstr` module will produce a usage message on `stderr`. It returns 0 for success and non-zero for failure.

```
example% /usr/sadm/bin/valstr
usage: valstr [-l length] [[-r regexp] [ . . . ]] input
```

EXIT STATUS The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on `-W` option, or usage error.
- 2 Invalid regular expression.
- 3 User termination (quit).

cksum(1)

NAME	cksum – write file checksums and sizes
SYNOPSIS	cksum [<i>file...</i>]
DESCRIPTION	<p>The <code>cksum</code> command calculates and writes to standard output a cyclic redundancy check (CRC) for each input file, and also writes to standard output the number of octets in each file.</p> <p>For each file processed successfully, <code>cksum</code> will write in the following format:</p> <pre>"%u %d %s\n" <checksum>, <# of octets>, <path name></pre> <p>If no <i>file</i> operand was specified, the path name and its leading space will be omitted.</p> <p>The CRC used is based on the polynomial used for CRC error checking in the referenced Ethernet standard.</p> <p>The encoding for the CRC checksum is defined by the generating polynomial:</p> $G(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$ <p>Mathematically, the CRC value corresponding to a given file is defined by the following procedure:</p> <ol style="list-style-type: none">1. The n bits to be evaluated are considered to be the coefficients of a mod 2 polynomial $M(x)$ of degree $n-1$. These n bits are the bits from the file, with the most significant bit being the most significant bit of the first octet of the file and the last bit being the least significant bit of the last octet, padded with zero bits (if necessary) to achieve an integral number of octets, followed by one or more octets representing the length of the file as a binary value, least significant octet first. The smallest number of octets capable of representing this integer is used.2. $M(x)$ is multiplied by x^{32} (that is, shifted left 32 bits) and divided by $G(x)$ using mod 2 division, producing a remainder $R(x)$ of degree ≤ 31.3. The coefficients of $R(x)$ are considered to be a 32-bit sequence.4. The bit sequence is complemented and the result is the CRC.
OPERANDS	<p>The following operand is supported:</p> <p><i>file</i> A path name of a file to be checked. If no <i>file</i> operands are specified, the standard input is used.</p>
USAGE	<p>The <code>cksum</code> command is typically used to quickly compare a suspect file against a trusted version of the same, such as to ensure that files transmitted over noisy media arrive intact. However, this comparison cannot be considered cryptographically secure. The chances of a damaged file producing the same CRC as the original are astronomically small; deliberate deception is difficult, but probably not impossible.</p>

Although input files to `cksum` can be any type, the results need not be what would be expected on character special device files. Since this document does not specify the block size used when doing input, checksums of character special files need not process all of the data in those files.

The algorithm is expressed in terms of a bitstream divided into octets. If a file is transmitted between two systems and undergoes any data transformation (such as moving 8-bit characters into 9-bit bytes or changing “Little Endian” byte ordering to “Big Endian”), identical CRC values cannot be expected. Implementations performing such transformations may extend `cksum` to handle such situations.

See `largefile(5)` for the description of the behavior of `cksum` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cksum`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 All files were processed successfully.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

cktime(1)

NAME	cktime, errtime, helptime, valtime – display a prompt; verify and return a time of day
SYNOPSIS	<pre>cktime [-Q] [-W width] [-f format] [-d default] [-h help] [-e error] [-p prompt] [-k pid [-s signal]] /usr/sadm/bin/errtime [-W width] [-e error] [-f format] /usr/sadm/bin/helptime [-W width] [-h help] [-f format] /usr/sadm/bin/valtime [-f format] input</pre>
DESCRIPTION	<p>The <code>cktime</code> utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be a time, text for help and error messages, and a default value (which is returned if the user responds with a RETURN). The user response must match the defined format for the time of day.</p> <p>All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including NEWLINE) is stripped. The <code>-W</code> option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under NOTES) is displayed.</p> <p>Three visual tool modules are linked to the <code>cktime</code> command. They are <code>errtime</code> (which formats and displays an error message), <code>helptime</code> (which formats and displays a help message), and <code>valtime</code> (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt. When <code>format</code> is defined in the <code>errtime</code> and <code>helptime</code> modules, the messages will describe the expected format.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-d default</code> Defines the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria. <code>-e error</code> Defines the error message as <i>error</i>. <code>-f format</code> Specifies the format against which the input will be verified. Possible formats and their definitions are: <ul style="list-style-type: none"> <code>%H</code> = hour (00 - 23) <code>%I</code> = hour (00 - 12) <code>%M</code> = minute (00 - 59) <code>%p</code> = ante meridian or post meridian <code>%r</code> = time as <code>%I:%M:%S %p</code> <code>%R</code> = time as <code>%H:%M</code> (the default format) <code>%S</code> = seconds (00 - 59) <code>%T</code> = time as <code>%H:%M:%S</code> <code>-h help</code> Defines the help messages as <i>help</i>.

-k <i>pid</i>	Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.
-p <i>prompt</i>	Defines the prompt message as <i>prompt</i> .
-Q	Specifies that quit will not be allowed as a valid response.
-s <i>signal</i>	Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.
-W <i>width</i>	Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i> .

OPERANDS The following operand is supported:

input Input to be verified against format criteria.

EXIT STATUS The following exit values are returned:

0	Successful execution.
1	EOF on input, or negative width on -W option, or usage error .
3	User termination (quit) .
4	Garbled format argument.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`

NOTES The default prompt for `cktime` is:

Enter a time of day [?,q]:

The default error message is:

ERROR: Please enter the time of day. Format is <format>.

The default help message is:

Please enter the time of day. Format is <format>.

When the quit option is chosen (and allowed), `q` is returned along with the return code 3. The `valtime` module will not produce any output. It returns 0 for success and non-zero for failure.

ckuid(1)

NAME	ckuid, erruid, helpuid, valuid – prompts for and validates a user ID
SYNOPSIS	ckuid [-Q] [-W <i>width</i>] [-m] [-d <i>default</i>] [-h <i>help</i>] [-e <i>error</i>] [-p <i>prompt</i>] [-k <i>pid</i> [-s <i>signal</i>]] /usr/sadm/bin/erruid [-W <i>width</i>] [-e <i>error</i>] /usr/sadm/bin/helpuid [-W <i>width</i>] [-m] [-h <i>help</i>] /usr/sadm/bin/valuid <i>input</i>
DESCRIPTION	<p>The <code>ckuid</code> utility prompts a user and validates the response. It defines, among other things, a prompt message whose response should be an existing user ID, text for help and error messages, and a default value (which are returned if the user responds with a RETURN).</p> <p>All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including NEWLINE) is stripped. The <code>-w</code> option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under NOTES) is displayed.</p> <p>Three visual tool modules are linked to the <code>ckuid</code> command. They are <code>erruid</code> (which formats and displays an error message), <code>helpuid</code> (which formats and displays a help message), and <code>valuid</code> (which validates a response). These modules should be used in conjunction with FML objects. In this instance, the FML object defines the prompt.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-d <i>default</i> Defines the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria.-e <i>error</i> Defines the error message as <i>error</i>.-h <i>help</i> Defines the help messages as <i>help</i>.-k <i>pid</i> Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.-m Displays a list of all logins when help is requested or when the user makes an error.-p <i>prompt</i> Defines the prompt message as <i>prompt</i>.-Q Specifies that quit will not be allowed as a valid response.-s <i>signal</i> Specifies that the process ID <i>pid</i> defined with the <code>-k</code> option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.

-w width Specifies that prompt, help and error messages will be formatted to a line length of *width*.

OPERANDS The following operand is supported:

input Input to be verified against */etc/passwd*.

EXIT STATUS The following exit values are returned:

0 Successful execution.
 1 EOF on input, or negative width on *-W* option, or usage error.
 2 Usage error.
 3 User termination (quit).

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO *attributes(5)*

NOTES The default prompt for *ckuid* is:

Enter the login name of an existing user [?,q]:

The default error message is:

ERROR - Please enter the login name of an existing user.

If the *-m* option is used, the default error message is:

ERROR: Please enter one of the following login names: <List>

The default help message is:

Please enter the login name of an existing user.

If the *-m* option is used, the default help message is:

Please enter one of the following login names: <List>

When the quit option is chosen (and allowed), *q* is returned along with the return code 3. The *valuid* module will not produce any output. It returns 0 for success and non-zero for failure.

ckyorn(1)

NAME	ckyorn, erryorn, helpyorn, valyorn – prompts for and validates yes/no
SYNOPSIS	ckyorn [-Q] [-W <i>width</i>] [-d <i>default</i>] [-h <i>help</i>] [-e <i>error</i>] [-p <i>prompt</i>] [-k <i>pid</i> [-s <i>signal</i>]] /usr/sadm/bin/erryorn [-W <i>width</i>] [-e <i>error</i>] /usr/sadm/bin/helpyorn [-W <i>width</i>] [-h <i>help</i>] /usr/sadm/bin/valyorn <i>input</i>
DESCRIPTION	<p>ckyorn prompts a user and validates the response. It defines, among other things, a prompt message for a yes or no answer, text for help and error messages, and a default value (which is returned if the user responds with a RETURN).</p> <p>All messages are limited in length to 70 characters and are formatted automatically. Any white space used in the definition (including newline) is stripped. The -w option cancels the automatic formatting. When a tilde is placed at the beginning or end of a message definition, the default text is inserted at that point, allowing both custom text and the default text to be displayed.</p> <p>If the prompt, help or error message is not defined, the default message (as defined under NOTES) is displayed.</p> <p>Three visual tool modules are linked to the ckyorn command. They are erryorn (which formats and displays an error message), helpyorn (which formats and displays a help message), and valyorn (which validates a response). These modules should be used in conjunction with FACE objects. In this instance, the FACE object defines the prompt.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-d <i>default</i> Defines the default value as <i>default</i>. The default is not validated and so does not have to meet any criteria.-e <i>error</i> Defines the error message as <i>error</i>.-h <i>help</i> Defines the help messages as <i>help</i>.-k <i>pid</i> Specifies that process ID <i>pid</i> is to be sent a signal if the user chooses to abort.-p <i>prompt</i> Defines the prompt message as <i>prompt</i>.-Q Specifies that quit will not be allowed as a valid response.-s <i>signal</i> Specifies that the process ID <i>pid</i> defined with the -k option is to be sent signal <i>signal</i> when quit is chosen. If no signal is specified, SIGTERM is used.-w <i>width</i> Specifies that prompt, help and error messages will be formatted to a line length of <i>width</i>.
OPERANDS	The following operand is supported:

input Input to be verified as *y*, *yes*, or *n*, *no* (in any combination of upper- and lower-case letters).

EXIT STATUS The following exit values are returned:

- 0 Successful execution.
- 1 EOF on input, or negative width on *-W* option, or usage error.
- 2 Usage error.
- 3 User termination (quit).

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO *attributes(5)*

NOTES The default prompt for *ckyornd* is:

Yes or No [y,n,?,q]:

The default error message is:

ERROR - Please enter yes or no.

The default help message is:

To respond in the affirmative, enter *y*, *yes*, *Y*, or *YES*.
 To respond in the negative, enter *n*, *no*, *N*, or *NO*.

When the quit option is chosen (and allowed), *q* is returned along with the return code 3. The *valyornd* module will not produce any output. It returns 0 for success and non-zero for failure.

clear(1)

NAME clear – clear the terminal screen

SYNOPSIS `clear`

DESCRIPTION `clear` clears your screen if this is possible. It looks in the environment for the terminal type and then in the terminfo database to figure out how to clear the screen.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `attributes(5)`

NAME	cmp – compare two files
SYNOPSIS	cmp [-l] [-s] <i>file1 file2</i> [<i>skip1</i>] [<i>skip2</i>]
DESCRIPTION	The cmp utility compares two files. cmp will write no output if the files are the same. Under default options, if they differ, it writes to standard output the byte and line numbers at which the first difference occurred. Bytes and lines are numbered beginning with 1. If one file is an initial subsequence of the other, that fact is noted. <i>skip1</i> and <i>skip2</i> are initial byte offsets into <i>file1</i> and <i>file2</i> respectively, and may be either octal or decimal; a leading 0 denotes octal.
OPTIONS	<p>-l Write the byte number (decimal) and the differing bytes (octal) for each difference.</p> <p>-s Write nothing for differing files; return exit statuses only.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>file1</i> A path name of the first file to be compared. If <i>file1</i> is –, the standard input will be used.</p> <p><i>file2</i> A path name of the second file to be compared. If <i>file2</i> is –, the standard input will be used.</p> <p>If both <i>file1</i> and <i>file2</i> refer to standard input or refer to the same FIFO special, block special or character special file, an error results.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of cmp when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 Byte for byte comparison of files.</p> <p>The following example:</p> <pre>example% cmp file1 file2 0 1024</pre> <p>does a byte for byte comparison of <i>file1</i> and <i>file2</i>. It skips the first 1024 bytes in <i>file2</i> before starting the comparison.</p>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of cmp : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>The following error values are returned:</p> <p>0 The files are identical.</p> <p>1 The files are different; this includes the case where one file is identical to the first part of the other.</p> <p>>1 An error occurred.</p>

NAME	col – reverse line-feeds filter												
SYNOPSIS	col [-bfp x]												
DESCRIPTION	<p>The <code>col</code> utility reads from the standard input and writes to the standard output. It performs the line overlays implied by reverse line-feeds, and by forward and reverse half-line-feeds. Unless <code>-x</code> is used, all blank characters in the input will be converted to tab characters wherever possible. <code>col</code> is particularly useful for filtering multi-column output made with the <code>.rt</code> command of <code>nroff(1)</code> and output resulting from use of the <code>tbl(1)</code> preprocessor.</p> <p>The ASCII control characters SO and SI are assumed by <code>col</code> to start and end text in an alternative character set. The character set to which each input character belongs is remembered, and on output SI and SO characters are generated as appropriate to ensure that each character is written in the correct character set.</p> <p>On input, the only control characters accepted are space, backspace, tab, carriage-return and newline characters, SI, SO, VT, reverse line-feed, forward half-line-feed and reverse half-line-feed. The VT character is an alternative form of full reverse line-feed, included for compatibility with some earlier programs of this type. The only other characters to be copied to the output are those that are printable.</p> <p>The ASCII codes for the control functions and line-motion sequences mentioned above are as given in the table below. ESC stands for the ASCII escape character, with the octal code 033; ESC– means a sequence of two characters, ESC followed by the character x.</p> <table border="0" style="width: 100%; margin-top: 10px;"> <tr> <td style="padding-right: 40px;">reverse line-feed</td> <td>ESC–7</td> </tr> <tr> <td>reverse half-line-feed</td> <td>ESC–8</td> </tr> <tr> <td>forward half-line-feed</td> <td>ESC–9</td> </tr> <tr> <td>vertical-tab (VT)</td> <td>013</td> </tr> <tr> <td>start-of-text (SO)</td> <td>016</td> </tr> <tr> <td>end-of-text (SI)</td> <td>017</td> </tr> </table>	reverse line-feed	ESC–7	reverse half-line-feed	ESC–8	forward half-line-feed	ESC–9	vertical-tab (VT)	013	start-of-text (SO)	016	end-of-text (SI)	017
reverse line-feed	ESC–7												
reverse half-line-feed	ESC–8												
forward half-line-feed	ESC–9												
vertical-tab (VT)	013												
start-of-text (SO)	016												
end-of-text (SI)	017												
OPTIONS	<p><code>-b</code> Assume that the output device in use is not capable of backspacing. In this case, if two or more characters are to appear in the same place, only the last one read will be output.</p> <p><code>-f</code> Although <code>col</code> accepts half-line motions in its input, it normally does not emit them on output. Instead, text that would appear between lines is moved to the next lower full-line boundary. This treatment can be suppressed by the <code>-f</code> (fine) option; in this case, the output from <code>col</code> may contain forward half-line-feeds (ESC-9), but will still never contain either kind of reverse line motion.</p>												

col(1)

- p Normally, col will ignore any escape sequences unknown to it that are found in its input; the -p option may be used to cause col to output these sequences as regular characters, subject to overprinting from reverse line motions. The use of this option is highly discouraged unless the user is fully aware of the textual position of the escape sequences.
- x Prevent col from converting blank characters to tab characters on output wherever possible. Tab stops are considered to be at each column position *n* such that *n* modulo 8 equals 1.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of col: LC_CTYPE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following error values are returned:

- 0 Successful completion.
- >0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	enabled

SEE ALSO

`nroff(1)`, `tbl(1)`, `ascii(5)`, `attributes(5)`, `environ(5)`

NOTES

The input format accepted by col matches the output produced by `nroff` with either the -T37 or -Tlp options. Use -T37 (and the -f option of col) if the ultimate disposition of the output of col will be a device that can interpret half-line motions, and -Tlp otherwise.

col cannot back up more than 128 lines or handle more than 800 characters per line.

Local vertical motions that would result in backing up over the first line of the document are ignored. As a result, the first line must not have any superscripts.

NAME	comm – select or reject lines common to two files
SYNOPSIS	comm [-123] <i>file1 file2</i>
DESCRIPTION	<p>The <code>comm</code> utility will read <i>file1</i> and <i>file2</i>, which should be ordered in the current collating sequence, and produce three text columns as output: lines only in <i>file1</i>; lines only in <i>file2</i>; and lines in both files.</p> <p>If the input files were ordered according to the collating sequence of the current locale, the lines written will be in the collating sequence of the original lines. If not, the results are unspecified.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -1 Suppress the output column of lines unique to <i>file1</i>. -2 Suppress the output column of lines unique to <i>file2</i>. -3 Suppress the output column of lines duplicated in <i>file1</i> and <i>file2</i>.
OPERANDS	<p>The following operands are supported:</p> <p><i>file1</i> A path name of the first file to be compared. If <i>file1</i> is <code>-</code>, the standard input is used.</p> <p><i>file2</i> A path name of the second file to be compared. If <i>file2</i> is <code>-</code>, the standard input is used.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>comm</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
EXAMPLES	<p>EXAMPLE 1 Printing a list of utilities specified by files.</p> <p>If <i>file1</i>, <i>file2</i>, and <i>file3</i> each contained a sorted list of utilities:</p> <pre>example% comm -23 file1 file2 comm -23 - file3</pre> <p>would print a list of utilities in <i>file1</i> not specified by either of the other files;</p> <pre>example% comm -12 file1 file2 comm -12 - file3</pre> <p>would print a list of utilities specified by all three files; and</p> <pre>example% comm -12 file2 file3 comm -23 -file1</pre> <p>would print a list of utilities specified by both <i>file2</i> and <i>file3</i>, but not specified in <i>file1</i>.</p>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>comm</code> : <code>LC_COLLATE</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none"> 0 All input files were successfully output as specified. >0 An error occurred.

NAME	command – execute a simple command
SYNOPSIS	<p>command [-p] <i>command_name</i> [<i>argument...</i>]</p> <p>command [-v -V] <i>command_name</i></p>
DESCRIPTION	<p>The <code>command</code> utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup.</p> <p>If the <i>command_name</i> is the same as the name of one of the special built-in utilities, the special properties will not occur. In every other respect, if <i>command_name</i> is not the name of a function, the effect of <code>command</code> will be the same as omitting <code>command</code>.</p> <p>The <code>command</code> utility also provides information concerning how a command name will be interpreted by the shell; see <code>-v</code> and <code>-V</code>.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-p</code> Perform the command search using a default value for <code>PATH</code> that is guaranteed to find all of the standard utilities.</p> <p><code>-v</code> Write a string to standard output that indicates the path or command that will be used by the shell, in the current shell execution environment to invoke <i>command_name</i>.</p> <ul style="list-style-type: none"> ■ Utilities, regular built-in utilities, <i>command_names</i> including a slash character, and any implementation-provided functions that are found using the <code>PATH</code> variable will be written as absolute path names. ■ Shell functions, special built-in utilities, regular built-in utilities not associated with a <code>PATH</code> search, and shell reserved words will be written as just their names. ■ An alias will be written as a command line that represents its alias definition. ■ Otherwise, no output will be written and the exit status will reflect that the name was not found. <p><code>-V</code> Write a string to standard output that indicates how the name given in the <i>command_name</i> operand will be interpreted by the shell, in the current shell execution environment. Although the format of this string is unspecified, it will indicate in which of the following categories <i>command_name</i> falls and include the information stated:</p> <ul style="list-style-type: none"> ■ Utilities, regular built-in utilities, and any implementation-provided functions that are found using the <code>PATH</code> variable will be identified as such and include the absolute path name in the string. ■ Other shell functions will be identified as functions. ■ Aliases will be identified as aliases and their definitions will be included in the string. ■ Special built-in utilities will be identified as special built-in utilities. ■ Regular built-in utilities not associated with a <code>PATH</code> search will be identified as regular built-in utilities.

command(1)

- Shell reserved words will be identified as reserved words.

OPERANDS The following operands are supported:

argument One of the strings treated as an argument to *command_name*.
command_name The name of a utility or a special built-in utility.

EXAMPLES **EXAMPLE 1** Make a version of `cd` that always prints out the new working directory exactly once:

```
cd() {  
    command cd "$@" >/dev/null  
    pwd  
}
```

EXAMPLE 2 Start off a “secure shell script” in which the script avoids being spoofed by its parent:

```
IFS='  
'  
# The preceding value should be <space><tab><newline>.  
# Set IFS to its default value.  
\unalias -a  
# Unset all possible aliases.  
# Note that unalias is escaped to prevent an alias  
# being used for unalias.  
unset -f command  
# Ensure command is not a user function.  
PATH="$(command -p getconf _CS_PATH):$PATH"  
# Put on a reliable PATH prefix.  
# . . .
```

At this point, given correct permissions on the directories called by `PATH`, the script has the ability to ensure that any utility it calls is the intended one. It is being very cautious because it assumes that implementation extensions may be present that would allow user functions to exist when it is invoked; this capability is not specified by this document, but it is not prohibited as an extension. For example, the `ENV` variable precedes the invocation of the script with a user startup script. Such a script could define functions to spoof the application.

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `command`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`PATH` Determine the search path used during the command search, except as described under the `-p` option.

EXIT STATUS When the `-v` or `-V` options are specified, the following exit values are returned:

0 Successful completion.
>0 The *command_name* could not be found or an error occurred.

Otherwise, the following exit values are returned:

command(1)

126 The utility specified by *command_name* was found but could not be invoked.

127 An error occurred in the `command` utility or the utility specified by *command_name* could not be found.

Otherwise, the exit status of `command` will be that of the simple command specified by the arguments to `command`.

compress(1)

NAME	compress, uncompress, zcat – compress, uncompress files or display expanded files
SYNOPSIS	compress [-fv] [-b <i>bits</i>] [<i>file...</i>] compress [-cfv] [-b <i>bits</i>] [<i>file</i>] uncompress [-cfv] [<i>file...</i>] zcat [<i>file...</i>]
DESCRIPTION	<p>compress The <code>compress</code> utility will attempt to reduce the size of the named files by using adaptive Lempel-Ziv coding. Except when the output is to the standard output, each file will be replaced by one with the extension <code>.Z</code>, while keeping the same ownership modes, change times and modification times. If appending the <code>.Z</code> to the file pathname would make the pathname exceed 1023 bytes, the command will fail. If no files are specified, the standard input will be compressed to the standard output.</p> <p>The amount of compression obtained depends on the size of the input, the number of <i>bits</i> per code, and the distribution of common substrings. Typically, text such as source code or English is reduced by 50–60%. Compression is generally much better than that achieved by Huffman coding (as used in <code>pack(1)</code>), and takes less time to compute. The <i>bits</i> parameter specified during compression is encoded within the compressed file, along with a magic number to ensure that neither decompression of random data nor recompression of compressed data is subsequently allowed.</p> <p>uncompress The <code>uncompress</code> utility will restore files to their original state after they have been compressed using the <code>compress</code> utility. If no files are specified, the standard input will be uncompressed to the standard output.</p> <p>This utility supports the uncompressing of any files produced by <code>compress</code>. For files produced by <code>compress</code> on other systems, <code>uncompress</code> supports 9- to 16-bit compression (see <code>-b</code>).</p> <p>zcat The <code>zcat</code> utility will write to standard output the uncompressed form of files that have been compressed using <code>compress</code>. It is the equivalent of <code>uncompress -c</code>. Input files are not affected.</p>
OPTIONS	The following options are supported: <ul style="list-style-type: none"><code>-c</code> Write to the standard output; no files are changed and no <code>.Z</code> files are created. The behavior of <code>zcat</code> is identical to that of <code>'uncompress -c'</code>.<code>-f</code> When compressing, force compression of <i>file</i>, even if it does not actually reduce the size of the file, or if the corresponding <i>file.Z</i> file already exists. If the <code>-f</code> option is not given, and the process is not running in the background, prompt to verify whether an existing <i>file.Z</i> file should be overwritten. When uncompressing, do not prompt for overwriting files. If the <code>-f</code> option is not given, and the process is not running in the background, prompt to verify whether an existing file should be

overwritten. If the standard input is not a terminal and `-f` is not given, write a diagnostic message to standard error and exit with a status greater than 0.

- `-v` Verbose. Write to standard error messages concerning the percentage reduction or expansion of each file.
- `-b bits` Set the upper limit (in bits) for common substring codes. *bits* must be between 9 and 16 (16 is the default). Lowering the number of bits will result in larger, less compressed files.

OPERANDS The following operands are supported:

file A path name of a file to be compressed. If *file* is `-`, or if no *file* is specified, the standard input will be used.

USAGE See `largefile(5)` for the description of the behavior of `compress`, `uncompress`, and `zcat` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `compress`, `uncompress`, and `zcat`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following error values are returned:

- 0 Successful completion.
- 1 An error occurred.
- 2 One or more files were not compressed because they would have increased in size (and the `-f` option was not specified).
- >2 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled

SEE ALSO `ln(1)`, `pack(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

DIAGNOSTICS Usage: `compress [-fvc] [-b maxbits] [file ...]`
 Invalid options were specified on the command line.

Missing maxbits
 Maxbits must follow `-b`, or invalid maxbits, not a numeric value.

file: not in compressed format
 The file specified to `uncompress` has not been compressed.

compress(1)

file: compressed with *xx*bits, can only handle *yy*bits
 file was compressed by a program that could deal with more *bits* than the
 compress code on this machine. Recompress the file with smaller *bits*.

file: already has .Z suffix -- no change
 The file is assumed to be already compressed. Rename the file and try again.

file: already exists; do you wish to overwrite (y or n)?
 Respond y if you want the output file to be replaced; n if not.

uncompress: corrupt input
 A SIGSEGV violation was detected, which usually means that the input file is
 corrupted.

Compression: *xx.xx*%
 Percentage of the input saved by compression. (Relevant only for -v.)

-- not a regular file: unchanged
 When the input file is not a regular file, (such as a directory), it is left unaltered.

-- has *xx* other links: unchanged
 The input file has links; it is left unchanged. See `ln(1)` for more information.

-- file unchanged
 No savings are achieved by compression. The input remains uncompressed.

filename too long to tack on .Z
 The path name is too long to append the .Z suffix.

NOTES Although compressed files are compatible between machines with large memory, -b
12 should be used for file transfer to architectures with a small process data space
(64KB or less).

compress should be more flexible about the existence of the . Z suffix.

NAME	coproc, cocreate, cosend, cocheck, coreceive, codestroy – communicate with a process
SYNOPSIS	<pre>cocreate [-r <i>rpath</i>] [-w <i>wpath</i>] [-i <i>id</i>] [-R <i>refname</i>] [-s <i>send_string</i>] [-e <i>expect_string</i>] <i>command</i> cosend [-n] <i>proc_id</i> <i>string</i> cocheck <i>proc_id</i> coreceive <i>proc_id</i> codestroy [-R <i>refname</i>] <i>proc_id</i> [<i>string</i>]</pre>
DESCRIPTION	<p>These co-processing functions provide a flexible means of interaction between FMLI and an independent process; especially, they enable FMLI to be responsive to asynchronous activity.</p> <p>The <code>cocreate</code> function starts <i>command</i> as a co-process and initializes communications by setting up pipes between FMLI and the standard input and standard output of <i>command</i>. The argument <i>command</i> must be an executable and its arguments (if any). This means that <i>command</i> expects strings on its input (supplied by <code>cosend</code>) and sends information on its output that can be handled in various ways by FMLI.</p> <p>The <code>cosend</code> function sends <i>string</i> to the co-process identified by <i>proc_id</i> via the pipe set up by <code>cocreate</code> (optionally <i>wpath</i>), where <i>proc_id</i> can be either the <i>command</i> or <i>id</i> specified in <code>cocreate</code>. By default, <code>cosend</code> blocks, waiting for a response from the co-process. Also by default, FMLI does not send a <i>send_string</i> and does not expect an <i>expect_string</i> (except a newline). That is, it reads only one line of output from the co-process. If <code>-e expect_string</code> was not defined when the pipe was created, then the output of the co-process is any single string followed by a newline: any other lines of output remain on the pipe. If the <code>-e</code> option was specified when the pipe was created, <code>cosend</code> reads lines from the pipe until it reads a line starting with <i>expect_string</i>. All lines except the line starting with <i>expect_string</i> become the output of <code>cosend</code>.</p> <p>The <code>cocheck</code> function determines if input is available from the process identified by <i>proc_id</i>, where <i>proc_id</i> can be either the <i>command</i> or <i>id</i> specified in <code>cocreate</code>. It returns a Boolean value, which makes <code>cocheck</code> useful in <code>if</code> statements and in other backquoted expressions in Boolean descriptors. <code>cocheck</code> receives no input from the co-process; it simply indicates if input is available from the co-process. You must use <code>coreceive</code> to actually accept the input. The <code>cocheck</code> function can be called from a <code>reread</code> descriptor to force a frame to update when new data is available. This is useful when the default value of a field in a form includes <code>coreceive</code>.</p> <p>The <code>coreceive</code> function is used to read input from the co-process identified by <i>proc_id</i>, where <i>proc_id</i> can be either the <i>command</i> or <i>id</i> specified in <code>cocreate</code>. It should only be used when it has been determined, using <code>cocheck</code>, that input is actually available. If the <code>-e</code> option was used when the co-process was created, <code>coreceive</code> will continue to return lines of input until <i>expect_string</i> is read. At this point, <code>coreceive</code> will terminate. The output of <code>coreceive</code> is all the lines that were read excluding the</p>

coproc(1F)

line starting with *expect_string*. If the `-e` option was not used in the `cocreate`, each invocation of `coreceive` will return exactly one line from the co-process. If no input is available when `coreceive` is invoked, it will simply terminate without producing output.

The `codestroy` function terminates the read/write pipes to *proc-id*, where *proc-id* can be either the *command* or *id* specified in `cocreate`. It generates a SIGPIPE signal to the (child) co-process. This kills the co-process, unless the co-process ignores the SIGPIPE signal. If the co-process ignores the SIGPIPE, it will not die, even after the FMLI process terminates (the parent process id of the co-process will be 1).

The optional argument *string* is sent to the co-process before the co-process dies. If *string* is not supplied, a NULL string is passed, followed by the normal *send_string* (newline by default). That is, `codestroy` will call `cosend proc_id string`: this implies that `codestroy` will write any output generated by the co-process to *stdout*. For example, if an interactive co-process is written to expect a "quit" string when the communication is over, the `close` descriptor could be defined; `close='codestroy ID 'quit' | message'` and any output generated by the co-process when the string quit is sent to it via `codestroy` (using `cosend`) would be redirected to the message line.

The `codestroy` function should usually be given the `-R` option, since you may have more than one process with the same name, and you do not want to kill the wrong one. `codestroy` keeps track of the number of *refnames* you have assigned to a process with `cocreate`, and when the last instance is killed, it kills the process (*id*) for you. `codestroy` is typically called as part of a `close` descriptor because `close` is evaluated when a frame is closed. This is important because the co-process will continue to run if `codestroy` is not issued.

When writing programs to use as co-processes, the following tips may be useful. If the co-process program is written in C language, be sure to flush output after writing to the pipe. (Currently, `awk(1)` and `sed(1)` cannot be used in a co-process program because they do not flush after lines of output.) Shell scripts are well-mannered, but slow. C language is recommended. If possible, use the default *send_string*, *rpath* and *wpath*. In most cases, *expect_string* will have to be specified. This, of course, depends on the co-process.

In the case where asynchronous communication from a co-process is desired, a co-process program should use `vsig` to force strings into the pipe and then signal FMLI that output from the co-process is available. This causes the `reread` descriptor of all frames to be evaluated immediately.

OPTIONS

`cocreate` options are:

`-r rpath`

If `-r` is specified, *rpath* is the pathname from which FMLI reads information. This option is usually used to set up communication with processes that naturally write to a certain path. If `-r` is not specified, `cocreate` will choose a unique path in `/var/tmp`.

<code>-w <i>wpath</i></code>	If <code>-w</code> is specified, <i>wpath</i> is the pathname to which <code>cosend</code> writes information. This option is usually used so that one process can talk to many different FMLI processes through the same pipe. If <code>-w</code> is not specified, <code>cocreate</code> will choose a unique path in <code>/var/tmp</code> .
<code>-i <i>id</i></code>	If <code>-i</code> is specified, <i>id</i> is an alternative name for the co-process initialized by this <code>cocreate</code> . If <code>-i</code> is not specified, <i>id</i> defaults to <i>command</i> . The argument <i>id</i> can later be used with the other co-processing functions rather than <i>command</i> . This option is typically used, since it facilitates the creation of two or more co-processes generated from the same <i>command</i> . (For example, <code>cocreate -i ID1 program args</code> and <code>cocreate -i ID2 program different_args</code>).
<code>-R <i>refname</i></code>	If <code>-R</code> is specified, <i>refname</i> is a local name for the co-process. Since the <code>cocreate</code> function can be issued more than once, a <i>refname</i> is useful when the same co-process is referenced a second or subsequent time. With the <code>-R</code> option, if the co-process already exists a new one will not be created: the same pipes will be shared. Then, <i>refname</i> can be used as an argument to the <code>-R</code> option to <code>codestroy</code> when you want to end a particular connection to a co-process and leave other connections undisturbed. (The co-process is only killed after <code>codestroy -R</code> has been called as many times as <code>cocreate -R</code> was called.)
<code>-s <i>send_string</i></code>	The <code>-s</code> option specifies <i>send_string</i> as a string that will be appended to all output sent to the co-process using <code>cosend</code> . This option allows a co-process to know when input from FMLI has completed. The default <i>send_string</i> is a newline if <code>-s</code> is not specified.
<code>-e <i>expect_string</i></code>	The <code>-e</code> option specifies <i>expect_string</i> as a string that identifies the end of all output returned by the co-process. (Note: <i>expect_string</i> need only be the initial part of a line, and there must be a newline at the end of the co-process output.) This option allows FMLI to know when output from the co-process has completed. The default <i>expect_string</i> is a newline if <code>-e</code> is not specified.

`cosend` options are:

<code>-n</code>	If the <code>-n</code> option is specified, <code>cosend</code> will not wait for a response from the co-process. It simply returns, providing no output. If the <code>-n</code> option is not used, a co-process that does not answer will cause FMLI to permanently hang, waiting for input from the co-process.
-----------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

coproc(1F)

EXAMPLES

EXAMPLE 1 Sample commands

```
.  
. .  
init='cocreate -i BIGPROCESS initialize'  
close='codestroy BIGPROCESS'  
. .  
reread='cocheck BIGPROCESS'  
  
name='cosend -n BIGPROCESS field1'  
. .  
name="Receive field"  
inactive=TRUE  
value='coreceive BIGPROCESS'
```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`awk(1)`, `cat(1)`, `sed(1)`, `vsig(1F)`, `attributes(5)`

NOTES

If `cosend` is used without the `-n` option, a co-process that does not answer will cause FMLI to permanently hang.

The use of non-alphabetic characters in input and output strings to a co-process should be avoided because they may not get transferred correctly.

NAME	cp – copy files
SYNOPSIS	<pre> /usr/bin/cp [-fip] source_file target_file /usr/bin/cp [-fip] source_file... target /usr/bin/cp -r -R [-fip] source_dir... target /usr/xpg4/bin/cp [-fip] source_file target_file /usr/xpg4/bin/cp [-fip] source_file... target /usr/xpg4/bin/cp -r -R [-fip] source_dir... target </pre>
DESCRIPTION	<p>In the first synopsis form, neither <i>source_file</i> nor <i>target_file</i> are directory files, nor can they have the same name. The <code>cp</code> utility will copy the contents of <i>source_file</i> to the destination path named by <i>target_file</i>. If <i>target_file</i> exists, <code>cp</code> will overwrite its contents, but the mode (and ACL if applicable), owner, and group associated with it are not changed. The last modification time of <i>target_file</i> and the last access time of <i>source_file</i> are set to the time the copy was made. If <i>target_file</i> does not exist, <code>cp</code> creates a new file named <i>target_file</i> that has the same mode as <i>source_file</i> except that the sticky bit is not set unless the user is superuser; the owner and group of <i>target_file</i> are those of the user. If <i>target_file</i> is a link to another file, <code>cp</code> will overwrite the link destination with the contents of <i>source_file</i>; the link(s) from <i>target_file</i> will remain.</p> <p>In the second synopsis form, one or more <i>source_files</i> are copied to the directory specified by <i>target</i>. For each <i>source_file</i> specified, a new file with the same mode (and ACL if applicable), is created in <i>target</i>; the owner and group are those of the user making the copy. It is an error if any <i>source_file</i> is a file of type directory, if <i>target</i> either does not exist or is not a directory.</p> <p>In the third synopsis form, one or more directories specified by <i>source_dir</i> are copied to the directory specified by <i>target</i>. Either <code>-r</code> or <code>-R</code> must be specified. For each <i>source_dir</i>, <code>cp</code> will copy all files and subdirectories.</p>
OPTIONS	<p>The following options are supported for both <code>/usr/bin/cp</code> and <code>/usr/xpg4/bin/cp</code>:</p> <ul style="list-style-type: none"> <code>-f</code> Unlink. If a file descriptor for a destination file cannot be obtained, attempt to unlink the destination file and proceed. <code>-i</code> Interactive. <code>cp</code> will prompt for confirmation whenever the copy would overwrite an existing <i>target</i>. A <code>y</code> answer means that the copy should proceed. Any other answer prevents <code>cp</code> from overwriting <i>target</i>. <code>-r</code> Recursive. <code>cp</code> will copy the directory and all its files, including any subdirectories and their files to <i>target</i>. <code>-R</code> Same as <code>-r</code>, except pipes are replicated, not read from.
<code>/usr/bin/cp</code>	<p>The following option is supported for <code>/usr/bin/cp</code> only:</p> <ul style="list-style-type: none"> <code>-p</code> Preserve. <code>cp</code> duplicates not only the contents of <i>source_file</i>, but also preserves the owner and group id, permissions modes, modification and

cp(1)

access time, and ACLs if applicable. Note that the command may fail if ACLs are copied to a file system that does not support ACLs. The command will not fail if unable to preserve modification and access time or permission modes. If unable to preserve owner and group id, cp will not fail, and it will clear `S_ISUID` and `S_ISGID` bits in the target. cp will print a diagnostic message to `stderr` and return a non-zero exit status if unable to clear these bits.

In order to preserve the owner and group id, permission modes, and modification and access times, users must have the appropriate file access permissions; this includes being superuser or the same owner id as the destination file.

`/usr/xpg4/bin/cp`

The following option is supported for `/usr/xpg4/bin/cp` only:

`-p` Preserve. cp duplicates not only the contents of *source_file*, but also preserves the owner and group id, permission modes, modification and access time, and ACLs if applicable. Note that the command may fail if ACLs are copied to a file system that does not support ACLs. If unable to duplicate the modification and access time or the permission modes, cp will print a diagnostic message to `stderr` and return a non-zero exit status. If unable to preserve owner and group id, cp will not fail, and it will clear `S_ISUID` and `S_ISGID` bits in the target. cp will print a diagnostic message to `stderr` and return a non-zero exit status if unable to clear these bits.

In order to preserve the owner and group id, permission modes, and modification and access times, users must have the appropriate file access permissions; this includes being superuser or the same owner id as the destination file.

OPERANDS

The following operands are supported:

source_file A pathname of a regular file to be copied.
source_dir A pathname of a directory to be copied.
target_file A pathname of an existing or non-existing file, used for the output when a single file is copied.
target A pathname of a directory to contain the copied files.

USAGE

See `largefile(5)` for the description of the behavior of cp when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES

EXAMPLE 1 To copy a file:

```
example% cp goodies goodies.old
example% ls goodies*
goodies goodies.old
```

EXAMPLE 1 To copy a file: (Continued)

EXAMPLE 2 To copy a list of files to a destination directory:

```
example% cp ~/src/* /tmp
```

EXAMPLE 3 To copy a directory, first to a new, and then to an existing destination directory:

```
example% ls ~/bkup
/usr/example/fred/bkup not foundexample% cp -r ~/src ~/bkupexample% ls -R ~/bkup
x.c y.c z.shexample% cp -r ~/src ~/bkupexample% ls -R ~/bkup
src x.c y.c z.sh
src:
x.c y.c z.s
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cp`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 All files were copied successfully.
>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

/usr/bin/cp

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

/usr/xpg4/bin/cp

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	enabled

SEE ALSO

`chmod(1)`, `chown(1)`, `setfacl(1)`, `utime(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `XPG4(5)`

NOTES

The permission modes of the source file are preserved in the copy.

A `-` permits the user to mark the end of any command line options explicitly, thus allowing `cp` to recognize filename arguments that begin with a `-`. If a `-` and a `-` both appear on the same command line, the second will be interpreted as a filename.

cpio(1)

NAME	cpio – copy file archives in and out
SYNOPSIS	<pre>cpio -i [-bBcdfkmPrsStuvV6] [-C bufsize] [-E file] [-H header] [-I file [-M message]] [-R id] [pattern...] cpio -o [-aABcLPvV] [-C bufsize] [-H header] [-O file [-M message]] cpio -p [-adlLmPuvV] [-R id] directory</pre>
DESCRIPTION	The <code>cpio</code> command copies files into and out of a <code>cpio</code> archive. The <code>cpio</code> archive may span multiple volumes. The <code>-i</code> , <code>-o</code> , and <code>-p</code> options select the action to be performed. The following list describes each of the actions. These actions are mutually exclusive.
Copy In Mode	<code>cpio -i</code> (copy in) extracts files from the standard input, which is assumed to be the product of a previous <code>cpio -o</code> command. Only files with names that match one of the <i>patterns</i> are selected. See <code>sh(1)</code> and OPERANDS for more information about <i>pattern</i> . Extracted files are conditionally copied into the current directory tree, based on the options described below. The permissions of the files will be those of the previous <code>cpio -o</code> command. The owner and group will be the same as the current user, unless the current user is the super-user. If this is the case, owner and group will be the same as those resulting from the previous <code>cpio -o</code> command. Notice that if <code>cpio -i</code> tries to create a file that already exists and the existing file is the same age or younger (<code>newer</code>), <code>cpio</code> will output a warning message and not replace the file. The <code>-u</code> option can be used to unconditionally overwrite the existing file.
Copy Out Mode	<code>cpio -o</code> (copy out) reads a list of file path names from the standard input and copies those files to the standard output, together with path name and status information in the form of a <code>cpio</code> archive. Output is padded to an 8192-byte boundary by default or to the user-specified block size (with the <code>-B</code> or <code>-C</code> options) or to some device-dependent block size where necessary (as with the CTC tape).
Pass Mode	<code>cpio -p</code> (pass) reads a list of file path names from the standard input and conditionally copies those files into the destination directory tree, based on the options described below. <i>Note:</i> <code>cpio</code> assumes four-byte words. If, when writing to a character device (<code>-o</code>) or reading from a character device (<code>-i</code>), <code>cpio</code> reaches the end of a medium (such as the end of a diskette), and the <code>-O</code> and <code>-I</code> options are not used, <code>cpio</code> prints the following message: To continue, type device/file name when ready. To continue, you must replace the medium and type the character special device name (<code>/dev/rdiskette</code> for example) and press RETURN. You may want to continue by directing <code>cpio</code> to use a different device. For example, if you have two floppy drives you may want to switch between them so <code>cpio</code> can proceed while you are changing the floppies. Press RETURN to cause the <code>cpio</code> process to exit.
OPTIONS	The following options are supported:

- i (copy in) Reads an archive from the standard input and conditionally extracts the files contained in it and places them into the current directory tree.
- o (copy out) Reads a list of file path names from the standard input and copies those files to the standard output in the form of a `cpio` archive.
- p (pass) Reads a list of file path names from the standard input and conditionally copies those files into the destination directory tree.

The following options can be appended in any sequence to the `-i`, `-o`, or `-p` options:

- a Resets access times of input files after they have been copied, making `cpio`'s access invisible. Access times are not reset for linked files when `cpio -pla` is specified.
- A Appends files to an archive. The `-A` option requires the `-o` option. Valid only with archives that are files, or that are on floppy diskettes or hard disk partitions. The effect on files that are linked in the existing portion of the archive is unpredictable.
- b Reverses the order of the bytes within each word. Use only with the `-i` option.
- B Blocks input/output 5120 bytes to the record. The default buffer size is 8192 bytes when this and the `-C` options are not used. `-B` does not apply to the `-p` (pass) option.
- c Reads or writes header information in ASCII character form for portability. There are no UID or GID restrictions associated with this header format. Use this option between SVR4-based machines, or the `-H odc` option between unknown machines. The `-c` option implies the use of expanded device numbers, which are only supported on SVR4-based systems. When transferring files between SunOS 4 or Interactive UNIX and the Solaris 2.6 Operating environment or compatible versions, use `-H odc`.
- C *bufsize* Blocks input/output *bufsize* bytes to the record, where *bufsize* is replaced by a positive integer. The default buffer size is 8192 bytes when this and `-B` options are not used. `-C` does not apply to the `-p` (pass) option.
- d Creates directories as needed.
- E *file* Specifies an input file (*file*) that contains a list of filenames to be extracted from the archive (one filename per line).
- f Copies in all files except those in *patterns*. See OPERANDS for a description of *pattern*.

cpio(1)

<code>-H header</code>	<p>Reads or writes header information in <i>header</i> format. Always use this option or the <code>-c</code> option when the origin and the destination machines are different types. This option is mutually exclusive with options <code>-c</code> and <code>-6</code>.</p> <p>Valid values for <i>header</i> are:</p> <table><tr><td><code>bar</code></td><td><code>bar</code> head and format. Used only with the <code>-i</code> option (read only).</td></tr><tr><td><code>crc CRC</code></td><td>ASCII header with expanded device numbers and an additional per-file checksum. There are no UID or GID restrictions associated with this header format.</td></tr><tr><td><code>odc</code></td><td>ASCII header with small device numbers. This is the IEEE/P1003 Data Interchange Standard cpio header and format. It has the widest range of portability of any of the header formats. It is the official format for transferring files between POSIX-conforming systems (see <code>standards(5)</code>). Use this format to communicate with SunOS 4 and Interactive UNIX. This header format allows UIDs and GIDs up to 262143 to be stored in the header.</td></tr><tr><td><code>tar TAR</code></td><td><p><code>tar</code> header and format. This is an older <code>tar</code> header format that allows UIDs and GIDs up to 2097151 to be stored in the header. It is provided for the reading of legacy archives only, that is, in conjunction with option <code>-i</code>.</p><p>Specifying this archive format with option <code>-o</code> has the same effect as specifying the "ustar" format: the output archive is in <code>ustar</code> format, and must be read using <code>-H ustar</code>.</p></td></tr><tr><td><code>ustar USTAR</code></td><td>IEEE/P1003 Data Interchange Standard <code>tar</code> header and format. This header format allows UIDs and GIDs up to 2097151 to be stored in the header.</td></tr></table> <p>Files with UIDs and GIDs greater than the limit stated above will be archived with the UID and GID of 60001. To transfer a large file (8 Gb — 1 byte), the header format can be <code>tar TAR</code>, <code>ustar USTAR</code>, or <code>odc</code> only.</p>	<code>bar</code>	<code>bar</code> head and format. Used only with the <code>-i</code> option (read only).	<code>crc CRC</code>	ASCII header with expanded device numbers and an additional per-file checksum. There are no UID or GID restrictions associated with this header format.	<code>odc</code>	ASCII header with small device numbers. This is the IEEE/P1003 Data Interchange Standard cpio header and format. It has the widest range of portability of any of the header formats. It is the official format for transferring files between POSIX-conforming systems (see <code>standards(5)</code>). Use this format to communicate with SunOS 4 and Interactive UNIX. This header format allows UIDs and GIDs up to 262143 to be stored in the header.	<code>tar TAR</code>	<p><code>tar</code> header and format. This is an older <code>tar</code> header format that allows UIDs and GIDs up to 2097151 to be stored in the header. It is provided for the reading of legacy archives only, that is, in conjunction with option <code>-i</code>.</p> <p>Specifying this archive format with option <code>-o</code> has the same effect as specifying the "ustar" format: the output archive is in <code>ustar</code> format, and must be read using <code>-H ustar</code>.</p>	<code>ustar USTAR</code>	IEEE/P1003 Data Interchange Standard <code>tar</code> header and format. This header format allows UIDs and GIDs up to 2097151 to be stored in the header.
<code>bar</code>	<code>bar</code> head and format. Used only with the <code>-i</code> option (read only).										
<code>crc CRC</code>	ASCII header with expanded device numbers and an additional per-file checksum. There are no UID or GID restrictions associated with this header format.										
<code>odc</code>	ASCII header with small device numbers. This is the IEEE/P1003 Data Interchange Standard cpio header and format. It has the widest range of portability of any of the header formats. It is the official format for transferring files between POSIX-conforming systems (see <code>standards(5)</code>). Use this format to communicate with SunOS 4 and Interactive UNIX. This header format allows UIDs and GIDs up to 262143 to be stored in the header.										
<code>tar TAR</code>	<p><code>tar</code> header and format. This is an older <code>tar</code> header format that allows UIDs and GIDs up to 2097151 to be stored in the header. It is provided for the reading of legacy archives only, that is, in conjunction with option <code>-i</code>.</p> <p>Specifying this archive format with option <code>-o</code> has the same effect as specifying the "ustar" format: the output archive is in <code>ustar</code> format, and must be read using <code>-H ustar</code>.</p>										
<code>ustar USTAR</code>	IEEE/P1003 Data Interchange Standard <code>tar</code> header and format. This header format allows UIDs and GIDs up to 2097151 to be stored in the header.										
<code>-I file</code>	<p>Reads the contents of <i>file</i> as an input archive, instead of the standard input. If <i>file</i> is a character special device, and the current</p>										

medium has been completely read, replace the medium and press RETURN to continue to the next medium. This option is used only with the `-i` option.

- k
 Attempts to skip corrupted file headers and I/O errors that may be encountered. If you want to copy files from a medium that is corrupted or out of sequence, this option lets you read only those files with good headers. For `cpio` archives that contain other `cpio` archives, if an error is encountered, `cpio` may terminate prematurely. `cpio` will find the next good header, which may be one for a smaller archive, and terminate when the smaller archive's trailer is encountered. Use only with the `-i` option.
- l
 In pass mode, makes hard links between the source and destination whenever possible. If the `-L` option is also specified, the hard link will be to the file referred to by the symbolic link. Otherwise, the hard link will be to the symbolic link itself. Use only with the `-p` option.
- L
 Follows symbolic links. If a symbolic link to a directory is encountered, archives the directory referred to by the link, using the name of the link. Otherwise, archives the file referred to by the link, using the name of the link.
- m
 Retains previous file modification time. This option is ineffective on directories that are being copied.
- M *message*
 Defines a *message* to use when switching media. When you use the `-O` or `-I` options and specify a character special device, you can use this option to define the message that is printed when you reach the end of the medium. One `%d` can be placed in *message* to print the sequence number of the next medium needed to continue.
- O *file*
 Directs the output of `cpio` to *file*, instead of the standard output. If *file* is a character special device and the current medium is full, replace the medium and type a carriage return to continue to the next medium. Use only with the `-o` option.
- P
 Preserves ACLs. If the option is used for output, existing ACLs are written along with other attributes to the standard output. ACLs are created as special files with a special file type. If the option is used for input, existing ACLs are extracted along with other attributes from standard input. The option recognizes the special file type. Notice that errors will occur if a `cpio` archive with ACLs is extracted by previous versions of `cpio`. This option should not be used with the `-c` option, as ACL support may not be present on all systems, and hence is not portable. Use ASCII headers for portability.

cpio(1)

-r	Interactively renames files. If the user types a carriage return alone, the file is skipped. If the user types a ".", the original pathname will be retained. Not available with <code>cpio -p</code> .
-R <i>id</i>	Reassigns ownership and group information for each file to <i>user ID</i> . (<i>ID</i> must be a valid login ID from <code>/etc/passwd</code> .) This option is valid only for the super-user.
-s	Swaps bytes within each half word.
-S	Swaps halfwords within each word.
-t	Prints a table of contents of the input. No files are created. <code>-t</code> and <code>-v</code> are mutually exclusive.
-u	Copies unconditionally. Normally, an older file will not replace a newer file with the same name.
-v	Verbose. Prints a list of file names. When used with the <code>-t</code> option, the table of contents looks like the output of an <code>ls -l</code> command (see <code>ls(1)</code>).
-V	Special verbose. Prints a dot for each file read or written. Useful to assure the user that <code>cpio</code> is working without printing out all file names.
-6	Processes a UNIX System Sixth Edition archive format file. Use only with the <code>-i</code> option. This option is mutually exclusive with <code>-c</code> and <code>-H</code> .

OPERANDS The following operands are supported:

<i>directory</i>	A path name of an existing directory to be used as the target of <code>cpio -p</code> .
<i>pattern</i>	Expressions making use of a pattern-matching notation similar to that used by the shell (see <code>sh(1)</code>) for filename pattern matching, and similar to regular expressions. The following metacharacters are defined: <ul style="list-style-type: none">* Matches any string, including the empty string.? Matches any single character.[. . . Matches any one of the enclosed characters. A pair of characters separated by '-' matches any symbol between the pair (inclusive), as defined by the system default collating sequence. If the first character following the opening '[' is a '!', the results are unspecified.! The ! (exclamation point) means <i>not</i>. For example, the <code>!abc*</code> pattern would exclude all files that begin with <code>abc</code>.

In *pattern*, metacharacters `?`, `*`, and `[...]` match the slash (`/`) character, and backslash (`\`) is an escape character. Multiple cases of *pattern* can be specified and if no *pattern* is specified, the default for *pattern* is `*` (that is, select all files).

Each pattern must be enclosed in double quotes. Otherwise, the name of a file in the current directory might be used.

USAGE See `largefile(5)` for the description of the behavior of `cpio` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES The following examples show three uses of `cpio`.

EXAMPLE 1 Using standard input

```
example% ls | cpio -oc > ../newfile
```

When standard input is directed through a pipe to `cpio -o`, as in the example above, it groups the files so they can be directed (`>`) to a single file (`../newfile`). The `-c` option insures that the file will be portable to other machines (as would the `-H` option). Instead of `ls(1)`, you could use `find(1)`, `echo(1)`, `cat(1)`, and so on, to pipe a list of names to `cpio`. You could direct the output to a device instead of a file.

EXAMPLE 2 Extracting files into directories

```
example% cat newfile | cpio -icd "memo/a1" "memo/b*"
```

In this example, `cpio -i` uses the output file of `cpio -o` (directed through a pipe with `cat`), extracts those files that match the patterns (`memo/a1`, `memo/b*`), creates directories below the current directory as needed (`-d` option), and places the files in the appropriate directories. The `-c` option is used if the input file was created with a portable header. If no patterns were given, all files from `newfile` would be placed in the directory.

EXAMPLE 3 Copying or linking files to another directory

```
example% find . -depth -print | cpio -pdlmv newdir
```

In this example, `cpio -p` takes the file names piped to it and copies or links (`-l` option) those files to another directory, `newdir`. The `-d` option says to create directories as needed. The `-m` option says to retain the modification time. (It is important to use the `-depth` option of `find(1)` to generate path names for `cpio`. This eliminates problems that `cpio` could have trying to create files under read-only directories.) The destination directory, `newdir`, must exist.

Notice that when you use `cpio` in conjunction with `find`, if you use the `-L` option with `cpio`, you must use the `-follow` option with `find` and vice versa. Otherwise, there will be undesirable results.

cpio(1)

For multi-reel archives, dismount the old volume, mount the new one, and continue to the next tape by typing the name of the next device (probably the same as the first reel). To stop, type a RETURN and `cpio` will end.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cpio`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, `TZ`, and `NLSPATH`.

`TMPDIR` `cpio` creates its temporary file in `/var/tmp` by default. Otherwise, it uses the directory specified by `TMPDIR`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.
>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled
Interface Stability	Stable

SEE ALSO

`ar(1)`, `cat(1)`, `echo(1)`, `find(1)`, `ls(1)`, `setfacl(1)`, `sh(1)`, `tar(1)`, `vold(1M)`, `archives(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `standards(5)`

NOTES

The maximum path name length allowed in a `cpio` archive is determined by the header type involved. The following table shows the proper value for each supported archive header type.

Header type	Command line options	Maximum path name length
BINARY	"-o"	256
POSIX	"-oH odc"	256
ASCII	"-oc"	1023
CRC	"-oH crc"	1023
USTAR	"-oH ustar"	255

When the command line options "`-o -H tar`" are specified, the archive created is of type `USTAR`. This means that it is an error to read this same archive using the command line options "`-i -H tar`". The archive should be read using the command line options "`-i -H ustar`". The options "`-i -H tar`" refer to an older `tar` archive format.

An error message is output for files whose UID or GID are too large to fit in the selected header format. Use `-H crc` or `-c` to create archives that allow all UID or GID values.

Only the super-user can copy special files.

Blocks are reported in 512-byte quantities.

If a file has 000 permissions, contains more than 0 characters of data, and the user is not root, the file will not be saved or restored.

The inode number stored in the header (`/usr/include/archives.h`) is an unsigned short, which is 2 bytes. This limits the range of inode numbers from 0 to 65535. Files which are hard linked must fall in this inode range. This could be a problem when moving `cpio` archives between different vendors' machines.

When the Volume Management daemon is running, accesses to floppy devices through the conventional device names (for example, `/dev/rdiskette`) may not succeed. See `vold(1M)` for further details.

You must use the same blocking factor when you retrieve or copy files from the tape to the hard disk as you did when you copied files from the hard disk to the tape. Therefore, you must specify the `-B` or `-C` option.

During `-p` and `-o` processing, `cpio` buffers the file list presented on `stdin` in a temporary file.

cpp(1)

NAME	cpp – the C language preprocessor
SYNOPSIS	<code>/usr/lib/cpp [-BCHMpPRT] [-undef] [-Dname] [-Dname = def]</code> <code>[-Idirectory] [-Uname] [-Ydirectory] [input-file [output-file]]</code>
DESCRIPTION	<p>cpp is the C language preprocessor. It is invoked as the first pass of any C compilation started with the <code>cc(1B)</code> command; however, <code>cpp</code> can also be used as a first-pass preprocessor for other Sun compilers.</p> <p>Although <code>cpp</code> can be used as a macro processor, this is not normally recommended, as its output is geared toward that which would be acceptable as input to a compiler's second pass. Thus, the preferred way to invoke <code>cpp</code> is through the <code>cc(1B)</code> command, or some other compilation command. For general-purpose macro-processing, see <code>m4(1)</code>.</p> <p><code>cpp</code> optionally accepts two filenames as arguments. <i>input-file</i> and <i>output-file</i> are, respectively, the input and output files for the preprocessor. They default to the standard input and the standard output.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-B Support the C++ comment indicator <code>'/ /'</code>. With this indicator everything on the line after the <code>/ /</code> is treated as a comment.-C Pass all comments (except those that appear on <code>cpp</code> directive lines) through the preprocessor. By default, <code>cpp</code> strips out C-style comments.-H Print the pathnames of included files, one per line on the standard error.-M Generate a list of makefile dependencies and write them to the standard output. This list indicates that the object file which would be generated from the input file depends on the input file as well as the include files referenced.-p Use only the first eight characters to distinguish preprocessor symbols, and issue a warning if extra tokens appear at the end of a line containing a directive.-P Preprocess the input without producing the line control information used by the next pass of the C compiler.-R Allow recursive macros.-T Use only the first eight characters for distinguishing different preprocessor names. This option is included for backward compatibility with systems which always use only the first eight characters.-undef Remove initial definitions for all predefined symbols.

<i>-Dname</i>	<p>Define <i>name</i> as 1 (one). This is the same as if a <i>-Dname=1</i> option appeared on the <code>cpp</code> command line, or as if a</p> <pre>#define name 1</pre> <p>line appeared in the source file that <code>cpp</code> is processing.</p>								
<i>-Dname=def</i>	<p>Define <i>name</i> as if by a <code>#define</code> directive. This is the same as if a</p> <pre>#define name def</pre> <p>line appeared in the source file that <code>cpp</code> is processing. The <code>-D</code> option has lower precedence than the <code>-U</code> option. That is, if the same name is used in both a <code>-U</code> option and a <code>-D</code> option, the name will be undefined regardless of the order of the options.</p>								
<i>-Idirectory</i>	<p>Insert <i>directory</i> into the search path for <code>#include</code> files with names not beginning with <code>'/'</code>. <i>directory</i> is inserted ahead of the standard list of "include" directories. Thus, <code>#include</code> files with names enclosed in double-quotes (") are searched for first in the directory of the file with the <code>#include</code> line, then in directories named with <code>-I</code> options, and lastly, in directories from the standard list. For <code>#include</code> files with names enclosed in angle-brackets (< >), the directory of the file with the <code>#include</code> line is not searched. See <code>Details</code> below for exact details of this search order.</p>								
<i>-Uname</i>	<p>Remove any initial definition of <i>name</i>, where <i>name</i> is a symbol that is predefined by a particular preprocessor. USAGE

cpp(1)

Directives All `cpp` directives start with a hash symbol (`#`) as the first character on a line. White space (SPACE or TAB characters) can appear after the initial `#` for proper indentation.

`#define name token-string`
Replace subsequent instances of *name* with *token-string*.

`#define name (argument [, argument] . . .) token-string`
There can be no space between *name* and the `'`. Replace subsequent instances of *name*, followed by a parenthesized list of arguments, with *token-string*, where each occurrence of an *argument* in the *token-string* is replaced by the corresponding token in the comma-separated list. When a macro with arguments is expanded, the arguments are placed into the expanded *token-string* unchanged. After the entire *token-string* has been expanded, `cpp` re-starts its scan for names to expand at the beginning of the newly created *token-string*.

`#undef name`
Remove any definition for the symbol *name*. No additional tokens are permitted on the directive line after *name*.

`#include "filename "`
`#include <filename>`
Read in the contents of *filename* at this location. This data is processed by `cpp` as if it were part of the current file. When the `<filename>` notation is used, *filename* is only searched for in the standard "include" directories. See the `-I` and `-Y` options above for more detail. No additional tokens are permitted on the directive line after the final `"` or `>`.

`#line integer-constant "filename"`
Generate line control information for the next pass of the C compiler. *integer-constant* is interpreted as the line number of the next line and *filename* is interpreted as the file from where it comes. If `"filename"` is not given, the current filename is unchanged. No additional tokens are permitted on the directive line after the optional *filename*.

`#if constant-expression`
Subsequent lines up to the matching `#else`, `#elif`, or `#endif` directive, appear in the output only if *constant-expression* yields a nonzero value. All binary non-assignment C operators, including `&&`, `|`, `|`, and `,`, are legal in *constant-expression*. The `?:` operator, and the unary `'-`, `'!`, and `'~'` operators, are also legal in *constant-expression*.

The precedence of these operators is the same as that for C. In addition, the unary operator `defined`, can be used in *constant-expression* in these two forms: `'defined (name)'` or `'defined name'`. This allows the effect of `#ifdef` and `#ifndef` directives (described below) in the `#if` directive. Only these operators, integer constants, and names that are known by `cpp` should be used within *constant-expression*. In particular, the `sizeof` operator is not available.

`#ifdef name`
Subsequent lines up to the matching `#else`, `#elif`, or `#endif` appear in the output only if *name* has been defined, either with a `#define` directive or a `-D`

option, and in the absence of an intervening `#undef` directive. Additional tokens after *name* on the directive line will be silently ignored.

`#ifndef name`

Subsequent lines up to the matching `#else`, `#elif`, or `#endif` appear in the output only if *name* has *not* been defined, or if its definition has been removed with an `#undef` directive. No additional tokens are permitted on the directive line after *name*.

`#elif constant-expression`

Any number of `#elif` directives may appear between an `#if`, `#ifdef`, or `#ifndef` directive and a matching `#else` or `#endif` directive. The lines following the `#elif` directive appear in the output only if all of the following conditions hold:

- The *constant-expression* in the preceding `#if` directive evaluated to zero, the *name* in the preceding `#ifdef` is not defined, or the *name* in the preceding `#ifndef` directive *was* defined.
- The *constant-expression* in all intervening `#elif` directives evaluated to zero.
- The current *constant-expression* evaluates to non-zero.

If the *constant-expression* evaluates to non-zero, subsequent `#elif` and `#else` directives are ignored up to the matching `#endif`. Any *constant-expression* allowed in an `#if` directive is allowed in an `#elif` directive.

`#else`

This inverts the sense of the conditional directive otherwise in effect. If the preceding conditional would indicate that lines are to be included, then lines between the `#else` and the matching `#endif` are ignored. If the preceding conditional indicates that lines would be ignored, subsequent lines are included in the output. Conditional directives and corresponding `#else` directives can be nested.

`#endif`

End a section of lines begun by one of the conditional directives `#if`, `#ifdef`, or `#ifndef`. Each such directive must have a matching `#endif`.

Macros

Formal parameters for macros are recognized in `#define` directive bodies, even when they occur inside character constants and quoted strings. For instance, the output from:

```
#define abc(a) | `|a|
abc(xyz)
```

is:

```
# 1 ""
| `|xyz |
```

cpp(1)

The second line is a NEWLINE. The last seven characters are “| `|xyz |” (vertical-bar, backquote, vertical-bar, x, y, z, vertical-bar). Macro names are not recognized within character constants or quoted strings during the regular scan. Thus:

```
#define abc xyz
printf("abc");
```

does not expand `abc` in the second line, since it is inside a quoted string that is not part of a `#define` macro definition.

Macros are not expanded while processing a `#define` or `#undef`. Thus:

```
#define abc zingo
#define xyz abc
#undef abc
xyz
```

produces `abc`. The token appearing immediately after an `#ifdef` or `#ifndef` is not expanded.

Macros are not expanded during the scan which determines the actual parameters to another macro call. Thus:

```
#define reverse(first,second)second first
#define greeting hello
reverse(greeting,
#define greeting goodbye
)
```

produces “`#define hello goodbye hello`”.

Output Output consists of a copy of the input file, with modifications, plus lines of the form:

```
#lineno " filename " "level "
```

indicating the original source line number and filename of the following output line and whether this is the first such line after an include file has been entered (*level=1*), the first such line after an include file has been exited (*level=2*), or any other such line (*level* is empty).

Directory Search Order

`#include` files are searched for in the following order:

1. The directory of the file that contains the `#include` request (that is, `#include` is relative to the file being scanned when the request is made).
2. The directories specified by `-I` options, in left-to-right order.
3. The standard directory(s) (`/usr/include` on UNIX systems).

- Special Names* Two special names are understood by `cpp`. The name `__LINE__` is defined as the current line number (a decimal integer) as known by `cpp`, and `__FILE__` is defined as the current filename (a C string) as known by `cpp`. They can be used anywhere (including in macros) just as any other defined name.
- Newline Characters* A NEWLINE character terminates a character constant or quoted string. An escaped NEWLINE (that is, a backslash immediately followed by a NEWLINE) may be used in the body of a `#define` statement to continue the definition onto the next line. The escaped NEWLINE is not included in the macro value.
- Comments* Comments are removed (unless the `-C` option is used on the command line). Comments are also ignored, except that a comment terminates a token.

EXIT STATUS The following exit values are returned:

0 Successful completion.
non-zero An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWspot

SEE ALSO `cc(1B)`, `m4(1)`, `attributes(5)`

DIAGNOSTICS The error messages produced by `cpp` are intended to be self-explanatory. The line number and filename where the error occurred are printed along with the diagnostic.

NOTES When NEWLINE characters were found in argument lists for macros to be expanded, some previous versions of `cpp` put out the NEWLINE characters as they were found and expanded. The current version of `cpp` replaces them with SPACE characters.

Because the standard directory for included files may be different in different environments, this form of `#include` directive:

```
#include <file.h>
```

should be used, rather than one with an absolute path, like:

```
#include "/usr/include/file.h"
```

`cpp` warns about the use of the absolute pathname.

While the compiler allows 8-bit strings and comments, 8-bits are not allowed anywhere else.

cputrack(1)

NAME	<code>cputrack</code> – monitor process and LWP behavior using CPU performance counters
SYNOPSIS	<pre>cputrack -c <i>eventspec</i> [-c <i>eventspec</i>]... [-efntvD] [-N <i>count</i>] [-o <i>pathname</i>] [-T <i>interval</i>] <i>command</i> [<i>args</i>] cputrack -c <i>eventspec</i> [-c <i>eventspec</i>]... -p <i>pid</i> [-efntvD] [-N <i>count</i>] [-o <i>pathname</i>] [-T <i>interval</i>] cputrack -h</pre>
DESCRIPTION	<p>The <code>cputrack</code> utility allows CPU performance counters to be used to monitor the behavior of a process or family of processes running on the system. If <i>interval</i> is specified with the <code>-T</code> option, <code>cputrack</code> samples activity every <i>interval</i> seconds, repeating forever. If a <i>count</i> is specified with the <code>-N</code> option, the statistics are repeated <i>count</i> times for each process tracked. If neither are specified, an interval of one second is used. If <i>command</i> and optional <i>args</i> are specified, <code>cputrack</code> runs the command with the arguments given while monitoring the specified CPU performance events. Alternatively, the process ID of an existing process can be specified using the <code>-p</code> option.</p> <p>Because <code>cputrack</code> is an unprivileged program, it is subject to the same restrictions that apply to <code>truss(1)</code>. For example, <code>setuid(2)</code> executables cannot be tracked.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"><code>-c <i>eventspec</i></code> Specify a set of events for the CPU performance counters to monitor. The list of available events and the syntax of the event specifications for the system can be determined using the <code>-h</code> option. The semantics of these event specifications can be determined by reading the CPU manufacturers documentation for the events. See <code>cpc_strtoevent(3CPC)</code> for a description of the syntax.Multiple <code>-c</code> options may be specified, in which case <code>cputrack</code> cycles between the different event settings on each sample.<code>-D</code> Enable debug mode.<code>-e</code> Follow all <code>exec(2)</code>, or <code>execve(2)</code> system calls. Without this option, <code>cputrack</code> terminates when the process image is overlaid with a new executable.<code>-f</code> Follow all children created by <code>fork(2)</code>, <code>fork1(2)</code>, or <code>vfork(2)</code> system calls.<code>-h</code> Print an extended help message on how to use the utility and how to program the processor-dependent counters.<code>-n</code> Omit all header output (useful if <code>cputrack</code> is the beginning of a pipeline).<code>-N <i>count</i></code> Specify the maximum number of CPU performance counter samples to take before exiting.

<code>-o outfile</code>	File to be used for the <code>cputrack</code> output.
<code>-p pid</code>	Interpret the argument as the process ID of an existing process to which process counter context should be attached and monitored.
<code>-t</code>	Print an additional column of processor cycle counts, if available on the current architecture.
<code>-T interval</code>	Specify the interval between CPU performance counter samples in seconds.
<code>-v</code>	Enable more verbose output.

USAGE

The operating system enforces certain restrictions on the tracing of processes. In particular, a command whose object file cannot be read by a user cannot be tracked by that user; `set-uid` and `set-gid` commands can only be tracked by a privileged user. Unless it is run by a privileged user, `cputrack` loses control of any process that performs an `exec()` of a `set-id` or unreadable object file; such processes continue normally, though independently of `cputrack`, from the point of the `exec()`.

The system may run out of per-user process slots when the `-f` option is used, since `cputrack` runs one controlling process for each process being tracked.

The times printed by `cputrack` correspond to the wallclock time when the hardware counters were actually sampled, instead of when the program told the kernel to sample them. The time is derived from the same timebase as `gethrtime(3C)`.

The `cputrack` utility attaches performance counter context to each process that it examines. The presence of this context allows the performance counters to be multiplexed between different processes on the system, but it cannot be used at the same time as the `cpustat(1M)` utility.

Once an instance of the `cpustat` utility is running, further attempts to run `cputrack` will fail until all instances of `cpustat` terminate.

Sometimes `cputrack` provides sufficient flexibility and prints sufficient statistics to make adding the event selection code to an application unnecessary. However, more control is occasionally desired. Because the same performance counter context is used by both the application itself and by the agent LWP injected into the application by `cputrack`, it is possible for an application to interact with the counter context to achieve some interesting capabilities. See `cpc_count_usr_events(3CPC)`.

The processor cycle counts enabled by the `-t` option always apply to both user and system modes, regardless of the settings applied to the performance counter registers.

The output of `cputrack` is designed to be readily parseable by `nawk(1)` and `perl(1)`, thereby allowing performance tools to be composed by embedding `cputrack` in scripts. Alternatively, tools may be constructed directly using the same APIs that `cputrack` is built upon using the facilities of `libcpc(3LIB)` and `libpctx(3LIB)`. See `cpc(3CPC)`.

cputrack(1)

Although `cputrack` uses performance counter context to maintain separate performance counter values for each LWP, some of the events that can be counted will inevitably be impacted by other activities occurring on the system; particularly for limited resources that are shared between processes (for example, cache miss rates.) For such events, it may also be interesting to observe overall system behavior with `cpustat(1M)`.

EXAMPLES

SPARC **EXAMPLE 1** SPARC example of `cputrack`

In this example, the utility is being used on a machine containing an UltraSPARC 1 processor. The counters are set to count processor clock cycles and instructions dispatched in user mode while running the `sleep(1)` command.

```
% cputrack -c pic0=Cycle_cnt,pic1=Instr_cnt sleep 10
time lwp   event   pic0   pic1
2.040  1      tick   377820 202593
4.028  1      tick    0      0
6.028  1      tick    0      0
8.028  1      tick    0      0
10.028 1      tick   6930   954
10.036 1      exit  410623 212137
```

EXAMPLE 2 SPARC example of `cputrack`

This example shows more verbose output while following the `fork()` and `exec()` of a simple shell script on an UltraSPARC machine. The counters are measuring the number of external cache references and external cache hits. Note that the explicit `pic0` and `pic1` names can be omitted where there are no ambiguities.

```
% cputrack -fev -c EC_ref,EC_hit /bin/ulimit -c
time  pid lwp   event   pic0   pic1
0.032 101200 1  init_lwp    0      0
0.106 101200 1   fork          # 101201
0.115 101201 1  init_lwp    0      0
0.179 101201 1  fini_lwp   5934   5031
0.179 101201 1   exec       5934   5031
0.399 101201 1   exec          # 'basename /bin/ulimit'
0.413 101201 1  init_lwp    0      0
0.435 101201 1  fini_lwp  19780  17234
0.435 101201 1   exit      19780  17234
unlimited
0.454 101200 1  fini_lwp  63025  54583
0.454 101200 1   exit      63025  54583
```

IA **EXAMPLE 3** IA example of `cputrack`

This example shows how many instructions were executed in the application and in the kernel to print the date on a Pentium machine:

```
% cputrack -c inst_retired,inst_retired,nouser1,sys1 date
time lwp   event   pic0   pic1
```

EXAMPLE 3 IA example of cputrack (Continued)

```
Fri Aug 20 20:03:08 PDT 1999
 0.072  1      exit    246725  339666
```

WARNINGS By running any instance of the `cpustat(1M)` utility, all existing performance counter context is forcibly invalidated across the machine. This may in turn cause all invocations of the `cputrack` command to exit prematurely with unspecified errors.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

crle(1)

NAME	crle – configure runtime linking environment								
SYNOPSIS	crle [-64] [-a <i>name</i>] [-c <i>conf</i>] [-f <i>flags</i>] [-i <i>name</i>] [-I <i>name</i>] [-g <i>name</i>] [-G <i>name</i>] [-l <i>dir</i>] [-o <i>dir</i>] [-s <i>dir</i>] [-t [ELF AOUT]] [-u] [-v]								
DESCRIPTION	<p>The <code>crle</code> utility provides for the creation and display of a runtime linking configuration file. Without any arguments, or with just the <code>-c</code> option, <code>crle</code> displays the contents of a configuration file, any system defaults and the command-line required to regenerate the configuration file. When used with any other options, a new configuration file is created or updated. The configuration file is read and interpreted by the runtime linker, <code>ld.so.1(1)</code>, during process start-up.</p> <p>The default configuration file is <code>/var/ld/ld.config</code> for 32-bit objects and <code>/var/ld/64/ld.config</code> for 64-bit objects. <i>Note:</i> It is recommended that any new configuration file is first created in a temporary location. The environment variable <code>LD_CONFIG</code> can be set to this new configuration file to cause its use by the runtime linker instead of any default. After verification, the new configuration file can be moved to the default location if desired. Setting the environment variable <code>LD_NOCONFIG</code> to any value results in the runtime linker ignoring any configuration files, and may prove useful during experimentation.</p> <p>The configuration file may contain the following information:</p> <table><tr><td>Default Search Paths</td><td>The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. This search path starts with the components of any <code>LD_LIBRARY_PATH</code> definition, followed by the components of an object's <code>runpath</code> and finally any defaults specific to the object's type. This last component of the search path can be expressed within the configuration file. <i>Note:</i> Typical use of this facility should augment any system defaults; see the <code>-l</code> option.</td></tr><tr><td>Trusted Directories</td><td>When processing a secure application the runtime linker restricts the use of <code>LD_LIBRARY_PATH</code> and the directories from which preload and audit libraries may be used to known trusted directories. These trusted directories can be expressed within the configuration file. <i>Note:</i> Typical use of this facility should augment any system defaults; see the <code>-s</code> option.</td></tr><tr><td>Directory Cache</td><td>The location of shared objects within defined directories can be maintained as a cache within the configuration file. This directory cache can reduce the overhead of searching for application dependencies.</td></tr><tr><td>Alternative Objects</td><td>In conjunction with the directory cache, shared objects may have alternative objects specified for use at runtime. These alternate objects may be supplied by</td></tr></table>	Default Search Paths	The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. This search path starts with the components of any <code>LD_LIBRARY_PATH</code> definition, followed by the components of an object's <code>runpath</code> and finally any defaults specific to the object's type. This last component of the search path can be expressed within the configuration file. <i>Note:</i> Typical use of this facility should augment any system defaults; see the <code>-l</code> option.	Trusted Directories	When processing a secure application the runtime linker restricts the use of <code>LD_LIBRARY_PATH</code> and the directories from which preload and audit libraries may be used to known trusted directories. These trusted directories can be expressed within the configuration file. <i>Note:</i> Typical use of this facility should augment any system defaults; see the <code>-s</code> option.	Directory Cache	The location of shared objects within defined directories can be maintained as a cache within the configuration file. This directory cache can reduce the overhead of searching for application dependencies.	Alternative Objects	In conjunction with the directory cache, shared objects may have alternative objects specified for use at runtime. These alternate objects may be supplied by
Default Search Paths	The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. This search path starts with the components of any <code>LD_LIBRARY_PATH</code> definition, followed by the components of an object's <code>runpath</code> and finally any defaults specific to the object's type. This last component of the search path can be expressed within the configuration file. <i>Note:</i> Typical use of this facility should augment any system defaults; see the <code>-l</code> option.								
Trusted Directories	When processing a secure application the runtime linker restricts the use of <code>LD_LIBRARY_PATH</code> and the directories from which preload and audit libraries may be used to known trusted directories. These trusted directories can be expressed within the configuration file. <i>Note:</i> Typical use of this facility should augment any system defaults; see the <code>-s</code> option.								
Directory Cache	The location of shared objects within defined directories can be maintained as a cache within the configuration file. This directory cache can reduce the overhead of searching for application dependencies.								
Alternative Objects	In conjunction with the directory cache, shared objects may have alternative objects specified for use at runtime. These alternate objects may be supplied by								

the user, or can be created by `crle` as copies of shared objects fixed to known memory locations. These fixed alternative objects can require less processing at runtime than their original shared object counterpart.

Defining alternative default search paths, or additional trusted directories can be useful for administrators who wish to install third party software in a central location, or otherwise alter the search path of applications that may not have been coded with suitable runpaths.

Defining user supplied alternative objects provides a means of replacing dependencies other than via symbolic links or requiring `LD_LIBRARY_PATH` settings.

The directory cache and `crle` generated alternate objects can provide a means of reducing the runtime start-up overhead of applications that require many dependencies, or whose dependencies are expensive to relocate (this may be the case when shared objects contain *position-dependent* code).

When `crle` generated alternate objects are specified within a configuration file, `ld.so.1(1)` performs some minimal consistency verification of the alternative objects against their originating objects. This verification is intended to avert application failure should an applications configuration information become out-of-sync with the underlying system components. When this situation arises the flexibility offered by dynamic linking system components may be compromised, and diagnosing the application failure may be difficult. *Note:* No verification of directory cache information is performed. Any changes to the directory structure will not be seen by a process until the cache is rebuilt.

System shared objects are often well tuned and may have no benefit being cached. The directory cache and alternative object features are typically applicable to user applications and shared objects.

`crle` creates alternate objects for the shared objects discovered when using the `-I` and `-G` options by calls to `dlldump(3DL)`. The alternate object is created in the directory specified by the preceding `-o` option, or defaults to the directory in which the configuration file is created. The flags used for the `dlldump()` are specified using the `-f` option, or default to `RTLD_REL_RELATIVE`.

OPTIONS

The following options are supported:

- `-64` Specifies to process 64-bit objects, the default is 32-bit.
- `-a name` This option adds an alternative to *name* to the configuration file. The actual alternative file must be supplied by the user. Multiple occurrences of this option are permitted. If *name* is a directory each shared object within the directory is added to the cache. If *name* does not exist, it is marked in the cache as a nonexistent file.

crle(1)

<code>-c <i>conf</i></code>	Specifies to use the configuration file name <i>conf</i> . If this option is not supplied the default configuration file is used.
<code>-f <i>flags</i></code>	This option provides the symbolic <i>flags</i> argument to the <code>dlldump(3DL)</code> calls used to generate alternate objects. Any of the <code>RTLD_REL</code> flags defined in <code>/usr/include/dlfcn.h</code> can be used. Multiple flags can be or'ed together using the " " character, and in this case the string should be quoted to avoid expansion by the shell. If no <i>flags</i> values are provided the default flag is <code>RTLD_REL_RELATIVE</code> .
<code>-i <i>name</i></code>	This option adds an individual <i>name</i> to the configuration cache. Multiple occurrences of this option are permitted. <i>name</i> may be a shared object or a directory. If <i>name</i> is a directory each shared object within the directory is added to the cache. <i>Note:</i> If <i>name</i> does not exist, it is marked in the cache as a nonexistent directory.
<code>-I <i>name</i></code>	This option is the same as <code>-i</code> and in addition any shared objects have alternatives created via <code>dlldump(3DL)</code> . If the <code>-f</code> flag contains <code>RTLD_REL_EXEC</code> then <i>name</i> may be a dynamic executable, for which an alternative is created. Only one dynamic executable can be specified in this manner as the cache created is specific to this application.
<code>-g <i>name</i></code>	This option adds the group <i>name</i> to the configuration cache. Each object is expanded to determine its dependencies. Multiple occurrences of this option are permitted. <i>name</i> may be a dynamic executable, shared object or a directory. The <i>name</i> itself, if it is a shared object, and its dependencies are added to the cache. If <i>name</i> is a directory each shared object within the directory, and its dependencies, are added to the cache.
<code>-G <i>name</i></code>	This option is the same as <code>-g</code> and in addition any shared objects have alternatives created via <code>dlldump(3DL)</code> . If <i>name</i> is a dynamic executable, and the <code>-f</code> flag contains <code>RTLD_REL_EXEC</code> , then an alternative for the dynamic executable is also created. Only one dynamic executable can be specified in this manner as the cache created is specific to this application.
<code>-l <i>dir</i></code>	This option specifies a new default search directory <i>dir</i> for ELF or AOUT objects. Multiple occurrences of this

option are permitted. The type of object applicable to the search is specified by the preceding `-t` option, or defaults to ELF.

The system default search path for ELF objects is `/usr/lib` for 32-bit objects, and `/usr/lib/64` for 64-bit objects. The system default search paths for AOUT objects is `/usr/4lib`, `/usr/lib` and `/usr/local/lib`.

Use of this option *replaces* the system default search path, and thus it is normally required that a `-l` option be used to specify the original system default in relation to any new paths being applied. However, if the `-u` option is in effect, and a configuration file does *not* exist, the system defaults are added to the new configuration file before the new paths specified with the `-l` option.

`-o dir`

This option specifies the directory *dir* in which any alternate objects will be created. Without this option alternate objects are created in the directory in which the configuration file is created. Multiple occurrences of this option are permitted, the directory *dir* being used to locate alternatives for any following command-line options. Alternative objects are not permitted to override their associated originals.

`-s dir`

This option specifies a new trusted directory *dir* for *secure* ELF or AOUT objects. See SECURITY in `ld.so.1(1)` for a definition of secure objects.

Multiple occurrences of this option are permitted. The type of object applicable to the search is specified by the preceding `-t` option, or defaults to ELF.

The system default trusted directory for secure ELF objects is `/usr/lib/secure` for 32-bit objects and `/usr/lib/secure/64` for 64-bit objects. The system default trusted directories for secure AOUT objects are `/usr/4lib`, `/usr/lib`, `/usr/ucblib`, and `/usr/local/lib`.

Use of this option *replaces* the system default trusted directories, and thus it is normally required that a `-s` option be used to specify the original system default in relation to any new directories being applied. However,

crle(1)

	if the <code>-u</code> option is in effect, and a configuration file does <i>not</i> exist, the system defaults are added to the new configuration file before the new directories specified with the <code>-s</code> option.
<code>-t ELF AOUT</code>	This option toggles the object type applicable to any <code>-l</code> or <code>-s</code> options that follow. The default object type is ELF.
<code>-u</code>	This option requests that a configuration file be updated, possibly with the addition of new information. Without other options any existing configuration file is inspected and its contents recomputed. Additional arguments allow information to be appended to the recomputed contents. See NOTES. If a configuration file does not exist it will be created as directed by the other arguments. In the case of the <code>-l</code> and <code>-s</code> options any system defaults will first be applied to the configuration file before the directories specified with these options.
<code>-v</code>	Verbose mode. When creating a configuration file, a trace of the files being processed is written to the standard out. When printing the contents of a configuration file, more extensive directory and file information is provided.

By default the runtime linker attempts to read the configuration file `/var/ld/ld.config` for each 32-bit application it processes or `/var/ld/64/ld.config` for each 64-bit application. When processing an alternative application, the runtime linker will use a `$ORIGIN/ld.config.app-name` configuration file if present (see NOTES). Applications may reference an alternative configuration file either by setting the `LD_CONFIG` environment variable (see `ld.so.1(1)`), or by recording a configuration file name in the application at the time it is built using the link-editors `-c` option (see `ld(1)`).

EXAMPLES

EXAMPLE 1 Update (and display) of a new default search path for ELF objects

```
example% crle -u -l /local/lib
example% crle

Configuration file [2]: /var/ld/ld.config
  Default Library Path (ELF): /usr/lib:/local/lib
  Trusted Directories (ELF): /usr/lib/secure (system default)

Command line:
  crle -l /usr/lib:/local/lib
example% crle -u -l /usr/local/lib
example% crle
```

EXAMPLE 1 Update (and display) of a new default search path for ELF objects
(Continued)

```
Configuration file [2]: /var/ld/ld.config
  Default Library Path (ELF): /usr/lib:/local/lib:/usr/local/lib
  Trusted Directories (ELF): /usr/lib/secure (system default)

Command line:
  crle -l /usr/lib:/local/lib:/usr/local/lib
```

In this example, the default configuration file initially did not exist, and thus the new search path `/local/lib` is appended to the system default. The next update appends the search path `/usr/local/lib` to those already established in the configuration file.

EXAMPLE 2 Creation (and display) of a new default search path and new trusted directory for ELF objects

```
example% crle -l /local/lib -l /usr/lib -s /local/lib
example% crle
```

```
Configuration file [2]: /var/ld/ld.config
  Default Library Path (ELF): /local/lib:/usr/lib
  Trusted Directories (ELF): /local/lib

Command line:
  crle -l /local/lib:/usr/lib -s /local/lib
```

With this configuration, third party applications may be installed in `/local/bin` and their associated dependencies in `/local/lib`. The default search path allows the applications to locate their dependencies without the need to set `LD_LIBRARY_PATH`. *Note:* The system default trusted directory has been replaced with this example.

EXAMPLE 3 Creation of a directory cache for ELF objects

```
example% crle -i /usr/dt/lib -i /usr/openwin/lib -i /usr/lib \
-c config
example% ldd -s ./main
....
  find object=libc.so.1; required by ./main
  search path=/usr/dt/lib:/usr/openwin/lib (RPATH ./main)
  trying path=/usr/dt/lib/libc.so.1
  trying path=/usr/openwin/lib/libc.so.1
  search path=/usr/lib (default)
  trying path=/usr/lib/libc.so.1
  libc.so.1 => /usr/lib/libc.so.1

example% LD_CONFIG=config ldd -s ./main
....
  find object=libc.so.1; required by ./main
  search path=/usr/dt/lib:/usr/openwin/lib (RPATH ./main)
  search path=/usr/lib (default)
  trying path=/usr/lib/libc.so.1
```

crle(1)

EXAMPLE 3 Creation of a directory cache for ELF objects (Continued)

```
libc.so.1 => /usr/lib/libc.so.1
```

With this configuration, the cache reflects that the system library `libc.so.1` does not exist in the directories `/usr/dt/lib` or `/usr/openwin/lib`. Therefore, the search for this system file ignores these directories even though the application's runpath indicates they should be searched.

EXAMPLE 4 Creation of an alternative object cache for an ELF executable

```
example% crle -c /local/$HOST/.xterm/ld.config -f RTLD_REL_ALL \
-G /usr/openwin/bin/xterm
example% ln -s /local/$HOST/.xterm/xterm /local/$HOST/xterm
example% ldd /usr/local/$HOST/xterm
libXaw.so.5 => /local/$HOST/.xterm/libXaw.so.5 (alternate)
libXmu.so.4 => /local/$HOST/.xterm/libXmu.so.4 (alternate)
....
libc.so.1 => /local/$HOST/.xterm/libc.so.1 (alternate)
....
```

With this configuration, a new `xterm` and its dependencies are created. These new objects are fully relocated to themselves and result in faster start-up than the originating objects. *Note:* The execution of this application uses its own specific configuration file. This model is generally more flexible than using the environment variable `LD_CONFIG`, as the configuration file will not be erroneously used by other applications such as `ldd(1)` or `truss(1)`.

EXAMPLE 5 Creating an alternative object cache to replace an ELF shared object

```
example% ldd /usr/sbin/vold
libthread.so.1 => /usr/lib/libthread.so.1
....

example% crle -a /usr/lib/libthread.so.1 -o /usr/lib/lwp
example% crle

Configuration file [2]: /var/ld/ld.config
Default Library Path (ELF): /usr/lib (system default)
Trusted Directories (ELF): /usr/lib/secure (system default)

Directory: /usr/lib
libthread.so.1 (alternate: /usr/lib/lwp/libthread.so.1)

example% ldd /usr/sbin/vold
libthread.so.1 => /usr/lib/lwp/libthread.so.1 (alternate)
....
```

With this configuration, any dependency that would normally resolve to `/usr/lib/libthread.so.1` will instead resolve to `/usr/lib/lwp/libthread.so.1`. See `threads(3THR)`.

EXIT STATUS	The creation or display of a configuration file results in a 0 being returned; otherwise any error condition is accompanied with a diagnostic message and a non-zero value being returned.														
NOTES	<p>Tagging an alternative application to use an application specific configuration file can only be achieved if the original application contains one of the <i>.dynamic</i> tags <code>DT_FLAGS_1</code> or <code>DT_FEATURE_1</code>. Without these entries any application specific configuration file must be specified using the <code>LD_CONFIG</code> environment variable. Care should be exercised with this latter method as this environment variable will be visible to any forked applications.</p> <p>The use of the <code>-u</code> option requires version 2 of <code>crle</code>. This version level is evident from displaying the contents of a configuration file:</p> <pre>example% crle Configuration file [2]: /var/ld/ld.config</pre> <p>With a version 2 configuration file, <code>crle</code> is capable of constructing the command-line arguments required to regenerate the configuration file and to provide full update capabilities. Although the update of a version 1 configuration file is possible, the contents of the configuration file may be insufficient for <code>crle</code> to compute the entire update requirements.</p>

NAME	crontab – user crontab file
SYNOPSIS	crontab [<i>filename</i>] crontab [-elr] <i>username</i>
DESCRIPTION	The crontab utility manages a user's access with cron (see cron(1M)) by copying, creating, listing, and removing crontab files. If invoked without options, crontab copies the specified file, or the standard input if no file is specified, into a directory that holds all users' crontabs.
crontab Access Control	<p>Users: Access to crontab is allowed:</p> <ul style="list-style-type: none"> ■ if the user's name appears in /etc/cron.d/cron.allow. ■ if /etc/cron.d/cron.allow does not exist and the user's name is not in /etc/cron.d/cron.deny. <p>Users: Access to crontab is denied:</p> <ul style="list-style-type: none"> ■ if /etc/cron.d/cron.allow exists and the user's name is not in it. ■ if /etc/cron.d/cron.allow does not exist and user's name is in /etc/cron.d/cron.deny. ■ if neither file exists, only a user with the solaris.jobs.user authorization is allowed to submit a job. ■ If BSM audit is enabled, the user's shell is not audited and the user is not the crontab owner. This can occur if the user logs in via a program, such as some versions of SSH, which does not set audit parameters. <p>Notice that the rules for allow and deny apply to root only if the allow/deny files exist.</p> <p>The allow/deny files consist of one user name per line.</p>
crontab Entry Format	<p>A crontab file consists of lines of six fields each. The fields are separated by spaces or tabs. The first five are integer patterns that specify the following:</p> <pre>minute (0-59), hour (0-23), day of the month (1-31), month of the year (1-12), day of the week (0-6 with 0=Sunday).</pre> <p>Each of these patterns may be either an asterisk (meaning all legal values) or a list of elements separated by commas. An element is either a number or two numbers separated by a minus sign (meaning an inclusive range). Notice that the specification of days may be made by two fields (day of the month and day of the week). Both are adhered to if specified as a list of elements. See EXAMPLES.</p> <p>The sixth field of a line in a crontab file is a string that is executed by the shell at the specified times. A percent character in this field, unless it is escaped by \, is translated to a NEWLINE character.</p>

crontab(1)

Only the first line, up to a % or end of line, of the command field is executed by the shell. Other lines are made available to the command as standard input. Any line beginning with a # is a comment and is ignored. The file should not contain blank lines.

The shell is invoked from your \$HOME directory with an arg0 of sh. Users who desire to have their .profile executed must explicitly do so in the crontab file. cron supplies a default environment for every shell, defining HOME, LOGNAME, SHELL (= /bin/sh), TZ, and PATH. The default PATH for user cron jobs is /usr/bin. root cron jobs default to /usr/sbin:/usr/bin. The default PATH can be set in /etc/default/cron. See cron(1M).

If you do not redirect the standard output and standard error of your commands, any generated output or errors will be mailed to you.

OPTIONS

The following options are supported:

- e Edits a copy of the current user's crontab file, or creates an empty file to edit if crontab does not exist. When editing is complete, the file is installed as the user's crontab file. If a *username* is given, the specified user's crontab file is edited, rather than the current user's crontab file. This may only be done by a user with the `solaris.jobs.admin` authorization. The environment variable EDITOR determines which editor is invoked with the -e option. The default editor is ed(1). Notice that all crontab jobs should be submitted using crontab. Do not add jobs by just editing the crontab file, because cron will not be aware of changes made this way.
- l Lists the crontab file for the invoking user. Only a user with the `solaris.jobs.admin` authorization can specify a *username* following the -r or -l options to remove or list the crontab file of the specified user.
- r Removes a user's crontab from the crontab directory.

EXAMPLES

EXAMPLE 1 Cleaning up core files

This example cleans up core files every weekday morning at 3:15 am:

```
15 3 * * 1-5 find $HOME -name core 2>/dev/null | xargs rm -f
```

EXAMPLE 2 Mailing a birthday greeting

```
0 12 14 2 * mailx john%Happy Birthday!%Time for lunch.
```

EXAMPLE 3 Specifying days of the month and week

This example

```
0 0 1,15 * 1
```

would run a command on the first and fifteenth of each month, as well as on every Monday.

EXAMPLE 3 Specifying days of the month and week *(Continued)*

To specify days by only one field, the other field should be set to *. For example:

```
0 0 * * 1
```

would run a command only on Mondays.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `crontab`: `LC_TYPE`, `LC_MESSAGES`, and `NLSPATH`.

EDITOR Determine the editor to be invoked when the `-e` option is specified. The default editor is `ed(1)`. If both the `EDITOR` and `VISUAL` environment variables are set, the value of the `VISUAL` variable is selected as the editor.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES

<code>/etc/cron.d</code>	main cron directory
<code>/etc/cron.d/cron.allow</code>	list of allowed users
<code>/etc/default/cron</code>	contains cron default settings
<code>/etc/cron.d/cron.deny</code>	list of denied users
<code>/var/cron/log</code>	accounting information
<code>/var/spool/cron/crontabs</code>	spool area for <code>crontab</code>

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`atq(1)`, `atrm(1)`, `auths(1)`, `ed(1)`, `sh(1)`, `cron(1M)`, `su(1M)`, `auth_attr(4)`, `attributes(5)`, `environ(5)`

NOTES

If you inadvertently enter the `crontab` command with no argument(s), do not attempt to get out with Control-d. This removes all entries in your `crontab` file. Instead, exit with Control-c.

If an authorized user modifies another user's `crontab` file, resulting behavior may be unpredictable. Instead, the superuser should first `su(1M)` to the other user's login before making any changes to the `crontab` file.

crontab(1)

When updating a user's crontab file with the `crontab` command, the `cron` process sees this update immediately when no `cron` jobs are running. However, if `cron` is running any cron job(s) at the time of updating, it could take a maximum of 60 seconds before `cron` is aware of this update. Therefore, to be safe, a new job should be started at least 60 seconds after the current date and time.

NAME	crypt – encode or decode a file				
SYNOPSIS	crypt [<i>password</i>]				
DESCRIPTION	<p>crypt encrypts and decrypts the contents of a file. crypt reads from the standard input and writes on the standard output. The <i>password</i> is a key that selects a particular transformation. If no <i>password</i> is given, crypt demands a key from the terminal and turns off printing while the key is being typed in. crypt encrypts and decrypts with the same key:</p> <pre>example% crypt key<clear.file> encrypted.file example% crypt key<encrypted.file pr</pre> <p>will print the contents of <i>clear.file</i>.</p> <p>Files encrypted by crypt are compatible with those treated by the editors <i>ed</i>(1), <i>ex</i>(1), and <i>vi</i>(1) in encryption mode.</p> <p>The security of encrypted files depends on three factors: the fundamental method must be hard to solve; direct search of the key space must be infeasible; “sneak paths” by which keys or cleartext can become visible must be minimized.</p> <p>crypt implements a one-rotor machine designed along the lines of the German Enigma, but with a 256-element rotor. Methods of attack on such machines are widely known, thus crypt provides minimal security.</p> <p>The transformation of a key into the internal settings of the machine is deliberately designed to be expensive, that is, to take a substantial fraction of a second to compute. However, if keys are restricted to (say) three lower-case letters, then encrypted files can be read by expending only a substantial fraction of five minutes of machine time.</p> <p>Since the key is an argument to the crypt command, it is potentially visible to users executing <i>ps</i>(1) or a derivative command. To minimize this possibility, crypt takes care to destroy any record of the key immediately upon entry. No doubt the choice of keys and key security are the most vulnerable aspect of crypt.</p>

ssh(1)

NAME	ssh – shell command interpreter with a C-like syntax
SYNOPSIS	ssh [-bcefinstvVxX] [<i>argument...</i>]
DESCRIPTION	ssh, the C shell, is a command interpreter with a syntax reminiscent of the C language. It provides a number of convenient features for interactive use that are not available with the Bourne shell, including filename completion, command aliasing, history substitution, job control, and a number of built-in commands. As with the Bourne shell, the C shell provides variable, command and filename substitution.
Initialization and Termination	<p>When first started, the C shell normally performs commands from the <code>.sshrc</code> file in your home directory, provided that it is readable and you either own it or your real group ID matches its group ID. If the shell is invoked with a name that starts with '-', as when started by <code>login(1)</code>, the shell runs as a login shell.</p> <p>If the shell is a login shell, this is the sequence of invocations: First, commands in <code>/etc/.login</code> are executed. Next, commands from the <code>.sshrc</code> file your home directory are executed. Then the shell executes commands from the <code>.login</code> file in your home directory; the same permission checks as those for <code>.sshrc</code> are applied to this file. Typically, the <code>.login</code> file contains commands to specify the terminal type and environment. (For an explanation of file interpreters, see below "Command Execution" and <code>exec(2)</code>.)</p> <p>As a login shell terminates, it performs commands from the <code>.logout</code> file in your home directory; the same permission checks as those for <code>.sshrc</code> are applied to this file.</p>
Interactive Operation	After startup processing is complete, an interactive C shell begins reading commands from the terminal, prompting with <code>hostname%</code> (or <code>hostname#</code> for the privileged user). The shell then repeatedly performs the following actions: a line of command input is read and broken into <i>words</i> . This sequence of words is placed on the history list and then parsed, as described under USAGE, below. Finally, the shell executes each command in the current line.
Noninteractive Operation	When running noninteractively, the shell does not prompt for input from the terminal. A noninteractive C shell can execute a command supplied as an <i>argument</i> on its command line, or interpret commands from a file, also known as a script.
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-b Force a "break" from option processing. Subsequent command line arguments are not interpreted as C shell options. This allows the passing of options to a script without confusion. The shell does not run set-user-ID or set-group-ID scripts unless this option is present.-c Execute the first <i>argument</i> (which must be present). Remaining arguments are placed in <code>argv</code>, the argument-list variable, and passed directly to <code>ssh</code>.-e Exit if a command terminates abnormally or yields a nonzero exit status.

- f Fast start. Read neither the `.cshrc` file, nor the `.login` file (if a login shell) upon startup.
- i Forced interactive. Prompt for command line input, even if the standard input does not appear to be a terminal (character-special device).
- n Parse (interpret), but do not execute commands. This option can be used to check C shell scripts for syntax errors.
- s Take commands from the standard input.
- t Read and execute a single command line. A `'\'` (backslash) can be used to escape each newline for continuation of the command line onto subsequent input lines.
- v Verbose. Set the `verbose` predefined variable; command input is echoed after history substitution (but before other substitutions) and before execution.
- V Set `verbose` before reading `.cshrc`.
- x Echo. Set the `echo` variable; echo commands after all substitutions and just before execution.
- X Set `echo` before reading `.cshrc`.

Except with the options `-c`, `-i`, `-s`, or `-t`, the first nonoption *argument* is taken to be the name of a command or script. It is passed as argument zero, and subsequent arguments are added to the argument list for that command or script.

USAGE

Filename Completion

When enabled by setting the variable `filec`, an interactive C shell can complete a partially typed filename or user name. When an unambiguous partial filename is followed by an ESC character on the terminal input line, the shell fills in the remaining characters of a matching filename from the working directory.

If a partial filename is followed by the EOF character (usually typed as CTRL-d), the shell lists all filenames that match. It then prompts once again, supplying the incomplete command line typed in so far.

When the last (partial) word begins with a tilde (~), the shell attempts completion with a user name, rather than a file in the working directory.

The terminal bell signals errors or multiple matches; this can be inhibited by setting the variable `nobeeep`. You can exclude files with certain suffixes by listing those suffixes in the variable `ignore`. If, however, the only possible completion includes a suffix in the list, it is not ignored. `ignore` does not affect the listing of filenames by the EOF character.

cs(1)

Lexical Structure

The shell splits input lines into words at space and tab characters, except as noted below. The characters `&`, `|`, `;`, `<`, `>`, `(`, and `)` form separate words; if paired, the pairs form single words. These shell metacharacters can be made part of other words, and their special meaning can be suppressed by preceding them with a `\` (backslash). A newline preceded by a `\` is equivalent to a space character.

In addition, a string enclosed in matched pairs of single-quotes (`'`), double-quotes (`"`), or backquotes (```), forms a partial word; metacharacters in such a string, including any space or tab characters, do not form separate words. Within pairs of backquote (```) or double-quote (`"`) characters, a newline preceded by a `\` (backslash) gives a true newline character. Additional functions of each type of quote are described, below, under `Variable Substitution`, `Command Substitution`, and `Filename Substitution`.

When the shell's input is not a terminal, the character `#` introduces a comment that continues to the end of the input line. Its special meaning is suppressed when preceded by a `\` or enclosed in matching quotes.

Command Line Parsing

A *simple command* is composed of a sequence of words. The first word (that is not part of an I/O redirection) specifies the command to be executed. A simple command, or a set of simple commands separated by `|` or `|&` characters, forms a *pipeline*. With `|`, the standard output of the preceding command is redirected to the standard input of the command that follows. With `|&`, both the standard error and the standard output are redirected through the pipeline.

Pipelines can be separated by semicolons (`;`), in which case they are executed sequentially. Pipelines that are separated by `&&` or `| |` form conditional sequences in which the execution of pipelines on the right depends upon the success or failure, respectively, of the pipeline on the left.

A pipeline or sequence can be enclosed within parentheses (`()`) to form a simple command that can be a component in a pipeline or sequence.

A sequence of pipelines can be executed asynchronously or "in the background" by appending an `&`; rather than waiting for the sequence to finish before issuing a prompt, the shell displays the job number (see `Job Control`, below) and associated process IDs and prompts immediately.

History Substitution

History substitution allows you to use words from previous command lines in the command line you are typing. This simplifies spelling corrections and the repetition of complicated commands or arguments. Command lines are saved in the history list, the size of which is controlled by the `history` variable. The most recent command is retained in any case. A history substitution begins with a `!` (although you can change this with the `histchars` variable) and may occur anywhere on the command line; history substitutions do not nest. The `!` can be escaped with `\` to suppress its special meaning.

Input lines containing history substitutions are echoed on the terminal after being expanded, but before any other substitutions take place or the command gets executed.

Event Designators

An event designator is a reference to a command line entry in the history list.

- ! Start a history substitution, except when followed by a space character, tab, newline, = or (.
- !! Refer to the previous command. By itself, this substitution repeats the previous command.
- !*n* Refer to command line *n*.
- !-*n* Refer to the current command line minus *n*.
- !*str* Refer to the most recent command starting with *str*.
- !?*str*? Refer to the most recent command containing *str*.
- !?*str*? *additional* Refer to the most recent command containing *str* and append *additional* to that referenced command.
- !*{command}* *additional* Refer to the most recent command beginning with *command* and append *additional* to that referenced command.
- ^*previous_word*^*replacement*^ Repeat the previous command line replacing the string *previous_word* with the string *replacement*. This is equivalent to the history substitution:

! : s / *previous_word* / *replacement* / .

To re-execute a specific previous command AND make such a substitution, say, re-executing command #6,

! : 6 s / *previous_word* / *replacement* / .

Word Designators

A ':' (colon) separates the event specification from the word designator. It can be omitted if the word designator begins with a ^, \$, *, - or %. If the word is to be selected from the previous command, the second ! character can be omitted from the event specification. For instance, !! : 1 and ! : 1 both refer to the first word of the previous command, while !!\$ and !\$ both refer to the last word in the previous command. Word designators include:

cs(1)

#	The entire command line typed so far.
0	The first input word (command).
<i>n</i>	The <i>n</i> 'th argument.
^	The first argument, that is, 1.
\$	The last argument.
%	The word matched by (the most recent) ?s search.
<i>x-y</i>	A range of words; <i>-y</i> abbreviates 0- <i>y</i> .
*	All the arguments, or a null value if there is just one word in the event.
<i>x*</i>	Abbreviates <i>x-\$</i> .
<i>x-</i>	Like <i>x*</i> but omitting word \$.

Modifiers After the optional word designator, you can add one of the following modifiers, preceded by a `:`.

h	Remove a trailing pathname component, leaving the head.
r	Remove a trailing suffix of the form <code>' .xxx'</code> , leaving the basename.
e	Remove all but the suffix, leaving the Extension.
<i>s/l/r/</i>	Substitute <i>r</i> for <i>l</i> .
t	Remove all leading pathname components, leaving the tail.
&	Repeat the previous substitution.
g	Apply the change to the first occurrence of a match in each word, by prefixing the above (for example, <code>g&</code>).
p	Print the new command but do not execute it.
q	Quote the substituted words, escaping further substitutions.
x	Like <code>q</code> , but break into words at each space character, tab or newline.

Unless preceded by a `g`, the modification is applied only to the first string that matches *l*; an error results if no string matches.

The left-hand side of substitutions are not regular expressions, but character strings. Any character can be used as the delimiter in place of `/`. A backslash quotes the delimiter character. The character `&`, in the right hand side, is replaced by the text from the left-hand-side. The `&` can be quoted with a backslash. A null *l* uses the previous string either from a *l* or from a contextual scan string *s* from `! ?s`. You can omit the rightmost delimiter if a newline immediately follows *r*; the rightmost `?` in a context scan can similarly be omitted.

Without an event specification, a history reference refers either to the previous command, or to a previous history reference on the command line (if any).

Quick Substitution	<p><code>^l^r^</code> This is equivalent to the history substitution: <code>!:s/l/r/</code>.</p>
Aliases	<p>The C shell maintains a list of aliases that you can create, display, and modify using the <code>alias</code> and <code>unalias</code> commands. The shell checks the first word in each command to see if it matches the name of an existing alias. If it does, the command is reprocessed with the alias definition replacing its name; the history substitution mechanism is made available as though that command were the previous input line. This allows history substitutions, escaped with a backslash in the definition, to be replaced with actual command line arguments when the alias is used. If no history substitution is called for, the arguments remain unchanged.</p> <p>Aliases can be nested. That is, an alias definition can contain the name of another alias. Nested aliases are expanded before any history substitutions is applied. This is useful in pipelines such as</p> <pre>alias lm 'ls -l \!* more'</pre> <p>which when called, pipes the output of <code>ls(1)</code> through <code>more(1)</code>.</p> <p>Except for the first word, the name of the alias may not appear in its definition, nor in any alias referred to by its definition. Such loops are detected, and cause an error message.</p>
I/O Redirection	<p>The following metacharacters indicate that the subsequent word is the name of a file to which the command's standard input, standard output, or standard error is redirected; this word is variable, command, and filename expanded separately from the rest of the command.</p> <p><</p> <p>Redirect the standard input.</p> <p>< <i>word</i></p> <p>Read the standard input, up to a line that is identical with <i>word</i>, and place the resulting lines in a temporary file. Unless <i>word</i> is escaped or quoted, variable and command substitutions are performed on these lines. Then, the pipeline is invoked with the temporary file as its standard input. <i>word</i> is not subjected to variable, filename, or command substitution, and each line is compared to it before any substitutions are performed by the shell.</p> <p>> >! >& >&!</p> <p>Redirect the standard output to a file. If the file does not exist, it is created. If it does exist, it is overwritten; its previous contents are lost.</p> <p>When set, the variable <code>noclobber</code> prevents destruction of existing files. It also prevents redirection to terminals and <code>/dev/null</code>, unless one of the <code>!</code> forms is used. The <code>&</code> forms redirect both standard output and the standard error (diagnostic output) to the file.</p> <p>> > >& >>! >>&!</p> <p>Append the standard output. Like <code>></code>, but places output at the end of the file rather than overwriting it. If <code>noclobber</code> is set, it is an error for the file not to exist, unless</p>

cs(1)

Variable Substitution

one of the ! forms is used. The & forms append both the standard error and standard output to the file.

The C shell maintains a set of *variables*, each of which is composed of a *name* and a *value*. A variable name consists of up to 20 letters and digits, and starts with a letter (the underscore is considered a letter). A variable's value is a space-separated list of zero or more words.

To refer to a variable's value, precede its name with a '\$'. Certain references (described below) can be used to select specific words from the value, or to display other information about the variable. Braces can be used to insulate the reference from other characters in an input-line word.

Variable substitution takes place after the input line is analyzed, aliases are resolved, and I/O redirections are applied. Exceptions to this are variable references in I/O redirections (substituted at the time the redirection is made), and backquoted strings (see Command Substitution).

Variable substitution can be suppressed by preceding the \$ with a \, except within double-quotes where it always occurs. Variable substitution is suppressed inside of single-quotes. A \$ is escaped if followed by a space character, tab or newline.

Variables can be created, displayed, or destroyed using the `set` and `unset` commands. Some variables are maintained or used by the shell. For instance, the `argv` variable contains an image of the shell's argument list. Of the variables used by the shell, a number are toggles; the shell does not care what their value is, only whether they are set or not.

Numerical values can be operated on as numbers (as with the `@` built-in command). With numeric operations, an empty value is considered to be zero; the second and subsequent words of multiword values are ignored. For instance, when the `verbose` variable is set to any value (including an empty value), command input is echoed on the terminal.

Command and filename substitution is subsequently applied to the words that result from the variable substitution, except when suppressed by double-quotes, when `noglob` is set (suppressing filename substitution), or when the reference is quoted with the `:q` modifier. Within double-quotes, a reference is expanded to form (a portion of) a quoted string; multiword values are expanded to a string with embedded space characters. When the `:q` modifier is applied to the reference, it is expanded to a list of space-separated words, each of which is quoted to prevent subsequent command or filename substitutions.

Except as noted below, it is an error to refer to a variable that is not set.

`$var`

`${var}`

These are replaced by words from the value of *var*, each separated by a space character. If *var* is an environment variable, its value is returned (but ':' modifiers and the other forms given below are not available).

<code><i>\$var</i> [<i>index</i>]</code>	
<code>\${<i>var</i> [<i>index</i>] }</code>	These select only the indicated words from the value of <i>var</i> . Variable substitution is applied to <i>index</i> , which may consist of (or result in) a either single number, two numbers separated by a '-', or an asterisk. Words are indexed starting from 1; a '*' selects all words. If the first number of a range is omitted (as with <code>\$argv[-2]</code>), it defaults to 1. If the last number of a range is omitted (as with <code>\$argv[1-]</code>), it defaults to <code> \$#var</code> (the word count). It is not an error for a range to be empty if the second argument is omitted (or within range).
<code> \$#name</code>	
<code> \${ #name }</code>	These give the number of words in the variable.
<code> \$0</code>	This substitutes the name of the file from which command input is being read except for setuid shell scripts. An error occurs if the name is not known.
<code> \$n</code>	
<code> \${ n }</code>	Equivalent to <code> \$argv [n]</code> .
<code> \$*</code>	Equivalent to <code> \$argv [*]</code> .

The modifiers `:e`, `:h`, `:g`, `:r`, `:t`, and `:x` can be applied (see History Substitution), as can `:gh`, `:gt`, and `:gr`. If `{ }` (braces) are used, then the modifiers must appear within the braces. The current implementation allows only one such modifier per expansion.

The following references may not be modified with `:` modifiers.

<code> \$?var</code>	
<code> \${ ?var }</code>	Substitutes the string 1 if <i>var</i> is set or 0 if it is not set.
<code> \$?0</code>	Substitutes 1 if the current input filename is known or 0 if it is not.
<code> \$\$</code>	Substitutes the process number of the (parent) shell.
<code> \$<</code>	Substitutes a line from the standard input, with no further interpretation thereafter. It can be used to read from the keyboard in a C shell script.

Command and Filename Substitutions

Command and filename substitutions are applied selectively to the arguments of built-in commands. Portions of expressions that are not evaluated are not expanded. For non-built-in commands, filename expansion of the command name is done separately from that of the argument list; expansion occurs in a subshell, after I/O redirection is performed.

Command Substitution

A command enclosed by backquotes (`` . . . ``) is performed by a subshell. Its standard output is broken into separate words at each space character, tab and newline; null words are discarded. This text replaces the backquoted string on the current command

cs(1)

Filename Substitution

line. Within double-quotes, only newline characters force new words; space and tab characters are preserved. However, a final newline is ignored. It is therefore possible for a command substitution to yield a partial word.

Unquoted words containing any of the characters `*`, `?`, `[` or `{`, or that begin with `~`, are expanded (also known as *globbing*) to an alphabetically sorted list of filenames, as follows:

<code>*</code>	Match any (zero or more) characters.
<code>?</code>	Match any single character.
<code>[...]</code>	Match any single character in the enclosed list(s) or range(s). A list is a string of characters. A range is two characters separated by a dash (<code>-</code>), and includes all the characters in between in the ASCII collating sequence (see <code>ascii(5)</code>).
<code>{str, str, ...}</code>	Expand to each string (or filename-matching pattern) in the comma-separated list. Unlike the pattern-matching expressions above, the expansion of this construct is not sorted. For instance, <code>{b, a}</code> expands to <code>'b' 'a'</code> , (not <code>'a' 'b'</code>). As special cases, the characters <code>{</code> and <code>}</code> , along with the string <code>{ }</code> , are passed undisturbed.
<code>~[user]</code>	Your home directory, as indicated by the value of the variable <code>home</code> , or that of <code>user</code> , as indicated by the password entry for <code>user</code> .

Only the patterns `*`, `?` and `[...]` imply pattern matching; an error results if no filename matches a pattern that contains them. The `'.'` (dot character), when it is the first character in a filename or pathname component, must be matched explicitly. The `/` (slash) must also be matched explicitly.

Expressions and Operators

A number of C shell built-in commands accept expressions, in which the operators are similar to those of C and have the same precedence. These expressions typically appear in the `@`, `exit`, `if`, `set` and `while` commands, and are often used to regulate the flow of control for executing commands. Components of an expression are separated by white space.

Null or missing values are considered 0. The result of all expressions is a string, which may represent decimal numbers.

The following C shell operators are grouped in order of precedence:

<code>(...)</code>	grouping
<code>>~</code>	one's complement
<code>!</code>	logical negation
<code>* / %</code>	multiplication, division, remainder (these are right associative, which can lead to unexpected results; group combinations explicitly with parentheses.)

+ -	addition, subtraction (also right associative)
<< >>	bitwise shift left, bitwise shift right
< > <= >=	less than, greater than, less than or equal to, greater than or equal to
= = != =~ !~	equal to, not equal to, filename-substitution pattern match (described below), filename-substitution pattern mismatch
&	bitwise AND
^	bitwise XOR (exclusive or)
	bitwise inclusive OR
&&	logical AND
	logical OR

The operators: ==, !=, =~, and !~ compare their arguments as strings; other operators use numbers. The operators =~ and !~ each check whether or not a string to the left matches a filename substitution pattern on the right. This reduces the need for switch statements when pattern-matching between strings is all that is required.

Also available are file inquiries:

-r <i>filename</i>	Return true, or 1 if the user has read access. Otherwise it returns false, or 0.
-w <i>filename</i>	True if the user has write access.
-x <i>filename</i>	True if the user has execute permission (or search permission on a directory).
-e <i>filename</i>	True if <i>filename</i> exists.
-o <i>filename</i>	True if the user owns <i>filename</i> .
-z <i>filename</i>	True if <i>filename</i> is of zero length (empty).
-f <i>filename</i>	True if <i>filename</i> is a plain file.
-d <i>filename</i>	True if <i>filename</i> is a directory.

If *filename* does not exist or is inaccessible, then all inquiries return false.

An inquiry as to the success of a command is also available:

{ <i>command</i> }	If <i>command</i> runs successfully, the expression evaluates to true, 1. Otherwise, it evaluates to false, 0. (Note: Conversely, <i>command</i> itself typically returns 0 when it runs successfully, or some other value if it encounters a problem. If you want to get at the status directly, use the value of the <code>status</code> variable rather than this expression).
--------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

cs(1)

Control Flow	<p>The shell contains a number of commands to regulate the flow of control in scripts and within limits, from the terminal. These commands operate by forcing the shell either to reread input (to <i>loop</i>), or to skip input under certain conditions (to <i>branch</i>).</p> <p>Each occurrence of a <code>foreach</code>, <code>switch</code>, <code>while</code>, <code>if...then</code> and <code>else</code> built-in command must appear as the first word on its own input line.</p> <p>If the shell's input is not seekable and a loop is being read, that input is buffered. The shell performs seeks within the internal buffer to accomplish the rereading implied by the loop. (To the extent that this allows, backward <code>goto</code> commands will succeed on nonseekable inputs.)</p>
Command Execution	<p>If the command is a C shell built-in command, the shell executes it directly. Otherwise, the shell searches for a file by that name with execute access. If the command name contains a <code>/</code>, the shell takes it as a pathname, and searches for it. If the command name does not contain a <code>/</code>, the shell attempts to resolve it to a pathname, searching each directory in the <code>path</code> variable for the command. To speed the search, the shell uses its hash table (see the <code>rehash</code> built-in command) to eliminate directories that have no applicable files. This hashing can be disabled with the <code>-c</code> or <code>-t</code>, options, or the <code>unhash</code> built-in command.</p> <p>As a special case, if there is no <code>/</code> in the name of the script and there is an alias for the word <code>shell</code>, the expansion of the <code>shell</code> alias is prepended (without modification) to the command line. The system attempts to execute the first word of this special (late-occurring) alias, which should be a full pathname. Remaining words of the alias's definition, along with the text of the input line, are treated as arguments.</p> <p>When a pathname is found that has proper execute permissions, the shell forks a new process and passes it, along with its arguments, to the kernel using the <code>execve()</code> system call (see <code>exec(2)</code>). The kernel then attempts to overlay the new process with the desired program. If the file is an executable binary (in a <code>.out(4)</code> format) the kernel succeeds and begins executing the new process. If the file is a text file and the first line begins with <code>#!</code>, the next word is taken to be the pathname of a shell (or command) to interpret that script. Subsequent words on the first line are taken as options for that shell. The kernel invokes (overlays) the indicated shell, using the name of the script as an argument.</p> <p>If neither of the above conditions holds, the kernel cannot overlay the file and the <code>execve()</code> call fails (see <code>exec(2)</code>); the C shell then attempts to execute the file by spawning a new shell, as follows:</p> <ul style="list-style-type: none">■ If the first character of the file is a <code>#</code>, a C shell is invoked.■ Otherwise, a Bourne shell is invoked.
Signal Handling	<p>The shell normally ignores <code>QUIT</code> signals. Background jobs are immune to signals generated from the keyboard, including hangups (<code>HUP</code>). Other signals have the values that the C shell inherited from its environment. The shell's handling of interrupt and</p>

terminate signals within scripts can be controlled by the `onintr` built-in command. Login shells catch the TERM signal; otherwise, this signal is passed on to child processes. In no case are interrupts allowed when a login shell is reading the `.logout` file.

Job Control

The shell associates a numbered *job* with each command sequence to keep track of those commands that are running in the background or have been stopped with TSTP signals (typically CTRL-Z). When a command or command sequence (semicolon separated list) is started in the background using the `&` metacharacter, the shell displays a line with the job number in brackets and a list of associated process numbers:

```
[1] 1234
```

To see the current list of jobs, use the `jobs` built-in command. The job most recently stopped (or put into the background if none are stopped) is referred to as the *current* job and is indicated with a `'+'`. The previous job is indicated with a `'-'`; when the current job is terminated or moved to the foreground, this job takes its place (becomes the new current job).

To manipulate jobs, refer to the `bg`, `fg`, `kill`, `stop`, and `%` built-in commands.

A reference to a job begins with a `'%'`. By itself, the percent-sign refers to the current job.

<code>%</code>	<code> %+</code>	<code> %%</code>	The current job.
<code>%-</code>			The previous job.
<code>%j</code>			Refer to job <i>j</i> as in: <code>'kill -9 %j'</code> . <i>j</i> can be a job number, or a string that uniquely specifies the command line by which it was started; <code>'fg %vi'</code> might bring a stopped <code>vi</code> job to the foreground, for instance.
<code> %?string</code>			Specify the job for which the command line uniquely contains <i>string</i> .

A job running in the background stops when it attempts to read from the terminal. Background jobs can normally produce output, but this can be suppressed using the `'stty tostop'` command.

Status Reporting

While running interactively, the shell tracks the status of each job and reports whenever the job finishes or becomes blocked. It normally displays a message to this effect as it issues a prompt, in order to avoid disturbing the appearance of your input. When set, the `notify` variable indicates that the shell is to report status changes immediately. By default, the `notify` command marks the current process; after starting a background job, type `notify` to mark it.

Built-In Commands

Built-in commands are executed within the C shell. If a built-in command occurs as any component of a pipeline except the last, it is executed in a subshell.

cs(1)

:
Null command. This command is interpreted, but performs no action.

alias [*name* [*def*]]
Assign *def* to the alias *name*. *def* is a list of words that may contain escaped history-substitution metasyntax. *name* is not allowed to be `alias` or `unalias`. If *def* is omitted, the current definition for the alias *name* is displayed. If both *name* and *def* are omitted, all aliases are displayed with their definitions.

bg [%*job* . . .]
Run the current or specified jobs in the background.

break
Resume execution after the end of the nearest enclosing `foreach` or `while` loop. The remaining commands on the current line are executed. This allows multilevel breaks to be written as a list of `break` commands, all on one line.

breaksw
Break from a `switch`, resuming after the `endsw`.

case *label* :
A label in a `switch` statement.

cd [*dir*]
chdir [*dir*]
Change the shell's working directory to directory *dir*. If no argument is given, change to the home directory of the user. If *dir* is a relative pathname not found in the current directory, check for it in those directories listed in the `cdpath` variable. If *dir* is the name of a shell variable whose value starts with a `/`, change to the directory named by that value.

continue
Continue execution of the next iteration of the nearest enclosing `while` or `foreach` loop.

default :
Labels the default case in a `switch` statement. The default should come after all case labels. Any remaining commands on the command line are first executed.

dirs [-1]
Print the directory stack, most recent to the left; the first directory shown is the current directory. With the `-1` argument, produce an unabbreviated printout; use of the `~` notation is suppressed.

echo [-n] *list*
The words in *list* are written to the shell's standard output, separated by space characters. The output is terminated with a newline unless the `-n` option is used. `cs(1)` will, by default, invoke its built-in `echo`, if `echo` is called without the full pathname of a Unix command, regardless of the configuration of your `PATH` (see `echo(1)`).

`eval argument . . .`

Reads the arguments as input to the shell and executes the resulting command(s). This is usually used to execute commands generated as the result of command or variable substitution. See `tset(1B)` for an example of how to use `eval`.

`exec command`

Execute *command* in place of the current shell, which terminates.

`exit [(expr)]`

The calling shell or shell script exits, either with the value of the status variable or with the value specified by the expression *expr*.

`fg [%job]`

Bring the current or specified *job* into the foreground.

`foreach var (wordlist)`

...

`end`

The variable *var* is successively set to each member of *wordlist*. The sequence of commands between this command and the matching `end` is executed for each new value of *var*. Both `foreach` and `end` must appear alone on separate lines.

The built-in command `continue` may be used to terminate the execution of the current iteration of the loop and the built-in command `break` may be used to terminate execution of the `foreach` command. When this command is read from the terminal, the loop is read once prompting with `?` before any statements in the loop are executed.

`glob wordlist`

Perform filename expansion on *wordlist*. Like `echo`, but no `\` escapes are recognized. Words are delimited by NULL characters in the output.

`goto label`

The specified *label* is a filename and a command expanded to yield a label. The shell rewinds its input as much as possible and searches for a line of the form *label*: possibly preceded by space or tab characters. Execution continues after the indicated line. It is an error to jump to a label that occurs between a `while` or `for` built-in command and its corresponding `end`.

`hashstat`

Print a statistics line indicating how effective the internal hash table for the *path* variable has been at locating commands (and avoiding `execs`). An `exec` is attempted for each component of the *path* where the hash function indicates a possible hit and in each component that does not begin with a `'/'`. These statistics only reflect the effectiveness of the *path* variable, not the *cdpath* variable.

`history [-hr] [n]`

Display the history list; if *n* is given, display only the *n* most recent events.

`-r` Reverse the order of printout to be most recent first rather than oldest first.

cs(1)

-h Display the history list without leading numbers. This is used to produce files suitable for sourcing using the -h option to *source*.

if (expr) command
If the specified expression evaluates to true, the single *command* with arguments is executed. Variable substitution on *command* happens early, at the same time it does for the rest of the *if* command. *command* must be a simple command, not a pipeline, a command list, or a parenthesized command list. Note: I/O redirection occurs even if *expr* is false, when *command* is *not* executed (this is a bug).

if (expr) then
...
else if (expr2) then
...
else
...
endif
If *expr* is true, commands up to the first *else* are executed. Otherwise, if *expr2* is true, the commands between the *else if* and the second *else* are executed. Otherwise, commands between the *else* and the *endif* are executed. Any number of *else if* pairs are allowed, but only one *else*. Only one *endif* is needed, but it is required. The words *else* and *endif* must be the first nonwhite characters on a line. The *if* must appear alone on its input line or after an *else*.

jobs [-l]
List the active jobs under job control.

-l List process IDs, in addition to the normal information.

kill [-sig] [pid] [%job] . . .
kill -l
Send the TERM (terminate) signal, by default, or the signal specified, to the specified process ID, the *job* indicated, or the current *job*. Signals are either given by number or by name. There is no default. Typing *kill* does not send a signal to the current job. If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process is sent a CONT (continue) signal as well.

-l List the signal names that can be sent.

limit [-h] [resource [max-use]]
Limit the consumption by the current process or any process it spawns, each not to exceed *max-use* on the specified *resource*. If *max-use* is omitted, print the current limit; if *resource* is omitted, display all limits. (Run the *sysdef(1M)* command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the *bc(1)* command).

-h Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

resource is one of:

<code>cputime</code>	Maximum CPU seconds per process.
<code>filesize</code>	Largest single file allowed; limited to the size of the filesystem. (see <code>df(1M)</code>).
<code>datasize (heapsize)</code>	Maximum data size (including stack) for the process. This is the size of your virtual memory See <code>swap(1M)</code> .
<code>stacksize</code>	Maximum stack size for the process. See <code>swap(1M)</code> .
<code>coredumpsize</code>	Maximum size of a core dump (file). This limited to the size of the filesystem.
<code>descriptors</code>	Maximum number of file descriptors. Run <code>sysdef()</code> .
<code>memorysize</code>	Maximum size of virtual memory.

max-use is a number, with an optional scaling factor, as follows:

<code>nh</code>	Hours (for <code>cputime</code>).
<code>nk</code>	<i>n</i> kilobytes. This is the default for all but <code>cputime</code> .
<code>nm</code>	<i>n</i> megabytes or minutes (for <code>cputime</code>).
<code>mm:ss</code>	Minutes and seconds (for <code>cputime</code>).

Example of limit: to limit the size of a core file dump to 0 Megabytes, type the following:

```
limit coredumpsize 0M
```

`login [username | -p]`

Terminate a login shell and invoke `login(1)`. The `.logout` file is not processed. If *username* is omitted, `login` prompts for the name of a user.

`-p` Preserve the current environment (variables).

`logout`

Terminate a login shell.

`nice [+n | -n] [command]`

Increment the process priority value for the shell or for *command* by *n*. The higher the priority value, the lower the priority of a process, and the slower it runs. When given, *command* is always run in a subshell, and the restrictions placed on commands in simple `if` commands apply. If *command* is omitted, `nice` increments the value for the current shell. If no increment is specified, `nice` sets the process priority value to 4. The range of process priority values is from -20 to 20. Values of *n* outside this range set the value to the lower, or to the higher boundary, respectively.

`+n` Increment the process priority value by *n*.

`-n` Decrement by *n*. This argument can be used only by the privileged user.

`nohup [command]`
 Run *command* with HUPs ignored. With no arguments, ignore HUPs throughout the remainder of a script. When given, *command* is always run in a subshell, and the restrictions placed on commands in simple `if` statements apply. All processes detached with `&` are effectively `nohup'd`.

`notify [%job] ...`
 Notify the user asynchronously when the status of the current job or specified jobs changes.

`onintr [-l label]`
 Control the action of the shell on interrupts. With no arguments, `onintr` restores the default action of the shell on interrupts. (The shell terminates shell scripts and returns to the terminal command input level). With the `-` argument, the shell ignores all interrupts. With a *label* argument, the shell executes a `goto label` when an interrupt is received or a child process terminates because it was interrupted.

`popd [+n]`
 Pop the directory stack and `cd` to the new top directory. The elements of the directory stack are numbered from 0 starting at the top.

`+n` Discard the *n*'th entry in the stack.

`pushd [+n |dir]`
 Push a directory onto the directory stack. With no arguments, exchange the top two elements.

`+n` Rotate the *n*'th entry to the top of the stack and `cd` to it.

`dir` Push the current working directory onto the stack and change to *dir*.

`rehash`
 Recompute the internal hash table of the contents of directories listed in the *path* variable to account for new commands added. Recompute the internal hash table of the contents of directories listed in the *cdpath* variable to account for new directories added.

`repeat count command`
 Repeat *command* *count* times. *command* is subject to the same restrictions as with the one-line `if` statement.

`set [var [= value]]`
`set var [n] = word`
 With no arguments, `set` displays the values of all shell variables. Multiword values are displayed as a parenthesized list. With the *var* argument alone, `set` assigns an empty (null) value to the variable *var*. With arguments of the form *var = value* `set` assigns *value* to *var*, where *value* is one of:

word A single word (or quoted string).

(wordlist) A space-separated list of words enclosed in parentheses.

Values are command and filename expanded before being assigned. The form `set var [n] = word` replaces the *n*'th word in a multiword value with *word*.

`setenv [VAR [word]]`

With no arguments, `setenv` displays all environment variables. With the *VAR* argument, `setenv` sets the environment variable *VAR* to have an empty (null) value. (By convention, environment variables are normally given upper-case names.) With both *VAR* and *word* arguments, `setenv` sets the environment variable *NAME* to the value *word*, which must be either a single word or a quoted string. The most commonly used environment variables, *USER*, *TERM*, and *PATH*, are automatically imported to and exported from the `cs` variables `user`, `term`, and `path`; there is no need to use `setenv` for these. In addition, the shell sets the *PWD* environment variable from the `cs` variable `cwd` whenever the latter changes.

The environment variables *LC_CTYPE*, *LC_MESSAGES*, *LC_TIME*, *LC_COLLATE*, *LC_NUMERIC*, and *LC_MONETARY* take immediate effect when changed within the C shell.

If any of the *LC_** variables (*LC_CTYPE*, *LC_MESSAGES*, *LC_TIME*, *LC_COLLATE*, *LC_NUMERIC*, and *LC_MONETARY*) (see `environ(5)`) are not set in the environment, the operational behavior of `cs` for each corresponding locale category is determined by the value of the *LANG* environment variable. If *LC_ALL* is set, its contents are used to override both the *LANG* and the other *LC_** variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how `cs` behaves.

- LC_CTYPE* Determines how `cs` handles characters. When *LC_CTYPE* is set to a valid value, `cs` can display and handle text and filenames containing valid characters for that locale.
- LC_MESSAGES* Determines how diagnostic and informative messages are presented. This includes the language and style of the messages and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S./English).
- LC_NUMERIC* Determines the value of the radix character (decimal point (".") in the "C" locale) and thousand separator (empty string ("") in the "C" locale).

`shift [variable]`

The components of `argv`, or *variable*, if supplied, are shifted to the left, discarding the first component. It is an error for the variable not to be set or to have a null value.

`source [-h] name`

Reads commands from *name*. `source` commands may be nested, but if they are nested too deeply the shell may run out of file descriptors. An error in a sourced file at any level terminates all nested `source` commands.

cs(1)

-h Place commands from the file *name* on the history list without executing them.

stop %*jobid* . . .
Stop the current or specified background job.

stop *pid* . . .
Stop the specified process, *pid*. (see ps(1)).

suspend
Stop the shell in its tracks, much as if it had been sent a stop signal with ^Z. This is most often used to stop shells started by su.

switch (*string*)
case *label*:
...
breaksw
...
default:
...
breaksw
endsw

Each *label* is successively matched, against the specified *string*, which is first command and filename expanded. The file metacharacters *, ? and [...] may be used in the case labels, which are variable expanded. If none of the labels match before a "default" label is found, execution begins after the default label. Each case statement and the default statement must appear at the beginning of a line. The command breaksw continues execution after the endsw. Otherwise control falls through subsequent case and default statements as with C. If no label matches and there is no default, execution continues after the endsw.

time [*command*]
With no argument, print a summary of time used by this C shell and its children. With an optional *command*, execute *command* and print a summary of the time it uses. As of this writing, the time built-in command does NOT compute the last 6 fields of output, rendering the output to erroneously report the value "0" for these fields.

```
example %time ls -R
9.0u 11.0s 3:32 10% 0+0k 0+0io 0pf+0w
```

(See below the "Environment Variables and Predefined Shell Variables" sub-section on the time variable.)

umask [*value*]
Display the file creation mask. With *value*, set the file creation mask. With *value* given in octal, the user can turn-off any bits, but cannot turn-on bits to allow new permissions. Common values include 077, restricting all permissions from everyone else; 002, giving complete access to the group, and read (and directory search) access to others; or 022, giving read (and directory search) but not write permission to the group and others.

unalias *pattern*

Discard aliases that match (filename substitution) *pattern*. All aliases are removed by 'unalias *'.

unhash

Disable the internal hash tables for the *path* and *cdpath* variables.

unlimit [-h] [*resource*]

Remove a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the **limit** command for the list of resource names.

-h Remove corresponding hard limits. Only the privileged user may do this.

unset *pattern*

Remove variables whose names match (filename substitution) *pattern*. All variables are removed by 'unset *'; this has noticeably distasteful side effects.

unsetenv *variable*

Remove *variable* from the environment. As with **unset**, pattern matching is not performed.

wait

Wait for background jobs to finish (or for an interrupt) before prompting.

while (*expr*)

...

end

While *expr* is true (evaluates to nonzero), repeat commands between the **while** and the matching **end** statement. **break** and **continue** may be used to terminate or continue the loop prematurely. The **while** and **end** must appear alone on their input lines. If the shell's input is a terminal, it prompts for commands with a question-mark until the **end** command is entered and then performs the commands in the loop.

% [*job*] [&]

Bring the current or indicated *job* to the foreground. With the ampersand, continue running *job* in the background.

@ [*var* =*expr*]**@** [*var* [*n*] =*expr*]

With no arguments, display the values for all shell variables. With arguments, set the variable *var*, or the *n*'th word in the value of *var*, to the value that *expr* evaluates to. (If [*n*] is supplied, both *var* and its *n*'th component must already exist.)

If the expression contains the characters >, <, &, or |, then at least this part of *expr* must be placed within parentheses.

The operators *=, +=, and so forth, are available as in C. The space separating the name from the assignment operator is optional. Spaces are, however, mandatory in separating components of *expr* that would otherwise be single words.

cs(1)

**Environment
Variables and
Predefined Shell
Variables**

Special postfix operators, + + and - -, increment or decrement *name*, respectively.

Unlike the Bourne shell, the C shell maintains a distinction between environment variables, which are automatically exported to processes it invokes, and shell variables, which are not. Both types of variables are treated similarly under variable substitution. The shell sets the variables *argv*, *cwd*, *home*, *path*, *prompt*, *shell*, and *status* upon initialization. The shell copies the environment variable *USER* into the shell variable *user*, *TERM* into *term*, and *HOME* into *home*, and copies each back into the respective environment variable whenever the shell variables are reset. *PATH* and *path* are similarly handled. You need only set *path* once in the *.cshrc* or *.login* file. The environment variable *PWD* is set from *cwd* whenever the latter changes. The following shell variables have predefined meanings:

<i>argv</i>	Argument list. Contains the list of command line arguments supplied to the current invocation of the shell. This variable determines the value of the positional parameters \$1, \$2, and so on.
<i>cdpath</i>	Contains a list of directories to be searched by the <i>cd</i> , <i>chdir</i> , and <i>popd</i> commands, if the directory argument each accepts is not a subdirectory of the current directory.
<i>cwd</i>	The full pathname of the current directory.
<i>echo</i>	Echo commands (after substitutions) just before execution.
<i>ignore</i>	A list of filename suffixes to ignore when attempting filename completion. Typically the single word <i>.o</i> .
<i>filec</i>	Enable filename completion, in which case the CTRL-d character EOT and the ESC character have special significance when typed in at the end of a terminal input line: EOT Print a list of all filenames that start with the preceding string. ESC Replace the preceding string with the longest unambiguous extension.
<i>hardpaths</i>	If set, pathnames in the directory stack are resolved to contain no symbolic-link components.
<i>histchars</i>	A two-character string. The first character replaces ! as the history-substitution character. The second replaces the caret (^) for quick substitutions.
<i>history</i>	The number of lines saved in the history list. A very large number may use up all of the C shell's memory. If not set, the C shell saves only the most recent command.
<i>home</i>	The user's home directory. The filename expansion of ~ refers to the value of this variable.

ignoreeof	If set, the shell ignores EOF from terminals. This protects against accidentally killing a C shell by typing a CTRL-d.
mail	A list of files where the C shell checks for mail. If the first word of the value is a number, it specifies a mail checking interval in seconds (default 5 minutes).
nobeep	Suppress the bell during command completion when asking the C shell to extend an ambiguous filename.
noclobber	Restrict output redirection so that existing files are not destroyed by accident. > redirections can only be made to new files. >> redirections can only be made to existing files.
noglob	Inhibit filename substitution. This is most useful in shell scripts once filenames (if any) are obtained and no further expansion is desired.
nonomatch	Returns the filename substitution pattern, rather than an error, if the pattern is not matched. Malformed patterns still result in errors.
notify	If set, the shell notifies you immediately as jobs are completed, rather than waiting until just before issuing a prompt.
path	The list of directories in which to search for commands. <code>path</code> is initialized from the environment variable <code>PATH</code> , which the C shell updates whenever <code>path</code> changes. A null word ("") specifies the current directory. The default is typically <code>(/usr/bin .)</code> . One may override this initial search path upon <code>csh</code> start-up by setting it in <code>.cshrc</code> or <code>.login</code> (for login shells only). If <code>path</code> becomes unset, only full pathnames will execute. An interactive C shell will normally hash the contents of the directories listed after reading <code>.cshrc</code> , and whenever <code>path</code> is reset. If new commands are added, use the <code>rehash</code> command to update the table.
prompt	<p>The string an interactive C shell prompts with. Noninteractive shells leave the <code>prompt</code> variable unset. Aliases and other commands in the <code>.cshrc</code> file that are only useful interactively, can be placed after the following test: <code>'if (\$?prompt == 0) exit'</code>, to reduce startup time for noninteractive shells. A <code>!</code> in the <code>prompt</code> string is replaced by the current event number. The default prompt is <code>hostname%</code> for mere mortals, or <code>hostname#</code> for the privileged user.</p> <p>The setting of <code>\$prompt</code> has three meanings:</p> <p><code>\$prompt</code> not set non-interactive shell, test <code> \$?prompt</code>.</p> <p><code>\$prompt</code> set but <code>== ""</code> <code>.cshrc</code> called by the <code>which(1)</code> command.</p>

cs(1)

	<code>\$prompt</code> set and <code>!= ""</code> normal interactive shell.																								
<code>savehist</code>	The number of lines from the history list that are saved in <code>~/.history</code> when the user logs out. Large values for <code>savehist</code> slow down the C shell during startup.																								
<code>shell</code>	The file in which the C shell resides. This is used in forking shells to interpret files that have execute bits set, but that are not executable by the system.																								
<code>status</code>	The status returned by the most recent command. If that command terminated abnormally, 0200 is added to the status. Built-in commands that fail return exit status 1; all other built-in commands set status to 0.																								
<code>time</code>	<p>Control automatic timing of commands. Can be supplied with one or two values. The first is the reporting threshold in CPU seconds. The second is a string of tags and text indicating which resources to report on. A tag is a percent sign (%) followed by a single upper-case letter (unrecognized tags print as text):</p> <table><tr><td><code>%D</code></td><td>Average amount of unshared data space used in Kilobytes.</td></tr><tr><td><code>%E</code></td><td>Elapsed (wallclock) time for the command.</td></tr><tr><td><code>%F</code></td><td>Page faults.</td></tr><tr><td><code>%I</code></td><td>Number of block input operations.</td></tr><tr><td><code>%K</code></td><td>Average amount of unshared stack space used in Kilobytes.</td></tr><tr><td><code>%M</code></td><td>Maximum real memory used during execution of the process.</td></tr><tr><td><code>%O</code></td><td>Number of block output operations.</td></tr><tr><td><code>%P</code></td><td>Total CPU time — U (user) plus S (system) — as a percentage of E (elapsed) time.</td></tr><tr><td><code>%S</code></td><td>Number of seconds of CPU time consumed by the kernel on behalf of the user's process.</td></tr><tr><td><code>%U</code></td><td>Number of seconds of CPU time devoted to the user's process.</td></tr><tr><td><code>%W</code></td><td>Number of swaps.</td></tr><tr><td><code>%X</code></td><td>Average amount of shared memory used in Kilobytes.</td></tr></table> <p>The default summary display outputs from the <code>%U</code>, <code>%S</code>, <code>%E</code>, <code>%P</code>, <code>%X</code>, <code>%D</code>, <code>%I</code>, <code>%O</code>, <code>%F</code>, and <code>%W</code> tags, in that order.</p>	<code>%D</code>	Average amount of unshared data space used in Kilobytes.	<code>%E</code>	Elapsed (wallclock) time for the command.	<code>%F</code>	Page faults.	<code>%I</code>	Number of block input operations.	<code>%K</code>	Average amount of unshared stack space used in Kilobytes.	<code>%M</code>	Maximum real memory used during execution of the process.	<code>%O</code>	Number of block output operations.	<code>%P</code>	Total CPU time — U (user) plus S (system) — as a percentage of E (elapsed) time.	<code>%S</code>	Number of seconds of CPU time consumed by the kernel on behalf of the user's process.	<code>%U</code>	Number of seconds of CPU time devoted to the user's process.	<code>%W</code>	Number of swaps.	<code>%X</code>	Average amount of shared memory used in Kilobytes.
<code>%D</code>	Average amount of unshared data space used in Kilobytes.																								
<code>%E</code>	Elapsed (wallclock) time for the command.																								
<code>%F</code>	Page faults.																								
<code>%I</code>	Number of block input operations.																								
<code>%K</code>	Average amount of unshared stack space used in Kilobytes.																								
<code>%M</code>	Maximum real memory used during execution of the process.																								
<code>%O</code>	Number of block output operations.																								
<code>%P</code>	Total CPU time — U (user) plus S (system) — as a percentage of E (elapsed) time.																								
<code>%S</code>	Number of seconds of CPU time consumed by the kernel on behalf of the user's process.																								
<code>%U</code>	Number of seconds of CPU time devoted to the user's process.																								
<code>%W</code>	Number of swaps.																								
<code>%X</code>	Average amount of shared memory used in Kilobytes.																								

verbose Display each command after history substitution takes place.

Large File Behavior See `largefile(5)` for the description of the behavior of `cs` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

FILES

- `~/.cshrc` Read at beginning of execution by each shell.
- `~/.login` Read by login shells after `.cshrc` at login.
- `~/.logout` Read by login shells at logout.
- `~/.history` Saved history for use at next login.
- `/usr/bin/sh` The Bourne shell, for shell scripts not starting with a '#'.
- `/tmp/sh*` Temporary file for '<<'.
- `/etc/passwd` Source of home directories for '*~name*'.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

DIAGNOSTICS You have stopped jobs.
 You attempted to exit the C shell with stopped jobs under job control. An immediate second attempt to exit will succeed, terminating the stopped jobs.

WARNINGS The use of `setuid` shell scripts is *strongly* discouraged.

NOTES Words can be no longer than 1024 bytes. The system limits argument lists to 1,048,576 bytes. However, the maximum number of arguments to a command for which filename expansion applies is 1706. Command substitutions may expand to no more characters than are allowed in the argument list. To detect looping, the shell restricts the number of `alias` substitutions on a single line to 20.

When a command is restarted from a stop, the shell prints the directory it started in if this is different from the current directory; this can be misleading (that is, wrong) as the job may have changed directories internally.

cs(1)

Shell built-in functions are not stoppable/restartable. Command sequences of the form *a ; b ; c* are also not handled gracefully when stopping is attempted. If you suspend *b*, the shell never executes *c*. This is especially noticeable if the expansion results from an alias. It can be avoided by placing the sequence in parentheses to force it into a subshell.

Control over terminal output after processes are started is primitive; use the Sun Window system if you need better output control.

Commands within loops, prompted for by *?*, are not placed in the *history* list.

Control structures should be parsed rather than being recognized as built-in commands. This would allow control commands to be placed anywhere, to be combined with *|*, and to be used with *&* and *;* metasyntax.

It should be possible to use the *:* modifiers on the output of command substitutions. There are two problems with *:* modifier usage on variable substitutions: not all of the modifiers are available, and only one modifier per substitution is allowed.

The *g* (global) flag in history substitutions applies only to the first match in each word, rather than all matches in all words. The common text editors consistently do the latter when given the *g* flag in a substitution command.

Quoting conventions are confusing. Overriding the escape character to force variable substitutions within double quotes is counterintuitive and inconsistent with the Bourne shell.

Symbolic links can fool the shell. Setting the *hardpaths* variable alleviates this.

It is up to the user to manually remove all duplicate pathnames accrued from using built-in commands as

```
set path = pathnamesOR
```

```
setenv PATH = pathnamesmore than once. These often occur because a shell script or a .cshrc file does something like
```

```
'set path=(/usr/local /usr/hosts $path)'
```

to ensure that the named directories are in the *pathname* list.

The only way to direct the standard output and standard error separately is by invoking a subshell, as follows:

```
command > outfile ) >& errorfile
```

Although robust enough for general use, adventures into the esoteric periphery of the C shell may reveal unexpected quirks.

If you start *cs* as a login shell and you do not have a *.login* in your home directory, then the *cs* reads in the */etc/.login*.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

BUGS As of this writing, the `time` built-in command does NOT compute the last 6 fields of output, rendering the output to erroneously report the value "0" for these fields:

```
example %time ls -R
9.0u 11.0s 3:32 10% 0+0k 0+0io 0pf+0w
```

csplit(1)

NAME	csplit – split files based on context
SYNOPSIS	csplit [-ks] [-f <i>prefix</i>] [-n <i>number</i>] <i>file</i> <i>arg1</i> ... <i>argn</i>
DESCRIPTION	The <code>csplit</code> utility reads the file named by the <i>file</i> operand, writes all or part of that file into other files as directed by the <i>arg</i> operands, and writes the sizes of the files.
OPTIONS	<p>The following options are supported:</p> <p>-f <i>prefix</i> Name the created files <i>prefix00</i>, <i>prefix01</i>, . . . , <i>prefixn</i>. The default is <i>xx00</i> . . . <i>xxn</i>. If the <i>prefix</i> argument would create a file name exceeding 14 bytes, an error will result; <code>csplit</code> will exit with a diagnostic message and no files will be created.</p> <p>-k Leave previously created files intact. By default, <code>csplit</code> will remove created files if an error occurs.</p> <p>-n <i>number</i> Use <i>number</i> decimal digits to form filenames for the file pieces. The default is 2.</p> <p>-s Suppress the output of file size messages.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>file</i> The path name of a text file to be split. If <i>file</i> is -, the standard input will be used.</p> <p>The operands <i>arg1</i> . . . <i>argn</i> can be a combination of the following:</p> <p><i>/rexp/[offset]</i> Create a file using the content of the lines from the current line up to, but not including, the line that results from the evaluation of the regular expression with <i>offset</i>, if any, applied. The regular expression <i>rexp</i> must follow the rules for basic regular expressions. The optional <i>offset</i> must be a positive or negative integer value representing a number of lines. The integer value must be preceded by + or -. If the selection of lines from an offset expression of this type would create a file with zero lines, or one with greater than the number of lines left in the input file, the results are unspecified. After the section is created, the current line will be set to the line that results from the evaluation of the regular expression with any offset applied. The pattern match of <i>rexp</i> always is applied from the current line to the end of the file.</p> <p><i>%rexp%[offset]</i> This operand is the same as <i>/rexp/[offset]</i>, except that no file will be created for the selected section of the input file.</p> <p><i>line_no</i> Create a file from the current line up to (but not including) the line number <i>line_no</i>. Lines in the file will be numbered starting at one. The current line becomes <i>line_no</i>.</p> <p><i>{num}</i> Repeat operand. This operand can follow any of the operands described previously. If it follows a <i>rexp</i> type operand, that operand will be applied <i>num</i> more times. If it follows a <i>line_no</i></p>

operand, the file will be split every *line_no* lines, *num* times, from that point.

An error will be reported if an operand does not reference a line between the current position and the end of the file.

USAGE See `largefile(5)` for the description of the behavior of `csplit` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Splitting and combining files

This example creates four files, `cobol00` ... `cobol03`.

```
example% csplit -f cobol filename '/procedure division/' /par5./ /par16./
```

After editing the "split" files, they can be recombined as follows:

```
example% cat cobol0[0-3] > filename
```

Note: This example overwrites the original file.

EXAMPLE 2 Splitting a file into equal parts

This example splits the file at every 100 lines, up to 10,000 lines. The `-k` option causes the created files to be retained if there are less than 10,000 lines; however, an error message would still be printed.

```
example% csplit -k filename 100 {99}
```

EXAMPLE 3 Creating a file for separate C routines

If `prog.c` follows the normal C coding convention (the last line of a routine consists only of a `}` in the first character position), this example creates a file for each separate C routine (up to 21) in `prog.c`.

```
example% csplit -k prog.c '%main%' '/^}/+1' {20}
```

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `csplit`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

csplit(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	Enabled

SEE ALSO `sed(1)`, `split(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

DIAGNOSTICS The diagnostic messages are self-explanatory, except for the following:

arg – out of range The given argument did not reference a line between
the current position and the end of the file.

NAME	ct – spawn login to a remote terminal
SYNOPSIS	ct [<i>options</i>] <i>telno</i> ...
DESCRIPTION	<p>The ct utility dials the telephone number of a modem that is attached to a terminal and spawns a login process to that terminal. The <i>telno</i> is a telephone number, with equal signs for secondary dial tones and minus signs for delays at appropriate places. (The set of legal characters for <i>telno</i> is 0 through 9, -, =, *, and #. The maximum length <i>telno</i> is 31 characters). If more than one telephone number is specified, ct will try each in succession until one answers; this is useful for specifying alternate dialing paths.</p> <p>ct will try each line listed in the file <code>/etc/uucp/Devices</code> until it finds an available line with appropriate attributes, or runs out of entries.</p> <p>After the user on the destination terminal logs out, there are two things that could occur depending on what type of port monitor is monitoring the port. In the case of no port monitor, ct prompts: <code>Reconnect?</code> If the response begins with the letter <code>n</code>, the line will be dropped; otherwise, cttymon will be started again and the <code>login:</code> prompt will be printed. In the second case, where a port monitor is monitoring the port, the port monitor reissues the <code>login:</code> prompt.</p> <p>The user should log out properly before disconnecting.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -h Normally, ct will hang up the current line so that it can be used to answer the incoming call. The <code>-h</code> option will prevent this action. The <code>-h</code> option will also wait for the termination of the specified ct process before returning control to the user's terminal. -<i>sspeed</i> The data rate may be set with the <code>-s</code> option. <i>speed</i> is expressed in baud rates. The default baud rate is 1200. -v If the <code>-v</code> (verbose) option is used, ct will send a running narrative to the standard error output stream. -<i>wn</i> If there are no free lines ct will ask if it should wait, and for how many minutes, before it gives up. ct will continue to try to open the dialers at one-minute intervals until the specified limit is exceeded. This dialogue may be overridden by specifying the <code>-wn</code> option. <i>n</i> is the maximum number of minutes that ct is to wait for a line. -<i>xn</i> This option is used for debugging; it produces a detailed output of the program execution on <code>stderr</code>. <i>n</i> is a single number between 0 and 9. As <i>n</i> increases to 9, more detailed debugging information is given.
FILES	<p><code>/etc/uucp/Devices</code></p> <p><code>/var/adm/ctlog</code></p>

ct(1C)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

SEE ALSO `cu(1C)`, `login(1)`, `uucp(1C)`, `ttymon(1M)`, `attributes(5)`

NOTES The `ct` program will not work with a DATAKIT Multiplex interface.

For a shared port, one used for both dial-in and dial-out, the `ttymon` program running on the line must have the `-r` and `-b` options specified (see `ttymon(1M)`).

NAME	ctags – create a tags file for use with ex and vi
SYNOPSIS	<pre>/usr/bin/ctags [-aBFtuvwx] [-f tagsfile] file... /usr/xpg4/bin/ctags [-aBFuvwx] [-f tagsfile] file...</pre>
DESCRIPTION	<p>The ctags utility makes a tags file for ex(1) from the specified C, C++, Pascal, FORTRAN, yacc(1), and lex(1) sources. A tags file gives the locations of specified objects (in this case functions and typedefs) in a group of files. Each line of the tags file contains the object name, the file in which it is defined, and an address specification for the object definition. Functions are searched with a pattern, typedefs with a line number. Specifiers are given in separate fields on the line, separated by SPACE or TAB characters. Using the tags file, ex can quickly find these objects' definitions.</p> <p>Normally, ctags places the tag descriptions in a file called tags; this may be overridden with the -f option.</p> <p>Files with names ending in .c or .h are assumed to be either C or C++ source files and are searched for C/C++ routine and macro definitions. Files with names ending in .cc, .C, or .cxx, are assumed to be C++ source files. Files with names ending in .y are assumed to be yacc source files. Files with names ending in .l are assumed to be lex files. Others are first examined to see if they contain any Pascal or FORTRAN routine definitions; if not, they are processed again looking for C definitions.</p> <p>The tag main is treated specially in C or C++ programs. The tag formed is created by prepending M to file, with a trailing .c, .cc, .C, or .cxx removed, if any, and leading path name components also removed. This makes use of ctags practical in directories with more than one program.</p>
OPTIONS	<p>The precedence of the options that pertain to printing is -x, -v, then the remaining options. The following options are supported:</p> <ul style="list-style-type: none"> -a Append output to an existing tags file. -B Use backward searching patterns (?...?). -f tagsfile Places the tag descriptions in a file called tagsfile instead of tags. -F Use forward searching patterns (/.../) (default). -t Create tags for typedefs. /usr/xpg4/bin/ctags creates tags for typedefs by default. -u Update the specified files in tags, that is, all references to them are deleted, and the new values are appended to the file. Beware: this option is implemented in a way which is rather slow; it is usually faster to simply rebuild the tags file. -v Produce on the standard output an index listing the function name, file name, and page number (assuming 64 line pages). Since the output will be sorted into lexicographic order, it may be desired to run the output through sort -f.

ctags(1)

	<code>-w</code>	Suppress warning diagnostics.
	<code>-x</code>	Produce a list of object names, the line number and file name on which each is defined, as well as the text of that line and prints this on the standard output. This is a simple index which can be printed out as an off-line readable function index.
OPERANDS	The following <i>file</i> operands are supported:	
	<code>file.c</code>	Files with basenames ending with the <code>.c</code> suffix are treated as C-language source code.
	<code>file.h</code>	Files with basenames ending with the <code>.h</code> suffix are treated as C-language source code.
	<code>file.f</code>	Files with basenames ending with the <code>.f</code> suffix are treated as FORTRAN-language source code.
USAGE	The <code>-v</code> option is mainly used with <code>vgrind</code> which will be part of the optional BSD Compatibility Package.	
EXAMPLES	EXAMPLE 1 Using the <code>ctags</code> Command Using <code>ctags</code> with the <code>-v</code> option produces entries in an order which may not always be appropriate for <code>vgrind</code> . To produce results in alphabetical order, you may want to run the output through <code>'sort -f'</code> . <pre>example% ctags -v filename.c filename.h sort -f > index example% vgrind -x index</pre> To build a tags file for C sources in a directory hierarchy rooted at <code>sourcedir</code> , first create an empty tags file, and then run <code>find(1)</code> <pre>example% cd sourcedir ; rm -f tags ; touch tags example% find . \(-name SCCS -prune -name \ '*.c' -o -name '*.h' \) -exec ctags -u {} \;</pre> Note that spaces must be entered exactly as shown.	
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>ctags</code> : <code>LC_COLLATE</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .	
EXIT STATUS	The following exit values are returned:	
	<code>0</code>	Successful completion.
	<code>>0</code>	An error occurred.
FILES	<code>tags</code>	output tags file

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NOTES Recognition of functions, subroutines, and procedures for FORTRAN and Pascal is done in a very simpleminded way. No attempt is made to deal with block structure; if you have two Pascal procedures in different blocks with the same name, you lose.

The method of deciding whether to look for C or Pascal and FORTRAN functions is a hack.

The `ctags` utility does not know about `#ifdefs`.

The `ctags` utility should know about Pascal types. Relies on the input being well formed to detect `typedefs`. Use of `-tx` shows only the last line of `typedefs`.

cu(1C)

NAME	cu – call another UNIX system
SYNOPSIS	cu [-c <i>device</i> -l <i>line</i>] [-s <i>speed</i>] [-b <i>bits</i>] [-h] [-n] [-t] [-d] [-o -e] [-L] [-C] [-H] <i>telno</i> <i>systemname</i> [<i>local-cmd</i>]
DESCRIPTION	The command <i>cu</i> calls up another UNIX system, a terminal, or possibly a non-UNIX system. It manages an interactive conversation with possible transfers of files. It is convenient to think of <i>cu</i> as operating in two phases. The first phase is the connection phase in which the connection is established. <i>cu</i> then enters the conversation phase. The -d option is the only one that applies to both phases.
OPTIONS	<p><i>cu</i> accepts many options. The -c, -l, and -s options play a part in selecting the medium; the remaining options are used in configuring the line.</p> <p>-c <i>device</i> Forces <i>cu</i> to use only entries in the "Type" field (the first field in the /etc/uucp/Devices file) that match the user specified <i>device</i>, usually the name of a local area network.</p> <p>-s <i>speed</i> Specifies the transmission speed (300, 1200, 2400, 4800, 9600, 19200, 38400). The default value is "Any" speed which will depend on the order of the lines in the /etc/uucp/Devices file.</p> <p>-l <i>line</i> Specifies a device name to use as the communication line. This can be used to override the search that would otherwise take place for the first available line having the right speed. When the -l option is used without the -s option, the speed of a line is taken from the /etc/uucp/Devices file record in which <i>line</i> matches the second field (the Line field). When the -l and -s options are both used together, <i>cu</i> will search the /etc/uucp/Devices file to check if the requested speed for the requested line is available. If so, the connection will be made at the requested speed, otherwise, an error message will be printed and the call will not be made. In the general case where a specified device is a directly connected asynchronous line (for instance, /dev/term/a), a telephone number (<i>telno</i>) is not required. The specified device need not be in the /dev directory. If the specified device is associated with an auto dialer, a telephone number must be provided.</p> <p>-b <i>bits</i> Forces <i>bits</i> to be the number of bits processed on the line. <i>bits</i> is either 7 or 8. This allows connection between systems with different character sizes. By default, the character size of the line is set to the same value as the current local terminal, but the character size setting is affected by LC_CTYPE also.</p> <p>-h Sets communication mode to half-duplex. This option emulates local echo in order to support calls to other computer systems that expect terminals to be set to half-duplex mode.</p> <p>-n Requests user prompt for telephone number. For added security, this option will prompt the user to provide the telephone number to be dialed, rather than taking it from the command line.</p>

- t Dials a terminal which has been set to auto answer. Appropriate mapping of carriage-return to carriage-return-line-feed pairs is set.
- d Prints diagnostic traces.
- o Sets an ODD data parity. This option designates that ODD parity is to be generated for data sent to the remote system.
- e Sets an EVEN data parity. This option designates that EVEN parity is to be generated for data sent to the remote system.
- L Goes through the login chat sequence specified in the `/etc/uucp/Systems` file. For more information about the chat sequence, see *System Administration Guide, Volume 3*
- C Runs the *local-cmd* specified at the end of the command line instead of entering interactive mode. The `stdin` and `stdout` of the command that is run refer to the remote connection.
- H Ignores one hangup. This allows the user to remain in `cu` while the remote machine disconnects and places a call back to the local machine. This option should be used when connecting to systems with callback or dialback modems. Once the callback occurs subsequent hangups will cause `cu` to terminate. This option can be specified more than once. For more information about dialback configuration, see `remote(4)` and *System Administration Guide, Volume 3*

OPERANDS The following operands are supported:

- telno* When using an automatic dialler, specifies the telephone number with equal signs for secondary dial tone or minus signs placed appropriately for delays of 4 seconds.
- systemname* Specifies a `uucp` system name, which can be used rather than a telephone number; in this case, `cu` will obtain an appropriate direct line or telephone number from a system file.

USAGE

Connection Phase

`cu` uses the same mechanism that `uucp(1C)` does to establish a connection. This means that it will use the `uucp` control files `/etc/uucp/Devices` and `/etc/uucp/Systems`. This gives `cu` the ability to choose from several different media to establish the connection. The possible media include telephone lines, direct connections, and local area networks (LAN). The `/etc/uucp/Devices` file contains a list of media that are available on your system. The `/etc/uucp/Systems` file contains information for connecting to remote systems, but it is not generally readable.

cu(1C)

Note: `cu` determines which `/etc/uucp/Systems` and `/etc/uucp/Devices` files to use based upon the name used to invoke `cu`. In the simple case, this name will be "cu", but you could also have created a link to `cu` with another name, such as "pppcu", in which case `cu` would then look for a "service=pppcu" entry in the `/etc/uucp/Sysfiles` file to determine which `/etc/uucp/Systems` file to use.

The `telno` or `systemname` parameter from the command line is used to tell `cu` what system you wish to connect to. This parameter can be blank, a telephone number, a system name, or a LAN specific address.

telephone number	A telephone number is a string consisting of the tone dial characters (the digits 0 through 9, *, and #) plus the special characters = and -. The equal sign designates a secondary dial tone and the minus sign creates a 4 second delay.
system name	A system name is the name of any computer that <code>uucp</code> can call; the <code>uname(1C)</code> command prints a list of these names.
LAN address	The documentation for your LAN will show the form of the LAN specific address.

If `cu`'s default behavior is invoked (not using the `-c` or `-l` options), `cu` will use the `telno` or `systemname` parameter to determine which medium to use. If a telephone number is specified, `cu` will assume that you wish to use a telephone line and it will select an automatic call unit (ACU). Otherwise, `cu` will assume that it is a system name. `cu` will follow the `uucp` calling mechanism and use the `/etc/uucp/Systems` and `/etc/uucp/Devices` files to obtain the best available connection. Since `cu` will choose a speed that is appropriate for the medium that it selects, you may not use the `-s` option when this parameter is a system name.

The `-c` and `-l` options modify this default behavior. `-c` is most often used to select a LAN by specifying a Type field from the `/etc/uucp/Devices` file. You must include either a `telno` or `systemname` value when using the `-c` option. If the connection to `systemname` fails, a connection will be attempted using `systemname` as a LAN specific address. The `-l` option is used to specify a device associated with a direct connection. If the connection is truly a direct connection to the remote machine, then there is no need to specify a `systemname`. This is the only case where a `telno` or `systemname` parameter is unnecessary. On the other hand, there may be cases in which the specified device connects to a dialer, so it is valid to specify a telephone number. The `-c` and `-l` options should not be specified on the same command line.

Conversation Phase

After making the connection, `cu` runs as two processes: the `transmit` process reads data from the standard input and, except for lines beginning with `~`, passes it to the remote system; the `receive` process accepts data from the remote system and, except for lines beginning with `~`, passes it to the standard output. Normally, an automatic DC3/DC1 protocol is used to control input from the remote so the buffer is not overrun. Lines beginning with `~` have special meanings.

Commands	The <i>transmit</i> process interprets the following user initiated commands:
~.	Terminates the conversation.
~!	Escapes to an interactive shell on the local system.
~!cmd ...	Runs <i>cmd</i> on the local system (via <i>sh -c</i>).
~\$cmd ...	Runs <i>cmd</i> locally and send its output to the remote system.
~%cd	Changes the directory on the local system. Note: ~!cd will cause the command to be run by a sub-shell, probably not what was intended.
~%take <i>from</i> [<i>to</i>]	Copies file <i>from</i> (on the remote system) to file <i>to</i> on the local system. If <i>to</i> is omitted, the <i>from</i> argument is used in both places.
~%put <i>from</i> [<i>to</i>]	Copies file <i>from</i> (on local system) to file <i>to</i> on remote system. If <i>to</i> is omitted, the <i>from</i> argument is used in both places.
~~ <i>line</i>	Sends the line ~ <i>line</i> to the remote system.
~%break	Transmits a BREAK to the remote system (which can also be specified as ~%b).
~%debug	Toggles the -d debugging option on or off (which can also be specified as ~%d).
~t	Prints the values of the termio structure variables for the user's terminal (useful for debugging).
~l	Prints the values of the termio structure variables for the remote communication line (useful for debugging).
~%ifc	Toggles between DC3/DC1 input control protocol and no input control. This is useful when the remote system does not respond properly to the DC3 and DC1 characters (can also be specified as ~%nostop).
~%ofc	Toggles the output flow control setting. When enabled, outgoing data may be flow controlled by the remote host (can also be specified as ~%noostop).
~%divert	Allows/disallows unsolicited diversions. That is, diversions not specified by ~%take.
~%old	Allows/disallows old style syntax for received diversions.
~%nostop	Same as ~%ifc.

cu(1C)

The *receive* process normally copies data from the remote system to the standard output of the local system. It may also direct the output to local files.

The use of `~%put` requires `stty(1)` and `cat(1)` on the remote side. It also requires that the current erase and kill characters on the remote system be identical to these current control characters on the local system. Backslashes are inserted at appropriate places.

The use of `~%take` requires the existence of `echo(1)` and `cat(1)` on the remote system, and that the remote system must be using the Bourne shell, `sh`. Also, `tabs` mode (see `stty(1)`) should be set on the remote system if tabs are to be copied without expansion to spaces.

When `cu` is used on system `X` to connect to system `Y` and subsequently used on system `Y` to connect to system `Z`, commands on system `Y` can be executed by using `~ ~`. Executing a tilde command reminds the user of the local system `uname`. For example, `uname` can be executed on `Z`, `X`, and `Y` as follows:

```
uname
Z
~ [X] !uname
X
~~ [Y] !uname
Y
```

In general, `~` causes the command to be executed on the original machine. `~ ~` causes the command to be executed on the next machine in the chain.

EXAMPLES **EXAMPLE 1** Dialling a system

To dial a system whose telephone number is 9 1 201 555 1234 using 1200 baud (where dialtone is expected after the 9):

```
example% cu -s 1200 9=12015551234
If the speed is not specified, "Any" is the default value.
```

EXAMPLE 2 Logging in to a system on a direct line

To login to a system connected by a direct line:

```
example% cu -l /dev/term/b
OR
example% cu -l term/b
```

EXAMPLE 3 Dialling a system with specific line and speed

To dial a system with a specific line and speed:

```
example% cu -s 1200 -l term/b
```

EXAMPLE 3 Dialling a system with specific line and speed (Continued)

EXAMPLE 4 Using a system name

To use a system name:

```
example% cu systemname
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `cu`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 Successful completion.
>0 An error occurred.

FILES

`/etc/uucp/Devices` device file
`/etc/uucp/Sysfiles` system file
`/etc/uucp/Systems` system file
`/var/spool/locks/*` lock file

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbnuu

SEE ALSO

`cat(1)`, `echo(1)`, `stty(1)`, `uname(1)`, `ct(1C)`, `uuname(1C)`, `uucp(1C)`, `remote(4)`, `attributes(5)`, `environ(5)`

System Administration Guide, Volume 3

NOTES

The `cu` utility takes the default action upon receipt of signals, with the exception of:

`SIGHUP` Close the connection and terminate.
`SIGINT` Forward to the remote system.
`SIGQUIT` Forward to the remote system.
`SIGUSR1` Terminate the `cu` process without the normal connection closing sequence.

The `cu` command does not do any integrity checking on data it transfers. Data fields with special `cu` characters may not be transmitted properly. Depending on the interconnection hardware, it may be necessary to use a `~.` to terminate the conversion,

cu(1C)

even if `stty 0` has been used. Non-printing characters are not dependably transmitted using either the `~%put` or `~%take` commands. `~%put` and `~%take` cannot be used over multiple links. Files must be moved one link at a time.

There is an artificial slowing of transmission by `cu` during the `~%put` operation so that loss of data is unlikely. Files transferred using `~%take` or `~%put` must contain a trailing newline, otherwise, the operation will hang. Entering a CTRL-D command usually clears the hang condition.

NAME	cut – cut out selected fields of each line of a file
SYNOPSIS	<pre>cut -b list [-n] [file...]</pre> <pre>cut -c list [file...]</pre> <pre>cut -f list [-d delim] [-s] [file...]</pre>
DESCRIPTION	<p>Use the <code>cut</code> utility to cut out columns from a table or fields from each line of a file; in data base parlance, it implements the projection of a relation. The fields as specified by <i>list</i> can be fixed length, that is, character positions as on a punched card (<code>-c</code> option) or the length can vary from line to line and be marked with a field delimiter character like TAB (<code>-f</code> option). <code>cut</code> can be used as a filter.</p> <p>Either the <code>-b</code>, <code>-c</code>, or <code>-f</code> option must be specified.</p> <p>Use <code>grep(1)</code> to make horizontal “cuts” (by context) through a file, or <code>paste(1)</code> to put files together column-wise (that is, horizontally). To reorder columns in a table, use <code>cut</code> and <code>paste</code>.</p>
OPTIONS	<p>The following options are supported:</p> <p><i>list</i> A comma-separated or blank-character-separated list of integer field numbers (in increasing order), with optional <code>-</code> to indicate ranges (for instance, <code>1, 4, 7</code>; <code>1-3, 8</code>; <code>-5, 10</code> (short for <code>1-5, 10</code>); or <code>3-</code> (short for third through last field)).</p> <p><code>-b list</code> The <i>list</i> following <code>-b</code> specifies byte positions (for instance, <code>-b1-72</code> would pass the first 72 bytes of each line). When <code>-b</code> and <code>-n</code> are used together, <i>list</i> is adjusted so that no multi-byte character is split.</p> <p><code>-c list</code> The <i>list</i> following <code>-c</code> specifies character positions (for instance, <code>-c1-72</code> would pass the first 72 characters of each line).</p> <p><code>-d delim</code> The character following <code>-d</code> is the field delimiter (<code>-f</code> option only). Default is <code>tab</code>. Space or other characters with special meaning to the shell must be quoted. <i>delim</i> can be a multi-byte character.</p> <p><code>-f list</code> The <i>list</i> following <code>-f</code> is a list of fields assumed to be separated in the file by a delimiter character (see <code>-d</code>); for instance, <code>-f1, 7</code> copies the first and seventh field only. Lines with no field delimiters will be passed through intact (useful for table subheadings), unless <code>-s</code> is specified.</p> <p><code>-n</code> Do not split characters. When <code>-b list</code> and <code>-n</code> are used together, <i>list</i> is adjusted so that no multi-byte character is split.</p> <p><code>-s</code> Suppresses lines with no delimiter characters in case of <code>-f</code> option. Unless specified, lines with no delimiters will be passed through untouched.</p>
OPERANDS	The following operands are supported:

cut(1)

file A path name of an input file. If no *file* operands are specified, or if a *file* operand is `-`, the standard input will be used.

USAGE See `largefile(5)` for the description of the behavior of `cut` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Mapping user IDs

A mapping of user IDs to names follows:

```
example% cut -d: -f1,5 /etc/passwd
```

EXAMPLE 2 Setting current login name

To set name to current login name:

```
example$ name=`who am i | cut -f1 -d' '`
```

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `cut`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS The following exit values are returned:

0 All input files were output successfully.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

SEE ALSO `grep(1)`, `paste(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

DIAGNOSTICS `cut: -n` may only be used with `-b`

`cut: -d` may only be used with `-f`

`cut: -s` may only be used with `-f`

`cut: cannot open <file>`

Either *file* cannot be read or does not exist. If multiple files are present, processing continues.

`cut: no delimiter specified`

Missing *delim* on `-d` option.

cut(1)

```
cut: invalid delimiter
cut: no list specified
    Missing list on -b, -c, or -f option.
cut: invalid range specifier
cut: too many ranges specified
cut: range must be increasing
cut: invalid character in range
cut: internal error processing input
cut: invalid multibyte character
cut: unable to allocate enough memory
```

date(1)

NAME	date – write the date and time				
SYNOPSIS	<pre>/usr/bin/date [-u] [+ format] /usr/bin/date [-a [-] sss.fff] /usr/bin/date [-u] [[mmdd] HHMM mmddHHMM [cc] yy] [.SS] /usr/xpg4/bin/date [-u] [+ format] /usr/xpg4/bin/date [-a [-] sss.fff] /usr/xpg4/bin/date [-u] [[mmdd] HHMM mmddHHMM [cc] yy] [.SS]</pre>				
DESCRIPTION	<p>The <code>date</code> utility writes the date and time to standard output or attempts to set the system date and time. By default, the current date and time will be written.</p> <p>Specifications of native language translations of month and weekday names are supported. The month and weekday names used for a language are based on the locale specified by the environment variable <code>LC_TIME</code>; see <code>environ(5)</code>.</p> <p>The following is the default form for the "C" locale:</p> <pre>%a %b %e %T %Z %Y</pre> <p>for example,</p> <pre>Fri Dec 23 10:10:42 EST 1988</pre>				
OPTIONS	<p>The following options are supported:</p> <table><tr><td>-a [-] sss.fff</td><td>Slowly adjust the time by <i>sss.fff</i> seconds (<i>fff</i> represents fractions of a second). This adjustment can be positive or negative. The system's clock will be sped up or slowed down until it has drifted by the number of seconds specified. Only the super-user may adjust the time.</td></tr><tr><td>-u</td><td>Display (or set) the date in Greenwich Mean Time (GMT—universal time), bypassing the normal conversion to (or from) local time.</td></tr></table>	-a [-] sss.fff	Slowly adjust the time by <i>sss.fff</i> seconds (<i>fff</i> represents fractions of a second). This adjustment can be positive or negative. The system's clock will be sped up or slowed down until it has drifted by the number of seconds specified. Only the super-user may adjust the time.	-u	Display (or set) the date in Greenwich Mean Time (GMT—universal time), bypassing the normal conversion to (or from) local time.
-a [-] sss.fff	Slowly adjust the time by <i>sss.fff</i> seconds (<i>fff</i> represents fractions of a second). This adjustment can be positive or negative. The system's clock will be sped up or slowed down until it has drifted by the number of seconds specified. Only the super-user may adjust the time.				
-u	Display (or set) the date in Greenwich Mean Time (GMT—universal time), bypassing the normal conversion to (or from) local time.				
OPERANDS	<p>The following operands are supported:</p> <table><tr><td>+format</td><td>If the argument begins with +, the output of <code>date</code> is the result of passing <i>format</i> and the current time to <code>strftime()</code>. <code>date</code> uses the conversion specifications listed on the <code>strftime(3C)</code> manual page, with the conversion specification for %C determined by whether <code>/usr/bin/date</code> or <code>/usr/xpg4/bin/date</code> is used:</td></tr><tr><td><code>/usr/bin/date</code></td><td>Locale's date and time representation. This is the default output for <code>date</code>.</td></tr></table>	+format	If the argument begins with +, the output of <code>date</code> is the result of passing <i>format</i> and the current time to <code>strftime()</code> . <code>date</code> uses the conversion specifications listed on the <code>strftime(3C)</code> manual page, with the conversion specification for %C determined by whether <code>/usr/bin/date</code> or <code>/usr/xpg4/bin/date</code> is used:	<code>/usr/bin/date</code>	Locale's date and time representation. This is the default output for <code>date</code> .
+format	If the argument begins with +, the output of <code>date</code> is the result of passing <i>format</i> and the current time to <code>strftime()</code> . <code>date</code> uses the conversion specifications listed on the <code>strftime(3C)</code> manual page, with the conversion specification for %C determined by whether <code>/usr/bin/date</code> or <code>/usr/xpg4/bin/date</code> is used:				
<code>/usr/bin/date</code>	Locale's date and time representation. This is the default output for <code>date</code> .				

date(1)

/usr/xpg4/bin/date

Century (a year divided by 100 and truncated to an integer) as a decimal number [00-99].

The string is always terminated with a NEWLINE. An argument containing blanks must be quoted; see the `EXAMPLES` section.

mm Month number
dd Day number in the month
HH Hour number (24 hour system)
MM Minute number
SS Second number
cc Century minus one
yy Last 2 digits of the year number

The month, day, year, and century may be omitted; the current values are applied as defaults. For example, the following entry:

```
example% date 10080045
```

sets the date to Oct 8, 12:45 a.m. The current year is the default because no year is supplied. The system operates in GMT. `date` takes care of the conversion to and from local standard and daylight time. Only the super-user may change the date. After successfully setting the date and time, `date` displays the new date according to the default format. The `date` command uses `TZ` to determine the correct time zone information; see `environ(5)`.

EXAMPLES **EXAMPLE 1** Generating output

The command

```
example% date '+DATE: %m/%d/%y%nTIME:%H:%M:%S'
```

generates as output

```
DATE: 08/01/76
```

```
TIME: 14:45:05
```

EXAMPLE 2 Setting the current time

The command

```
example# date 1234.56
```

sets the current time to 12:34:56.

date(1)

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `date`: `LC_CTYPE`, `LC_TIME`, `LC_MESSAGES`, and `NLSPATH`.

`TZ` Determine the timezone in which the time and date are written, unless the `-u` option is specified. If the `TZ` variable is not set and the `-u` is not specified, the system default timezone is used.

EXIT STATUS

The following exit values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/date`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

`/usr/xpg4/bin/date`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	enabled

SEE ALSO

`strftime(3C)`, `attributes(5)`, `environ(5)`, `XPG4(5)`

DIAGNOSTICS

`no permission` You are not the super-user and you tried to change the date.

`bad conversion` The date set is syntactically incorrect.

NOTES

If you attempt to set the current date to one of the dates that the standard and alternate time zones change (for example, the date that daylight time is starting or ending), and you attempt to set the time to a time in the interval between the end of standard time and the beginning of the alternate time (or the end of the alternate time and the beginning of standard time), the results are unpredictable.

Using the `date` command from within windowing environments to change the date can lead to unpredictable results and is unsafe. It may also be unsafe in the multi-user mode, that is, outside of a windowing system, if the date is changed rapidly back and forth. The recommended method of changing the date is `'date -a'`.

NAME	dc – desk calculator																
SYNOPSIS	dc [<i>filename</i>]																
DESCRIPTION	<p>dc is an arbitrary precision arithmetic package. Ordinarily it operates on decimal integers, but one may specify an input base, output base, and a number of fractional digits to be maintained. The overall structure of dc is a stacking (reverse Polish) calculator. If an argument is given, input is taken from that file until its end, then from the standard input.</p> <p>bc is a preprocessor for dc that provides infix notation and a C-like syntax that implements functions. bc also provides reasonable control structures for programs. See bc(1).</p>																
USAGE	<p>The following constructions are recognized:</p> <table border="0"> <tr> <td style="vertical-align: top;"><i>number</i></td> <td>The value of the number is pushed on the stack. A number is an unbroken string of the digits 0–9. It may be preceded by an underscore (<code>_</code>) to input a negative number. Numbers may contain decimal points.</td> </tr> <tr> <td style="vertical-align: top;"><code>+ - / * % ^</code></td> <td>The top two values on the stack are added (+), subtracted (-), multiplied (*), divided (/), remaindered (%), or exponentiated (^). The two entries are popped off the stack; the result is pushed on the stack in their place. Any fractional part of an exponent is ignored.</td> </tr> <tr> <td style="vertical-align: top;"><code>sx</code></td> <td>The top of the stack is popped and stored into a register named <i>x</i>, where <i>x</i> may be any character. If the <i>s</i> is capitalized, <i>x</i> is treated as a stack and the value is pushed on it.</td> </tr> <tr> <td style="vertical-align: top;"><code>lx</code></td> <td>The value in register <i>x</i> is pushed on the stack. The register <i>x</i> is not altered. All registers start with zero value. If the <i>l</i> is capitalized, register <i>x</i> is treated as a stack and its top value is popped onto the main stack.</td> </tr> <tr> <td style="vertical-align: top;"><code>d</code></td> <td>The top value on the stack is duplicated.</td> </tr> <tr> <td style="vertical-align: top;"><code>p</code></td> <td>The top value on the stack is printed. The top value remains unchanged.</td> </tr> <tr> <td style="vertical-align: top;"><code>P</code></td> <td>Interprets the top of the stack as an ASCII string, removes it, and prints it.</td> </tr> <tr> <td style="vertical-align: top;"><code>f</code></td> <td>All values on the stack are printed.</td> </tr> </table>	<i>number</i>	The value of the number is pushed on the stack. A number is an unbroken string of the digits 0–9. It may be preceded by an underscore (<code>_</code>) to input a negative number. Numbers may contain decimal points.	<code>+ - / * % ^</code>	The top two values on the stack are added (+), subtracted (-), multiplied (*), divided (/), remaindered (%), or exponentiated (^). The two entries are popped off the stack; the result is pushed on the stack in their place. Any fractional part of an exponent is ignored.	<code>sx</code>	The top of the stack is popped and stored into a register named <i>x</i> , where <i>x</i> may be any character. If the <i>s</i> is capitalized, <i>x</i> is treated as a stack and the value is pushed on it.	<code>lx</code>	The value in register <i>x</i> is pushed on the stack. The register <i>x</i> is not altered. All registers start with zero value. If the <i>l</i> is capitalized, register <i>x</i> is treated as a stack and its top value is popped onto the main stack.	<code>d</code>	The top value on the stack is duplicated.	<code>p</code>	The top value on the stack is printed. The top value remains unchanged.	<code>P</code>	Interprets the top of the stack as an ASCII string, removes it, and prints it.	<code>f</code>	All values on the stack are printed.
<i>number</i>	The value of the number is pushed on the stack. A number is an unbroken string of the digits 0–9. It may be preceded by an underscore (<code>_</code>) to input a negative number. Numbers may contain decimal points.																
<code>+ - / * % ^</code>	The top two values on the stack are added (+), subtracted (-), multiplied (*), divided (/), remaindered (%), or exponentiated (^). The two entries are popped off the stack; the result is pushed on the stack in their place. Any fractional part of an exponent is ignored.																
<code>sx</code>	The top of the stack is popped and stored into a register named <i>x</i> , where <i>x</i> may be any character. If the <i>s</i> is capitalized, <i>x</i> is treated as a stack and the value is pushed on it.																
<code>lx</code>	The value in register <i>x</i> is pushed on the stack. The register <i>x</i> is not altered. All registers start with zero value. If the <i>l</i> is capitalized, register <i>x</i> is treated as a stack and its top value is popped onto the main stack.																
<code>d</code>	The top value on the stack is duplicated.																
<code>p</code>	The top value on the stack is printed. The top value remains unchanged.																
<code>P</code>	Interprets the top of the stack as an ASCII string, removes it, and prints it.																
<code>f</code>	All values on the stack are printed.																

dc(1)

q	Exits the program. If executing a string, the recursion level is popped by two.
Q	Exits the program. The top value on the stack is popped and the string execution level is popped by that value.
x	Treats the top element of the stack as a character string and executes it as a string of dc commands.
X	Replaces the number on the top of the stack with its scale factor.
[. . .]	Puts the bracketed ASCII string onto the top of the stack.
<x >x =x	The top two elements of the stack are popped and compared. Register x is evaluated if they obey the stated relation.
v	Replaces the top element on the stack by its square root. Any existing fractional part of the argument is taken into account, but otherwise the scale factor is ignored.
!	Interprets the rest of the line as a shell command.
c	All values on the stack are popped.
i	The top value on the stack is popped and used as the number radix for further input.
I	Pushes the input base on the top of the stack.
o	The top value on the stack is popped and used as the number radix for further output.
O	Pushes the output base on the top of the stack.
k	The top of the stack is popped, and that value is used as a non-negative scale factor: the appropriate number of places are printed on output, and maintained during multiplication, division, and exponentiation. The interaction of scale factor, input base, and output base will be reasonable if all are changed together.

dc(1)

input base is too small	The input base x : $2 \leq x \leq 16$.
output base is too large	The output base must be no larger than <code>BC_BASE_MAX</code> .
invalid scale factor	Scale factor cannot be less than 1.
scale factor is too large	A scale factor cannot be larger than <code>BC_SCALE_MAX</code> .
symbol table overflow	Too many variables have been specified.
invalid index	Index cannot be less than 1.
index is too large	An index cannot be larger than <code>BC_DIM_MAX</code> .

NAME	deroff – remove nroff/troff, tbl, and eqn constructs				
SYNOPSIS	deroff [-m [m s l]] [-w] [-i] [filename...]				
DESCRIPTION	deroff reads each of the <i>filenames</i> in sequence and removes all troff(1) requests, macro calls, backslash constructs, eqn(1) constructs (between .EQ and .EN lines, and between delimiters), and tbl(1) descriptions, perhaps replacing them with white space (blanks and blank lines), and writes the remainder of the file on the standard output. deroff follows chains of included files (.so and .nx troff commands); if a file has already been included, a .so naming that file is ignored and a .nx naming that file terminates execution. If no input file is given, deroff reads the standard input.				
OPTIONS	<p>-m The -m option may be followed by an m, s, or l. The -mm option causes the macros to be interpreted so that only running text is output (that is, no text from macro lines.) The -ml option forces the -mm option and also causes deletion of lists associated with the mm macros.</p> <p>-w If the -w option is given, the output is a word list, one “word” per line, with all other characters deleted. Otherwise, the output follows the original, with the deletions mentioned above. In text, a “word” is any string that <i>contains</i> at least two letters and is composed of letters, digits, ampersands (&), and apostrophes ('); in a macro call, however, a “word” is a string that <i>begins</i> with at least two letters and contains a total of at least three letters. Delimiters are any characters other than letters, digits, apostrophes, and ampersands. Trailing apostrophes and ampersands are removed from “words.”</p> <p>-i The -i option causes deroff to ignore .so and .nx commands.</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWdoc</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWdoc
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWdoc				
SEE ALSO	eqn(1), nroff(1), tbl(1), troff(1), attributes(5)				
NOTES	<p>deroff is not a complete troff interpreter, so it can be confused by subtle constructs. Most such errors result in too much rather than too little output.</p> <p>The -ml option does not handle nested lists correctly.</p>				

df(1B)

NAME	df – display status of disk space on file systems				
SYNOPSIS	<code>/usr/ucb/df [-a] [-i] [-t <i>type</i>] [<i>filesystem...</i>] [<i>filename...</i>]</code>				
DESCRIPTION	<p>The <code>df</code> utility displays the amount of disk space occupied by currently mounted file systems, the amount of used and available space, and how much of the file system's total capacity has been used.</p> <p>If arguments to <code>df</code> are path names, <code>df</code> produces a report on the file system containing the named file. Thus <code>'df .'</code> shows the amount of space on the file system containing the current directory.</p>				
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -a Report on all filesystems including the uninteresting ones which have zero total blocks (that is, auto-mounter). -i Report the number of used and free inodes. Print ' * ' if no information is available. -t <i>type</i> Report on filesystems of a given type (for example, nfs or ufs). 				
EXAMPLES	<p>EXAMPLE 1 Output sample</p> <p>A sample of output for <code>df</code> looks like:</p> <pre>example% df Filesystem kbytes used avail capacity Mounted on sparky:/ 7445 4714 1986 70% / sparky:/usr 42277 35291 2758 93% /usr</pre> <p>Note that <code>used+avail</code> is less than the amount of space in the file system (kbytes); this is because the system reserves a fraction of the space in the file system to allow its file system allocation routines to work well. The amount reserved is typically about 10%; this may be adjusted using <code>tunefs</code> (see <code>tunefs(1M)</code>). When all the space on a file system except for this reserve is in use, only the super-user can allocate new files and data blocks to existing files. When a file system is overallocated in this way, <code>df</code> may report that the file system is more than 100% utilized.</p>				
FILES	<p><code>/etc/mnttab</code> list of file systems currently mounted</p> <p><code>/etc/vfstab</code> list of default parameters for each file system</p>				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWscpu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWscpu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWscpu				
SEE ALSO	<code>du(1M)</code> , <code>quot(1M)</code> , <code>tunefs(1M)</code> , <code>mnttab(4)</code> , <code>attributes(5)</code>				

NAME dhcpcfg – display values of parameters received through DHCP

SYNOPSIS `dhcpcfg [-c] [-i interface] [-n limit] code`
`dhcpcfg [-c] [-i interface] [-n limit] identifier`

DESCRIPTION The dhcpcfg utility prints the DHCP-supplied value(s) of the parameter requested on the command line. The parameter may be identified either by its numeric code in the DHCP specification, or by its mnemonic identifier, as listed in dhcp_inittab(4). This command is intended to be used in command substitutions in the shell scripts invoked by init(1M) at system boot. It first contacts the DHCP client daemon dhcpd(1M) to verify that DHCP has successfully completed on the requested interface. If DHCP has successfully completed on the requested interface, dhcpcfg retrieves the values for the requested parameter. Parameter values echoed by dhcpcfg should not be used without checking its exit status. See EXIT STATUS.

See dhcp_inittab(4) for the list of mnemonic identifier codes for all DHCP parameters. See RFC 2132, *DHCP Options and BOOTP Vendor Extensions* for more detail.

Output Format The output from dhcpcfg consists of one or more lines of ASCII text; the format of the output depends upon the requested parameter. The number of values returned per line and the total number of lines output for a given parameter are determined by the parameter's *granularity* and *maximum* values, respectively, as defined by dhcp_inittab(4).

The format of each individual value is determined by the data type of the option, as determined by dhcp_inittab(4). The possible data types and their formats are listed below:

Data Type	Format	dhcp_inittab(4) type
Unsigned Number	One or more decimal digits	UNNUMBER8, UNNUMBER16, UNNUMBER32, UNNUMBER64
Signed Number	One or more decimal digits, optionally preceded by a minus sign	SNUMBER8, SNUMBER16, SNUMBER32, SNUMBER64
IP Address	Dotted-decimal notation	IP
Octet	The string "0x" followed by a two-digit hexadecimal value	OCTET
String	Zero or more ASCII characters	ASCII

OPTIONS The following options are supported:

-c Displays the output in a canonical format. This format is identical to the OCTET format with a granularity of 1.

dhcinfo(1)

-i interface Specifies the interface to retrieve values for DHCP parameters from. If this option is not specified, the primary interface is used.

-n limit Limits the list of values displayed to *limit* lines.

OPERANDS The following operands are supported:

code Numeric code for the requested DHCP parameter, as defined by the DHCP specification. Vendor options are specified by adding 256 to the actual vendor code.

identifier Mnemonic symbol for the requested DHCP parameter, as listed in `dhcp_inittab(4)`.

EXIT STATUS The following exit values are returned:

0 Successful operation.

2 The operation was not successful. The DHCP client daemon may not be running, the interface might have failed to configure, or no satisfactory DHCP responses were received.

3 Bad arguments.

4 The operation timed out.

6 Some system error (should never occur).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsr
Interface Stability	Evolving

SEE ALSO `dhcagent(1M)`, `ifconfig(1M)`, `init(1M)`, `dhcp_inittab(4)`, `attributes(5)`

NAME	diff – display line-by-line differences between pairs of text files
SYNOPSIS	<pre>diff [-bitw] [-c -e -f -h -n]file1 file2 diff [-bitw] [-C number] file1 file2 diff [-bitw] [-D string] file1 file2 diff [-bitw] [-c -e -f -h -n] [-l] [-r] [-s] [-S name] directory1 directory2</pre>
DESCRIPTION	<p>The <code>diff</code> utility will compare the contents of <i>file1</i> and <i>file2</i> and write to standard output a list of changes necessary to convert <i>file1</i> into <i>file2</i>. This list should be minimal. No output will be produced if the files are identical.</p> <p>The normal output contains lines of these forms:</p> <pre>n17 a n3,n4 n1,n2 d n3 n1,n2 c n3,n4</pre> <p>where <i>n1</i> and <i>n2</i> represent lines <i>file1</i> and <i>n3</i> and <i>n4</i> represent lines in <i>file2</i>. These lines resemble <code>ed(1)</code> commands to convert <i>file1</i> to <i>file2</i>. By exchanging a for d and reading backward, <i>file2</i> can be converted to <i>file1</i>. As in <code>ed</code>, identical pairs, where <i>n1</i>=<i>n2</i> or <i>n3</i>=<i>n4</i>, are abbreviated as a single number.</p> <p>Following each of these lines come all the lines that are affected in the first file flagged by '<code><</code>', then all the lines that are affected in the second file flagged by '<code>></code>'.</p>
OPTIONS	<p><code>-b</code> Ignores trailing blanks (spaces and tabs) and treats other strings of blanks as equivalent.</p> <p><code>-i</code> Ignores the case of letters; for example, 'A' will compare equal to 'a'.</p> <p><code>-t</code> Expands TAB characters in output lines. Normal or <code>-c</code> output adds character(s) to the front of each line that may adversely affect the indentation of the original source lines and make the output lines difficult to interpret. This option will preserve the original source's indentation.</p> <p><code>-w</code> Ignores all blanks (SPACE and TAB characters) and treats all other strings of blanks as equivalent; for example, 'if (a = = b)' will compare equal to 'if (a= =b)'.</p> <p>The following options are mutually exclusive:</p> <p><code>-c</code> Produces a listing of differences with three lines of context. With this option output format is modified slightly: output begins with identification of the files involved and their creation dates, then each change is separated by a line with a dozen *'s. The lines removed from <i>file1</i> are marked with '-'; those added to <i>file2</i> are marked with '+'. Lines that are changed from one file to the other are marked in both files with '!'. </p>

diff(1)

- C *number* Produces a listing of differences identical to that produced by -c with *number* lines of context.
- e Produces a script of only a, c, and d commands for the editor ed, which will recreate *file2* from *file1*. In connection with -e, the following shell program may help maintain multiple versions of a file. Only an ancestral file (\$1) and a chain of version-to-version ed scripts (\$2,\$3,...) made by diff need be on hand. A “latest version” appears on the standard output.

```
(shift; cat $*; echo `1,$p' ) | ed - $1
```

Except in rare circumstances, diff finds a smallest sufficient set of file differences.

- f Produces a similar script, not useful with ed, in the opposite order.
- h Does a fast, half-hearted job. It works only when changed stretches are short and well separated, but does work on files of unlimited length. Options -c, -e, -f, and -n are unavailable with -h. diff does not descend into directories with this option.
- n Produces a script similar to -e, but in the opposite order and with a count of changed lines on each insert or delete command.
- D *string* Creates a merged version of *file1* and *file2* with C preprocessor controls included so that a compilation of the result without defining *string* is equivalent to compiling *file1*, while defining *string* will yield *file2*.

The following options are used for comparing directories:

- l Produce output in long format. Before the diff, each text file is piped through pr(1) to paginate it. Other differences are remembered and summarized after all text file differences are reported.
- r Applies diff recursively to common subdirectories encountered.
- s Reports files that are the identical; these would not otherwise be mentioned.
- S *name* Starts a directory diff in the middle, beginning with the file *name*.

OPERANDS

The following operands are supported:

- file1, file2* A path name of a file or directory to be compared. If either *file1* or *file2* is -, the standard input will be used in its place.
- directory1, directory2* A path name of a directory to be compared.

If only one of *file1* and *file2* is a directory, `diff` will be applied to the non-directory file and the file contained in the directory file with a filename that is the same as the last component of the non-directory file.

USAGE See `largefile(5)` for the description of the behavior of `diff` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Example of the `diff` command.

If `dir1` is a directory containing a directory named `x`, `dir2` is a directory containing a directory named `x`, `dir1/x` and `dir2/x` both contain files named `date.out`, and `dir2/x` contains a file named `y`, the command:

```
example% diff -r dir1 dir2
could produce output similar to:

Common subdirectories: dir1/x and dir2/x

Only in dir2/x: y

diff -r dir1/x/date.out dir2/x/date.out

1c1
< Mon Jul  2 13:12:16 PDT 1990
---
> Tue Jun 19 21:41:39 PDT 1990
```

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of `diff`: `LC_CTYPE`, `LC_MESSAGES`, `LC_TIME`, and `NLSPATH`.

TZ Determine the locale for affecting the timezone used for calculating file timestamps written with the `-C` and `-c` options.

EXIT STATUS The following exit values are returned:

0 No differences were found.
 1 Differences were found.
 >1 An error occurred.

FILES `/tmp/d?????` temporary file used for comparison
`/usr/lib/diffh` executable file for `-h` option

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu

diff(1)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
CSI	Enabled

SEE ALSO `bdiff(1)`, `cmp(1)`, `comm(1)`, `dircmp(1)`, `ed(1)`, `pr(1)`, `sdiff(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

NOTES Editing scripts produced under the `-e` or `-f` options are naive about creating lines consisting of a single period (`.`).

Missing NEWLINE at end of file indicates that the last line of the file in question did not have a NEWLINE. If the lines are different, they will be flagged and output; although the output will seem to indicate they are the same.

NAME	diff3 – 3-way differential file comparison
SYNOPSIS	diff3 [-exEX3] <i>filename1 filename2 filename3</i>
DESCRIPTION	<p>diff3 compares three versions of a file, and publishes disagreeing ranges of text flagged with these codes:</p> <pre> ===== all three files differ =====1 <i>filename1</i> is different =====2 <i>filename2</i> is different =====3 <i>filename3</i> is different </pre> <p>The type of change suffered in converting a given range of a given file to some other is indicated in one of these ways:</p> <pre> <i>f</i> : <i>n1</i> a Text is to be appended after line number <i>n1</i> in file <i>f</i>, where <i>f</i> = 1, 2, or 3. <i>f</i> : <i>n1</i> , <i>n2</i> c Text is to be changed in the range line <i>n1</i> to line <i>n2</i>. If <i>n1</i> = <i>n2</i>, the range may be abbreviated to <i>n1</i>. </pre> <p>The original contents of the range follows immediately after a <i>c</i> indication. When the contents of two files are identical, the contents of the lower-numbered file is suppressed.</p> <p>The following command will apply the resulting script to <i>filename1</i>.</p> <pre>(cat script; echo `1,\$p`) ed - <i>filename1</i></pre>
OPTIONS	<pre> -e Produce a script for the ed(1) editor that will incorporate into <i>filename1</i> all changes between <i>filename2</i> and <i>filename3</i> (that is, the changes that normally would be flagged ===== and =====3). -x Produce a script to incorporate only changes flagged =====. -3 Produce a script to incorporate only changes flagged =====3. -E Produce a script that will incorporate all changes between <i>filename2</i> and <i>filename3</i>, but treat overlapping changes (that is, changes that would be flagged with ===== in the normal listing) differently. The overlapping lines from both files will be inserted by the edit script, bracketed by <<<<<< and >>>>>> lines. -X Produce a script that will incorporate only changes flagged =====, but treat these changes in the manner of the -E option. </pre>
USAGE	See <code>largefile(5)</code> for the description of the behavior of <code>diff3</code> when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).
FILES	<pre> /tmp/d3* /usr/lib/diff3prog </pre>

diff3(1)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWesu
CSI	enabled

SEE ALSO `diff(1)`, `attributes(5)`, `largefile(5)`

NOTES Text lines that consist of a single `.` will defeat `-e`.
Files longer than 64 Kbytes will not work.

NAME	diffmk – mark differences between versions of a troff input file				
SYNOPSIS	diffmk <i>oldfile newfile markedfile</i>				
DESCRIPTION	diffmk compares two versions of a file and creates a third version that includes “change mark” (.mc) commands for nroff(1) and troff(1). <i>oldfile</i> and <i>newfile</i> are the old and new versions of the file. diffmk generates <i>markedfile</i> , which, contains the text from <i>newfile</i> with troff(1) “change mark” requests (.mc) inserted where <i>newfile</i> differs from <i>oldfile</i> . When <i>markedfile</i> is formatted, changed or inserted text is shown by at the right margin of each line. The position of deleted text is shown by a single *.				
USAGE	See largefile(5) for the description of the behavior of diffmk when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).				
EXAMPLES	<p>EXAMPLE 1 An example of the diffmk command.</p> <p>diffmk can also be used in conjunction with the proper troff requests to produce program listings with marked changes. In the following command line:</p> <pre>example% diffmk old.c new.c marked.c ; nroff reqs marked.c pr</pre> <p>the file reqs contains the following troff requests:</p> <pre>.pl 1 .ll 77 .nf .eo .nh</pre> <p>which eliminate page breaks, adjust the line length, set no-fill mode, ignore escape characters, and turn off hyphenation, respectively.</p> <p>If the characters and * are inappropriate, you might run <i>markedfile</i> through sed(1) to globally change them.</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWdoc</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWdoc
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWdoc				
SEE ALSO	diff(1), nroff(1), sed(1), troff(1), attributes(5), largefile(5)				
BUGS	Aesthetic considerations may dictate manual adjustment of some output. File differences involving only formatting requests may produce undesirable output, that is, replacing .sp by .sp 2 will produce a “change mark” on the preceding or following line of output.				

dircmp(1)

NAME	dircmp – directory comparison				
SYNOPSIS	dircmp [-ds] [-w <i>n</i>] <i>dir1 dir2</i>				
DESCRIPTION	The dircmp command examines <i>dir1</i> and <i>dir2</i> and generates various tabulated information about the contents of the directories. Listings of files that are unique to each directory are generated for all the options. If no option is entered, a list is output indicating whether the file names common to both directories have the same contents.				
OPTIONS	The following options are supported: -d Compare the contents of files with the same name in both directories and output a list telling what must be changed in the two files to bring them into agreement. The list format is described in diff(1) . -s Suppress messages about identical files. -w <i>n</i> Change the width of the output line to <i>n</i> characters. The default width is 72.				
OPERANDS	The following operands are supported: <i>dir1</i> <i>dir2</i> A path name of a directory to be compared.				
USAGE	See largefile(5) for the description of the behavior of dircmp when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).				
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of dircmp : LC_COLLATE , LC_CTYPE , LC_MESSAGES , and NLSPATH .				
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred. (differences in directory contents are not considered errors)				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes: <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWesu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWesu				
SEE ALSO	cmp(1) , diff(1) , attributes(5) , environ(5) , largefile(5)				

NAME	dis – object code disassembler
SYNOPSIS	<code>/usr/ccs/bin/dis [-C] [-o] [-V] [-L] [-d <i>sec</i>] [-D <i>sec</i>] [-F <i>function</i>] [-l <i>string</i>] [-t <i>sec</i>] <i>file...</i></code>
DESCRIPTION	The <code>dis</code> command produces an assembly language listing of <i>file</i> , which may be an object file or an archive of object files. The listing includes assembly statements and an octal or hexadecimal representation of the binary that produced those statements. However, the IA64 listing is limited to assembly statements only.
OPTIONS	<p>The following options are interpreted by the disassembler and may be specified in any order.</p> <ul style="list-style-type: none"> -C Displays demangled C++ symbol names in the disassembly. -d <i>sec</i> Disassembles the named section as data, printing the offset of the data from the beginning of the section. -D <i>sec</i> Disassembles the named section as data, printing the actual address of the data. -F <i>function</i> Disassembles only the named function in each object file specified on the command line. The -F option may be specified multiple times on the command line. -l <i>string</i> Disassembles the archive file specified by <i>string</i>. For example, one would issue the command <code>dis -l x -l z</code> to disassemble <code>libx.a</code> and <code>libz.a</code>, which are assumed to be in <code>LIBDIR</code>. -L Invokes a lookup of C-language source labels in the symbol table for subsequent writing to standard output. -o Prints numbers in octal. The default is hexadecimal. -t <i>sec</i> Disassembles the named section as text. -V Prints, on standard error, the version number of the disassembler being executed. <p>If the -d, -D, or -t options are specified, only those named sections from each user-supplied file will be disassembled. Otherwise, all sections containing text will be disassembled.</p> <p>On output, a number enclosed in brackets at the beginning of a line, such as [5], indicates that the break-pointable line number starts with the following instruction. These line numbers will be printed only if the file was compiled with additional debugging information, for example, the -g option of <code>cc(1B)</code>. An expression such as <code><40></code> in the operand field or in the symbolic disassembly, following a relative displacement for control transfer instructions, is the computed address within the section to which control will be transferred. A function name will appear in the first column, followed by () if the object file contains a symbol table.</p>
OPERANDS	The following operand is supported:

dis(1)

file A path name of an object file or an archive (see ar(1)) of object files.

ENVIRONMENT VARIABLES See environ(5) for descriptions of the following environment variables that affect the execution of dis: LC_CTYPE, LC_MESSAGES, and NLSPATH.

LIBDIR If this environment variable contains a value, use this as the path to search for the library. If the variable contains a null value, or is not set, it defaults to searching for the library under /usr/lib.

EXIT STATUS The following exit values are returned:

0 Successful completion.

>0 An error occurred.

FILES /usr/lib default LIBDIR

NAME	dos2unix – convert text file from DOS format to ISO format				
SYNOPSIS	dos2unix [-ascii] [-iso] [-7] <i>originalfile convertedfile</i>				
DESCRIPTION	<p>The dos2unix utility converts characters in the DOS extended character set to the corresponding ISO standard characters.</p> <p>This command can be invoked from either DOS or SunOS. However, the filenames must conform to the conventions of the environment in which the command is invoked.</p> <p>If the original file and the converted file are the same, dos2unix will rewrite the original file after converting it.</p>				
OPTIONS	<p>-ascii Removes extra carriage returns and converts end of file characters in DOS format text files to conform to SunOS requirements.</p> <p>-iso This is the default. It converts characters in the DOS extended character set to the corresponding ISO standard characters.</p> <p>-7 Convert 8 bit DOS graphics characters to 7 bit space characters so that SunOS can read the file.</p>				
ATTRIBUTES	See attributes(5) for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWesu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWesu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWesu				
SEE ALSO	unix2dos(1), attributes(5)				
DIAGNOSTICS	<p>File <i>filename</i> not found, or no read permission The input file you specified does not exist, or you do not have read permission (check with the SunOS <code>ls -l</code> command).</p> <p>Bad output filename <i>filename</i>, or no write permission The output file you specified is either invalid, or you do not have write permission for that file or the directory that contains it. Check also that the drive or diskette is not write-protected.</p> <p>Error while writing to temporary file An error occurred while converting your file, possibly because there is not enough space on the current drive. Check the amount of space on the current drive using the DIR command. Also be certain that the default diskette or drive is write-enabled (not write-protected). Note that when this error occurs, the original file remains intact.</p> <p>Could not rename temporary file to <i>filename</i>.</p> <p>Translated temporary file name = <i>filename</i>. The program could not perform the final step in converting your file. Your converted file is stored under the name indicated on the second line of this</p>				

dos2unix(1)

message.

NAME	download – host resident PostScript font downloader
SYNOPSIS	download [-f] [-p <i>printer</i>] [-m <i>name</i>] [-H <i>directory</i>] [<i>file...</i>] /usr/lib/lp/postscript/download
DESCRIPTION	<p>download prepends host resident fonts to <i>files</i> and writes the results on the standard output. If no <i>files</i> are specified, or if – is one of the input <i>files</i>, the standard input is read. download assumes the input <i>files</i> make up a single PostScript job and that requested fonts can be included at the start of each input file.</p> <p>Requested fonts are named in a comment (marked with %%DocumentFonts:) in the input <i>files</i>. Available fonts are the ones listed in the map table selected using the -m option.</p> <p>The map table consists of fontname–file pairs. The fontname is the full name of the PostScript font, exactly as it would appear in a %%DocumentFonts: comment. The file is the pathname of the host resident font. A file that begins with a / is used as is. Otherwise the pathname is relative to the host font directory. Comments are introduced by % (as in PostScript) and extend to the end of the line.</p> <p>The only candidates for downloading are fonts listed in the map table that point download to readable files. A font is downloaded once, at most. Requests for unlisted fonts or inaccessible files are ignored. All requests are ignored if the map table can not be read.</p>
OPTIONS	<p>-f Force a complete scan of each input file. In the absence of an explicit comment pointing download to the end of the file, the default scan stops immediately after the PostScript header comments.</p> <p>-p <i>printer</i> Check the list of printer-resident fonts in /etc/lp/printers/<i>printer</i>/residentfonts before downloading.</p> <p>-m <i>name</i> Use <i>name</i> as the font map table. A <i>name</i> that begins with / is the full pathname of the map table and is used as is. Otherwise <i>name</i> is appended to the pathname of the host font directory.</p> <p>-H <i>directory</i> Use <i>dir</i> as the host font directory. The default is /usr/lib/lp/postscript.</p>
EXAMPLES	<p>EXAMPLE 1 Examples of the download command.</p> <p>The following map table could be used to control the downloading of the Bookman font family:</p> <pre> % % The first string is the full PostScript font name. The second string % is the file name - relative to the host font directory unless it begins % with a /. %</pre>

download(1)

EXAMPLE 1 Examples of the download command. (Continued)

```
Bookman-Light          bookman/light
Bookman-LightItalic    bookman/lightitalic
Bookman-Demi           bookman/demi
Bookman-DemiItalic     bookman/demiitalic
```

Using the file `myprinter/map` (in the default host font directory) as the map table, you could download fonts by issuing the following command:

```
example% download -m myprinter/map file
```

EXIT STATUS The following exit values are returned:

0 Successful completion.

non-zero An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsf

SEE ALSO `dpost(1)`, `postdaisy(1)`, `postdmd(1)`, `postio(1)`, `postmd(1)`, `postprint(1)`, `posttek(1)`, `attributes(5)`

NOTES The download program should be part of a more general program.

`download` does not look for `%%PageFonts:` comments and there is no way to force multiple downloads of a particular font.

Using full pathnames in either map tables or the names of map tables is not recommended.

NAME	dpost – troff postprocessor for PostScript printers
SYNOPSIS	dpost [-c <i>num</i>] [-e <i>num</i>] [-m <i>num</i>] [-n <i>num</i>] [-o <i>list</i>] [-w <i>num</i>] [-x <i>num</i>] [-y <i>num</i>] [-F <i>dir</i>] [-H <i>dir</i>] [-L <i>file</i>] [-O] [-T <i>name</i>] [<i>file...</i>] /usr/lib/lp/postscript/dpost
DESCRIPTION	<p>dpost translates <i>files</i> created by troff(1) into PostScript and writes the results on the standard output. If no <i>files</i> are specified, or if – is one of the input <i>files</i>, the standard input is read.</p> <p>The <i>files</i> should be prepared by troff. The default font files in /usr/lib/font/devpost produce the best and most efficient output. They assume a resolution of 720 dpi, and can be used to format files by adding the -Tpost option to the troff call. Older versions of the eqn and pic preprocessors need to know the resolution that troff will be using to format the <i>files</i>. If those are the versions installed on your system, use the -r720 option with eqn and -T720 with pic.</p> <p>dpost makes no assumptions about resolutions. The first x res command sets the resolution used to translate the input <i>files</i>, the DESC.out file, usually /usr/lib/font/devpost/DESC.out, defines the resolution used in the binary font files, and the PostScript prologue is responsible for setting up an appropriate user coordinate system.</p>
OPTIONS	<p>-c <i>num</i> Print <i>num</i> copies of each page. By default only one copy is printed.</p> <p>-e <i>num</i> Sets the text encoding level to <i>num</i>. The recognized choices are 0, 1, and 2. The size of the output file and print time should decrease as <i>num</i> increases. Level 2 encoding will typically be about 20 percent faster than level 0, which is the default and produces output essentially identical to previous versions of dpost.</p> <p>-m <i>num</i> Magnify each logical page by the factor <i>num</i>. Pages are scaled uniformly about the origin, which is located near the upper left corner of each page. The default magnification is 1.0.</p> <p>-n <i>num</i> Print <i>num</i> logical pages on each piece of paper, where <i>num</i> can be any positive integer. By default, <i>num</i> is set to 1.</p> <p>-o <i>list</i> Print those pages for which numbers are given in the comma-separated <i>list</i>. The list contains single numbers <i>N</i> and ranges <i>N1–N2</i>. A missing <i>N1</i> means the lowest numbered page, a missing <i>N2</i> means the highest. The page range is an expression of logical pages rather than physical sheets of paper. For example, if you are printing two logical pages to a sheet, and you specified a range of 4, then two sheets of paper would print, containing four page layouts. If you specified a page range of 3–4, when requesting two logical pages to a sheet; then <i>only</i> page 3 and page 4 layouts would print, and they would appear on one physical sheet of paper.</p>

dpost(1)

<code>-p <i>mode</i></code>	Print <i>files</i> in either portrait or landscape <i>mode</i> . Only the first character of <i>mode</i> is significant. The default <i>mode</i> is portrait.
<code>-w <i>num</i></code>	Set the line width used to implement <code>troff</code> graphics commands to <i>num</i> points, where a point is approximately 1/72 of an inch. By default, <i>num</i> is set to 0.3 points.
<code>-x <i>num</i></code>	Translate the origin <i>num</i> inches along the positive x axis. The default coordinate system has the origin fixed near the upper left corner of the page, with positive x to the right and positive y down the page. Positive <i>num</i> moves everything right. The default offset is 0 inches.
<code>-y <i>num</i></code>	Translate the origin <i>num</i> inches along the positive y axis. Positive <i>num</i> moves text up the page. The default offset is 0.
<code>-F <i>dir</i></code>	Use <i>dir</i> as the font directory. The default <i>dir</i> is <code>/usr/lib/font</code> , and <code>dpost</code> reads binary font files from directory <code>/usr/lib/font/devpost</code> .
<code>-H <i>dir</i></code>	Use <i>dir</i> as the host resident font directory. Files in this directory should be complete PostScript font descriptions, and must be assigned a name that corresponds to the appropriate two-character <code>troff</code> font name. Each font file is copied to the output file only when needed and at most once during each job. There is no default directory.
<code>-L <i>file</i></code>	Use <i>file</i> as the PostScript prologue which, by default, is <code>/usr/lib/lp/postscript/dpost.ps</code> .
<code>-O</code>	Disables PostScript picture inclusion. A recommended option when <code>dpost</code> is run by a spooler in a networked environment.
<code>-T <i>name</i></code>	Use font files for device <i>name</i> as the best description of available PostScript fonts. By default, <i>name</i> is set to <code>post</code> and <code>dpost</code> reads binary files from <code>/usr/lib/font/devpost</code> .

EXAMPLES

EXAMPLE 1 Examples of the `dpost` command.

If the old versions of `eqn` and `pic` are installed on your system, you can obtain the best possible looking output by issuing a command line such as the following:

```
example% pic -T720 file | tbl | eqn -r720 | troff -mm -Tpost | dpost
```

Otherwise,

```
example% pic file | tbl | eqn | troff -mm -Tpost | dpost
```

should give the best results.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
---	------------------------

non-zero An error occurred.

FILES /usr/lib/font/devpost/*.out
 /usr/lib/font/devpost/charlib/*
 /usr/lib/lp/postscript/color.ps
 /usr/lib/lp/postscript/draw.ps
 /usr/lib/lp/postscript/forms.ps
 /usr/lib/lp/postscript/ps.requests
 /usr/lib/macros/pictures
 /usr/lib/macros/color

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWpsf

SEE ALSO download(1), postdaisy(1), postdmd(1), postio(1), postmd(1), postprint(1), postreverse(1), posttek(1), troff(1), attributes(5)

NOTES Output files often do not conform to Adobe's file structuring conventions. Piping the output of dpost through postreverse(1) should produce a minimally conforming PostScript file.

Although dpost can handle files formatted for any device, emulation is expensive and can easily double the print time and the size of the output file. No attempt has been made to implement the character sets or fonts available on all devices supported by troff. Missing characters will be replaced by white space, and unrecognized fonts will usually default to one of the Times fonts (that is, R, I, B, or BI).

An x res command must precede the first x init command, and all the input *files* should have been prepared for the same output device.

Use of the -T option is not encouraged. Its only purpose is to enable the use of other PostScript font and device description files, that perhaps use different resolutions, character sets, or fonts.

Although level 0 encoding is the only scheme that has been thoroughly tested, level 2 is fast and may be worth a try.

du(1B)

NAME	du – display the number of disk blocks used per directory or file
SYNOPSIS	<pre>/usr/ucb/du /usr/ucb/du [-a] [-s] [filename]</pre>
DESCRIPTION	<p>The du utility gives the number of kilobytes contained in all files and, recursively, directories within each specified directory or file <i>filename</i>. If <i>filename</i> is missing, '.' (the current directory) is used.</p> <p>A file which has multiple links to it is only counted once.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Generate an entry for each file.-s Only display the grand total for each of the specified <i>filenames</i>. <p>Entries are generated only for each directory in the absence of options.</p>
EXAMPLES	<p>EXAMPLE 1 Using du in a directory</p> <p>Here is an example of using du in a directory. We used the pwd(1) command to identify the directory, then used du to show the usage of all the subdirectories in that directory. The grand total for the directory is the last entry in the display:</p> <pre>example% pwd /usr/ralph/misc example% du 5 ./jokes 33 ./squash 44 ./tech.papers/lpr.document 217 ./tech.papers/new.manager 401 ./tech.papers 144 ./memos 80 ./letters 388 ./window 93 ./messages 15 ./useful.news 1211 . example%</pre>
ENVIRONMENT VARIABLES	<p>If any of the LC_* variables (LC_CTYPE, LC_MESSAGES, LC_TIME, LC_COLLATE, LC_NUMERIC, and LC_MONETARY) (see environ(5)) are not set in the environment, the operational behavior of du for each corresponding locale category is determined by the value of the LANG environment variable. If LC_ALL is set, its contents are used to override both the LANG and the other LC_* variables. If none of the above variables is set in the environment, the "C" (U.S. style) locale determines how du behaves.</p> <p>LC_CTYPE Determines how du handles characters. When LC_CTYPE is set to a valid value, du can display and handle text and filenames containing valid characters for that locale. du can display and handle Extended</p>

du(1B)

Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. du can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

LC_MESSAGES

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWscpu

SEE ALSO `pwd(1)`, `df(1M)`, `quot(1M)`, `attributes(5)`, `environ(5)`

NOTES Filename arguments that are not directory names are ignored, unless you use `-a`.

If there are too many distinct linked files, du will count the excess files more than once.

dump(1)

NAME	dump – dump selected parts of an object file
SYNOPSIS	dump [-aCcFghLorstV] [-T <i>index</i> [, <i>indexn</i>]] <i>filename</i> ... dump [-afhorstL [<i>v</i>]] <i>filename</i> ... dump [-hsr [-d <i>number</i> [, <i>numbern</i>]]] <i>filename</i> ... dump [-hsrt [-n <i>name</i>]] <i>filename</i> ...
DESCRIPTION	The dump utility dumps selected parts of each of its object <i>file</i> arguments. The dump utility is best suited for use in shell scripts, whereas the <code>elfdump(1)</code> command is recommended for more human-readable output.
OPTIONS	This utility will accept both object files and archives of object files. It processes each file argument according to one or more of the following options: -a Dumps the archive header of each member of an archive. -c Dumps the string table(s). -C Dumps decoded C++ symbol table names. -f Dumps each file header. -g Dumps the global symbols in the symbol table of an archive. -h Dumps the section headers. -L Dumps dynamic linking information and static shared library information, if available. -o Dumps each program execution header. -r Dumps relocation information. -s Dumps section contents in hexadecimal. -t Dumps symbol table entries. -T <i>index</i> -T <i>index1,index2</i> Dumps only the indexed symbol table entry defined by <i>index</i> or a range of entries defined by <i>index1</i> , <i>index2</i> . -V Prints version information. The following modifiers are used in conjunction with the options listed above to modify their capabilities. -d <i>number</i> -d <i>number1,number2</i> Dumps the section number indicated by <i>number</i> or the range of sections starting at <i>number1</i> and ending at <i>number2</i> . This modifier can be used with -h, -s, and -r. When -d is used with -h or -s, the argument is

treated as the number of a section or range of sections. When `-d` is used with `-r`, the argument is treated as the number of the section or range of sections to which the relocation applies. For example, to print out all relocation entries associated with the `.text` section, specify the number of the section as the argument to `-d`. If `.text` is section number 2 in the file, `dump -r -d 2` will print all associated entries. To print out a specific relocation section, use `dump -s -n name` for raw data output, or `dump -sv -n name` for interpreted output.

`-n name`

Dumps information pertaining only to the named entity. This modifier can be used with `-h`, `-s`, `-r`, and `-t`. When `-n` is used with `-h` or `-s`, the argument will be treated as the name of a section. When `-n` is used with `-t` or `-r`, the argument will be treated as the name of a symbol. For example, `dump -t -n .text` will dump the symbol table entry associated with the symbol whose name is `.text`, where `dump -h -n .text` will dump the section header information for the `.text` section.

`-p`

Suppresses printing of the headings.

`-v`

Dumps information in symbolic representation rather than numeric. This modifier can be used with

- `-a` (date, user id, group id)
- `-f` (class, data, type, machine, version, flags)
- `-h` (type, flags)
- `-L` (value)
- `-o` (type, flags)
- `-r` (name, type)
- `-s` (interpret section contents wherever possible)
- `-t` (type, bind)

When `-v` is used with `-s`, all sections that can be interpreted, such as the string table or symbol table, will be interpreted. For example, `dump -sv -n .symtab filename. . .` will produce the same formatted output as `dump -tv filename. . .`, but `dump -s -n .symtab filename. . .` will print raw data in hexadecimal. Without additional modifiers, `dump -sv filename. . .` will dump

dump(1)

all sections in the files, interpreting all those that it can and dumping the rest (such as `.text` or `.data`) as raw data.

The `dump` utility attempts to format the information it dumps in a meaningful way, printing certain information in character, hexadecimal, octal, or decimal representation as appropriate.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

SEE ALSO `elfdump(1)`, `nm(1)`, `ar(3HEAD)`, `a.out(4)`, `attributes(5)`

NAME dumpcs – show codeset table for the current locale

SYNOPSIS `dumpcs [-0123vw]`

DESCRIPTION dumpcs shows a list of printable characters for the user’s current locale, along with their hexadecimal code values. The display device is assumed to be capable of displaying characters for a given locale. With no option, dumpcs displays the entire list of printable characters for the current locale.

With one or more numeric options specified, it shows EUC codeset(s) for the current locale according to the numbers specified, and in order of codeset number. Each non-printable character is represented by an asterisk “*” and enough ASCII space character(s) to fill that codeset’s column width.

OPTIONS

- 0 Show ASCII (or EUC primary) codeset.
- 1 Show EUC codeset 1, if used for the current locale.
- 2 Show EUC codeset 2, if used for the current locale.
- 3 Show EUC codeset 3, if used for the current locale.
- v “Verbose”. Normally, ranges of non-printable characters are collapsed into a single line. This option produces one line for each non-printable character.
- w Replace code values with corresponding wide character values (process codes).

ENVIRONMENT VARIABLES The environment variables LC_CTYPE and LANG control the character classification throughout dumpcs. On entry to dumpcs, these environment variables are checked in that order. This implies that a new setting for LANG does not override the setting of LC_CTYPE. When none of the values is valid, the character classification defaults to the POSIX.1 “C” locale.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO localedef(1), attributes(5)

NOTES dumpcs can only handle EUC locales.

echo(1)

NAME	echo – echo arguments																						
SYNOPSIS	<code>/usr/bin/echo</code> [<i>string...</i>]																						
DESCRIPTION	<p>The <code>echo</code> utility writes its arguments, separated by BLANKs and terminated by a NEWLINE, to the standard output. If there are no arguments, only the NEWLINE character will be written.</p> <p><code>echo</code> is useful for producing diagnostics in command files, for sending known data into a pipe, and for displaying the contents of environment variables.</p> <p>The C shell, the Korn shell, and the Bourne shell all have <code>echo</code> built-in commands, which, by default, will be invoked if the user calls <code>echo</code> without a full pathname. See <code>shell_builtins(1)</code>. <code>sh</code>'s <code>echo</code>, <code>ksh</code>'s <code>echo</code>, and <code>/usr/bin/echo</code> understand the back-slash escape characters, except that <code>sh</code>'s <code>echo</code> does not understand <code>\ a</code> as the alert character. In addition, <code>ksh</code>'s <code>echo</code>, does not have a <code>-n</code> option. <code>sh</code>'s <code>echo</code> and <code>/usr/bin/echo</code> only have a <code>-n</code> option if the <code>SYSV3</code> environment variable is set (see <code>ENVIRONMENT</code> below). If it is, none of the backslashed characters mentioned above are available. <code>cs</code>'s <code>echo</code> and <code>/usr/ucb/echo</code>, on the other hand, have a <code>-n</code> option, but do not understand the back-slash escape characters.</p>																						
OPERANDS	<p>The following operands are supported:</p> <table><tr><td><i>string</i></td><td>A string to be written to standard output. If any operand is “-n”, it will be treated as a string, not an option. The following character sequences will be recognized within any of the arguments:</td></tr><tr><td><code>\ a</code></td><td>alert character</td></tr><tr><td><code>\ b</code></td><td>backspace</td></tr><tr><td><code>\ c</code></td><td>print line without new-line</td></tr><tr><td><code>\ f</code></td><td>form-feed</td></tr><tr><td><code>\ n</code></td><td>new-line</td></tr><tr><td><code>\ r</code></td><td>carriage return</td></tr><tr><td><code>\ t</code></td><td>tab</td></tr><tr><td><code>\ v</code></td><td>vertical tab</td></tr><tr><td><code>\ \</code></td><td>backslash</td></tr><tr><td><code>\ 0n</code></td><td>where <i>n</i> is the 8-bit character whose ASCII code is the 1-, 2- or 3-digit octal number representing that character.</td></tr></table>	<i>string</i>	A string to be written to standard output. If any operand is “-n”, it will be treated as a string, not an option. The following character sequences will be recognized within any of the arguments:	<code>\ a</code>	alert character	<code>\ b</code>	backspace	<code>\ c</code>	print line without new-line	<code>\ f</code>	form-feed	<code>\ n</code>	new-line	<code>\ r</code>	carriage return	<code>\ t</code>	tab	<code>\ v</code>	vertical tab	<code>\ \</code>	backslash	<code>\ 0n</code>	where <i>n</i> is the 8-bit character whose ASCII code is the 1-, 2- or 3-digit octal number representing that character.
<i>string</i>	A string to be written to standard output. If any operand is “-n”, it will be treated as a string, not an option. The following character sequences will be recognized within any of the arguments:																						
<code>\ a</code>	alert character																						
<code>\ b</code>	backspace																						
<code>\ c</code>	print line without new-line																						
<code>\ f</code>	form-feed																						
<code>\ n</code>	new-line																						
<code>\ r</code>	carriage return																						
<code>\ t</code>	tab																						
<code>\ v</code>	vertical tab																						
<code>\ \</code>	backslash																						
<code>\ 0n</code>	where <i>n</i> is the 8-bit character whose ASCII code is the 1-, 2- or 3-digit octal number representing that character.																						
USAGE	<p>Portable applications should not use <code>-n</code> (as the first argument) or escape sequences.</p> <p>The <code>printf(1)</code> utility can be used portably to emulate any of the traditional behaviors of the <code>echo</code> utility as follows:</p>																						

- The Solaris 2.6 operating environment or compatible version's `/usr/bin/echo` is equivalent to:

```
printf "%b\n" "$*"

```

- The `/usr/ucb/echo` is equivalent to:

```
if [ "X$1" = "X-n" ]
then
    shift
    printf "%s" "$*"
else
    printf "%s\n" "$*"
fi

```

New applications are encouraged to use `printf` instead of `echo`.

EXAMPLES **EXAMPLE 1** Examples of the echo command.

You can use `echo` to determine how many subdirectories below the root directory (`/`) is your current directory, as follows:

- `echo` your current-working-directory's full pathname
- pipe the output through `tr` to translate the path's embedded slash-characters into space-characters
- pipe that output through `wc -w` for a count of the names in your path.

```
example% /usr/bin/echo $PWD | tr '/' ' ' | wc -w

```

See `tr(1)` and `wc(1)` for their functionality.

Below are the different flavors for echoing a string without a NEWLINE:

/usr/bin/echo	% /usr/bin/echo "\$USER's current directory is \$PWD\c"
sh/ksh shells	\$ echo "\$USER's current directory is \$PWD\c"
csh shell	% echo -n "\$USER's current directory is \$PWD"
/usr/ucb/echo	% /usr/ucb/echo -n "\$USER's current directory is \$PWD"

echo(1)

ENVIRONMENT VARIABLES

SYSV3 This environment variable is used to provide compatibility with INTERACTIVE UNIX System and SCO UNIX installation scripts. It is intended for compatibility only and should not be used in new scripts.

See `environ(5)` for descriptions of the following environment variables that affect the execution of `echo`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following error values are returned:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

SEE ALSO

`echo(1B)`, `printf(1)`, `shell_builtins(1)`, `tr(1)`, `fictionwc(1)`, `ascii(5)`, `attributes(5)`, `environ(5)`

NOTES

When representing an 8-bit character by using the escape convention `\ 0n`, the `n` must *always* be preceded by the digit zero (0).

For example, typing: `echo 'WARNING:\ 07'` will print the phrase `WARNING:` and sound the "bell" on your terminal. The use of single (or double) quotes (or two backslashes) is required to protect the `"\"` that precedes the `"07"`.

Following the `\ 0`, up to three digits are used in constructing the octal output character. If, following the `\ 0n`, you want to echo additional digits that are not part of the octal representation, you must use the full 3-digit `n`. For example, if you want to echo `"ESC 7"` you must use the three digits `"033"` rather than just the two digits `"33"` after the `\ 0`.

2 digits	Incorrect:	<code>echo"0337 od -xc</code>	
	produces:	<code>df0a</code>	(hex)
		<code>337</code>	(ascii)
3 digits	Correct:	<code>echo "00337" od -xc</code>	
	produces:	<code>1b37 0a00</code>	(hex)
		<code>033 7</code>	(ascii)

For the octal equivalents of each character, see `ascii(5)`.

NAME	echo – echo arguments to standard output				
SYNOPSIS	<code>/usr/ucb/echo [-n] [argument]</code>				
DESCRIPTION	<p>echo writes its arguments, separated by BLANKS and terminated by a NEWLINE, to the standard output.</p> <p>echo is useful for producing diagnostics in command files and for sending known data into a pipe, and for displaying the contents of environment variables.</p> <p>For example, you can use echo to determine how many subdirectories below the root directory (/) is your current directory, as follows:</p> <ul style="list-style-type: none"> ■ echo your current-working-directory's full pathname ■ pipe the output through <code>tr</code> to translate the path's embedded slash-characters into space-characters ■ pipe that output through <code>wc -w</code> for a count of the names in your path. <pre>example% /usr/bin/echo "echo \$PWD tr '/' ' ' wc -w"</pre> <p>See <code>tr(1)</code> and <code>wc(1)</code> for their functionality.</p> <p>The shells <code>csh(1)</code>, <code>ksh(1)</code>, and <code>sh(1)</code>, each have an <code>echo</code> built-in command, which, by default, will have precedence, and will be invoked if the user calls <code>echo</code> without a full pathname. <code>/usr/ucb/echo</code> and <code>csh's echo()</code> have an <code>-n</code> option, but do not understand back-slashed escape characters. <code>sh's echo()</code>, <code>ksh's echo()</code>, and <code>/usr/bin/echo</code>, on the other hand, understand the black-slashed escape characters, and <code>ksh's echo()</code> also understands <code>\a</code> as the audible bell character; however, these commands do not have an <code>-n</code> option.</p>				
OPTIONS	<code>-n</code> Do not add the NEWLINE to the output.				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWscpu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWscpu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWscpu				
SEE ALSO	<code>csh(1)</code> , <code>echo(1)</code> , <code>ksh(1)</code> , <code>sh(1)</code> , <code>tr(1)</code> , <code>wc(1)</code> , <code>attributes(5)</code>				
NOTES	The <code>-n</code> option is a transition aid for BSD applications, and may not be supported in future releases.				

echo(1F)

NAME echo – put string on virtual output

SYNOPSIS **echo** [*string...*]

DESCRIPTION The echo function directs each string it is passed to the standard output. If no argument is given, echo looks to the standard input for input. It is often used in conditional execution or for passing a string to another command.

EXAMPLES **EXAMPLE 1** A sample of the echo command.

Set the done descriptor to help if a test fails:

```
done='if [ -s $F1 ];
      then echo close;
      else echo help;
      fi`
```

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	ed, red – text editor
SYNOPSIS	<pre> /usr/bin/ed [-s -] [-p <i>string</i>] [-x] [-C] [<i>file</i>] /usr/xpg4/bin/ed [-s -] [-p <i>string</i>] [-x] [-C] [<i>file</i>] /usr/bin/red [-s -] [-p <i>string</i>] [-x] [-C] [<i>file</i>] </pre>
DESCRIPTION	<p>The ed utility is the standard text editor. If <i>file</i> is specified, ed simulates an e command (see below) on the named file; that is to say, the file is read into ed's buffer so that it can be edited.</p> <p>The ed utility operates on a copy of the file it is editing; changes made to the copy have no effect on the file until a w (write) command is given. The copy of the text being edited resides in a temporary file called the <i>buffer</i>. There is only one buffer.</p> <p>The red utility is a restricted version of ed. It will only allow editing of files in the current directory. It prohibits executing shell commands via <i>!shell command</i>. Attempts to bypass these restrictions result in an error message (<i>restricted shell</i>).</p> <p>Both ed and red support the <i>fspec(4)</i> formatting capability. The default terminal mode is either <i>stty -tabs</i> or <i>stty tab3</i>, where tab stops are set at eight columns (see <i>stty(1)</i>). If, however, the first line of <i>file</i> contains a format specification, that specification will override the default mode. For example, if the first line of <i>file</i> contains</p> <pre><:t5,10,15 s72:></pre> <p>tab stops would be set at 5, 10, and 15, and a maximum line length of 72 would be imposed.</p> <p>Commands to ed have a simple and regular structure: zero, one, or two <i>addresses</i> followed by a single-character <i>command</i>, possibly followed by parameters to that command. These addresses specify one or more lines in the buffer. Every command that requires addresses has default addresses, so that the addresses can very often be omitted.</p> <p>In general, only one command may appear on a line. Certain commands allow the input of text. This text is placed in the appropriate place in the buffer. While ed is accepting text, it is said to be in <i>input mode</i>. In this mode, <i>no</i> commands are recognized; all input is merely collected. Leave input mode by typing a period (.) at the beginning of a line, followed immediately by a carriage return.</p>
/usr/bin/ed	If ed executes commands with arguments, it uses the default shell /usr/bin/sh (see <i>sh(1)</i>).
/usr/xpg4/bin/ed	If ed executes commands with arguments, it uses /usr/xpg4/bin/sh (see <i>ksh(1)</i>).
Regular Expressions	The ed utility supports a limited form of <i>regular expression</i> notation. Regular expressions are used in addresses to specify lines and in some commands (for example, s) to specify portions of a line that are to be substituted. To understand

ed(1)

addressing in `ed`, it is necessary to know that at any time there is a *current line*. Generally speaking, the current line is the last line affected by a command; the exact effect on the current line is discussed under the description of each command.

Internationalized Basic Regular Expressions are used for all system-supplied locales. See `regex(5)`.

ed Commands

Commands may require zero, one, or two addresses. Commands that require no addresses regard the presence of an address as an error. Commands that accept one or two addresses assume default addresses when an insufficient number of addresses is given; if more addresses are given than such a command requires, the last one(s) are used.

Typically, addresses are separated from each other by a comma (,). They may also be separated by a semicolon (;). In the latter case, the first address is calculated, the current line (.) is set to that value, and then the second address is calculated. This feature can be used to determine the starting line for forward and backward searches (see Rules 5 and 6, above). The second address of any two-address sequence must correspond to a line in the buffer that follows the line corresponding to the first address.

In the following list of `ed` commands, the parentheses shown prior to the command are *not* part of the address; rather, they show the default address(es) for the command.

Each address component can be preceded by zero or more blank characters. The command letter can be preceded by zero or more blank characters. If a suffix letter (l, n, or p) is given, it must immediately follow the command.

The `e`, `E`, `f`, `r`, and `w` commands take an optional `file` parameter, separated from the command letter by one or more blank characters.

If changes have been made in the buffer since the last `w` command that wrote the entire buffer, `ed` will warn the user if an attempt is made to destroy the editor buffer via the `e` or `q` commands. The `ed` utility will write the string:

```
"?\ n"
```

(followed by an explanatory message if *help mode* has been enabled via the `H` command) to standard output and will continue in command mode with the current line number unchanged. If the `e` or `q` command is repeated with no intervening command, it will take effect.

If an end-of-file is detected on standard input when a command is expected, the `ed` utility acts as if a `q` command had been entered.

It is generally illegal for more than one command to appear on a line. However, any command (except `e`, `f`, `r`, or `w`) may be suffixed by `l`, `n`, or `p` in which case the current line is either listed, numbered or written, respectively, as discussed below under the `l`, `n`, and `p` commands.

(.) a
 <text>

The append command accepts zero or more lines of text and appends it after the addressed line in the buffer. The current line (.) is left at the last inserted line, or, if there were none, at the addressed line. Address 0 is legal for this command: it causes the “appended” text to be placed at the beginning of the buffer. The maximum number of characters that may be entered from a terminal is 256 per line (including the new-line character).

(.) c
 <text>

The change command deletes the addressed lines from the buffer, then accepts zero or more lines of text that replaces these lines in the buffer. The current line (.) is left at the last line input, or, if there were none, at the first line that was not deleted; if the lines deleted were originally at the end of the buffer, the current line number will be set to the address of the new last line; if no lines remain in the buffer, the current line number will be set to 0.

C

Same as the X command, described later, except that ed assumes all text read in for the e and r commands is encrypted unless a null key is typed in.

(. , .) d

The delete command deletes the addressed lines from the buffer. The line after the last line deleted becomes the current line; if the lines deleted were originally at the end of the buffer, the new last line becomes the current line. If no lines remain in the buffer, the current line number will be set to 0.

e *file*

The edit command deletes the entire contents of the buffer and then reads the contents of *file* into the buffer. The current line (.) is set to the last line of the buffer. If *file* is not given, the currently remembered file name, if any, is used (see the f command). The number of bytes read will be written to standard output, unless the -s option was specified, in the following format:

```
"%d\ n" <number of bytes read>
```

file is remembered for possible use as a default file name in subsequent e, E, r, and w commands. If *file* is replaced by !, the rest of the line is taken to be a shell (sh(1)) command whose output is to be read. Such a shell command is *not* remembered as the current file name. See also DIAGNOSTICS below. All marks will be discarded upon the completion of a successful e command. If the buffer has changed since the last time the entire buffer was written, the user will be warned, as described previously.

E *file*

The Edit command is like e, except that the editor does not check to see if any changes have been made to the buffer since the last w command.

ed(1)

f *file*

If *file* is given, the *f* command will change the currently remembered path name to *file*; whether the name is changed or not, it then will write the (possibly new) currently remembered path name to the standard output in the following format:

```
"%s\ n"pathname
```

The current line number is unchanged.

(*l* , \$) *g*/*RE*/*command list*

In the global command, the first step is to mark every line that matches the given *RE*. Then, for every such line, the given *command list* is executed with the current line (.) initially set to that line. When the *g* command completes, the current line number will have the value assigned by the last command in the command list. If there were no matching lines, the current line number will not be changed. A single command or the first of a list of commands appears on the same line as the global command. All lines of a multi-line list except the last line must be ended with a backslash (\); *a*, *i*, and *c* commands and associated input are permitted. The . terminating input mode may be omitted if it would be the last line of the *command list*. An empty *command list* is equivalent to the *p* command. The *g*, *G*, *v*, *V*, and *!* commands are *not* permitted in the *command list*. See also the NOTES and the last paragraph before FILES below. Any character other than space or newline can be used instead of a slash to delimit the *RE*. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

(*l* , \$) *G*/*RE*/

In the interactive Global command, the first step is to mark every line that matches the given *RE*. Then, for every such line, that line is written to standard output, the current line (.) is changed to that line, and any *one* command (other than one of the *a*, *c*, *i*, *g*, *G*, *v*, and *V* commands) may be input and is executed. After the execution of that command, the next marked line is written, and so on; a new-line acts as a null command; an *&* causes the re-execution of the most recent non-null command executed within the current invocation of *G*. Note: The commands input as part of the execution of the *G* command may address and affect *any* lines in the buffer. The final value of the current line number will be the value set by the last command successfully executed. (Note that the last command successfully executed will be the *G* command itself if a command fails or the null command is specified.) If there were no matching lines, the current line number will not be changed. The *G* command can be terminated by a SIGINT signal. The *G* command can be terminated by an interrupt signal (ASCII DEL or BREAK). Any character other than space or newline can be used instead of a slash to delimit the *RE*. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash.

h

The *help* command gives a short error message that explains the reason for the most recent ? diagnostic. The current line number is unchanged.

H

The `Help` command causes `ed` to enter a mode in which error messages are written for all subsequent `?` diagnostics. It will also explain the previous `?` if there was one. The `H` command alternately turns this mode on and off; it is initially off. The current line number is unchanged.

(.) i
 <text>

The `insert` command accepts zero or more lines of text and inserts it before the addressed line in the buffer. The current line (.) is left at the last inserted line, or, if there were none, at the addressed line. This command differs from the `a` command only in the placement of the input text. Address 0 is not legal for this command. The maximum number of characters that may be entered from a terminal is 256 per line (including the new-line character).

(. , .+1) j

The `join` command joins contiguous lines by removing the appropriate new-line characters. If exactly one address is given, this command does nothing. If lines are joined, the current line number will be set to the address of the joined line; otherwise, the current line number is unchanged.

(.) kx

The `mark` command marks the addressed line with name *x*, which must be an ASCII lower-case letter (a-z). The address `'x` then addresses this line; the current line (.) is unchanged.

(. , .) l

The `l` command writes to standard output the addressed lines in a visually unambiguous form. The characters (`\\`, `\ a`, `\ b`, `\ f`, `\ r`, `\ t`, `\ v`) will be written as the corresponding escape sequence; the `\ n` in that table is not applicable. Non-printable characters not in the table will be written as one three-digit octal number (with a preceding backslash character) for each byte in the character (most significant byte first).

Long lines will be folded, with the point of folding indicated by writing backslash/newline character; the length at which folding occurs is unspecified, but should be appropriate for the output device. The end of each line will be marked with a `$`. An `l` command can be appended to any other command other than `e`, `E`, `f`, `q`, `Q`, `r`, `w`, or `!`. The current line number will be set to the address of the last line written.

(. , .) ma

The `move` command repositions the addressed line(s) after the line addressed by *a*. Address 0 is legal for *a* and causes the addressed line(s) to be moved to the beginning of the file. It is an error if address *a* falls within the range of moved lines; the current line (.) is left at the last line moved.

ed(1)

(. , .)n

The number command writes the addressed lines, preceding each line by its line number and a tab character; the current line (.) is left at the last line written. The n command may be appended to any command other than e, E, f, g, Q, r, w, or !.

(. , .)p

The print command writes the addressed lines to standard output; the current line (.) is left at the last line written. The p command may be appended to any command other than e, E, f, g, Q, r, w, or !. For example, dp deletes the current line and writes the new current line.

P

The P command causes ed to prompt with an asterisk (*) (or *string*, if -p is specified) for all subsequent commands. The P command alternatively turns this mode on and off; it is initially on if the -p option is specified, otherwise off. The current line is unchanged.

q

The quit command causes ed to exit. If the buffer has changed since the last time the entire buffer was written, the user will be warned; see `DIAGNOSTICS`.

Q

The editor exits without checking if changes have been made in the buffer since the last w command.

(\$)r file

The read command reads the contents of *file* into the buffer. If *file* is not given, the currently remembered file name, if any, is used (see the e and f commands). The currently remembered file name is *not* changed unless *file* is the very first file name mentioned since ed was invoked. Address 0 is legal for r and causes the file to be read in at the beginning of the buffer. If the read is successful and the -s option was not specified, the number of characters read is written to standard output in the following format:

```
%d\ n, <number of bytes read>
```

The current line (.) is set to the last line read. If *file* is replaced by !, the rest of the line is taken to be a shell command (see `sh(1)`) whose output is to be read. For example, \$r !ls appends the current directory to the end of the file being edited. Such a shell command is *not* remembered as the current file name.

(. , .)s/RE/replacement/

(. , .)s/RE/replacement/count, count=[1-512]

(. , .)s/RE/replacement/g

(. , .)s/RE/replacement/l

(. , .)s/RE/replacement/n

(. , .)s/RE/replacement/p

The substitute command searches each addressed line for an occurrence of the specified *RE*. Zero or more substitution commands can be specified. In each line in which a match is found, all (non-overlapped) matched strings are replaced by the

replacement if the global replacement indicator `g` appears after the command. If the global indicator does not appear, only the first occurrence of the matched string is replaced. If a number *count* appears after the command, only the *count*-th occurrence of the matched string on each addressed line is replaced. It is an error if the substitution fails on *all* addressed lines. Any character other than space or new-line may be used instead of the slash (/) to delimit the *RE* and the *replacement*; the current line (.) is left at the last line on which a substitution occurred. Within the *RE*, the *RE* delimiter itself can be used as a literal character if it is preceded by a backslash. See also the last paragraph before `FILES` below.

An ampersand (&) appearing in the *replacement* is replaced by the string matching the *RE* on the current line. The special meaning of & in this context may be suppressed by preceding it by \. As a more general feature, the characters \n, where *n* is a digit, are replaced by the text matched by the *n*-th regular subexpression of the specified *RE* enclosed between \ (and \). When nested parenthesized subexpressions are present, *n* is determined by counting occurrences of \ (starting from the left. When the character % is the only character in the *replacement*, the *replacement* used in the most recent substitute command is used as the *replacement* in the current substitute command; if there was no previous substitute command, the use of % in this manner is an error. The % loses its special meaning when it is in a replacement string of more than one character or is preceded by a \. For each backslash (\) encountered in scanning *replacement* from beginning to end, the following character loses its special meaning (if any). It is unspecified what special meaning is given to any character other than &, \, %, or digits.

A line may be split by substituting a new-line character into it. The new-line in the *replacement* must be escaped by preceding it by \. Such substitution cannot be done as part of a `g` or `v` command list. The current line number will be set to the address of the last line on which a substitution is performed. If no substitution is performed, the current line number is unchanged. If a line is split, a substitution is considered to have been performed on each of the new lines for the purpose of determining the new current line number. A substitution is considered to have been performed even if the replacement string is identical to the string that it replaces.

The substitute command supports the following indicators:

- | | |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>count</i> | Substitute for the <i>count</i> th occurrence only of the <i>RE</i> found on each addressed line. <i>count</i> must be between 1-512. |
| <code>g</code> | Globally substitute for all non-overlapping instances of the <i>RE</i> rather than just the first one. If both <code>g</code> and <i>count</i> are specified, the results are unspecified. |
| <code>l</code> | Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the <code>l</code> command. |
| <code>n</code> | Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the <code>n</code> command. |

ed(1)

- p** Write to standard output the final line in which a substitution was made. The line will be written in the format specified for the **p** command.
- (. , .) **ta**
This command acts just like the **m** command, except that a *copy* of the addressed lines is placed after address *a* (which may be 0); the current line (.) is left at the last line copied.
- u**
The undo command nullifies the effect of the most recent command that modified anything in the buffer, namely the most recent **a**, **c**, **d**, **g**, **i**, **j**, **m**, **r**, **s**, **t**, **u**, **v**, **G**, or **V** command. All changes made to the buffer by a **g**, **G**, **v**, or **V** global command will be undone as a single change; if no changes were made by the global command (such as with **g**/*RE*/**p**), the **u** command will have no effect. The current line number will be set to the value it had immediately before the command being undone started.
- (1 , \$) **v**/*RE*/*command list*
This command is the same as the global command **g**, except that the lines marked during the first step are those that do *not* match the *RE*.
- (1 , \$) **V**/*RE*/
This command is the same as the interactive global command **G**, except that the lines that are marked during the first step are those that do *not* match the *RE*.
- (1 , \$) **w***file*
The write command writes the addressed lines into *file*. If *file* does not exist, it is created with mode **666** (readable and writable by everyone), unless your file creation mask dictates otherwise; see the description of the **umask** special command on **sh**(1). The currently remembered file name is *not* changed unless *file* is the very first file name mentioned since **ed** was invoked. If no file name is given, the currently remembered file name, if any, is used (see the **e** and **f** commands); the current line (.) is unchanged. If the command is successful, the number of characters written is printed, unless the **-s** option is specified in the following format:

"%d\ n" , <number of bytes written>
- If *file* is replaced by **!**, the rest of the line is taken to be a shell (see **sh**(1)) command whose standard input is the addressed lines. Such a shell command is *not* remembered as the current path name. This usage of the write command with **!** is to be considered as a "last **w** command that wrote the entire buffer".
- (1 , \$) **W***file*
This command is the same as the write command above, except that it appends the addressed lines to the end of *file* if it exists. If *file* does not exist, it is created as described above for the **w** command.
- X**
An educated guess is made to determine whether text read for the **e** and **r** commands is encrypted. A null key turns off encryption. Subsequent **e**, **r**, and **w**

commands will use this key to encrypt or decrypt the text. An explicitly empty key turns off encryption. Also, see the `-x` option of `ed`.

(`$`) =

The line number of the addressed line will be written to standard output in the following format:

```
"%d\ n"<line number>
```

The current line number is unchanged by this command.

!shell command

The remainder of the line after the `!` is sent to the UNIX system shell (see `sh(1)`) to be interpreted as a command. Within the text of that command, the unescaped character `%` is replaced with the remembered file name; if a `!` appears as the first character of the shell command, it is replaced with the text of the previous shell command. Thus, `!!` will repeat the last shell command. If any replacements of `%` or `!` are performed, the modified line will be written to the standard output before command is executed. The `!` command will write:

```
"!\ n"
```

to standard output upon completion, unless the `-s` option is specified. The current line number is unchanged.

(`.+1`) <new-line>

An address alone on a line causes the addressed line to be written. A new-line alone is equivalent to `.+1p`; it is useful for stepping forward through the buffer. The current line number will be set to the address of the written line.

If an interrupt signal (ASCII DEL or BREAK) is sent, `ed` writes a `"?\ n"` and returns to *its* command level.

The `ed` utility will take the standard action for all signals with the following exceptions:

SIGINT	The <code>ed</code> utility will interrupt its current activity, write the string <code>"?\ n"</code> to standard output, and return to command mode.
SIGHUP	If the buffer is not empty and has changed since the last write, the <code>ed</code> utility will attempt to write a copy of the buffer in a file. First, the file named <code>ed.hup</code> in the current directory will be used; if that fails, the file named <code>ed.hup</code> in the directory named by the <code>HOME</code> environment variable will be used. In any case, the <code>ed</code> utility will exit without returning to command mode.

Some size limitations are in effect: 512 characters in a line, 256 characters in a global command list, and 255 characters in the path name of a file (counting slashes). The limit on the number of lines depends on the amount of user memory; each line takes 1 word.

ed(1)

When reading a file, ed discards ASCII and NUL characters.

If a file is not terminated by a new-line character, ed adds one and puts out a message explaining what it did.

If the closing delimiter of an RE or of a replacement string (for example, /) would be the last character before a new-line, that delimiter may be omitted, in which case the addressed line is written. The following pairs of commands are equivalent:

```
s/s1/s2      s/s1/s2/p
g/s1         g/s1/p
?s1         ?s1?
```

If an invalid command is entered, ed will write the string:

```
"?\ n"
```

(followed by an explanatory message if *help mode* has been enabled by the H command) to standard output and will continue in command mode with the current line number unchanged.

OPTIONS

- C Encryption option; the same as the -x option, except that ed simulates a C command. The C command is like the X command, except that all text read in is assumed to have been encrypted.
- p *string* Allows the user to specify a prompt string. By default, there is no prompt string.
- s | -; Suppresses the writing of character counts by e, r, and w commands, of diagnostics from e and q commands, and of the ! prompt after a *!shell command*.
- x Encryption option; when used, ed simulates an X command and prompts the user for a key. The X command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the -x option. See NOTES.

OPERANDS

The following operand is supported:

file If *file* is specified, ed simulates an e command on the file named by the path name *file* before accepting commands from the standard input.

USAGE

See [largefile\(5\)](#) for the description of the behavior of ed and red when encountering files greater than or equal to 2 Gbyte (2³¹ bytes).

ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of ed: HOME, LC_CTYPE, LC_COLLATE, LC_MESSAGES, and NLSPATH.

EXIT STATUS

The following exit values are returned:

0 Successful completion without any file or command errors.
 >0 An error occurred.

FILES

\$TMPDIR If this environment variable is not NULL, its value is used in place of /var/tmp as the directory name for the temporary work file.

/var/tmp If /var/tmp exists, it is used as the directory name for the temporary work file.

/tmp If the environment variable TMPDIR does not exist or is NULL, and if /var/tmp does not exist, then /tmp is used as the directory name for the temporary work file.

ed.hup Work is saved here if the terminal is hung up.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

/usr/bin/red and
/usr/bin/ed

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

/usr/xpg4/bin/ed

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled

SEE ALSO

`bfs(1)`, `edit(1)`, `ex(1)`, `grep(1)`, `ksh(1)`, `sed(1)`, `sh(1)`, `stty(1)`, `umask(1)`, `vi(1)`, `fspec(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `regex(5)`, `XPG4(5)`

DIAGNOSTICS

? for command errors.

?file for an inaccessible file. (use the `help` and `Help` commands for detailed explanations).

If changes have been made in the buffer since the last `w` command that wrote the entire buffer, `ed` warns the user if an attempt is made to destroy `ed`'s buffer via the `e` or `q` commands. It writes `?` and allows one to continue editing. A second `e` or `q` command at this point will take effect. The `-s` command-line option inhibits this feature.

NOTES

The `-` option, although it continues to be supported, has been replaced in the documentation by the `-s` option that follows the `Command Syntax Standard` (see `intro(1)`).

A `!` command cannot be subject to a `g` or a `v` command.

The `!` command and the `!` escape from the `e`, `r`, and `w` commands cannot be used if the editor is invoked from a restricted shell (see `sh(1)`).

ed(1)

The sequence `\ n` in an RE does not match a new-line character.

If the editor input is coming from a command file (for example, `ed file < ed_cmd_file`), the editor exits at the first failure.

NAME	edit – text editor (variant of ex for casual users)								
SYNOPSIS	<pre> /usr/bin/edit [- -s] [-l] [-L] [-R] [-r [filename]] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command] filename... /usr/xpg4/bin/edit [- -s] [-l] [-L] [-R] [-r [filename]] [-t tag] [-v] [-V] [-x] [-wn] [-C] [+command -c command] filename... </pre>								
DESCRIPTION	<p>The <code>edit</code> utility is a variant of the text editor <code>ex</code> recommended for new or casual users who wish to use a command-oriented editor. It operates precisely as <code>ex</code> with the following options automatically set:</p> <table border="0" style="margin-left: 20px;"> <tr> <td>novice</td> <td>ON</td> </tr> <tr> <td>report</td> <td>ON</td> </tr> <tr> <td>showmode</td> <td>ON</td> </tr> <tr> <td>magic</td> <td>OFF</td> </tr> </table> <p>The following brief introduction should help you get started with <code>edit</code>. If you are using a CRT terminal you may want to learn about the display editor <code>vi</code>.</p> <p>To edit the contents of an existing file you begin with the command <code>edit name</code> to the shell. <code>edit</code> makes a copy of the file that you can then edit, and tells you how many lines and characters are in the file. To create a new file, you also begin with the command <code>edit</code> with a filename: <code>edit name</code>; the editor will tell you it is a [New File].</p> <p>The <code>edit</code> command prompt is the colon (:), which you should see after starting the editor. If you are editing an existing file, then you will have some lines in <code>edit</code>'s buffer (its name for the copy of the file you are editing). When you start editing, <code>edit</code> makes the last line of the file the current line. Most commands to <code>edit</code> use the current line if you do not tell them which line to use. Thus if you say <code>print</code> (which can be abbreviated <code>p</code>) and type carriage return (as you should after all <code>edit</code> commands), the current line will be printed. If you <code>delete</code> (<code>d</code>) the current line, <code>edit</code> will print the new current line, which is usually the next line in the file. If you <code>delete</code> the last line, then the new last line becomes the current one.</p> <p>If you start with an empty file or wish to add some new lines, then the <code>append</code> (<code>a</code>) command can be used. After you execute this command (typing a carriage return after the word <code>append</code>), <code>edit</code> will read lines from your terminal until you type a line consisting of just a dot (.); it places these lines after the current line. The last line you type then becomes the current line. The <code>insert</code> (<code>i</code>) command is like <code>append</code>, but places the lines you type before, rather than after, the current line.</p> <p>The <code>edit</code> utility numbers the lines in the buffer, with the first line having number 1. If you execute the command <code>1</code>, then <code>edit</code> will type the first line of the buffer. If you then execute the command <code>d</code>, <code>edit</code> will delete the first line, line 2 will become line 1, and <code>edit</code> will print the current line (the new line 1) so you can see where you are. In general, the current line will always be the last line affected by a command.</p>	novice	ON	report	ON	showmode	ON	magic	OFF
novice	ON								
report	ON								
showmode	ON								
magic	OFF								

edit(1)

You can make a change to some text within the current line by using the `substitute` (`s`) command: `s/old/new/` where `old` is the string of characters you want to replace and `new` is the string of characters you want to replace `old` with.

The `filename` (`f`) command will tell you how many lines there are in the buffer you are editing and will say `[Modified]` if you have changed the buffer. After modifying a file, you can save the contents of the file by executing a `write` (`w`) command. You can leave the editor by issuing a `quit` (`q`) command. If you run `edit` on a file, but do not change it, it is not necessary (but does no harm) to `write` the file back. If you try to quit from `edit` after modifying the buffer without writing it out, you will receive the message `No write since last change (:quit! overrides)`, and `edit` will wait for another command. If you do not want to write the buffer out, issue the `quit` command followed by an exclamation point (`q!`). The buffer is then irretrievably discarded and you return to the shell.

By using the `d` and `a` commands and giving line numbers to see lines in the file, you can make any changes you want. You should learn at least a few more things, however, if you will use `edit` more than a few times.

The `change` (`c`) command changes the current line to a sequence of lines you supply (as in `append`, you type lines up to a line consisting of only a dot (`.`)). You can tell `change` to change more than one line by giving the line numbers of the lines you want to change, that is, `3,5c`. You can print lines this way too: `1,23p` prints the first 23 lines of the file.

The `undo` (`u`) command reverses the effect of the last command you executed that changed the buffer. Thus if you execute a `substitute` command that does not do what you want, type `u` and the old contents of the line will be restored. You can also undo an `undo` command. `edit` will give you a warning message when a command affects more than one line of the buffer. Note that commands such as `write` and `quit` cannot be undone.

To look at the next line in the buffer, type carriage return. To look at a number of lines, type `^D` (while holding down the control key, press `d`) rather than carriage return. This will show you a half-screen of lines on a CRT or 12 lines on a hardcopy terminal. You can look at nearby text by executing the `z` command. The current line will appear in the middle of the text displayed, and the last line displayed will become the current line; you can get back to the line where you were before you executed the `z` command by typing `''`. The `z` command has other options: `z-` prints a screen of text (or 24 lines) ending where you are; `z+` prints the next screenful. If you want less than a screenful of lines, type `z.11` to display five lines before and five lines after the current line. (Typing `z.n`, when `n` is an odd number, displays a total of `n` lines, centered about the current line; when `n` is an even number, it displays `n-1` lines, so that the lines displayed are centered around the current line.) You can give counts after other commands; for example, you can delete 5 lines starting with the current line with the command `d5`.

To find things in the file, you can use line numbers if you happen to know them; since the line numbers change when you insert and delete lines this is somewhat unreliable. You can search backwards and forwards in the file for strings by giving commands of the form `/text/` to search forward for `text` or `?text?` to search backward for `text`. If a search reaches the end of the file without finding `text`, it wraps around and continues to search back to the line where you are. A useful feature here is a search of the form `/^text/` which searches for `text` at the beginning of a line. Similarly `/text$/` searches for `text` at the end of a line. You can leave off the trailing `/` or `?` in these commands.

The current line has the symbolic name dot (`.`); this is most useful in a range of lines as in `., $p` which prints the current line plus the rest of the lines in the file. To move to the last line in the file, you can refer to it by its symbolic name `$`. Thus the command `$d` deletes the last line in the file, no matter what the current line is. Arithmetic with line references is also possible. Thus the line `$-5` is the fifth before the last and `.+20` is 20 lines after the current line.

You can find out the current line by typing ``.='`. This is useful if you wish to move or copy a section of text within a file or between files. Find the first and last line numbers you wish to copy or move. To move lines 10 through 20, type `10,20d a` to delete these lines from the file and place them in a buffer named `a`. `edit` has 26 such buffers named `a` through `z`. To put the contents of buffer `a` after the current line, type `put a`. If you want to move or copy these lines to another file, execute an `edit (e)` command after copying the lines; following the `e` command with the name of the other file you wish to edit, that is, `edit chapter2`. To copy lines without deleting them, use `yank (y)` in place of `d`. If the text you wish to move or copy is all within one file, it is not necessary to use named buffers. For example, to move lines 10 through 20 to the end of the file, type `10,20m $`.

OPTIONS

These options can be turned on or off using the `set` command in `ex(1)`.

<code>-l -s</code>	Suppress all interactive user feedback. This is useful when processing editor scripts.
<code>-l</code>	Set up for editing LISP programs.
<code>-L</code>	List the name of all files saved as the result of an editor or system crash.
<code>-R</code>	Readonly mode; the <code>readonly</code> flag is set, preventing accidental overwriting of the file.
<code>-r filename</code>	Edit <code>filename</code> after an editor or system crash. (Recovers the version of <code>filename</code> that was in the buffer when the crash occurred.)
<code>-t tag</code>	Edit the file containing the <code>tag</code> and position the editor at its definition.
<code>-v</code>	Start up in display editing state using <code>vi</code> . You can achieve the same effect by simply typing the <code>vi</code> command itself.

edit(1)

-V	Verbose. When <code>ex</code> commands are read by means of standard input, the input will be echoed to standard error. This may be useful when processing <code>ex</code> commands within shell scripts.
-x	Encryption option; when used, <code>edit</code> simulates the <code>X</code> command of <code>ex</code> and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the <code>crypt</code> command. The <code>X</code> command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the <code>-x</code> option.
-wn	Set the default window size to <i>n</i> . This is useful when using the editor over a slow speed line.
-C	Encryption option; same as the <code>-x</code> option, except that <code>vi</code> simulates the <code>C</code> command of <code>ex</code> . The <code>C</code> command is like the <code>X</code> command of <code>ex</code> , except that all text read in is assumed to have been encrypted.
+ <i>command</i> -c <i>command</i>	Begin editing by executing the specified editor command (usually a search or positioning command).

The *filename* argument indicates one or more files to be edited.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

`/usr/bin/edit`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

`/usr/xpg4/bin/edit`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	Enabled

SEE ALSO `ed(1)`, `ex(1)`, `vi(1)`, `attributes(5)`, `XPG4(5)`

NOTES The encryption options are provided with the Security Administration Utilities package, which is available only in the United States.

The `/usr/xpg4/bin/edit` utility is identical to `/usr/bin/edit`.

NAME	egrep – search a file for a pattern using full regular expressions
SYNOPSIS	<pre> /usr/bin/egrep [-bchilnsv] [-e <i>pattern_list</i>] [-f <i>file</i>] [<i>strings</i>] [<i>file...</i>] /usr/xpg4/bin/egrep [-bchilnsvx] [-e <i>pattern_list</i>] [-f <i>file</i>] [<i>strings</i>] [<i>file...</i>] </pre>
DESCRIPTION	<p>The <i>egrep</i> (<i>expression grep</i>) utility searches files for a pattern of characters and prints all lines that contain that pattern. <i>egrep</i> uses full regular expressions (expressions that have string values that use the full set of alphanumeric and special characters) to match the patterns. It uses a fast deterministic algorithm that sometimes needs exponential space.</p> <p>If no files are specified, <i>egrep</i> assumes standard input. Normally, each line found is copied to the standard output. The file name is printed before each line found if there is more than one input file.</p>
/usr/bin/egrep	<p>The <i>/usr/bin/egrep</i> utility accepts full regular expressions as described on the <i>regex(5)</i> manual page, except for \ (and \), \ (and \), \{ and \}, \< and \>, and \n, and with the addition of:</p> <ol style="list-style-type: none"> 1. A full regular expression followed by + that matches one or more occurrences of the full regular expression. 2. A full regular expression followed by ? that matches 0 or 1 occurrences of the full regular expression. 3. Full regular expressions separated by or by a NEWLINE that match strings that are matched by any of the expressions. 4. A full regular expression that may be enclosed in parentheses () for grouping. <p>Be careful using the characters \$, *, [, ^, , (,), and \ in <i>full regular expression</i>, because they are also meaningful to the shell. It is safest to enclose the entire <i>full regular expression</i> in single quotes `...`.</p> <p>The order of precedence of operators is [], then * ? +, then concatenation, then and NEWLINE.</p>
/usr/xpg4/bin/egrep	<p>The <i>/usr/xpg4/bin/egrep</i> utility uses the regular expressions described in the EXTENDED REGULAR EXPRESSIONS section of the <i>regex(5)</i> manual page.</p>
OPTIONS	<p>The following options are supported for both <i>/usr/bin/egrep</i> and <i>/usr/xpg4/bin/egrep</i>:</p> <ul style="list-style-type: none"> -b Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0). -c Print only a count of the lines that contain the pattern. -e <i>pattern_list</i> Search for a <i>pattern_list</i> (<i>full regular expression</i> that begins with a -). -f <i>file</i> Take the list of <i>full regular expressions</i> from <i>file</i>.

egrep(1)

- h Suppress printing of filenames when searching multiple files.
- i Ignore upper/lower case distinction during comparisons.
- l Print the names of files with matching lines once, separated by NEWLINEs. Does not repeat the names of files when the pattern is found more than once.
- n Precede each line by its line number in the file (first line is 1).
- s Work silently, that is, display nothing except error messages. This is useful for checking the error status.
- v Print all lines except those that contain the pattern.

/usr/xpg4/bin/egrep

The following option is supported for `/usr/xpg4/bin/egrep` only:

- x Consider only input lines that use all characters in the line to match an entire fixed string or regular expression to be matching lines.

OPERANDS

The following operands are supported:

file A path name of a file to be searched for the patterns. If no *file* operands are specified, the standard input will be used.

/usr/bin/egrep

pattern Specify a pattern to be used during the search for input.

/usr/xpg4/bin/egrep

pattern Specify one or more patterns to be used during the search for input. This operand is treated as if it were specified as *-epattern_list*.

USAGE

See `largefile(5)` for the description of the behavior of `egrep` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `egrep`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLS_PATH`.

EXIT STATUS

The following exit values are returned:

- 0 If any matches are found.
- 1 If no matches are found.
- 2 For syntax errors or inaccessible files (even if matches were found).

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

/usr/bin/egrep

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

`/usr/xpg4/bin/egrep`

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWxcu4
CSI	enabled

SEE ALSO `fgrep(1)`, `grep(1)`, `sed(1)`, `sh(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`, `regex(5)`, `regexp(5)`, `XPG4(5)`

NOTES Ideally there should be only one `grep` command, but there is not a single algorithm that spans a wide enough range of space-time tradeoffs.

Lines are limited only by the size of the available virtual memory.

`/usr/xpg4/bin/egrep`

The `/usr/xpg4/bin/egrep` utility is identical to `/usr/xpg4/bin/grep -E` (see `grep(1)`). Portable applications should use `/usr/xpg4/bin/grep -E`.

eject(1)

NAME	<code>eject</code> – eject media such as CD-ROM and floppy from drive																								
SYNOPSIS	<code>eject</code> [-dfnpq] [<i>device</i> <i>nickname</i>]																								
DESCRIPTION	<p><code>eject</code> is used for those removable media devices that do not have a manual eject button, or for those that do, but are managed by Volume Management (see <code>voladm(1M)</code>). The device may be specified by its name or by a nickname; if Volume Management is running and no device is specified, the default device is used.</p> <p>Only devices that support <code>eject</code> under program control respond to this command. <code>eject</code> responds differently, depending on whether or not Volume Management is running.</p>																								
With Volume Management	<p>When <code>eject</code> is used on media that can only be ejected manually, it will do everything except remove the media, including unmounting the file system if it is mounted. In this case, <code>eject</code> displays a message that the media can now be manually ejected. If a window system is running, the message is displayed as a pop-up window, unless the <code>-p</code> option is supplied. If no window system is running or the <code>-p</code> option is supplied, a message is displayed both to <code>stderr</code> and to the system console that the media can now be physically removed.</p> <p>Volume Management has the concept of a default device, which <code>eject</code> uses if no pathname or nickname is specified. Use the <code>-d</code> option to check what default device will be used.</p>																								
Without Volume Management	<p>When Volume Management is not running and a pathname is specified, <code>eject</code> sends the <code>eject</code> command to that pathname. If a nickname is supplied instead of a pathname, <code>eject</code> will recognize the following list:</p>																								
	<table border="1"><thead><tr><th>Nickname</th><th>Path</th></tr></thead><tbody><tr><td><code>fd</code></td><td><code>/dev/rdiskette</code></td></tr><tr><td><code>fd0</code></td><td><code>/dev/rdiskette</code></td></tr><tr><td><code>fd1</code></td><td><code>/dev/rdiskette1</code></td></tr><tr><td><code>diskette</code></td><td><code>/dev/rdiskette</code></td></tr><tr><td><code>diskette0</code></td><td><code>/dev/rdiskette0</code></td></tr><tr><td><code>diskette1</code></td><td><code>/dev/rdiskette1</code></td></tr><tr><td><code>rdiskette</code></td><td><code>/dev/rdiskette</code></td></tr><tr><td><code>rdiskette0</code></td><td><code>/dev/rdiskette0</code></td></tr><tr><td><code>rdiskette1</code></td><td><code>/dev/rdiskette1</code></td></tr><tr><td><code>floppy</code></td><td><code>/dev/rdiskette</code></td></tr><tr><td><code>floppy0</code></td><td><code>/dev/rdiskette0</code></td></tr></tbody></table>	Nickname	Path	<code>fd</code>	<code>/dev/rdiskette</code>	<code>fd0</code>	<code>/dev/rdiskette</code>	<code>fd1</code>	<code>/dev/rdiskette1</code>	<code>diskette</code>	<code>/dev/rdiskette</code>	<code>diskette0</code>	<code>/dev/rdiskette0</code>	<code>diskette1</code>	<code>/dev/rdiskette1</code>	<code>rdiskette</code>	<code>/dev/rdiskette</code>	<code>rdiskette0</code>	<code>/dev/rdiskette0</code>	<code>rdiskette1</code>	<code>/dev/rdiskette1</code>	<code>floppy</code>	<code>/dev/rdiskette</code>	<code>floppy0</code>	<code>/dev/rdiskette0</code>
Nickname	Path																								
<code>fd</code>	<code>/dev/rdiskette</code>																								
<code>fd0</code>	<code>/dev/rdiskette</code>																								
<code>fd1</code>	<code>/dev/rdiskette1</code>																								
<code>diskette</code>	<code>/dev/rdiskette</code>																								
<code>diskette0</code>	<code>/dev/rdiskette0</code>																								
<code>diskette1</code>	<code>/dev/rdiskette1</code>																								
<code>rdiskette</code>	<code>/dev/rdiskette</code>																								
<code>rdiskette0</code>	<code>/dev/rdiskette0</code>																								
<code>rdiskette1</code>	<code>/dev/rdiskette1</code>																								
<code>floppy</code>	<code>/dev/rdiskette</code>																								
<code>floppy0</code>	<code>/dev/rdiskette0</code>																								

floppy1	/dev/rdiskette1
---------	-----------------

The list above can be reproduced with the `-n` option.

Do not physically eject media from a device which contains mounted file systems. `eject` automatically searches for any mounted file systems which reside on the device and attempts to unmount them prior to ejecting the media (see `mount(1M)`). If the unmount operation fails, `eject` prints a warning message and exits. The `-f` option may be used to specify an eject even if the device contains mounted partitions; this option works only if Volume Management is not running.

`eject` can also display its default device and a list of nicknames.

If you have inserted a floppy diskette, you must use `volcheck(1)` before ejecting the media to inform Volume Management of the floppy's presence.

OPTIONS The following options are supported:

- `-d` Display the name of the default device to be ejected.
- `-f` Force the device to eject even if it is busy, if Volume Management is *not* running.
- `-n` Display the nickname to device name translation table.
- `-p` Do not try to call the `eject_popup` program.
- `-q` Query to see if the media is present.

OPERANDS The following operands are supported:

- device* Specify which device to eject, by the name it appears in the directory `/dev`.
- nickname* Specify which device to eject, by its nickname as known to this command.

EXAMPLES **EXAMPLE 1** Examples of the `eject` command.

To eject a CD from its drive, while Volume Management is running (assuming only one CD-ROM drive):

```
example> eject cdrom0
```

To eject a floppy disk (whether or not Volume Management is running):

```
example> eject floppy0
```

To eject a CD-ROM drive with pathname `/dev/dsk/c0t3d0s2`, without Volume Management running:

```
example> eject /dev/dsk/c0t3d0s2
```

eject(1)

EXAMPLE 1 Examples of the `eject` command. (Continued)

EXIT STATUS The following exit codes are returned:

- 0 The operation was successful or, with the `-q` option, the media *is* in the drive.
- 1 The operation was unsuccessful or, with the `-q` option, the media is *not* in the drive.
- 2 Invalid options were specified.
- 3 An `ioctl()` request failed.
- 4 Manually ejectable media is now okay to remove.

FILES

<code>/dev/diskette0</code>	default diskette file
<code>/dev/sr0</code>	default CD-ROM file (deprecated)
<code>/dev/dsk/c0t6d0s2</code>	default CD-ROM file
<code>/usr/lib/vold/eject_popup</code>	popup used for manually ejected media

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `volcancel(1)`, `volcheck(1)`, `volmissing(1)`, `mount(1M)`, `rmmount(1M)`, `vold(1M)`, `ioctl(2)`, `rmmount.conf(4)`, `vold.conf(4)`, `attributes(5)`, `volfs(7FS)`

DIAGNOSTICS A short help message is printed if an unknown option is specified. A diagnostic is printed if the device name cannot be opened or does not support `eject`.

Device Busy An attempt was made to eject a device that has a mounted file system. A warning message is printed when doing a forced `eject` of a mounted device.

BUGS There should be a way to change the default on a per-user basis.

If Volume Management is not running, it is possible to eject a volume that is currently mounted (see `mount(1M)`). For example, if you have a CD-ROM drive at `/dev/dsk/c0t3d0s2` mounted on `/mnt`, the following command (without Volume Management running) will work:

```
example> eject /dev/dsk/c0t3d0s0
```

since both slices `s0` and `s2` reference the whole CD-ROM drive.

NAME	elfdump – dump selected parts of an object file
SYNOPSIS	elfdump [-Ccodeihikmnrsv] [-N <i>name</i>] [-w <i>file</i>] <i>filename...</i>
DESCRIPTION	<p>The <code>elfdump</code> utility symbolically dumps selected parts of the specified object file(s). The options allow specific portions of the file to be displayed.</p> <p>The <code>elfdump</code> utility is similar in function to the <code>dump(1)</code> utility, which offers an older and less user-friendly interface than <code>elfdump</code>, although <code>dump</code> may be more appropriate for certain uses such as in shell scripts.</p> <p>Archive files, produced by <code>ar(1)</code>, can also be inspected with <code>elfdump</code>. In this case each object within the archive is processed using the options supplied.</p> <p>For a complete description of the displayed information, refer to the <i>Linker and Libraries Guide</i>.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> - c Dumps section header information. -C Demangles C++ symbol names. -d Dumps the contents of the <code>.dynamic</code> section. -e Dumps the elf header. -G Dumps the contents of the <code>.got</code> section. -h Dumps the contents of the <code>.hash</code> section. -i Dumps the contents of the <code>.interp</code> section. -k Calculates the elf checksum (see <code>gelf_checksum(3ELF)</code>). -m Dumps the contents of the <code>.SUNW_move</code> section. -n Dumps the contents of the <code>.note</code> section. -N <i>name</i> Qualifies an option with a specific name. For example, in a file that contains more than one symbol table, the <code>.dynsym</code> table can be displayed using: <ul style="list-style-type: none"> % <code>elfdump -s -N .dynsym filename</code> -p Dumps the program headers. -r Dumps the contents of the relocation sections (that is, <code>.rel[a]</code>). -s Dumps the contents of the symbol table sections (that is, <code>.dynsym</code> and/or <code>.symtab</code>) and, in the case of archives, dumps the archive symbol table. Individual sections can be specified with the <code>-N</code> option, or an archive symbol table can be specified using the special section name <code>-N ARSYM</code>.

elfdump(1)

In addition to the standard symbol table information, the version definition index of the symbol is also provided under the *ver* heading.

- v** Dumps the contents of the version sections (that is, *.SUNW_version*).
- w *file*** Writes the contents of a section specified with the **-N** option to the named file. This is useful for extracting an individual section's data for additional processing. For example, extracting the *.text* section of a file can be carried out with:
- ```
% elfdump -w text.out -N .text filename
```

**OPERANDS** The following operand is supported:

*filename* The name of the specified object file.

**FILES** *liblddb.g.so* linker debugging library

**ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | enable, disable – enable/disable LP printers                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre>/usr/bin/enable printer...</pre> <pre>/usr/bin/disable [-c   -W] [-r [reason]] printer...</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The <code>enable</code> command activates printers, enabling them to print requests submitted by the <code>lp</code> command. <code>enable</code> must be run on the printer server.</p> <p>The <code>disable</code> command deactivates printers, disabling them from printing requests submitted by the <code>lp</code> command. By default, any requests that are currently printing on <i>printer</i> will be reprinted in their entirety either on <i>printer</i> or another member of the same class of printers. The <code>disable</code> command must be run on the print server.</p> <p>Use <code>lpstat -p</code> to check the status of printers.</p> <p><code>enable</code> and <code>disable</code> only effect queueing on the print server's spooling system. Executing these commands from a client system will have no effect on the server.</p>                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p>The following options are supported for use with <code>disable</code>:</p> <ul style="list-style-type: none"> <li>-c               Cancel any requests that are currently printing on <i>printer</i>. This option cannot be used with the <code>-W</code> option. If the printer is remote, the <code>-c</code> option will be silently ignored.</li> <li>-W               Wait until the request currently being printed is finished before disabling <i>printer</i>. This option cannot be used with the <code>-c</code> option. If the printer is remote, the <code>-W</code> option will be silently ignored.</li> <li>-r [<i>reason</i>]     Assign a <i>reason</i> for the disabling of the printer(s). This <i>reason</i> applies to all printers specified. This <i>reason</i> is reported by <code>lpstat -p</code>. Enclose <i>reason</i> in quotes if it contains blanks. The default reason is <code>unknown reason</code> for the existing printer, and <code>new printer</code> for a printer added to the system but not yet enabled.</li> </ul> |
| <b>OPERANDS</b>    | <p>The following operands are supported for both <code>enable</code> and <code>disable</code>:</p> <p><i>printer</i>           The name of the printer to be enabled or disabled. Specify <i>printer</i> using atomic name. See <code>printers.conf(4)</code> for information regarding the naming conventions for atomic names.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <ul style="list-style-type: none"> <li>0                Successful completion.</li> <li>non-zero        An error occurred.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>                  | env – set environment for command invocation                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>              | <pre> /usr/bin/env [-i   -] [name=value...] [utility [arg... ]] /usr/xpg4/bin/env [-i   -] [name=value...] [utility [arg... ]] </pre>                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b>           | <p>The env utility obtains the current environment, modifies it according to its arguments, then invokes the utility named by the <i>utility</i> operand with the modified environment.</p> <p>Optional arguments are passed to <i>utility</i>. If no <i>utility</i> operand is specified, the resulting environment is written to the standard output, with one <i>name=value</i> pair per line.</p>                                                                                                                |
| <b>/usr/bin</b>              | If env executes commands with arguments, it uses the default shell /usr/bin/sh (see sh(1)).                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>/usr/xpg4/bin</b>         | If env executes commands with arguments, it uses /usr/xpg4/bin/sh (see ksh(1)).                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPTIONS</b>               | <p>The following options are supported:</p> <p><b>-i   -</b>                Ignores the environment that would otherwise be inherited from the current shell. Restricts the environment for <i>utility</i> to that specified by the arguments.</p>                                                                                                                                                                                                                                                                   |
| <b>OPERANDS</b>              | <p>The following operands are supported:</p> <p><i>name=value</i>            Arguments of the form <i>name=value</i> modify the execution environment, and are placed into the inherited environment before <i>utility</i> is invoked.</p> <p><i>utility</i>                The name of the utility to be invoked. If <i>utility</i> names any of the special shell built-in utilities, the results are undefined.</p> <p><i>arg</i>                    A string to pass as an argument for the invoked utility.</p> |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Invoking utilities with new PATH values</p> <p>The following utility:</p> <pre>example% env -i PATH=/mybin mygrep xyz myfile</pre> <p>invokes the utility mygrep with a new PATH value as the only entry in its environment. In this case, PATH is used to locate mygrep, which then must reside in /mybin.</p>                                                                                                                                                                                  |
| <b>ENVIRONMENT VARIABLES</b> | See environ(5) for descriptions of the following environment variables that affect the execution of env: LC_CTYPE, LC_MESSAGES, and NLSPATH.                                                                                                                                                                                                                                                                                                                                                                         |
| <b>EXIT STATUS</b>           | <p>If <i>utility</i> is invoked, the exit status of env is the exit status of <i>utility</i>; otherwise, the env utility is with one of the following values:</p> <p><b>0</b>                    Successful completion.</p>                                                                                                                                                                                                                                                                                          |

env(1)

- 1-125 An error occurred.
- 126 *utility* was found but could not be invoked.
- 127 *utility* could not be found.

| <b>NAME</b>         | eqn, neqn, checkeq – typeset mathematics test                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>     | <pre>eqn [-d xy] [-f n] [-p n] [-s n] [file...] neqn [file...] checkeq [file...]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b>  | <p>eqn and neqn are language processors to assist in describing equations. eqn is a preprocessor for troff(1) and is intended for devices that can print troff's output. neqn is a preprocessor for nroff(1) and is intended for use with terminals. Usage is almost always:</p> <pre>example% eqn file . . .   troff example% neqn file . . .   nroff</pre> <p>If no <i>files</i> are specified, eqn and neqn read from the standard input. A line beginning with .EQ marks the start of an equation; the end of an equation is marked by a line beginning with .EN. Neither of these lines is altered, so they may be defined in macro packages to get centering, numbering, etc. It is also possible to set two characters as "delimiters"; subsequent text between delimiters is also treated as eqn input.</p> <p>checkeq reports missing or unbalanced delimiters and .EQ/.EN pairs.</p>                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>      | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-dxy      Set equation delimiters set to characters <i>x</i> and <i>y</i> with the command-line argument. The more common way to do this is with <code>delim xy</code> between .EQ and .EN. The left and right delimiters may be identical. Delimiters are turned off by <code>delim off</code> appearing in the text. All text that is neither between delimiters nor between .EQ and .EN is passed through untouched.</li> <li>-fn        Change font to <i>n</i> globally in the document. The font can also be changed globally in the body of the document by using the <code>gfont n</code> directive, where <i>n</i> is the font specification.</li> <li>-pn        Reduce subscripts and superscripts by <i>n</i> point sizes from the previous size. In the absence of the -p option, subscripts and superscripts are reduced by 3 point sizes from the previous size.</li> <li>-sn        Change point size to <i>n</i> globally in the document. The point size can also be changed globally in the body of the document by using the <code>gsize n</code> directive, where <i>n</i> is the point size.</li> </ul> |
| <b>OPERANDS</b>     | <p>The following operands are supported:</p> <p><i>file</i>                      The nroff or troff file processed by eqn or neqn.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>EQN LANGUAGE</b> | <p>The nroff version of this description depicts the output of neqn to the terminal screen exactly as neqn is able to display it. To see an accurate depiction of the output the printed version of this page should be viewed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

eqn(1)

Tokens within eqn are separated by braces, double quotes, tildes, circumflexes, SPACE, TAB, or NEWLINE characters. Braces { } are used for grouping; generally speaking, anywhere a single character like  $x$  could appear, a complicated construction enclosed in braces may be used instead. A tilde (~) represents a full SPACE in the output; a circumflex (^) half as much.

Subscripts and superscripts:

These are produced with the keywords sub and sup.

|                           |                     |
|---------------------------|---------------------|
| x sub i                   | makes $x_i$         |
| a sub i sup 2             | produces $a_i^2$    |
| e sup {x sup 2 + y sup 2} | gives $e^{x^2+y^2}$ |

Fractions:

Fractions are made with over.

a over b  
yields

$$\frac{a}{b}$$

Square Roots:

These are made with sqrt

1 over sqrt {ax sup 2 +bx+c}  
results in

$$\frac{1}{\sqrt{ax^2+bx+c}}$$

Limits:

The keywords from and to introduce lower and upper limits on arbitrary things:

lim from {n→ inf } sum from 0 to n x sub i  
makes

$$\lim_{n \rightarrow \infty} \sum_0^n x_i$$

**EXAMPLE 1** Invoking utilities with new PATH values (Continued)**Brackets and Braces:**

Left and right brackets, braces, etc., of the right height are made with `left` and `right`.

`left [ x sup 2 + y sup 2 over alpha right ] ~~~1`  
produces

$$\left[ x^2 + \frac{y^2}{\alpha} \right] = 1$$

The `right` clause is optional. Legal characters after `left` and `right` are braces, brackets, bars, `c` and `f` for ceiling and floor, and `"` for nothing at all (useful for a right-side-only bracket).

**Vertical piles:**

Vertical piles of things are made with `pile`, `lpile`, `cpile`, and `rpile`.

`pile {a above b above c}`  
produces

*a*  
*b*  
*c*

There can be an arbitrary number of elements in a pile. `lpile` left-justifies, `pile` and `cpile` center, with different vertical spacing, and `rpile` right justifies.

**Matrices:**

Matrices are made with `matrix`.

`matrix { lcol { x sub i above y sub 2 } ccol { 1 above 2 } }`  
produces  $\$matrix \{ lcol \{ x \text{ sub } i \text{ above } y \text{ sub } 2 \} ccol \{ 1 \text{ above } 2 \} \$$

$x_i \ 1$   
 $y_2 \ 2$

In addition, there is `rcol` for a right-justified column.

eqn(1)

Diacritical marks:

Diacritical marks are made with dot, dotdot, hat, tilde, bar, vec, dyad, and under.

x dot = f(t) bar  
is

$$\dot{x} = \overline{f(t)}$$

y dotdot bar ~~~ n under  
is

$$\ddot{y} = \underline{n}$$

x vec ~~~ y dyad  
is

$$\vec{x} = \hat{y}$$

Sizes and Fonts:

Sizes and font can be changed with size *n* or size  $\pm n$ , roman, italic, bold, and font *n*. Size and fonts can be changed globally in a document by gsize *n* and gfont *n*, or by the command-line arguments -*sn* and -*fn*.

Successive display arguments:

Successive display arguments can be lined up. Place mark before the desired lineup point in the first equation; place lineup at the place that is to line up vertically in subsequent equations.

Shorthands:

Shorthands may be defined or existing keywords redefined with define:

```
define thing % replacement %
```

Defines a new token called *thing* which will be replaced by *replacement* whenever it appears thereafter. The % may be any character that does not occur in *replacement*.

Keywords and Shorthands:

Keywords like sum int inf and shorthands like >= → and != are recognized.

**Greek letters:**

Greek letters are spelled out in the desired case, as in `alpha` or `GAMMA`.

**Mathematical words:**

Mathematical words like `sin`, `cos`, and `log` are made Roman automatically.

`troff(1)` four-character escapes like `\(b(•)` can be used anywhere. Strings enclosed in double quotes `"..."` are passed through untouched; this permits keywords to be entered as text, and can be used to communicate with `troff` when all else fails.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWdoc         |

**SEE ALSO**

`nroff(1)`, `tbl(1)`, `troff(1)`, `attributes(5)`, `ms(5)`

**BUGS**

To embolden characters such as digits and parentheses, it is necessary to quote them, as in `'bold "12.3"'`.

## error(1)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | error – insert compiler error messages at right source lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>error</b> [-n] [-q] [-s] [-v] [-t <i>suffixlist</i> ] [-I <i>ignorefile</i> ] [ <i>filename</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>error analyzes error messages produced by a number of compilers and language processors. It replaces the painful, traditional methods of scribbling abbreviations of errors on paper, and permits error messages and source code to be viewed simultaneously.</p> <p>error looks at error messages, either from the specified file <i>filename</i> or from the standard input, and:</p> <ul style="list-style-type: none"><li>■ Determines which language processor produced each error message.</li><li>■ Determines the file name and line number of the erroneous line.</li><li>■ Inserts the error message into the source file immediately preceding the erroneous line.</li></ul> <p>Error messages that can't be categorized by language processor or content are not inserted into any file, but are sent to the standard output. <i>error</i> touches source files only after all input has been read.</p> <p><i>error</i> is intended to be run with its standard input connected with a pipe to the error message source. Some language processors put error messages on their standard error file; others put their messages on the standard output. Hence, both error sources should be piped together into <i>error</i>. For example, when using the <i>cs</i>h syntax, the following command analyzes all the error messages produced by whatever programs <i>make</i>(1S) runs when making <i>lint</i>:</p> <pre>example% make -s lint   &amp; error -q -v</pre> <p><i>error</i> knows about the error messages produced by: <i>as</i>(1), <i>cpp</i>(1), <i>ld</i>(1), <i>cc</i>(1B), <i>make</i>(1S) and other compilers. For all languages except Pascal, error messages are restricted to one line. Some error messages refer to more than one line in more than one file, in which case <i>error</i> duplicates the error message and inserts it in all the appropriate places.</p> |
| <b>OPTIONS</b>     | <p>-n Do <i>not</i> touch any files; all error messages are sent to the standard output.</p> <p>-q <i>error</i> asks whether the file should be touched. A 'y' or 'n' to the question is necessary to continue. Absence of the -q option implies that all referenced files (except those referring to discarded error messages) are to be touched.</p> <p>-s Print out statistics regarding the error categorization.</p> <p>-v After all files have been touched, overlay the visual editor <i>vi</i> with it set up to edit all files touched, and positioned in the first touched file at the first error. If <i>vi</i>(1) can't be found, try <i>ex</i>(1) or <i>ed</i>(1) from standard places.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

error(1)

`-t suffixlist` Take the following argument as a suffix list. Files whose suffices do not appear in the suffix list are not touched. The suffix list is dot separated, and '\*' wildcards work. Thus the suffix list:

`.c.y.f*.h`

allows error to touch files ending with '.c', '.y', '.f\*' and '.h'.

error catches interrupt and terminate signals, and terminates in an orderly fashion.

#### EXAMPLES **EXAMPLE 1** Examples of the error command.

In the following C shell (`/usr/bin/csh`) example, error takes its input from the FORTRAN compiler:

```
example% f77 -c any.f |& error options
```

Here is the same example using the Korn shell (`/usr/bin/ksh`):

```
example% f77 -c any.f 2>&1 | error options
```

#### USAGE error does one of six things with error messages.

**synchronize** Some language processors produce short errors describing which file they are processing. error uses these to determine the file name for languages that do not include the file name in each error message. These synchronization messages are consumed entirely by error.

**discard** Error messages from lint that refer to one of the two lint libraries, `/usr/lib/lint/llib-1c` and `/usr/lib/lint/llib-port` are discarded, to prevent accidentally touching these libraries. Again, these error messages are consumed entirely by error.

**nullify** Error messages from lint can be nullified if they refer to a specific function, which is known to generate diagnostics which are not interesting. Nullified error messages are not inserted into the source file, but are written to the standard output. The names of functions to ignore are taken from either the file named `.errorrc` in the user's home directory, or from the file named by the `-I` option. If the file does not exist, no error messages are nullified. If the file does exist, there must be one function name per line.

## error(1)

|                   |                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| not file specific | Error messages that can't be intuited are grouped together, and written to the standard output before any files are touched. They are not inserted into any source file. |
| file specific     | Error messages that refer to a specific file but to no specific line are written to the standard output when that file is touched.                                       |
| true errors       | Error messages that can be intuited are candidates for insertion into the file to which they refer.                                                                      |

Only true error messages are inserted into source files. Other error messages are consumed entirely by `error` or are written to the standard output. `error` inserts the error messages into the source file on the line preceding the line number in the error message. Each error message is turned into a one line comment for the language, and is internally flagged with the string `###` at the beginning of the error, and `%%%` at the end of the error. This makes pattern searching for errors easier with an editor, and allows the messages to be easily removed. In addition, each error message contains the source line number for the line the message refers to. A reasonably formatted source program can be recompiled with the error messages still in it, without having the error messages themselves cause future errors. For poorly formatted source programs in free format languages, such as C or Pascal, it is possible to insert a comment into another comment, which can wreak havoc with a future compilation. To avoid this, format the source program so there are no language statements on the same line as the end of a comment.

**FILES** `~/ .errorrc` function names to ignore for lint error messages  
`/dev/tty` user's teletype

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWbtool       |

**SEE ALSO** `as(1)`, `cc(1B)`, `cpp(1)`, `csh(1)`, `ed(1)`, `ex(1)`, `make(1S)`, `ld(1)`, `vi(1)`, `attributes(5)`

**BUGS** Opens the `tty`-device directly for user input.

Source files with links make a new copy of the file with only one link to it.

Changing a language processor's error message format may cause `error` to not understand the error message.

`error`, since it is purely mechanical, will not filter out subsequent errors caused by "floodgating" initiated by one syntactically trivial error. Humans are still much better at discarding these related errors.

error(1)

Pascal error messages belong after the lines affected, error puts them before. The alignment of the `|` marking the point of error is also disturbed by error.

error was designed for work on CRT 's at reasonably high speed. It is less pleasant on slow speed terminals, and was not designed for use on hardcopy terminals.

| <b>DESCRIPTION</b> | <p>The <code>ex</code> utility is the root of a family of editors: <code>ex</code> and <code>vi</code>. <code>ex</code> is a superset of <code>ed(1)</code>, with the most notable extension being a display editing facility. Display based editing is the focus of <code>vi</code>.</p> <p>If you have a CRT terminal, you may wish to use a display based editor; in this case see <code>vi(1)</code>, which is a command which focuses on the display-editing portion of <code>ex</code>.</p> <p>If you have used <code>ed</code> you will find that, in addition to having all of the <code>ed</code> commands available, <code>ex</code> has a number of additional features useful on CRT terminals. Intelligent terminals and high speed terminals are very pleasant to use with <code>vi</code>. Generally, the <code>ex</code> editor uses far more of the capabilities of terminals than <code>ed</code> does, and uses the terminal capability data base (see <code>terminfo(4)</code>) and the type of the terminal you are using from the environment variable <code>TERM</code> to determine how to drive your terminal efficiently. The editor makes use of features such as insert and delete character and line in its <code>visual</code> command (which can be abbreviated <code>vi</code>) and which is the central mode of editing when using the <code>vi</code> command.</p> <p>The <code>ex</code> utility contains a number of features for easily viewing the text of the file. The <code>z</code> command gives easy access to windows of text. Typing <code>^D</code> (CTRL-D) causes the editor to scroll a half-window of text and is more useful for quickly stepping through a file than just typing return. Of course, the screen-oriented <code>visual</code> mode gives constant access to editing context.</p> <p>The <code>ex</code> utility gives you help when you make mistakes. The <code>undo</code> (<code>u</code>) command allows you to reverse any single change which goes astray. <code>ex</code> gives you a lot of feedback, normally printing changed lines, and indicates when more than a few lines are affected by a command so that it is easy to detect when a command has affected more lines than it should have.</p> <p>The editor also normally prevents overwriting existing files, unless you edited them, so that you do not accidentally overwrite a file other than the one you are editing. If the system (or editor) crashes, or you accidentally hang up the telephone, you can use the editor <code>recover</code> command (or <code>-r file</code> option) to retrieve your work. This will get you back to within a few lines of where you left off.</p> <p>The <code>ex</code> utility has several features for dealing with more than one file at a time. You can give it a list of files on the command line and use the <code>next</code> (<code>n</code>) command to deal with each in turn. The <code>next</code> command can also be given a list of file names, or a pattern as used by the shell to specify a new set of files to be dealt with. In general, file names in the editor may be formed with full shell metasyntax. The metacharacter <code>'%</code>' is also available in forming file names and is replaced by the name of the current file.</p> |

The editor has a group of buffers whose names are the ASCII lower-case letters (a-z). You can place text in these named buffers where it is available to be inserted elsewhere in the file. The contents of these buffers remain available when you begin editing a new file using the `edit (e)` command.

There is a command `&` in `ex` which repeats the last `substitute` command. In addition, there is a confirmed substitute command. You give a range of substitutions to be done and the editor interactively asks whether each substitution is desired.

It is possible to ignore the case of letters in searches and substitutions. `ex` also allows regular expressions which match words to be constructed. This is convenient, for example, in searching for the word "edit" if your document also contains the word "editor."

`ex` has a set of options which you can set to tailor it to your liking. One option which is very useful is the `autoindent` option that allows the editor to supply leading white space to align text automatically. You can then use `^D` as a backtab and space or tab to move forward to align new code easily.

Miscellaneous useful features include an intelligent `join (j)` command that supplies white space between joined lines automatically, commands `<` and `>` which shift groups of lines, and the ability to filter portions of the buffer through commands such as `sort`.

**OPTIONS** The following options are supported:

|                      |                                                                                                                                                                                                           |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-l -s</code>   | Suppress all interactive user feedback. This is useful when processing editor scripts.                                                                                                                    |
| <code>-l</code>      | Set up for editing LISP programs.                                                                                                                                                                         |
| <code>-L</code>      | List the name of all files saved as the result of an editor or system crash.                                                                                                                              |
| <code>-R</code>      | Readonly mode; the <code>readonly</code> flag is set, preventing accidental overwriting of the file.                                                                                                      |
| <code>-r file</code> | Edit <i>file</i> after an editor or system crash. (Recovers the version of <i>file</i> that was in the buffer when the crash occurred.)                                                                   |
| <code>-t tag</code>  | Edit the file containing the <i>tag</i> and position the editor at its definition.                                                                                                                        |
| <code>-v</code>      | Start up in display editing state using <code>vi</code> . You can achieve the same effect by simply typing the <code>vi</code> command itself.                                                            |
| <code>-V</code>      | Verbose. When <code>ex</code> commands are read by means of standard input, the input will be echoed to standard error. This may be useful when processing <code>ex</code> commands within shell scripts. |

ex(1)

**-x** Encryption option. Simulates the X command and prompts the user for a key. This key is used to encrypt and decrypt text using the algorithm of the `crypt` command. The X command makes an educated guess to determine whether text read in is encrypted or not. The temporary buffer file is encrypted also, using a transformed version of the key typed in for the `-x` option.

**-wn** Set the default window size to *n*. This is useful when using the editor over a slow speed line.

**-C** Encryption option. Same as the `-x` option, except simulates the C command. The C command is like the X command, except that all text read in is assumed to have been encrypted.

**+command | -c command** Begin editing by executing the specified editor *command* (usually a search or positioning command).

**/usr/xpg4/bin/ex** If both the `-t tag` and the `-c command` options are given, the `-t tag` will be processed first. That is, the file containing the tag is selected by `-t` and then the command is executed.

**OPERANDS** The following operand is supported:

*file* A path name of a file to be edited.

**USAGE**

**ex States**

**Command** Normal and initial state. Input prompted for by “:”. Your line kill character cancels a partial command.

**Insert** Entered by `a`, `i`, or `c`. Arbitrary text may be entered. Insert state normally is terminated by a line having only “.” on it, or, abnormally, with an interrupt.

**Visual** Entered by typing `vi`; terminated by typing `Q` or `^\` (CTRL-`\`).

**ex Command Names and Abbreviations**

| Command Name | Abbrev-iation | Command Name | Abbrev-iation | Command Name | Abbrev-iation |
|--------------|---------------|--------------|---------------|--------------|---------------|
| abbrev       | ab            | map          |               | set          | se            |
| append       | a             | mark         | ma            | shell        | sh            |
| args         | ar            | move         | m             | source       | so            |
| change       | c             | next         | n             | substitute   | s             |
| copy         | co            | number       | nu            | unabbrev     | unab          |
| delete       | d             | preserve     | pre           | undo         | u             |

| Command Name | Abbrev-iation | Command Name | Abbrev-iation | Command Name | Abbrev-iation |
|--------------|---------------|--------------|---------------|--------------|---------------|
| edit         | e             | print        | p             | unmap        | unm           |
| file         | f             | put          | pu            | version      | ve            |

### ex Command Arguments

For all of the `ex` commands listed below, if both a count and a range are specified for a command that uses them, the number of lines affected will be taken from the count value rather than the range. The starting line for the command is taken to be the first line addressed by the range.

|                  |                                                                       |
|------------------|-----------------------------------------------------------------------|
| Abbreviate       | ab[brev] word rhs                                                     |
| Append           | [line] a[ppend][!]                                                    |
| Arguments        | ar[gs]                                                                |
| Change           | [range] c[hange][!] [count]                                           |
| Change Directory | chd[ir][!] [directory]; cd[!] [directory]                             |

*OpenWindows Advanced User's Guide*

**AUTHOR** The vi and ex utilities are based on software developed by The University of California, Berkeley California, Computer Science Division, Department of Electrical Engineering and Computer Science.

**NOTES** Several options, although they continue to be supported, have been replaced in the documentation by options that follow the Command Syntax Standard (see *intro(1)*). The `-` option has been replaced by `-s`, a `-r` option that is not followed with an option-argument has been replaced by `-L`, and `+command` has been replaced by `-c command`.

The message file `too large to recover` with `-r` option, which is seen when a file is loaded, indicates that the file can be edited and saved successfully, but if the editing session is lost, recovery of the file with the `-r` option will not be possible.

The `z` command prints the number of logical rather than physical lines. More than a screen full of output may result if long lines are present.

File input/output errors do not print a name if the command line `-s` option is used.

The editing environment defaults to certain configuration options. When an editing session is initiated, `ex` attempts to read the `EXINIT` environment variable. If it exists, the editor uses the values defined in `EXINIT`, otherwise the values set in `$HOME/.exrc` are used. If `$HOME/.exrc` does not exist, the default values are used.

To use a copy of `.exrc` located in the current directory other than `$HOME`, set the `exrc` option in `EXINIT` or `$HOME/.exrc`. Options set in `EXINIT` can be turned off in a local `.exrc` only if `exrc` is set in `EXINIT` or `$HOME/.exrc`.

There is no easy way to do a single scan ignoring case.

The editor does not warn if text is placed in named buffers and not used before exiting the editor.

Null characters are discarded in input files and cannot appear in resultant files.

The standard Solaris version of `ex` will be replaced by the POSIX.2-conforming version (see *standards(5)*) in the future. Scripts which use the `ex` family of addressing and features should use the `/usr/xpg4/bin` version of these utilities.

## exec(1)

| <b>DESCRIPTION</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>sh</b>          | The <b>exec</b> command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and, if no other arguments are given, cause the shell input/output to be modified.<br><br>The <i>arguments</i> to the <b>eval</b> built-in are read as input to the shell and the resulting command(s) executed.                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>cs</b> <b>h</b> | <b>exec</b> executes <i>command</i> in place of the current shell, which terminates.<br><br><b>eval</b> reads its <i>arguments</i> as input to the shell and executes the resulting command(s). This is usually used to execute commands generated as the result of command or variable substitution.<br><br><b>source</b> reads commands from <i>name</i> . <b>source</b> commands may be nested, but if they are nested too deeply the shell may run out of file descriptors. An error in a sourced file at any level terminates all nested <b>source</b> commands.<br><br>-h           Place commands from the file <i>name</i> on the history list without executing them.                                                                                        |
| <b>ksh</b>         | With the <b>exec</b> built-in, if <i>arg</i> is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.<br><br>The arguments to <b>eval</b> are read as input to the shell and the resulting command(s) executed.<br><br>On this man page, <b>ksh(1)</b> commands that are preceded by one or two * (asterisks) are treated specially in the following ways: |

exec(1)

1. Variable assignment lists preceding the command remain in effect when the command completes.
2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>sh</b>          | <p><b>exit</b> will cause the calling shell or shell script to exit with the exit status specified by <i>n</i>. If <i>n</i> is omitted the exit status is that of the last command executed (an EOF will also cause the shell to exit.)</p> <p><b>return</b> causes a function to exit with the return value specified by <i>n</i>. If <i>n</i> is omitted, the return status is that of the last command executed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>cs</b> <b>h</b> | <p><b>exit</b> will cause the calling shell or shell script to exit, either with the value of the status variable or with the value specified by the expression <i>expr</i>.</p> <p>The <b>goto</b> built-in uses a specified <i>label</i> as a search string amongst commands. The shell rewinds its input as much as possible and searches for a line of the form <i>label</i> : possibly preceded by space or tab characters. Execution continues after the indicated line. It is an error to jump to a label that occurs between a <b>while</b> or <b>for</b> built-in command and its corresponding <b>end</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>ksh</b>         | <p><b>exit</b> will cause the calling shell or shell script to exit with the exit status specified by <i>n</i>. The value will be the least significant 8 bits of the specified status. If <i>n</i> is omitted then the exit status is that of the last command executed. When <b>exit</b> occurs when executing a <b>trap</b>, the last command refers to the command that executed before the trap was invoked. An end-of-file will also cause the shell to exit except for a shell which has the <b>ignoreeof</b> option (See <b>set</b> below) turned on.</p> <p><b>return</b> causes a shell function or <b>'.'</b> script to return to the invoking script with the return status specified by <i>n</i>. The value will be the least significant 8 bits of the specified status. If <i>n</i> is omitted then the return status is that of the last command executed. If <b>return</b> is invoked while not in a function or a <b>'.'</b> script, then it is the same as an <b>exit</b>.</p> <p>On this man page, <b>ksh(1)</b> commands that are preceded by one or two * (asterisks) are treated specially in the following ways:</p> <ol style="list-style-type: none"><li>1. Variable assignment lists preceding the command remain in effect when the command completes.</li></ol> |

exit(1)

2. I/O redirections are processed after variable assignments.
3. Errors cause a script that contains them to abort.
4. Words, following a command preceded by \*\* that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.

| <b>NAME</b>        | expand, unexpand – expand TAB characters to SPACE characters, and vice versa                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>expand</b> [-t <i>tablist</i> ] [ <i>file...</i> ]<br><b>expand</b> [- <i>tabstop</i> ] [- <i>tab1</i> , <i>tab2</i> , . . ., <i>tabn</i> ] [ <i>file...</i> ]<br><b>unexpand</b> [-a] [-t <i>tablist</i> ] [ <i>file...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>expand copies <i>files</i> (or the standard input) to the standard output, with TAB characters expanded to SPACE characters. BACKSPACE characters are preserved into the output and decrement the column count for TAB calculations. expand is useful for pre-processing character files (before sorting, looking at specific columns, and so forth) that contain TAB characters.</p> <p>unexpand copies <i>files</i> (or the standard input) to the standard output, putting TAB characters back into the data. By default, only leading SPACE and TAB characters are converted to strings of tabs, but this can be overridden by the -a option (see the OPTIONS section below).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>OPTIONS</b>     | <p>The following options are supported for expand:</p> <p>-t <i>tablist</i> Specify the tab stops. The argument <i>tablist</i> must consist of a single positive decimal integer or multiple positive decimal integers, separated by blank characters or commas, in ascending order. If a single number is given, tabs will be set <i>tablist</i> column positions apart instead of the default 8. If multiple numbers are given, the tabs will be set at those specific column positions.</p> <p>Each tab-stop position <i>N</i> must be an integer value greater than zero, and the list must be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position <i>N</i> causes the next character output to be in the (<i>N</i>+1)th column position on that line.</p> <p>In the event of expand having to process a tab character at a position beyond the last of those specified in a multiple tab-stop list, the tab character is replaced by a single space character in the output.</p> <p>-<i>tabstop</i> Specify as a single argument, sets TAB characters <i>tabstop</i> SPACE characters apart instead of the default 8.</p> <p>-<i>tab1</i>, <i>tab2</i>, . . ., <i>tabn</i> Set TAB characters at the columns specified by -<i>tab1</i>, <i>tab2</i>, . . ., <i>tabn</i></p> <p>The following options are supported for unexpand:</p> <p>-a Insert TAB characters when replacing a run of two or more SPACE characters would produce a smaller output file.</p> |

**-t *tablist***

Specify the tab stops. The option-argument *tablist* must be a single argument consisting of a single positive decimal integer or multiple positive decimal integers, separated by blank characters or commas, in ascending order. If a single number is given, tabs will be set *tablist* column positions apart instead of the default 8. If multiple numbers are given, the tabs will be set at those specific column positions. Each tab-stop position *N* must be an integer value greater than zero, and the list must be in strictly ascending order. This is taken to mean that, from the start of a line of output, tabbing to position *N* will cause the next character output to be in the (*N*+1)th column position on that line. When the **-t** option is not specified, the default is the equivalent of specifying **-t 8** (except for the interaction with **-a**, described below).

No space-to-tab character conversions occur for characters at positions beyond the last of those specified in a multiple tab-stop list.

When **-t** is specified, the presence or absence of the **-a** option is ignored; conversion will not be limited to the processing of leading blank characters.

**OPERANDS** The following operand is supported for `expand` and `unexpand`:

*file* The path name of a text file to be used as input.

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `expand` and `unexpand`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

0 Successful completion

>0 An error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |
| CSI            | enabled         |

## exportfs(1B)

| <b>NAME</b>        | exportfs – translates exportfs options to share/unshare commands                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <code>/usr/sbin/exportfs [-aiuv] [-o <i>options</i>] [<i>pathname</i>]</code>                                                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>exportfs translates SunOS 4.x exportfs options to the corresponding share/unshare options and invokes share/unshare with the translated options.</p> <p>With no options or arguments, exportfs invokes share to print out the list of all currently shared NFS filesystems.</p> <p>exportfs is the BSD/Compatibility Package command of share(1M) and unshare(1M). Use share(1M)/ unshare(1M) whenever possible.</p>                                                                                         |                |                 |              |         |
| <b>OPTIONS</b>     | <p>-a               Invokes shareall(1M), or if -u is specified, invokes unshareall(1M).</p> <p>-i               Ignore options in /etc/dfs/dfstab.</p> <p>-u               Invokes unshare(1M) on <i>pathname</i>.</p> <p>-v               Verbose.</p> <p>-o <i>options</i>      Specify a comma-separated list of optional characteristics for the filesystems being exported. exportfs translates <i>options</i> to share-equivalent options. (see share(1M) for information about individual options).</p> |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |

| <b>NAME</b>        | expr – evaluate arguments as an expression                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <pre>/usr/bin/expr argument...</pre> <pre>/usr/xpg4/bin/expr argument...</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>DESCRIPTION</b> | <p>The <code>expr</code> utility evaluates the expression and writes the result to standard output. The character 0 is written to indicate a zero value and nothing is written to indicate a null string.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>OPERANDS</b>    | <p>The <i>argument</i> operand is evaluated as an expression. Terms of the expression must be separated by blanks. Characters special to the shell must be escaped (see <code>sh(1)</code>). Strings containing blanks or other special characters should be quoted. The length of the expression is limited to <code>LINE_MAX</code> (2048 characters).</p> <p>The operators and keywords are listed below. The list is in order of increasing precedence, with equal precedence operators grouped within { } symbols. All of the operators are left-associative.</p> <p><i>expr</i> \   <i>expr</i><br/>Returns the first <i>expr</i> if it is neither NULL or 0, otherwise returns the second <i>expr</i>.</p> <p><i>expr</i> \&amp; <i>expr</i><br/>Returns the first <i>expr</i> if neither <i>expr</i> is NULL or 0, otherwise returns 0.</p> <p><i>expr</i>{ =, \&gt;, \&gt;=, \&lt;, \&lt;=, !=} <i>expr</i><br/>Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a string comparison using the locale-specific coalition sequence. The result of each comparison will be 1 if the specified relationship is TRUE, 0 if the relationship is FALSE.</p> <p><i>expr</i> { +, - } <i>expr</i><br/>Addition or subtraction of integer-valued arguments.</p> <p><i>expr</i> { \*, /, % } <i>expr</i><br/>Multiplication, division, or remainder of the integer-valued arguments.</p> <p><i>expr</i> : <i>expr</i><br/>The matching operator : (colon) compares the first argument with the second argument, which must be an internationalized basic regular expression (BRE); see <code>regex(5)</code> and NOTES. Normally, the <code>/usr/bin/expr</code> matching operator returns the number of bytes matched and the <code>/usr/xpg4/bin/expr</code> matching operator returns the number of characters matched (0 on failure). If the second argument contains at least one BRE sub-expression [ \ ( . . \ ) ], the matching operator returns the string corresponding to \1.</p> <p><i>integer</i><br/>An argument consisting only of an (optional) unary minus followed by digits.</p> <p><i>string</i><br/>A string argument that cannot be identified as an <i>integer</i> argument or as one of the expression operator symbols.</p> |

expr(1)

**Compatibility Operators (IA only)**

The following operators are included for compatibility with INTERACTIVE UNIX System only and are not intended to be used by non- INTERACTIVE UNIX System scripts:

`index string character-list`

Report the first position in which any one of the bytes in *character-list* matches a byte in *string*.

`length string`

Return the length (that is, the number of bytes) of *string*.

`substr string integer-1 integer-2`

Extract the substring of *string* starting at position *integer-1* and of length *integer-2* bytes. If *integer-1* has a value greater than the number of bytes in *string*, `expr` returns a null string. If you try to extract more bytes than there are in *string*, `expr` returns all the remaining bytes from *string*. Results are unspecified if either *integer-1* or *integer-2* is a negative value.

**EXAMPLES**

**EXAMPLE 1** Examples of the `expr` command.

Add 1 to the shell variable `a`:

```
example$ a='expr $a + 1'
```

The following example emulates `basename(1)` — it returns the last segment of the path name `$a`. For `$a` equal to either `/usr/abc/file` or just `file`, the example returns `file`. (Watch out for `/` alone as an argument: `expr` takes it as the division operator; see NOTES below.)

```
example$ expr $a : '.*\/(.*\)' \| $a
```

Here is a better version of the previous example. The addition of the `//` characters eliminates any ambiguity about the division operator and simplifies the whole expression.

```
example$ expr // $a : '.*\/(.*\)'
```

**/usr/bin/expr**

**EXAMPLE 2** Return the number of bytes in `$VAR`:

```
example$ expr "$VAR" : '.*'
```

**/usr/xpg4/bin/expr**

**EXAMPLE 3** Return the number of characters in `$VAR`:

```
example$ expr "$VAR" : '.*'
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `expr`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

As a side effect of expression evaluation, `expr` returns the following exit values:

- 0 if the expression is neither NULL nor 0
- 1 if the expression is either NULL or 0

2 for invalid expressions.

>2 an error occurred.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**SEE ALSO** `basename(1)`, `ed(1)`, `sh(1)`, `Intro(3)`, `attributes(5)`, `environ(5)`, `regex(5)`, `XPG4(5)`

**DIAGNOSTICS** `syntax error` Operator and operand errors.

`non-numeric argument` Arithmetic is attempted on such a string.

**NOTES** After argument processing by the shell, `expr` cannot tell the difference between an operator and an operand except by the value. If `$a` is an `=`, the command:

```
example$ expr $a = '= 'looks like:
```

```
example$ expr = = -as the arguments are passed to expr (and they are all taken as the = operator). The following works:
```

```
example$ expr X$a = X=
```

**Regular Expressions** Unlike some previous versions, `expr` uses Internationalized Basic Regular Expressions for all system-provided locales. Internationalized Regular Expressions are explained on the `regex(5)` manual page.

expr(1B)

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>NAME</b>        | expr – evaluate arguments as a logical, arithmetic, or string expression                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>    | <code>/usr/ucb/expr</code> <i>argument...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>The <code>expr</code> utility evaluates expressions as specified by its arguments. After evaluation, the result is written on the standard output. Each token of the expression is a separate argument, so terms of the expression must be separated by blanks. Characters special to the shell must be escaped. Note: 0 is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, two's-complement numbers.</p> <p>The operators and keywords are listed below. Characters that need to be escaped are preceded by '\'. The list is in order of increasing precedence, with equal precedence operators grouped within { } symbols.</p> <p><i>expr</i> \  <i>expr</i><br/>Returns the first <i>expr</i> if it is neither NULL nor 0, otherwise returns the second <i>expr</i>.</p> <p><i>expr</i> \&amp; <i>expr</i><br/>Returns the first <i>expr</i> if neither <i>expr</i> is NULL or 0, otherwise returns 0.</p> <p><i>expr</i> { =, \, \, \&lt;, \&lt;=, != } <i>expr</i><br/>Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison.</p> <p><i>expr</i> { +, - } <i>expr</i><br/>Addition or subtraction of integer-valued arguments.</p> <p><i>expr</i> { \, /, % } <i>expr</i><br/>Multiplication, division, or remainder of the integer-valued arguments.</p> <p><i>string</i> : <i>regular-expression</i><br/><code>match</code> <i>string</i> <i>regular-expression</i><br/>The two forms of the matching operator above are synonymous. The matching operators : and <code>match</code> compare the first argument with the second argument which must be a regular expression. Regular expression syntax is the same as that of <code>regexp(5)</code>, except that all patterns are “anchored” (treated as if they begin with ^) and therefore ^ is not a special character, in that context. Normally, the matching operator returns the number of characters matched (0 on failure). Alternatively, the \ . . . \ pattern symbols can be used to return a portion of the first argument.</p> <p><code>substr</code> <i>string</i> <i>integer-1</i> <i>integer-2</i><br/>Extract the substring of <i>string</i> starting at position <i>integer-1</i> and of length <i>integer-2</i> characters. If <i>integer-1</i> has a value greater than the length of <i>string</i>, <code>expr</code> returns a null string. If you try to extract more characters than there are in <i>string</i>, <code>expr</code> returns all the remaining characters from <i>string</i>. Beware of using negative values for either <i>integer-1</i> or <i>integer-2</i> as <code>expr</code> tends to run forever in these cases.</p> <p><code>index</code> <i>string</i> <i>character-list</i><br/>Report the first position in <i>string</i> at which any one of the characters in <i>character-list</i> matches a character in <i>string</i>.</p> |

length *string*

Return the length (that is, the number of characters) of *string*.

( *expr* )

Parentheses may be used for grouping.

## EXAMPLES

**EXAMPLE 1** Adding an integer to a shell variable

Add 1 to the shell variable *a*.

```
a='expr $a + 1'
```

**EXAMPLE 2** Returning a path name segment

Return the last segment of a path name (that is, the filename part). Watch out for / alone as an argument: *expr* will take it as the division operator (see BUGS below).

```
'For $a equal to either "/usr/abc/file" or just "file"
expr $a : '.*\ \ $a
```

**EXAMPLE 3** Using // characters to simplify the expression

The addition of the // characters eliminates any ambiguity about the division operator and simplifies the whole expression.

```
A better representation of example 2.
expr //$a : '.*\
```

**EXAMPLE 4** Returning the value of a variable

Returns the number of characters in \$VAR.

```
expr $VAR : '.*'
```

## EXIT STATUS

*expr* returns the following exit codes:

|   |                                         |
|---|-----------------------------------------|
| 0 | if the expression is neither NULL nor 0 |
| 1 | if the expression is NULL or 0          |
| 2 | for invalid expressions.                |

## ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

## DIAGNOSTICS

|                      |                                             |
|----------------------|---------------------------------------------|
| syntax error         | for operator/operand errors                 |
| non-numeric argument | if arithmetic is attempted on such a string |

## expr(1B)

division by zero                      if an attempt to divide by zero is made

**BUGS** After argument processing by the shell, `expr` cannot tell the difference between an operator and an operand except by the value. If `$a` is an `=`, the command:

```
expr $a = '='
```

looks like:

```
expr = = =
```

as the arguments are passed to `expr` (and they will all be taken as the `=` operator). The following works:

```
expr X$a = X=
```

Note: the `match`, `substr`, `length`, and `index` operators cannot themselves be used as ordinary strings. That is, the expression:

```
example% expr index expurgatorious length
syntax error
example%
```

generates the 'syntax error' message as shown instead of the value 1 as you might expect.

| <b>NAME</b>        | exstr – extract strings from source files                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <pre>exstr filename... exstr -e filename... exstr -r [-d] filename...</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b> | <p>The <code>exstr</code> utility is used to extract strings from C-language source files and replace them by calls to the message retrieval function (see <code>gettext(3C)</code>). This utility will extract all character strings surrounded by double quotes, not just strings used as arguments to the <code>printf</code> command or the <code>printf</code> routine. In the first form, <code>exstr</code> finds all strings in the source files and writes them on the standard output. Each string is preceded by the source file name and a colon (:).</p> <p>The first step is to use <code>exstr -e</code> to extract a list of strings and save it in a file. Next, examine this list and determine which strings can be translated and subsequently retrieved by the message retrieval function. Then, modify this file by deleting lines that can't be translated and, for lines that can be translated, by adding the message file names and the message numbers as the fourth (<i>msgfile</i>) and fifth (<i>msgnum</i>) entries on a line. The message files named must have been created by <code>mkmsgs(1)</code> and exist in <code>/usr/lib/locale/locale/LC_MESSAGES</code>. (The directory <code>locale</code> corresponds to the language in which the text strings are written; see <code>setlocale(3C)</code>). The message numbers used must correspond to the sequence numbers of strings in the message files.</p> <p>Now use this modified file as input to <code>exstr -r</code> to produce a new version of the original C-language source file in which the strings have been replaced by calls to the message retrieval function <code>gettext()</code>. The <i>msgfile</i> and <i>msgnum</i> fields are used to construct the first argument to <code>gettext()</code>. The second argument to <code>gettext()</code> is printed if the message retrieval fails at run-time. This argument is the null string, unless the <code>-d</code> option is used.</p> <p>This utility cannot replace strings in all instances. For example, a static initialized character string cannot be replaced by a function call. A second example is that a string could be in a form of an escape sequence which could not be translated. In order not to break existing code, the files created by invoking <code>exstr -e</code> must be examined and lines containing strings not replaceable by function calls must be deleted. In some cases the code may require modifications so that strings can be extracted and replaced by calls to the message retrieval function.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-e        Extract a list of strings from the named C-language source files, with positional information. This list is produced on standard output in the following format:</li> </ul> <pre style="margin-left: 40px;"><i>file:line:position:msgfile:msgnum:string</i></pre> <p style="margin-left: 40px;"><i>file</i>                    the name of a C-language source file</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## exstr(1)

|                 |                                |
|-----------------|--------------------------------|
| <i>line</i>     | line number in the file        |
| <i>position</i> | character position in the line |
| <i>msgfile</i>  | null                           |
| <i>msgnum</i>   | null                           |
| <i>string</i>   | the extracted text string      |

Normally you would redirect this output into a file. Then you would edit this file to add the values you want to use for *msgfile* and *msgnum*:

*msgfile*            the file that contains the text strings that will replace *string*. A file with this name must be created and installed in the appropriate place by the `mkmsgs(1)` utility.

*msgnum*            the sequence number of the string in *msgfile*.

The next step is to use `exstr -r` to replace *strings* in *file*.

- r    Replace strings in a C-language source file with function calls to the message retrieval function `gettext()`.
- d    This option is used together with the `-r` option. If the message retrieval fails when `gettext()` is invoked at run-time, then the extracted string is printed. You would use the capability provided by `exstr` on an application program that needs to run in an international environment and have messages print in more than one language. `exstr` replaces text strings with function calls that point at strings in a message data base. The data base used depends on the run-time value of the `LC_MESSAGES` environment variable (see `environ(5)`).

**EXAMPLES**    **EXAMPLE 1** The following examples show uses of `exstr`.

Assume that the file `example.c` contains two strings:

```
main()
{
 printf("This is an example\n");
 printf("Hello world!\n");
}
```

The `exstr` utility, invoked with the argument `example.c` extracts strings from the named file and prints them on the standard output.

```
example% exstr example.c
produces the following output:
```

**EXAMPLE 1** The following examples show uses of `exstr`. (Continued)

```
example.c:This is an example\n
example.c:Hello world!\n
```

The `exstr` utility, invoked with the `-e` option and the argument `example.c`, and redirecting output to the file `example.stringsout`

```
example% exstr -e example.c > example.stringsout
produces the following output in the file example.stringsout
```

```
example.c:3:8:::This is an example\n
example.c:4:8:::Hello world!\n
```

You must edit `example.stringsout` to add the values you want to use for the `msgfile` and `msgnum` fields before these strings can be replaced by calls to the retrieval function. If `UX` is the name of the message file, and the numbers 1 and 2 represent the sequence number of the strings in the file, here is what `example.stringsout` looks like after you add this information:

```
example.c:3:8:UX:1:This is an example\n
example.c:4:8:UX:2:Hello world!\n
```

The `exstr` utility can now be invoked with the `-r` option to replace the strings in the source file by calls to the message retrieval function `gettext()`.

```
example% exstr -r example.c <example.stringsout >intlexample.c
produces the following output:
```

```
extern char *gettext();

main()

{
 printf(gettext("UX:1", ""));

 printf(gettext("UX:2", ""));

}
```

The following example

```
example% exstr -rd example.c <example.stringsout >intlexample.c
uses the extracted strings as a second argument to gettext():
```

```
extern char *gettext();

main()

{
 printf(gettext("UX:1", "This is an example\n"));

 printf(gettext("UX:2", "Hello world!\n"));

}
```

exstr(1)

**EXAMPLE 1** The following examples show uses of `exstr`. (Continued)

**FILES** /usr/lib/locale/locale/LC\_MESSAGES/\*  
files created by `mkmsgs(1)`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWtoo         |

**SEE ALSO** `gettext(1)`, `mkmsgs(1)`, `printf(1)`, `srchtxt(1)`, `gettext(3C)`, `printf(3C)`, `setlocale(3C)`, `attributes(5)`, `environ(5)`

**DIAGNOSTICS** The error messages produced by `exstr` are intended to be self-explanatory. They indicate errors in the command line or format errors encountered within the input file.

| <b>NAME</b>        | face – executable for the Framed Access Command Environment Interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                 |              |         |

| <b>SYNOPSIS</b>    | <b>face</b> [-i <i>init_file</i> ] [-c <i>command_file</i> ] [-a <i>alias_file</i> ] [ <i>filename...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                 |              |         |
| <b>DESCRIPTION</b> | <p>The Framed Access Command Environment Interface (FACE) presents your files and file folders on the screen through a system of menus and forms if you are properly set up as a FACE user.</p> <p><i>filename</i> must follow the naming convention <code>Menu.xxx</code> for a menu, <code>Form.xxx</code> for a form, and <code>Text.xxx</code> for a text file, where <i>xxx</i> is any string that conforms to the UNIX system file naming conventions. The Form and Menu Language Interpreter (FMLI) descriptor <code>lifetime</code> will be ignored for all frames opened by argument to <code>face</code>. These frames have a lifetime of <code>immortal</code> by default. If <i>filename</i> is not specified on the command line, the FACE Menu will be opened along with those objects specified by the <code>LOGINWIN</code> environment variables. These variables are found in the user's <code>.environ</code> file.</p> |                |                 |              |         |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a <i>alias_file</i>                      Alias file</li> <li>-c <i>command_file</i>                    Command file</li> <li>-i <i>init_file</i>                        Initial file</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                 |              |         |

factor(1)

**NAME** factor – obtain the prime factors of a number

**SYNOPSIS** **factor** [*integer*]

**DESCRIPTION** **factor** writes to standard input all prime factors for any positive integer less than or equal to  $10^{14}$ . The prime factors are written the proper number of times.

If **factor** is used *without* an argument, it waits for an integer to be entered. After entry of the integer, it factors it, writes its prime factors the proper number of times, and then waits for another integer. **factor** exits if a 0 or any non-numeric character is entered.

If **factor** is invoked *with* an argument (*integer*), it writes the integer, factors it and writes all the prime factors as described above, and then exits. If the argument is 0 or non-numeric, **factor** writes a 0 and then exits.

The maximum time to factor an integer is proportional to  $\sqrt{n}$ , where  $n$  is the integer which is entered. **factor** will take this time when  $n$  is prime or the square of a prime.

**OPERANDS** *integer* Any positive integer less than or equal to  $10^{14}$ .

**EXIT STATUS**

|   |                        |
|---|------------------------|
| 0 | Successful completion. |
| 1 | An error occurred.     |

**DIAGNOSTICS** **factor** prints the error message Ouch! for input out of range or for garbage input.

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

- NAME** fastboot, fasthalt – reboot/halt the system without checking the disks
- SYNOPSIS** `/usr/ucb/fastboot` [*boot-options*]  
`/usr/ucb/fasthalt` [*halt-options*]
- DESCRIPTION** fastboot and fasthalt are shell scripts that invoke reboot and halt with the proper arguments.
- These commands are provided for compatibility only.
- ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

| <b>NAME</b>        | <code>fdformat</code> – format floppy diskette or PCMCIA memory card                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>SYNOPSIS</b>    | <code>fdformat</code> [-dDeEfHlLmMUqvX] [-b <i>label</i> ] [-B <i>filename</i> ] [-t <i>dostype</i> ]<br>[ <i>devname</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p><code>fdformat</code> has been superseded by <code>rmmount(1M)</code> which provides most but not all of <code>fdformat</code>'s functionality.</p> <p>The <code>fdformat</code> utility is used to format diskettes and PCMCIA memory cards. All new, blank diskettes or PCMCIA memory cards must be formatted before they can be used.</p> <p><code>fdformat</code> formats and verifies the media, and indicates whether any bad sectors were encountered. All existing data on the diskette or PCMCIA memory card, if any, is destroyed by formatting. If no device name is given, <code>fdformat</code> uses the diskette as a default.</p> <p>By default, <code>fdformat</code> uses the configured capacity of the drive to format the diskette. A 3.5 inch high-density drive uses diskettes with a formatted capacity of 1.44 megabytes. A 5.25 inch high-density drive uses diskettes with a formatted capacity of 1.2 megabytes. In either case, a density option does not have to be specified to <code>fdformat</code>. However, a density option must be specified when using a diskette with a lower capacity than the drive's default. Use the <code>-H</code> option to format high-density diskettes (1.44-megabyte capacity) in an extra-high-density (ED) drive. Use the <code>-D</code> option, the <code>-l</code> option, or the <code>-L</code> option to format double-density (or low-density) diskettes (720KB capacity) in an HD or ED drive. To format medium-density diskettes (1.2-megabyte capacity), use the <code>-M</code> option with <code>-t nec</code> (this is the same as using the <code>-m</code> option with <code>-t nec</code>).</p> <p>Extended density uses double-sided, extended-density (or extra-high-density) (DS/ED) diskettes. Medium and high densities use the same media: double-sided, high-density (DS/HD) diskettes. Double (low) density uses double-sided, double-density (DS/DD) diskettes. Substituting diskettes of one density for diskettes of either a higher or lower density generally does not work. Data integrity cannot be assured whenever a diskette is formatted to a capacity not matching its density.</p> <p>A PCMCIA memory card with densities from 512 KBytes to 64 MBytes may be formatted.</p> <p><code>fdformat</code> writes new identification and data fields for each sector on all tracks unless the <code>-x</code> option is specified. For diskettes, each sector is verified if the <code>-v</code> option is specified.</p> <p>After formatting and verifying, <code>fdformat</code> writes an operating-system label on block 0. Use the <code>-t dos</code> option (same as the <code>-d</code> option) to put an MS-DOS file system on the diskette or PCMCIA memory card after the format is done. Use the <code>-t nec</code> option with the <code>-M</code> option (same as the <code>-m</code> option) to put an NEC-DOS file system on a diskette. Otherwise, <code>fdformat</code> writes a SunOS label in block 0.</p> |
| <b>OPTIONS</b>     | The following options are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                    |                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -b <i>label</i>    | Labels the media with volume label. A SunOS volume label is restricted to 8 characters. A DOS volume label is restricted to 11 upper-case characters.                                                                      |
| -B <i>filename</i> | Installs special boot loader in <i>filename</i> on an MS-DOS diskette. This option is only meaningful when the -d option (or -t dos) is also specified.                                                                    |
| -D                 | Formats a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as the -l or -L options). This is the default for double-density type drives. It is needed if the drive is a high- or extended-density type. |
| -e                 | Ejects the diskette when done. This feature is not available on all systems.                                                                                                                                               |
| -E                 | Formats a 2.88-megabyte (3.5 inch) extended-density diskette. This is the default for extended-density type drives.                                                                                                        |
| -f                 | Force. Do not ask for confirmation before starting format.                                                                                                                                                                 |
| -H                 | Formats a 1.44-megabyte (3.5 inch) or 1.2-megabyte (5.25 inch) high-density diskette. This is the default for high-density type drives; it is needed if the drive is the extended-density type.                            |
| -M                 | Writes a 1.2-megabyte (3.5 inch) medium-density format on a high-density diskette (use only with the -t nec option). This is the same as using -m.<br><br>This feature is not available on all systems.                    |
| -q                 | Quiet; do not print status messages.                                                                                                                                                                                       |
| -t dos             | Installs an MS-DOS file system and boot sector formatting. This is equivalent to the DOS format command or the -d option.                                                                                                  |
| -t nec             | Installs an NEC-DOS file system and boot sector on the disk after formatting. This should be used only with the -M option. This feature is not available on all systems.                                                   |
| -U                 | Performs umount on any file systems and then formats. See mount(1M).                                                                                                                                                       |
| -v                 | Verifies each block of the diskette after the format.                                                                                                                                                                      |
| -x                 | Skips the format, and only writes a SunOS label or an MS-DOS file system.                                                                                                                                                  |

**OPERANDS** The following operands are supported:

|                |                                                                                                                                                                                                                                                                             |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>devname</i> | Replaces <i>devname</i> with <i>rdiskette0</i> (systems without Volume Management) or <i>floppy0</i> (systems with Volume Management) to use the first drive or <i>rdiskette1</i> (systems without Volume Management) or <i>floppy1</i> (systems with Volume Management) to |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## fdformat(1)

use the second drive. If *devname* is omitted, the first drive, if one exists, is used. For PCMCIA memory cards, replace *devname* with the device name for the PCMCIA memory card which resides in `/dev/rdisk/cNtNdNsN` or `/dev/dsk/cNtNdNsN`. If *devname* is omitted, the default diskette drive, if one exists, is used.

If *devname* is omitted, the default diskette drive, if one exists, will be used. *N* represents a decimal number and can be specified as follows:

|            |                                      |
|------------|--------------------------------------|
| <i>c N</i> | Controller <i>N</i>                  |
| <i>tN</i>  | Technology type <i>N</i> :           |
|            | 0x1 ROM                              |
|            | 0x2 OTPROM                           |
|            | 0x3 EPROM                            |
|            | 0x4 EEPROM                           |
|            | 0x5 FLASH                            |
|            | 0x6 SRAM                             |
|            | 0x7 DRAM                             |
| <i>dN</i>  | Technology region in type <i>N</i> . |
| <i>sN</i>  | Slice <i>N</i> .                     |

The following options are provided for compatibility with previous versions of `fdformat`. Their use is discouraged.

- `-d` Formats an MS-DOS floppy diskette or PCMCIA memory card (same as `-t dos`). This is equivalent to the MS-DOS `FORMAT` command.
- `-l` Formats a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as `-D` or `-L`). This is the default for double-density type drives; it is needed if the drive is the high- or extended-density type.
- `-L` Formats a 720KB (3.5 inch) or 360KB (5.25 inch) double-density diskette (same as `-l` or `-D`). This is the default for double-density type drives.
- `-m` Writes a 1.2-megabyte (3.5 inch) medium-density format on a high-density diskette (use only with the `-t nec` option). This is the same as using `-M`. This feature is not available on all systems.

**FILES** `/vol/dev/diskette0`  
Directory providing block device access for the media in floppy drive 0.

`/vol/dev/diskette0`  
Directory providing character device access for the media in floppy drive 0.

`/vol/dev/aliases/floppy0`  
Symbolic link to the character device for the media in floppy drive 0.

`/dev/rdiskette`  
Directory providing character device access for the media in the primary floppy drive, usually drive 0.

`/vol/dev/dsk/cNt NdNsN`  
Directory providing block device access for the PCMCIA memory card. See OPERANDS for a description of *N*.

`/vol/dev/rdsk/cNt NdNsN`  
Directory providing character device access for the PCMCIA memory card. See OPERANDS for a description of *N*.

`/vol/dev/aliases/pcmS`  
Symbolic link to the character device for the PCMCIA memory card in socket *S* where *S* represents a PCMCIA socket number.

`/dev/rdsk/cNt NdNsN`  
Directory providing character device access for the PCMCIA memory card. See OPERANDS for a description of *N*.

`/dev/dsk/cNt NdNsN`  
Directory providing block device access for the PCMCIA memory card. See OPERANDS for a description of *N*.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `cpio(1)`, `eject(1)`, `tar(1)`, `volcancel(1)`, `volcheck(1)`, `volmissing(1)`, `volrmmount(1)`, `mount(1M)`, `newfs(1M)`, `prtvtoc(1M)`, `rmmount(1M)`, `vold(1M)`, `rmmount.conf(4)`, `vold.conf(4)`, `attributes(5)`, `pcfs(7FS)`, `volfs(7FS)`

**IA Only** `fd(7D)`

**NOTES** A diskette or PCMCIA memory card containing a `ufs` file system created on a SPARC based system (by using `fdformat` and `newfs(1M)`), is not identical to a diskette or PCMCIA memory card containing a `ufs` file system created on an IA based system. Do not interchange `ufs` diskettes or memory cards between these platforms; use `cpio(1)` or `tar(1)` to transfer files on diskettes or memory cards between them. A diskette or PCMCIA memory card formatted using the `-t dos` option (or `-d`) for MS-DOS does not have the necessary system files, and is therefore not bootable. Trying to boot from it on a PC produces the following message:

fdformat(1)

Non-System disk or disk error.  
Replace and strike any key when ready

**BUGS** Currently, bad sector mapping is not supported on floppy diskettes or PCMCIA memory cards. Therefore, a diskette or memory cards is unusable if `fdformat` finds an error (bad sector).

| <b>NAME</b>        | fgrep – search a file for a fixed-character string                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>SYNOPSIS</b>    | <pre> /usr/bin/fgrep [-bchilnsvx] [-e <i>pattern_list</i>] [-f <i>pattern-file</i>] [<i>pattern</i>] [<i>file...</i>]  /usr/xpg4/bin/fgrep [-bchilnsvx] [-e <i>pattern_list</i>] [-f <i>pattern-file</i>] [<i>pattern</i>] [<i>file...</i>] </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <code>fgrep</code> (fast <code>grep</code>) utility searches files for a character string and prints all lines that contain that string. <code>fgrep</code> is different from <code>grep(1)</code> and <code>egrep(1)</code> because it searches for a string, instead of searching for a pattern that matches an expression. It uses a fast and compact algorithm.</p> <p>The characters <code>\$</code>, <code>*</code>, <code>[</code>, <code>^</code>, <code> </code>, <code>(</code>, <code>)</code>, and <code>\</code> are interpreted literally by <code>fgrep</code>, that is, <code>fgrep</code> does not recognize full regular expressions as does <code>egrep</code>. Since these characters have special meaning to the shell, it is safest to enclose the entire <i>string</i> in single quotes <code>'...'</code>.</p> <p>If no files are specified, <code>fgrep</code> assumes standard input. Normally, each line found is copied to the standard output. The file name is printed before each line found if there is more than one input file.</p>                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-b               Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).</li> <li>-c               Print only a count of the lines that contain the pattern.</li> <li>-e <i>pattern_list</i> Search for a <i>string</i> in <i>pattern-list</i> (useful when the <i>string</i> begins with a <code>-</code>).</li> <li>-f <i>pattern-file</i> Take the list of patterns from <i>pattern-file</i>.</li> <li>-h               Suppress printing of files when searching multiple files.</li> <li>-i               Ignore upper/lower case distinction during comparisons.</li> <li>-l               Print the names of files with matching lines once, separated by new-lines. Does not repeat the names of files when the pattern is found more than once.</li> <li>-n               Precede each line by its line number in the file (first line is 1).</li> <li>-s               Work silently, that is, display nothing except error messages. This is useful for checking the error status.</li> <li>-v               Print all lines except those that contain the pattern.</li> <li>-x               Print only lines matched entirely.</li> </ul> |
| <b>OPERANDS</b>    | The following operands are supported:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

fgrep(1)

|                              | <i>file</i>                                                                                                                                                                                                           | A path name of a file to be searched for the patterns. If no <i>file</i> operands are specified, the standard input will be used.               |                |                 |              |          |     |         |
|------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|----------|-----|---------|
| <b>/usr/bin/fgrep</b>        | <i>pattern</i>                                                                                                                                                                                                        | Specify a pattern to be used during the search for input.                                                                                       |                |                 |              |          |     |         |
| <b>/usr/xpg4/bin/fgrep</b>   | <i>pattern</i>                                                                                                                                                                                                        | Specify one or more patterns to be used during the search for input. This operand is treated as if it were specified as <i>-epattern_list</i> . |                |                 |              |          |     |         |
| <b>USAGE</b>                 | See <i>largefile(5)</i> for the description of the behavior of <i>fgrep</i> when encountering files greater than or equal to 2 Gbyte ( 2 <sup>31</sup> bytes).                                                        |                                                                                                                                                 |                |                 |              |          |     |         |
| <b>ENVIRONMENT VARIABLES</b> | See <i>environ(5)</i> for descriptions of the following environment variables that affect the execution of <i>fgrep</i> : LC_COLLATE, LC_CTYPE, LC_MESSAGES, and NLSPATH.                                             |                                                                                                                                                 |                |                 |              |          |     |         |
| <b>EXIT STATUS</b>           | The following exit values are returned:                                                                                                                                                                               |                                                                                                                                                 |                |                 |              |          |     |         |

| <b>NAME</b>        | file – determine file type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <p><b>file</b> [-h] [-m <i>mfile</i>] [-f <i>ffile</i>] <i>file</i>...</p> <p><b>file</b> [-h] [-m <i>mfile</i>] -f <i>ffile</i></p> <p><b>file</b> -c [-m <i>mfile</i>]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p>The <i>file</i> utility performs a series of tests on each file supplied by <i>file</i> and, optionally, on each file listed in <i>ffile</i> in an attempt to classify it. If the file is not a regular file, its file type is identified. The file types directory, FIFO, block special, and character special are identified as such. If the file is a regular file and the file is zero-length, it is identified as an empty file.</p> <p>If <i>file</i> appears to be a text file, <i>file</i> examines the first 512 bytes and tries to determine its programming language. If <i>file</i> is an executable a.out, <i>file</i> prints the version stamp, provided it is greater than 0. If <i>file</i> is a symbolic link, by default the link is followed and <i>file</i> tests the file to which the symbolic link refers.</p> <p>By default, <i>file</i> will try to use the localized magic file <code>/usr/lib/locale/locale/LC_MESSAGES/magic</code>, if it exists, to identify files that have a magic number. For example, in the Japanese locale, <i>file</i> will try to use <code>/usr/lib/locale/ja/LC_MESSAGES/magic</code>. If a localized magic file does not exist, <i>file</i> will utilize <code>/etc/magic</code>. A magic number is a numeric or string constant that indicates the file type. See <code>magic(4)</code> for an explanation of the format of <code>/etc/magic</code>.</p> <p>If <i>file</i> does not exist, cannot be read, or its file status could not be determined, it is not considered an error that affects the exit status. The output will indicate that the file was processed, but that its type could not be determined.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-c                   Check the magic file for format errors. For reasons of efficiency, this validation is normally not carried out.</li> <li>-h                   Do not follow symbolic links.</li> <li>-f <i>ffile</i>           <i>ffile</i> contains a list of the files to be examined.</li> <li>-m <i>mfile</i>          Use <i>mfile</i> as an alternate magic file, instead of <code>/etc/magic</code>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <ul style="list-style-type: none"> <li><i>file</i>                A path name of a file to be tested.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>USAGE</b>       | See <code>largefile(5)</code> for the description of the behavior of <i>file</i> when encountering files greater than or equal to 2 Gbyte ( $2^{31}$ bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Binary executable files</p> <p>Determine if an argument is a binary executable file:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

file(1)

**EXAMPLE 1** Binary executable files (Continued)

```
file "$1" | grep -Fq executable &&
printf "%s is executable.\n" "$1"
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `file`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

0 Successful completion.  
>0 An error occurred.

**FILES**

`/etc/magic` file's magic number file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**SEE ALSO**

`ls(1)`, `magic(4)`, `attributes(5)`, `environ(5)`, `largefile(5)`

**DIAGNOSTICS**

If the `-h` option is specified and `file` is a symbolic link, `file` prints the error message:  
`symbolic link to file`

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>NAME</b>                  | file – determine the type of a file by examining its contents                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>              | <code>/usr/ucb/file</code> [-f <i>ffile</i> ] [-cL] [-m <i>mfile</i> ] <i>filename...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>DESCRIPTION</b>           | <p>file performs a series of tests on each <i>filename</i> in an attempt to determine what it contains. If the contents of a file appear to be ASCII text, <i>file</i> examines the first 512 bytes and tries to guess its language.</p> <p><i>file</i> uses the file <code>/etc/magic</code> to identify files that have some sort of <i>magic number</i>, that is, any file containing a numeric or string constant that indicates its type.</p>                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>               | <p>-c                   Check for format errors in the magic number file. For reasons of efficiency, this validation is not normally carried out. No file type-checking is done under -c.</p> <p>-f <i>ffile</i>            Get a list of filenames to identify from <i>ffile</i>.</p> <p>-L                    If a file is a symbolic link, test the file the link references rather than the link itself.</p> <p>-m <i>mfile</i>            Use <i>mfile</i> as the name of an alternate magic number file.</p>                                                                                                                                                                                 |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> Using <i>file</i> on all the files in a specific user's directory.</p> <p>This example illustrates the use of <i>file</i> on all the files in a specific user's directory:</p> <pre>example% pwd /usr/blort/misc  example% /usr/ucb/file *</pre> <pre>code:          mc68020 demand paged executable code.c:        c program text counts:        ascii text doc:           roff,nroff, or eqn input text empty.file:    empty libz:          archive random library memos:         directory project:       symboliclink to /usr/project script:        executable shell script titles:        ascii text s5.stuff:      cpio archive example%</pre>                          |
| <b>ENVIRONMENT VARIABLES</b> | The environment variables <code>LC_CTYPE</code> , <code>LANG</code> , and <code>LC_default</code> control the character classification throughout <i>file</i> . On entry to <i>file</i> , these environment variables are checked in the following order: <code>LC_CTYPE</code> , <code>LANG</code> , and <code>LC_default</code> . When a valid value is found, remaining environment variables for character classification are ignored. For example, a new setting for <code>LANG</code> does not override the current valid character classification rules of <code>LC_CTYPE</code> . When none of the values is valid, the shell character classification defaults to the POSIX.1 "C" locale. |
| <b>FILES</b>                 | <code>/etc/magic</code>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

file(1B)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

**SEE ALSO** `magic(4)`, `attributes(5)`

**BUGS** `file` often makes mistakes. In particular, it often suggests that command files are C programs.

`file` does not recognize Pascal or LISP.

| <b>SYNOPSIS</b>                            | <pre>filesync [-aehmnqvy] [-o src   dst] [-f src   dst   old   new]         [-r directory...]  filesync [-aehmnqvy] -s source-dir -d dest-dir filename...</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b>                         | <p>The <code>filesync</code> utility <i>synchronizes</i> files between multiple computer systems, typically a server and a portable computer. <code>filesync</code> synchronizes ordinary, directory or special files. Although intended for use on nomadic systems, <code>filesync</code> is useful for backup and file replication on more permanently connected systems.</p> <p>If files are synchronized between systems, the corresponding files on each of the systems are <i>identical</i>. Changing a file on one or both of the systems causes the files to become different (not synchronized). In order to make the files identical again, the differences between the files must be <i>reconciled</i>. See <i>Reconciling and Synchronizing Files</i> for specific details about how <code>filesync</code> reconciles and synchronizes files.</p> <p>There are two forms of the <code>filesync</code> command. The first form of <code>filesync</code> is invoked without file arguments. This form of <code>filesync</code> reconciles differences between the files and systems specified in the <code>\$HOME/.packingrules</code> file. <code>\$HOME/.packingrules</code> is a packing rules list for <code>filesync</code> and <code>cachefspack</code>, and contains a list of files to be kept synchronized. See <code>packingrules(4)</code> and <code>cachefspack(1M)</code>.</p> <p>The second form of <code>filesync</code> copies specific files from a directory on the source system to a directory on the destination system. In addition, this form of <code>filesync</code> adds the file or files specified as arguments (<i>filename</i>) to <code>\$HOME/.packingrules</code>. See <code>-s</code> and <code>-d</code> for information about specifying directories on source and destination systems. See <code>OPERANDS</code> for details about specifying file (<i>filename</i>) arguments.</p> <p>Multiple <code>filesync</code> commands are cumulative (that is, the specified files are added to the already existing packing rules file list). See <i>Multiple filesync Commands</i>.</p> <p><code>filesync</code> synchronizes files between computer systems by performing the following two tasks:</p> <ol style="list-style-type: none"> <li><code>filesync</code> examines the directories and files specified in the packing rules file on both systems, and determines whether or not they are identical. Any file that differs requires reconciliation. <p><code>filesync</code> also maintains a baseline summary in the <code>\$HOME/.filesync-base</code> file for all of the files that are being monitored. This file lists the names, types, and sizes of all files as of the last reconciliation.</p> </li> <li>Based on the information contained in the baseline file and the specified options (see <i>Resolving filesync Conflicts</i>), <code>filesync</code> determines which of the various copies is the correct one, and makes the corresponding changes to the other system. Once this has been done, the two copies are, again, identical (synchronized).</li> </ol> |
| <b>Reconciling and Synchronizing Files</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

filesync(1)

|                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                     | <p>If a source file has changed and the destination file has not, the changes on the source system are propagated to the destination system. If a destination file has changed and the corresponding source file has not, the changes on the destination file are propagated to the source system. If both systems have changed (and the files are not still identical) a warning message will be printed out, asking the user to resolve the conflict manually. See <a href="#">Resolving filesync Conflicts</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Resolving filesync Conflicts</b> | <p>In cases where files on both sides have changed, <code>filesync</code> attempts to determine which version should be chosen. If <code>filesync</code> cannot automatically determine which version should be selected, it prints out a warning message and leaves the two incompatible versions of the file unreconciled.</p> <p>In these cases, you must either resolve the differences manually, or tell <code>filesync</code> how to choose which file should win. Use the <code>-o</code> and <code>-f</code> options to tell <code>filesync</code> how to resolve conflicts (see <a href="#">OPTIONS</a>).</p> <p>Alternatively, for each conflicting file, you can examine the two versions, determine which one should be kept, and manually bring the two versions into agreement (by copying, deleting, or changing the ownership or protection to be correct). You can then re-run <code>filesync</code> to see whether or not any other conflicts remain.</p> |
| <b>Packing Rules File</b>           | <p>The packing rules file <code>\$HOME/.packingrules</code> contains a list of files to be kept synchronized. The syntax of this file is described in <a href="#">packingrules(4)</a>.</p> <p>The <code>\$HOME/.packingrules</code> file is automatically created if users invoke <code>filesync</code> with filename arguments. By using <code>filesync</code> options, users can augment the packing rules in <code>\$HOME/.packingrules</code>.</p> <p>Many users choose to create the packing rules file manually and edit it by hand. Users can edit <code>\$HOME/.packingrules</code> (using any editor) to permanently change the <code>\$HOME/.packingrules</code> file, or to gain access to more powerful options that are not available from the command line (such as <code>IGNORE</code> commands). It is much easier to enter complex wildcard expressions by editing the <code>\$HOME/.packingrules</code> file.</p>                                         |
| <b>Baseline File</b>                | <p><code>\$HOME/.filesync-base</code> is the <code>filesync</code> baseline summary file. <code>filesync</code> uses the information in <code>\$HOME/.filesync-base</code> to identify the differences between files during the reconciliation and synchronization process. Users do not create or edit the baseline file. It is created automatically by <code>filesync</code> and records the last known state of agreement between all of the files being maintained.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Multiple filesync Commands</b>   | <p>Over a period of time, the set of files you want to keep synchronized can change. It is common, for instance, to want to keep files pertaining to only a few active projects on your notebook. If you continue to keep files associated with every project you have ever worked on synchronized, your notebook's disk will fill up with old files. Each <code>filesync</code> command will waste a lot of time updating files you no longer care about.</p> <p>If you delete the files from your notebook, <code>filesync</code> will want to perform the corresponding deletes on the server, which would not be what you wanted. Rather, you would like a way to tell <code>filesync</code> to stop synchronizing some of the files. There are two ways to do this:</p>                                                                                                                                                                                                |

1. Edit `$HOME/.packingrules`. Delete the rules for the files that you want to delete.
2. Delete `$HOME/.packingrules`. Use the `filesync` command to specify the files that you want synchronized.

Either way works, and you can choose the one that seems easiest to you. For minor changes, it is probably easier to just edit `$HOME/.packingrules`. For major changes it is probably easier to start from scratch.

Once `filesync` is no longer synchronizing a set of files, you can delete them from your notebook without having any effect on the server.

### Nomadic Machines

When using `filesync` to keep files synchronized between nomadic machines and a server, store the packing rules and baseline files on the nomadic machines, not the server. If, when logged into your notebook, the `HOME` environment variable does not normally point to a directory on your notebook, you can use the `FILESYNC` environment variable to specify an alternate location for the packing rules and baseline files.

Each nomadic machine should carry its own packing rules and baseline file. Incorrect file synchronization can result if a server carries a baseline file and multiple nomadic machines attempt to reconcile against the server's baseline file. In this case, a nomadic machine could be using a baseline file that does not accurately describe the state of its files. This might result in incorrect reconciliations.

To safeguard against the dangers associated with a single baseline file being shared by more than two machines, `filesync` adds a default rule to each new packing rules file. This default rule prevents the packing rules and baseline files from being copied.

### OPTIONS

The following options are supported:

`-a`

Force the checking of Access Control Lists (ACLs) and attempt to make them agree for all new and changed files. If it is not possible to set the ACL for a particular file, `filesync` stops ACL synchronization for that file.

Some file systems do not support ACLs. It is not possible to synchronize ACLs between file systems that support ACLs and those that do not; attempting to do so will result in numerous error messages.

`-d dest-dir`

Specify the directory on the destination system into which *filename* is to be copied. Use with the `-s source-dir` option and the *filename* operand. See `-s` and OPERANDS.

`-e`

Flag all differences. It may not be possible to resolve all conflicts involving modes and ownership (unless `filesync` is being run with root privileges). If you cannot change the ownership or protections on a file, `filesync` will normally ignore conflicts in ownership and protection. If you specify the `-e` (everything must agree) flag, however, `filesync` will flag these differences.

## filesync(1)

`-f src | dst | old | new`

The `-f` option tells `filesync` how to resolve conflicting changes. If a file has been changed on both systems, and an `-f` option has been specified, `filesync` will retain the changes made on the favored system and discard the changes made on the unfavored system.

Specify `-f src` to favor the source-system file. Specify `-f dst` to favor the destination-system file. Specify `-f old` to favor the older version of the file. Specify `-f new` to favor the newer version of the file.

It is possible to specify the `-f` and `-o` options in combination if they both specify the same preference (`src` and `dst`). If `-f` and `-o` conflict, the `-f` option is ignored. See the `-o` option description.

`-h`

Halt on error. Normally, if `filesync` encounters a read or write error while copying files, it notes the error and the program continues, in an attempt to reconcile other files. If the `-h` option is specified, `filesync` will immediately halt when one of these errors occurs and will not try to process any more files.

`-m`

Ensure that both copies of the file have the same modification time. The modification time for newly copied files is set to the time of reconciliation by default. File changes are ordered by increasing modification times so that the propagated files have the same relative modification time ordering as the original changes. Users should be warned that there is usually some time skew between any two systems, and transferring modification times from one system to another can occasionally produce strange results.

There are instances in which using `filesync` to update some (but not all) files in a directory will confuse the `make` program. If, for instance, `filesync` is keeping `.c` files synchronized, but ignoring `.o` files, a changed `.c` file may show up with a modification time prior to a `.o` file that was built from a prior version of the `.c` file.

`-n`

Do not really make the changes. If the `-n` option is specified, `filesync` determines what changes have been made to files, and what reconciliations are required and displays this information on the standard output. No changes are made to files, including the packing rules file.

Specifying both the `-n` and `-o` options causes `filesync` to analyze the prevailing system and report the changes that have been made on that system. Using `-n` and `-o` in combination is useful if your machine is disconnected (and you cannot access the server) but you want to know what changes have been made on the local machine. See the `-o` option description.

`-o src | dst`

The `-o` option forces a one-way reconciliation, favoring either the source system (`src`) or destination system (`dst`).

Specify `-o src` to propagate changes only from the source system to the destination system. Changes made on the destination system are ignored. `filesync` aborts if it cannot access a source or destination directory.

Specify `-o dst` to propagate changes only from the destination system to the source system. Changes made on the source system are ignored. `filesync` aborts if it cannot access a source or destination directory.

Specifying `-n` with the `-o` option causes `filesync` to analyze the prevailing system and reports on what changes have been made on that system. Using `-n` and `-o` in combination is useful if a machine is disconnected (and there is no access to the server), but you want to know what changes have been made on the local machine. See the `-n` option description.

It is possible to specify the `-o` and `-f` options in combination if they both specify the same preference (`src` or `dst`). If `-o` and `-f` options conflict, the `-f` option will be ignored. See the `-f` option description.

`-q`

Suppress the standard `filesync` messages that describe each reconciliation action as it is performed.

The standard `filesync` message describes each reconciliation action in the form of a UNIX shell command (for example, `mv`, `ln`, `cp`, `rm`, `chmod`, `chown`, `chgrp`, `setfacl`, and so forth).

`-r directory`

Limit the reconciliation to *directory*. Specify multiple directories with multiple `-r` specifications.

`-s source-dir`

Specify the directory on the source system from which the *filename* to be copied is located. Use with the `-d dest-dir` option and the *filename* operand. See the `-d` option description and OPERANDS.

`-v`

Display additional information about each file comparison as it is made on the standard output.

`-y`

Bypass safety check prompts. Nomadic machines occasionally move between domains, and many of the files on which `filesync` operates are expected to be accessed by NFS. There is a danger that someday `filesync` will be asked to reconcile local changes against the wrong file system or server. This could result in a large number of inappropriate copies and deletions. To prevent such a mishap, `filesync` performs a few safety checks prior to reconciliation. If large numbers of files are likely to be deleted, or if high level directories have changed their I-node numbers, `filesync` prompts for a confirmation before reconciliation. If you know that this is likely, and do not want to be prompted, use the `-y` (yes) option to automatically confirm these prompts.

## filesync(1)

### OPERANDS

The following operands are supported:

*filename* The name of the ordinary file, directory, symbolic link, or special file in the specified source directory (*source-dir*) to be synchronized. Specify multiple files by separating each filename by spaces. Use the *filename* operand with the `-s` and `-d` options. See `OPTIONS`.

If *filename* is an ordinary file, that ordinary file will be replicated (with the same *filename*) in the specified destination directory (*dest-dir*).

If *filename* is a directory, that directory and all of the files and subdirectories under it will be replicated (recursively) in the specified destination directory (*dest-dir*).

If *filename* is a symbolic link, a copy of that symbolic link will be replicated in the specified destination directory (*dest-dir*).

If *filename* is a special file, a special file with the same major or minor device numbers will be replicated in the specified destination directory (*dest-dir*). Only super-users can use `filesync` to create special files.

Files created in the destination directory (*dest-dir*) will have the same owner, group and other permissions as the files in the source directory.

If *filename* contains escaped shell wildcard characters, the wildcard characters are stored in `$HOME/.packingrules` and evaluated each time `filesync` is run.

For example, the following would make sure that the two specified files, currently in `$RHOME`, were replicated in `$HOME`:

```
filesync -s $RHOME -d $HOME a.c b.c
```

The following example would ensure that all of the `*.c` files in `$RHOME` were replicated in `$HOME`, even if those files were not created until later.

```
filesync -s $RHOME -d $HOME '*.c'
```

If any of the destination files already exist, `filesync` ensures that they are identical and issues warnings if they are not.

Once files have been copied, the distinction between the source and destination is a relatively arbitrary one (except for its use in the `-o` and `-f` switches).

### ENVIRONMENT VARIABLES

FILESYNC

Specifies the default location of the `filesync` packing rules and baseline files. The default value for this

variable is \$HOME. The suffixes `.packingrules` and `.filesync-base` will be appended to form the names of the packing rules and baseline files.

**LC\_MESSAGES**

Determines how diagnostic and informative messages are presented. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

**EXIT STATUS**

Normally, if all files are already up-to-date, or if all files were successfully reconciled, `filesync` will exit with a status of 0. However, if either the `-n` option was specified or any errors occurred, the exit status will be the logical OR of the following:

- 0           No conflicts, all files up to date.
- 1           Some resolvable conflicts.
- 2           Some conflicts requiring manual resolution.
- 4           Some specified files did not exist.
- 8           Insufficient permission for some files.
- 16          Errors accessing packing rules or baseline file.
- 32          Invalid arguments.
- 64          Unable to access either or both of the specified `src` or `dst` directories.
- 128         Miscellaneous other failures.

**FILES**

`$HOME/.packingrules`                   list of files to be kept synchronized  
`$HOME/.filesync-base`                 baseline summary file

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

| <b>Expressions</b> | <p>Valid expressions are:</p> <p><code>-atime n</code>            True if the file was accessed <i>n</i> days ago. The access time of directories in <i>path</i> is changed by <code>find</code> itself.</p> <p><code>-cpio device</code>        Always true; write the current file on <i>device</i> in <code>cpio</code> format (5120-byte records).</p> <p><code>-ctime n</code>            True if the file's status was changed <i>n</i> days ago.</p> <p><code>-depth</code>              Always true; causes descent of the directory hierarchy to be done so that all entries in a directory are acted on before the directory itself. This can be useful when <code>find</code> is used with <code>cpio(1)</code> to transfer files that are contained in directories without write permission.</p> <p><code>-exec command</code>      True if the executed <i>command</i> returns a zero value as exit status. The end of <i>command</i> must be punctuated by an escaped semicolon. A command argument <code>{ }</code> is replaced by the current path name.</p> <p><code>-follow</code>             Always true; causes symbolic links to be followed. When following symbolic links, <code>find</code> keeps track of the directories visited so that it can detect infinite loops; for example, such a loop would occur if a symbolic link pointed to an ancestor. This expression should not be used with the <code>-type l</code> expression.</p> |                 |                    |                |                  |                 |                    |

|                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <code>-fstype <i>type</i></code>  | True if the filesystem to which the file belongs is of type <i>type</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-group <i>gname</i></code>  | True if the file belongs to the group <i>gname</i> . If <i>gname</i> is numeric and does not appear in the <code>/etc/group</code> file, or in the NIS/NIS+ tables, it is taken as a group ID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>-inum <i>n</i></code>       | True if the file has inode number <i>n</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <code>-links <i>n</i></code>      | True if the file has <i>n</i> links.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>-local</code>               | True if the file system type is not a remote file system type as defined in the <code>/etc/dfs/fstypes</code> file. <code>nfs</code> is used as the default remote filesystem type if the <code>/etc/dfs/fstypes</code> file is not present. Note that <code>-local</code> will descend the hierarchy of non-local directories. See EXAMPLES for an example of how to search for local files without descending.                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-ls</code>                  | <p>Always true; prints current path name together with its associated statistics. These include (respectively):</p> <ul style="list-style-type: none"> <li>■ inode number</li> <li>■ size in kilobytes (1024 bytes)</li> <li>■ protection mode</li> <li>■ number of hard links</li> <li>■ user</li> <li>■ group</li> <li>■ size in bytes</li> <li>■ modification time.</li> </ul> <p>If the file is a special file the size field will instead contain the major and minor device numbers.</p> <p>If the file is a symbolic link the pathname of the linked-to file is printed preceded by <code>'→'</code>. The format is identical to that of <code>ls -gilds</code> (see <code>ls(1B)</code>). Note: Formatting is done internally, without executing the <code>ls</code> program.</p> |
| <code>-mount</code>               | Always true; restricts the search to the file system containing the directory specified. Does not list mount points to other file systems.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <code>-mtime <i>n</i></code>      | True if the file's data was modified <i>n</i> days ago.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <code>-name <i>pattern</i></code> | True if <i>pattern</i> matches the current file name. Normal shell file name generation characters (see <code>sh(1)</code> ) may be used. A backslash ( <code>\</code> ) is used as an escape character within the pattern. The pattern should be escaped or quoted when <code>find</code> is invoked from the shell.                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-ncpio <i>device</i></code> | Always true; write the current file on <i>device</i> in <code>cpio -c</code> format (5120 byte records).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## find(1)

|                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <code>-newer <i>file</i></code>       | True if the current file has been modified more recently than the argument <i>file</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-nogroup</code>                 | True if the file belongs to a group not in the <code>/etc/group</code> file, or in the NIS/NIS+ tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-nouser</code>                  | True if the file belongs to a user not in the <code>/etc/passwd</code> file, or in the NIS/NIS+ tables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <code>-ok <i>command</i></code>       | Like <code>-exec</code> except that the generated command line is printed with a question mark first, and is executed only if the user responds by typing <code>y</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <code>-perm [-]<i>mode</i></code>     | <p>The <i>mode</i> argument is used to represent file mode bits. It will be identical in format to the <code>&lt;symbolicmode&gt;</code> operand described in <code>chmod(1)</code>, and will be interpreted as follows. To start, a template will be assumed with all file mode bits cleared. An <i>op</i> symbol of:</p> <ul style="list-style-type: none"><li><code>+</code> will set the appropriate mode bits in the template;</li><li><code>-</code> will clear the appropriate bits;</li><li><code>=</code> will set the appropriate mode bits, without regard to the contents of process' file mode creation mask.</li></ul> <p>The <i>op</i> symbol of <code>-</code> cannot be the first character of <i>mode</i>; this avoids ambiguity with the optional leading hyphen. Since the initial mode is all bits off, there are not any symbolic modes that need to use <code>-</code> as the first character.</p> <p>If the hyphen is omitted, the primary will evaluate as true when the file permission bits exactly match the value of the resulting template.</p> <p>Otherwise, if <i>mode</i> is prefixed by a hyphen, the primary will evaluate as true if at least all the bits in the resulting template are set in the file permission bits.</p> |
| <code>-perm [-]<i>onum</i></code>     | True if the file permission flags exactly match the octal number <i>onum</i> (see <code>chmod(1)</code> ). If <i>onum</i> is prefixed by a minus sign ( <code>-</code> ), only the bits that are set in <i>onum</i> are compared with the file permission flags, and the expression evaluates true if they match.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <code>-print</code>                   | Always true; causes the current path name to be printed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <code>-prune</code>                   | Always yields true. Does not examine any directories or files in the directory structure below the <i>pattern</i> just matched. (See EXAMPLES). If <code>-depth</code> is specified, <code>-prune</code> will have no effect.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <code>-size <i>n</i>[<i>c</i>]</code> | True if the file is <i>n</i> blocks long (512 bytes per block). If <i>n</i> is followed by a <i>c</i> , the size is in bytes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                    |                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -type <i>c</i>     | True if the type of the file is <i>c</i> , where <i>c</i> is b, c, d, D, f, l, p, or s for block special file, character special file, directory, door, plain file, symbolic link, fifo (named pipe), or socket, respectively. |
| -user <i>uname</i> | True if the file belongs to the user <i>uname</i> . If <i>uname</i> is numeric and does not appear as a login name in the <code>/etc/passwd</code> file, or in the NIS/NIS+ tables, it is taken as a user ID.                  |
| -xdev              | Same as the <code>-mount</code> primary.                                                                                                                                                                                       |

**Complex Expressions**

The primaries may be combined using the following operators (in order of decreasing precedence):

- 1) ( *expression* ) True if the parenthesized expression is true (parentheses are special to the shell and must be escaped).
- 2) ! *expression* The negation of a primary (! is the unary *not* operator).
- 3) *expression* [-a] *expression* Concatenation of primaries (the *and* operation is implied by the juxtaposition of two primaries).
- 4) *expression* -o *expression* Alternation of primaries (-o is the *or* operator).

Note: When you use `find` in conjunction with `cpio`, if you use the `-L` option with `cpio` then you must use the `-follow` expression with `find` and vice versa. Otherwise there will be undesirable results.

If no *expression* is present, `-print` will be used as the expression. Otherwise, if the given expression does not contain any of the primaries `-exec`, `-ok` or `-print`, the given expression will be effectively replaced by:

```
(given_expression) -print
```

The `-user`, `-group`, and `-newer` primaries each will evaluate their respective arguments only once. Invocation of *command* specified by `-exec` or `-ok` does not affect subsequent primaries on the same file.

**USAGE** See `largefile(5)` for the description of the behavior of `find` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** Writing out the hierarchy directory

The following commands are equivalent:

```
example% find .example% find . -print
```

They both write out the entire directory hierarchy from the current directory.

## find(1)

### EXAMPLE 2 Removing files

Remove all files in your home directory named `a.out` or `*.o` that have not been accessed for a week:

```
example% find $HOME \(-name a.out -o -name *.o \) \
-atime +7 -exec rm {} \;
```

### EXAMPLE 3 Printing all file names but skipping SCCS directories

Recursively print all file names in the current directory and below, but skipping SCCS directories:

```
example% find . -name SCCS -prune -o -print
```

### EXAMPLE 4 Printing all file names and the SCCS directory name

Recursively print all file names in the current directory and below, skipping the contents of SCCS directories, but printing out the SCCS directory name:

```
example% find . -print -name SCCS -prune
```

### EXAMPLE 5 Testing for the newer file

The following command is basically equivalent to the `-nt` extension to `test(1)`:

```
example$ if [-n "$(find
file1 -prune -newer file2)"]; then

 printf %s\n "file1 is newer than file2"
```

### EXAMPLE 6 Selecting a file using 24-hour mode

The descriptions of `-atime`, `-ctime`, and `-mtime` use the terminology *n* "24-hour periods". For example, a file accessed at 23:59 will be selected by:

```
example% find . -atime -1 print
```

at 00:01 the next day (less than 24 hours later, not more than one day ago); the midnight boundary between days has no effect on the 24-hour calculation.

### EXAMPLE 7 Printing files matching a user's permission mode

Recursively print all file names whose permission mode exactly matches read, write, and execute access for user, and read and execute access for group and other:

```
example% find . -perm u=rwx,g=rx,o=rx
```

The above could alternatively be specified as follows:

```
example% find . -perm a=rwx,g-w,o-w
```

**EXAMPLE 7** Printing files matching a user's permission mode (Continued)

**EXAMPLE 8** Printing files with write access for other

Recursively print all file names whose permission includes, but is not limited to, write access for other:

```
example% find . -perm -o+w
```

**EXAMPLE 9** Printing local files without descending non-local directories

```
example% find . ! -local -prune -o -print
```

## ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `find`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

## EXIT STATUS

The following exit values are returned:

0 All *path* operands were traversed successfully.

>0 An error occurred.

## FILES

`/etc/passwd` password file

`/etc/group` group file

`/etc/dfs/fstypes` file that registers distributed file system packages

## ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

## SEE ALSO

`chmod(1)`, `cpio(1)`, `ls(1B)`, `sh(1)`, `test(1)`, `stat(2)`, `umask(2)`, `attributes(5)`, `environ(5)`, `largefile(5)`

## WARNINGS

The following options are obsolete and will not be supported in future releases:

`-cpio device` Always true; write the current file on *device* in `cpio` format (5120-byte records).

`-ncpio device` Always true; write the current file on *device* in `cpio -c` format (5120 byte records).

## NOTES

When using `find` to determine files modified within a range of time, one must use the `-time` argument *before* the `-print` argument; otherwise, `find` will give all files.

## finger(1)

| <b>NAME</b>        | <code>finger</code> – display information about local and remote users                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <code>finger</code> [-bfhilmpqsw] [ <i>username</i> ...]<br><code>finger</code> [-1] [ <i>username@hostname</i> 1 [ <i>@hostname</i> 2 .. <i>@hostname</i> n...]]<br><code>finger</code> [-1] [ <i>@hostname</i> 1 [ <i>@hostname</i> 2 .. <i>@hostname</i> n...]]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>DESCRIPTION</b> | <p>By default, the <code>finger</code> command displays in multi-column format the following information about each logged-in user:</p> <ul style="list-style-type: none"><li>■ user name</li><li>■ user's full name</li><li>■ terminal name (preended with a '*' (asterisk) if write-permission is denied)</li><li>■ idle time</li><li>■ login time</li><li>■ host name, if logged in remotely</li></ul> <p>Idle time is in minutes if it is a single integer, in hours and minutes if a ':' (colon) is present, or in days and hours if a 'd' is present.</p> <p>When one or more <i>username</i> arguments are given, more detailed information is given for each <i>username</i> specified, whether they are logged in or not. <i>username</i> must be that of a local user, and may be a first or last name, or an account name. Information is presented in multi-line format as follows:</p> <ul style="list-style-type: none"><li>■ the user name and the user's full name</li><li>■ the user's home directory and login shell</li><li>■ time the user logged in if currently logged in, or the time the user last logged in; and the terminal or host from which the user logged in</li><li>■ last time the user received mail, and the last time the user read mail</li><li>■ the first line of the <code>\$HOME/.project</code> file, if it exists</li><li>■ the contents of the <code>\$HOME/.plan</code> file, if it exists</li></ul> <p>Note: when the comment (GECOS) field in <code>/etc/passwd</code> includes a comma, <code>finger</code> does not display the information following the comma.</p> <p>If the arguments <code>username@hostname1[@hostname2 .. @hostnamen]</code> or <code>@hostname1[@hostname2 .. @hostnamen]</code> are used, the request is sent first to <code>hostnamen</code> and forwarded through each <code>hostname1</code> to <code>hostname1</code>. The program uses the <code>finger</code> user information protocol (see <i>RFC 1288</i>) to query that remote host for information about the named user (if <i>username</i> is specified), or about each logged-in user. The information displayed is server dependent.</p> |

As required by RFC 1288, `finger` passes only printable, 7-bit ASCII data. This behavior may be modified by a system administrator by using the `PASS` option in `/etc/default/finger`. Specifying `PASS=low` allows all characters less than decimal 32 ASCII. Specifying `PASS=high` allows all characters greater than decimal 126 ASCII. `PASS=low,high` or `PASS=high,low` allows both characters less than 32 and greater than 126 to pass through.

**OPTIONS** The following options are supported, except that the `username@hostname` form supports only the `-l` option:

- b Suppress printing the user's home directory and shell in a long format printout.
- f Suppress printing the header that is normally printed in a non-long format printout.
- h Suppress printing of the `.project` file in a long format printout.
- i Force "idle" output format, which is similar to short format except that only the login name, terminal, login time, and idle time are printed.
- l Force long output format.
- m Match arguments only on user name (not first or last name).
- p Suppress printing of the `.plan` file in a long format printout.
- q Force quick output format, which is similar to short format except that only the login name, terminal, and login time are printed.
- s Force short output format.
- w Suppress printing the full name in a short format printout.

**USAGE** The `finger` command is IPv6-enabled. See `ip6(7P)`.

| <b>NAME</b>        | fmlcut – cut out selected fields of each line of a file                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <pre>fmlcut -clist [filename...]</pre> <pre>fmlcut -flist [-dchar] [-s] [filename...]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>The <code>fmlcut</code> function cuts out columns from a table or fields from each line in <i>filename</i>; in database parlance, it implements the projection of a relation. <code>fmlcut</code> can be used as a filter; if <i>filename</i> is not specified or is <code>-</code>, the standard input is read. <i>list</i> specifies the fields to be selected. Fields can be fixed length (character positions) or variable length (separated by a field delimiter character), depending on whether <code>-c</code> or <code>-f</code> is specified.</p> <p>Note: Either the <code>-c</code> or the <code>-f</code> option must be specified.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>OPTIONS</b>     | <p><i>list</i>      A comma-separated list of integer field numbers (in increasing order), with optional <code>-</code> to indicate ranges. For example: <code>1,4,7</code>; <code>1-3,8</code>; <code>-5,10</code> (short for <code>1-5,10</code>); or <code>3-</code> (short for third through last field).</p> <p><code>-clist</code>    If <code>-c</code> is specified, <i>list</i> specifies character positions (for instance, <code>-c1-72</code> would pass the first 72 characters of each line). Note: No space intervenes between <code>-c</code> and <i>list</i>.</p> <p><code>-flist</code>    If <code>-f</code> is specified, <i>list</i> is a list of fields assumed to be separated in the file by the default delimiter character, TAB, or by <i>char</i> if the <code>-d</code> option is specified. For example, <code>-f1,7</code> copies the first and seventh field only. Lines with no delimiter characters are passed through intact (useful for table subheadings), unless <code>-s</code> is specified. Note: No space intervenes between <code>-f</code> and <i>list</i>. The following options can be used if you have specified <code>-f</code>.</p> <p>      <code>-dchar</code>    If <code>-d</code> is specified, <i>char</i> is the field delimiter. Space or other characters with special meaning to FMLI must be quoted. Note: No space intervenes between <code>-d</code> and <i>char</i>. The default field delimiter is TAB.</p> <p>      <code>-s</code>        Suppresses lines with no delimiter characters. If <code>-s</code> is not specified, lines with no delimiters will be passed through untouched.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Getting login IDs and names</p> <p>The following example gets the login IDs and names.</p> <pre>example% fmlcut -d: -f1,5 /etc/passwd</pre> <p><b>EXAMPLE 2</b> Getting the current login name</p> <p>The next example gets the current login name.</p> <pre>example% `who am i   fmlcut -f1 -d" "`</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

fmlcut(1F)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `fmlgrep(1F)`, `attributes(5)`

**DIAGNOSTICS** `fmlcut` returns the following exit values:

- 0 when the selected field is successfully cut out
- 2 on syntax errors

The following error messages may be displayed on the FMLI message line:

ERROR: line too long

A line has more than 1023 characters or fields, or there is no new-line character.

ERROR: bad list for `c / f` option

Missing `-c` or `-f` option or incorrectly specified *list*. No error occurs if a line has fewer fields than the *list* calls for.

ERROR: no fields

The *list* is empty.

ERROR: no delimiter

Missing *char* on `-d` option.

**NOTES** `fmlcut` cannot correctly process lines longer than 1023 characters, or lines with no newline character.

| <b>NAME</b>        | fmlexpr – evaluate arguments as an expression                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>SYNOPSIS</b>    | <b>fmlexpr</b> <i>arguments</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | <p>The <code>fmlexpr</code> function evaluates its arguments as an expression. After evaluation, the result is written on the standard output. Terms of the expression must be separated by blanks. Characters special to FMLI must be escaped. Note that 30 is returned to indicate a zero value, rather than the null string. Strings containing blanks or other special characters should be quoted. Integer-valued arguments may be preceded by a unary minus sign. Internally, integers are treated as 32-bit, 2s complement numbers.</p> <p>The operators and keywords are listed below. Characters that need to be escaped are preceded by <code>\</code>. The list is in order of increasing precedence, with equal precedence operators grouped within <code>{ }</code> symbols.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>USAGE</b>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Expressions</b> | <p><code>expr \  expr</code><br/>Returns the first <code>expr</code> if it is neither NULL nor 0, otherwise returns the second <code>expr</code>.</p> <p><code>expr \&amp; expr</code><br/>Returns the first <code>expr</code> if neither <code>expr</code> is NULL or 0, otherwise returns 0.</p> <p><code>expr { =, \&gt;, \&gt;=, \&lt;, \&lt;=, != } expr</code><br/>Returns the result of an integer comparison if both arguments are integers, otherwise returns the result of a lexical comparison.</p> <p><code>expr { +, - } expr</code><br/>Addition or subtraction of integer-valued arguments.</p> <p><code>expr { *, /, % } expr</code><br/>Multiplication, division, or remainder of the integer-valued arguments.</p> <p><code>expr : expr</code><br/>The matching operator <code>:</code> (colon) compares the first argument with the second argument which must be a regular expression. Regular expression syntax is the same as that of <code>ed(1)</code>, except that all patterns are "anchored" (that is, begin with <code>^</code>) and, therefore, <code>^</code> is not a special character, in that context. Normally, the matching operator returns the number of bytes matched (0 on failure). Alternatively, the <code>( . . . )</code> pattern symbols can be used to return a portion of the first argument.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Incrementing a variable</p> <p>Add 1 to the variable <code>a</code>:</p> <pre>example% fmlexpr \$a + 1   set -1 a</pre> <p><b>EXAMPLE 2</b> Setting a variable equal to a filename</p> <p>For <code>\$a</code> equal to either <code>/usr/abc/file</code> or just <code>file</code>:</p> <pre>example% fmlexpr \$a : .*/\(.*\) \  \$a</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## fmlexpr(1F)

**EXAMPLE 2** Setting a variable equal to a filename *(Continued)*

returns the last segment of a path name (that is, *file*). Watch out for / alone as an argument: `fmlexpr` will take it as the division operator (see **NOTES** below).

**EXAMPLE 3** A better representation of Example 2

```
example% fmlexpr // $a : .*/\(.*)
```

The addition of the // characters eliminates any ambiguity about the division operator (because it makes it impossible for the left-hand expression to be interpreted as the division operator), and simplifies the whole expression.

**EXAMPLE 4** Counting characters in a variable

Return the number of characters in \$VAR:

```
example% fmlexpr $VAR : .*
```

**EXIT STATUS** As a side effect of expression evaluation, `fmlexpr` returns the following exit values:

- 0 if the expression is neither NULL nor 0 (that is, TRUE)
- 1 if the expression is NULL or 0 (that is, FALSE)
- 2 for invalid expressions (that is, FALSE).

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `ed(1)`, `expr(1)`, `set(1F)`, `sh(1)`, `attributes(5)`

**DIAGNOSTICS** `syntax error` for operator/operand errors

`non-numeric argument` if arithmetic is attempted on such a string

In the case of syntax errors and non-numeric arguments, an error message will be printed at the current cursor position. Use `refresh` to redraw the screen.

**NOTES** After argument processing by FMLI, `fmlexpr` cannot tell the difference between an operator and an operand except by the value. If \$a is an =, the command:

```
example% fmlexpr $a = =
```

looks like:

```
example% fmlexpr = = =
```

as the arguments are passed to `fmlexpr` (and they will all be taken as the = operator). The following works, and returns TRUE:

fmlexpr(1F)

```
example% fmlexpr X$a = X=
```

## fmlgrep(1F)

| <b>NAME</b>        | fmlgrep – search a file for a pattern                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SYNOPSIS</b>    | <b>fmlgrep</b> [-b] [-c] [-i] [-l] [-n] [-s] [-v] <i>limited_regular_expression</i><br>[ <i>filename...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>DESCRIPTION</b> | <p>fmlgrep searches <i>filename</i> for a pattern and prints all lines that contain that pattern. fmlgrep uses limited regular expressions (expressions that have string values that use a subset of the possible alphanumeric and special characters) like those described on the <code>regex(5)</code> manual page to match the patterns. It uses a compact non-deterministic algorithm.</p> <p>Be careful when using FMLI special characters (for instance, \$, \, ', ") in <i>limited_regular_expression</i>. It is safest to enclose the entire <i>limited_regular_expression</i> in single quotes ' . . . '.</p> <p>If <i>filename</i> is not specified, fmlgrep assumes standard input. Normally, each line matched is copied to standard output. The file name is printed before each line matched if there is more than one input file.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-b        Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).</li><li>-c        Print only a count of the lines that contain the pattern.</li><li>-i        Ignore upper/lower case distinction during comparisons.</li><li>-l        Print only the names of files with matching lines, separated by new-lines. Does not repeat the names of files when the pattern is found more than once.</li><li>-n        Precede each line by its line number in the file (first line is 1).</li><li>-s        Suppress error messages about nonexistent or unreadable files.</li><li>-v        Print all lines except those that contain the pattern.</li></ul>                       |
| <b>EXIT STATUS</b> | <p>The following exit values are returned:</p> <ul style="list-style-type: none"><li>0        if the pattern is found (that is, TRUE)</li><li>1        if the pattern is not found (that is, FALSE)</li><li>2        if an invalid expression was used or <i>filename</i> is inaccessible</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>ATTRIBUTES</b>  | See <code>attributes(5)</code> for descriptions of the following attributes:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** | egrep(1), fgrep(1), fmlcut(1F), grep(1), attributes(5), regexp(5)

**NOTES** | Lines are limited to BUFSIZ characters; longer lines are truncated. BUFSIZ is defined in /usr/include/stdio.h.

If there is a line with embedded nulls, fmlgrep will only match up to the first null; if it matches, it will print the entire line.

| <b>NAME</b>        | fml - invoke FMLI                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <b>fml</b> [-a <i>alias_file</i> ] [-c <i>command_file</i> ] [-i <i>initialization_file</i> ] <i>filename...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | The <code>fml</code> command invokes the Form and Menu Language Interpreter and opens the frame(s) specified by the <i>filename</i> argument. The <i>filename</i> argument is the pathname of the initial frame definition file(s), and must follow the naming convention <code>Menu.xxx</code> , <code>Form.xxx</code> , or <code>Text.xxx</code> for a menu, form or text frame respectively, where <i>xxx</i> is any string that conforms to UNIX system file naming conventions. The FMLI descriptor <code>lifetime</code> will be ignored for all frames opened by argument to <code>fml</code> . These frames have a lifetime of <code>immortal</code> by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-a <i>alias_file</i>                      If -a is specified, <i>alias_file</i> is the name of a file which contains lines of the form <code>alias=pathname</code>. Thereafter, <code>\$alias</code> can be used in definition files to simplify references to objects or devices with lengthy pathnames, or to define a search path (similar to <code>\$PATH</code> in the UNIX system shell).</p> <p>-c <i>command_file</i>                    If -c is specified, <i>command_file</i> is the name of a file in which default FMLI commands can be disabled, and new application-specific commands can be defined. The contents of <i>command_file</i> are reflected in the FMLI Command Menu.</p> <p>-i <i>initialization_file</i>            If -i is specified, <i>initialization_file</i> is the name of a file in which the following characteristics of the application as a whole can be specified:</p> <ul style="list-style-type: none"><li>-                                      A transient introductory frame displaying product information</li><li>-                                      A banner, its position, and other elements of the banner line</li><li>-                                      Color attributes for all elements of the screen</li><li>-                                      Screen Labeled Keys (SLKs) and their layout on the screen.</li></ul> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples of the <code>fml</code> command.</p> <p>To invoke <code>fml</code>:</p> <pre>example% fml Menu.start</pre> <p>where <code>Menu.start</code> is an example of <i>filename</i> named according to the file name conventions for menu definition files explained above.</p> <p>To invoke <code>fml</code> and name an initialization file:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**EXAMPLE 1** Examples of the `fml` command. (Continued)

```
example% fml -i init.myapp Menu.start
```

where `init.myapp` is an example of *initialization\_file*.

## ENVIRONMENT VARIABLES Variables

**LOADPFK** Leaving this environment variable unset tells FMLI, for certain terminals like the AT&T 5620 and 630, to download its equivalent character sequences for using function keys into the terminal's programmable function keys, wiping out any settings the user may already have set in the function keys. Setting `LOADPFK=NO` in the environment will prevent this downloading.

**COLUMNS** Can be used to override the width of the logical screen defined for the terminal set in `TERM`. For terminals with a 132-column mode, for example, invoking FMLI with the line

```
COLUMNS=132 fml frame-file
```

will allow this wider screen width to be used.

**LINES** Can be used to override the length of the logical screen defined for the terminal set in `TERM`.

**FILES** `/usr/bin/fml`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `vsig(1F)`, `attributes(5)`

**DIAGNOSTICS** If *filename* is not supplied to the `fml` command, `fml` returns the message:

```
Initial object must be specified.
```

If *filename* does not exist or is not readable, `fml` returns an error message and exits. The example command line above returns the following message and exits:

```
Can't open object "Menu.start"
```

## fml(1)

If *filename* exists, but does not start with one of the three correct object names (Menu . , Form . , or Text .) or if it is named correctly but does not contain the proper data, fml starts to build the screen by putting out the screen labels for function keys, after which it flashes the message:

```
I do not recognize that kind of object
```

and then exits.

| <b>NAME</b>                  | fmt – simple text formatters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

| <b>SYNOPSIS</b>              | <b>fmt</b> [-cs] [-w <i>width</i>   -width] [ <i>inputfile</i> ...]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |
| <b>DESCRIPTION</b>           | <p>fmt is a simple text formatter that fills and joins lines to produce output lines of (up to) the number of characters specified in the -w <i>width</i> option. The default <i>width</i> is 72. fmt concatenates the <i>inputfiles</i> listed as arguments. If none are given, fmt formats text from the standard input.</p> <p>Blank lines are preserved in the output, as is the spacing between words. fmt does not fill nor split lines beginning with a '.' (dot), for compatibility with nroff(1). Nor does it fill or split a set of contiguous non-blank lines which is determined to be a mail header, the first line of which must begin with "From".</p> <p>Indentation is preserved in the output, and input lines with differing indentation are not joined (unless -c is used).</p> <p>fmt can also be used as an in-line text filter for vi(1). The vi command:</p> <pre>!}fmt</pre> <p>reformats the text between the cursor location and the end of the paragraph.</p> |                |                 |              |         |
| <b>OPTIONS</b>               | <p>-c Crown margin mode. Preserve the indentation of the first two lines within a paragraph, and align the left margin of each subsequent line with that of the second line. This is useful for tagged paragraphs.</p> <p>-s Split lines only. Do not join short lines to form longer ones. This prevents sample lines of code, and other such formatted text, from being unduly combined.</p> <p>-w <i>width</i>   -width Fill output lines to up to <i>width</i> columns.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                |                 |              |         |
| <b>OPERANDS</b>              | <i>inputfile</i> Input file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                |                 |              |         |

| <b>DESCRIPTION</b> | <p>Based on a message's classification component, <code>fmtmsg</code> either writes a formatted message to <code>stderr</code> or writes a formatted message to the console.</p> <p>A formatted message consists of up to five standard components (see environment variable <code>MSGVERB</code> in the <code>ENVIRONMENT</code> section of this page.) The classification and subclass components are not displayed as part of the standard message, but rather define the source of the message and direct the display of the formatted message.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |                                                          |      |                                          |      |                                          |      |                                          |                    |                                                                                                                                       |      |                                                                                                                                                  |      |                                                                                                                                             |       |                                                                                                                                           |       |                                                                                                                            |        |                                                                                                                               |       |                                                                      |         |                                                                                                           |                 |                                       |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <table><tr><td>-c <i>class</i></td><td>Describes the source of the message. Valid keywords are:</td></tr><tr><td>    hard</td><td>The source of the condition is hardware.</td></tr><tr><td>    soft</td><td>The source of the condition is software.</td></tr><tr><td>    firm</td><td>The source of the condition is firmware.</td></tr><tr><td>-u <i>subclass</i></td><td>A list of keywords (separated by commas) that further defines the message and directs the display of the message. Valid keywords are:</td></tr><tr><td>    appl</td><td>The condition originated in an application. This keyword should not be used in combination with either <code>util</code> or <code>opsys</code>.</td></tr><tr><td>    util</td><td>The condition originated in a utility. This keyword should not be used in combination with either <code>appl</code> or <code>opsys</code>.</td></tr><tr><td>    opsys</td><td>The message originated in the kernel. This keyword should not be used in combination with either <code>appl</code> or <code>util</code>.</td></tr><tr><td>    recov</td><td>The application will recover from the condition. This keyword should not be used in combination with <code>nrecov</code>.</td></tr><tr><td>    nrecov</td><td>The application will not recover from the condition. This keyword should not be used in combination with <code>recov</code>.</td></tr><tr><td>    print</td><td>Print the message to the standard error stream <code>stderr</code>.</td></tr><tr><td>    console</td><td>Write the message to the system console. <code>print</code>, <code>console</code>, or both may be used.</td></tr><tr><td>-l <i>label</i></td><td>Identifies the source of the message.</td></tr></table> | -c <i>class</i> | Describes the source of the message. Valid keywords are: | hard | The source of the condition is hardware. | soft | The source of the condition is software. | firm | The source of the condition is firmware. | -u <i>subclass</i> | A list of keywords (separated by commas) that further defines the message and directs the display of the message. Valid keywords are: | appl | The condition originated in an application. This keyword should not be used in combination with either <code>util</code> or <code>opsys</code> . | util | The condition originated in a utility. This keyword should not be used in combination with either <code>appl</code> or <code>opsys</code> . | opsys | The message originated in the kernel. This keyword should not be used in combination with either <code>appl</code> or <code>util</code> . | recov | The application will recover from the condition. This keyword should not be used in combination with <code>nrecov</code> . | nrecov | The application will not recover from the condition. This keyword should not be used in combination with <code>recov</code> . | print | Print the message to the standard error stream <code>stderr</code> . | console | Write the message to the system console. <code>print</code> , <code>console</code> , or both may be used. | -l <i>label</i> | Identifies the source of the message. |
| -c <i>class</i>    | Describes the source of the message. Valid keywords are:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                 |                                                          |      |                                          |      |                                          |      |                                          |                    |                                                                                                                                       |      |                                                                                                                                                  |      |                                                                                                                                             |       |                                                                                                                                           |       |                                                                                                                            |        |                                                                                                                               |       |                                                                      |         |                                                                                                           |                 |                                       |
| hard               | The source of the condition is hardware.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                 |                                                          |      |                                          |      |                                          |      |                                          |                    |                                                                                                                                       |      |                                                                                                                                                  |      |                                                                                                                                             |       |                                                                                                                                           |       |                                                                                                                            |        |                                                                                                                               |       |                                                                      |         |                                                                                                           |                 |                                       |

| <i>-s severity</i> | Indicates the seriousness of the error. The keywords and definitions of the standard levels of <i>severity</i> are:                                                                                                                                                                                                                                                                                                                          |      |                                                                |       |                                       |      |                                                                                              |      |                                                                                  |
|                    | <table> <tr> <td>halt</td> <td>The application has encountered a severe fault and is halting.</td> </tr> <tr> <td>error</td> <td>The application has detected a fault.</td> </tr> <tr> <td>warn</td> <td>The application has detected a condition that is out of the ordinary and might be a problem.</td> </tr> <tr> <td>info</td> <td>The application is providing information about a condition that is not in error.</td> </tr> </table> | halt | The application has encountered a severe fault and is halting. | error | The application has detected a fault. | warn | The application has detected a condition that is out of the ordinary and might be a problem. | info | The application is providing information about a condition that is not in error. |
| halt               | The application has encountered a severe fault and is halting.                                                                                                                                                                                                                                                                                                                                                                               |      |                                                                |       |                                       |      |                                                                                              |      |                                                                                  |
| error              | The application has detected a fault.                                                                                                                                                                                                                                                                                                                                                                                                        |      |                                                                |       |                                       |      |                                                                                              |      |                                                                                  |
| warn               | The application has detected a condition that is out of the ordinary and might be a problem.                                                                                                                                                                                                                                                                                                                                                 |      |                                                                |       |                                       |      |                                                                                              |      |                                                                                  |
| info               | The application is providing information about a condition that is not in error.                                                                                                                                                                                                                                                                                                                                                             |      |                                                                |       |                                       |      |                                                                                              |      |                                                                                  |
| <i>-t tag</i>      | The string containing an identifier for the message.                                                                                                                                                                                                                                                                                                                                                                                         |      |                                                                |       |                                       |      |                                                                                              |      |                                                                                  |
| <i>-a action</i>   | A text string describing the first step in the error recovery process. This string must be written so that the entire <i>action</i> argument is interpreted as a single argument. <code>fmtmsg</code> precedes each action string with the <code>TO FIX:</code> prefix.                                                                                                                                                                      |      |                                                                |       |                                       |      |                                                                                              |      |                                                                                  |
| <i>text</i>        | A text string describing the condition. Must be written so that the entire <i>text</i> argument is interpreted as a single argument.                                                                                                                                                                                                                                                                                                         |      |                                                                |       |                                       |      |                                                                                              |      |                                                                                  |

**EXAMPLES****EXAMPLE 1** Standard message format

The following example of `fmtmsg` produces a complete message in the standard message format and displays it to the standard error stream:

```
example% fmtmsg -c soft -u recov,print,appl -l UX:cat -s error -t UX:cat:001
-a "refer to manual" "invalid syntax"
```

produces:

```
UX:cat: ERROR: invalid syntax
TO FIX: refer to manual UX:cat:138
```

**EXAMPLE 2** Using MSGVERB

When the environment variable `MSGVERB` is set as follows:

```
MSGVERB=severity:text:action
```

and Example 1 is used, `fmtmsg` produces:

```
ERROR: invalid syntax
TO FIX: refer to manual
```

**EXAMPLE 3** Using SEV\_LEVEL

When the environment variable `SEV_LEVEL` is set as follows:

```
SEV_LEVEL=note,5,NOTE
```

the following `fmtmsg` command:

fmtmsg(1)

## ENVIRONMENT VARIABLES

### EXAMPLE 3 Using SEV\_LEVEL (Continued)

```
example% fmtmsg -c soft -u print -l UX:cat -s note -a "refer to manual"
"invalid syntax"
```

produces:

NOTE: invalid syntax  
TO FIX: refer to manual

and displays the message on `stderr`.

The environment variables `MSGVERB` and `SEV_LEVEL` control the behavior of `fmtmsg`. `MSGVERB` is set by the administrator in the `/etc/profile` for the system. Users can override the value of `MSGVERB` set by the system by resetting `MSGVERB` in their own `.profile` files or by changing the value in their current shell session. `SEV_LEVEL` can be used in shell scripts.

`MSGVERB` tells `fmtmsg` which message components to select when writing messages to `stderr`. The value of `MSGVERB` is a colon-separated list of optional keywords. `MSGVERB` can be set as follows:

```
MSGVERB=[keyword[:keyword[:...]]]
export MSGVERB
```

Valid *keywords* are: `label`, `severity`, `text`, `action`, and `tag`. If `MSGVERB` contains a keyword for a component and the component's value is not the component's null value, `fmtmsg` includes that component in the message when writing the message to `stderr`. If `MSGVERB` does not include a keyword for a message component, that component is not included in the display of the message. The keywords may appear in any order. If `MSGVERB` is not defined, if its value is the null string, if its value is not of the correct format, or if it contains keywords other than the valid ones listed above, `fmtmsg` selects all components.

`MSGVERB` affects only which message components are selected for display. All message components are included in console messages.

`SEV_LEVEL` defines severity levels and associates print strings with them for use by `fmtmsg`. The standard severity levels shown below cannot be modified. Additional severity levels can be defined, redefined, and removed.

|   |                       |
|---|-----------------------|
| 0 | (no severity is used) |
| 1 | HALT                  |
| 2 | ERROR                 |
| 3 | WARNING               |
| 4 | INFO                  |

SEV\_LEVEL is set as follows:

```
SEV_LEVEL= [description[:description[...]]]
export SEV_LEVEL
```

*description* is a comma-separated list containing three fields:

*description=severity\_keyword, level, printstring*

*severity\_keyword* is a character string used as the keyword with the `-s severity` option to `fmtmsg`.

*level* is a character string that evaluates to a positive integer (other than 0, 1, 2, 3, or 4, which are reserved for the standard severity levels). If the keyword *severity\_keyword* is used, *level* is the severity value passed on to `fmtmsg(3C)`.

*printstring* is the character string used by `fmtmsg` in the standard message format whenever the severity value *level* is used.

If `SEV_LEVEL` is not defined, or if its value is null, no severity levels other than the defaults are available. If a *description* in the colon separated list is not a comma separated list containing three fields, or if the second field of a comma separated list does not evaluate to a positive integer, that *description* in the colon separated list is ignored.

**EXIT STATUS** The following exit values are returned:

- 0 All the requested functions were executed successfully.
- 1 The command contains a syntax error, an invalid option, or an invalid argument to an option.
- 2 The function executed with partial success, however the message was not displayed on `stderr`.
- 4 The function executed with partial success; however, the message was not displayed on the system console.
- 32 No requested functions were executed successfully.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>SYNOPSIS</b>    | <pre>fnattr [-AL] composite_name [ [-O   -U] identifier...]</pre> <pre>fnattr [-L] composite_name [ {-a [-s] [-O   -U] identifier [value...]}   {-d</pre> <pre>  [ [-O   -U] identifier [value...]] }   {-m [-O   -U] identifier old_value</pre> <pre>  new_value}...]</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>DESCRIPTION</b> | The <code>fnattr</code> command is for updating and examining attributes associated with an FNS named object. There are four uses for this command: add an attribute or value, delete an attribute or value, modify an attribute's value, and list the contents of an attribute.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p>The options for adding, modifying, and deleting attributes and their values can be combined in the same command line. The modifications will be executed in the order that they are specified.</p> <p>Any unsuccessful modification will abort all subsequent modifications specified in the command line; any modifications already carried out will remain. The unsuccessful modifications are displayed as output of <code>fnattr</code>.</p> <ul style="list-style-type: none"> <li>-a        Add an attribute or add a value to an attribute associated with object named by <i>composite_name</i>. <i>identifier</i> is the identifier of the attribute to manipulate; its format is <code>FN_ID_STRING</code> unless the <code>-O</code> or <code>-U</code> option is given. <i>value . . .</i> represents the attribute values to add. The attribute syntax used for storing <i>value</i> is <code>fn_attr_syntax_ascii</code>.</li> <li>-A        Consult the authoritative source to get attribute information.</li> <li>-d        Delete attributes associated with object named by <i>composite_name</i>. If <i>identifier</i> is not specified, all attributes associated with the named object are deleted. If <i>identifier</i> is specified without accompanying values (<i>value . . .</i>), the entire attribute identified by <i>identifier</i> is removed. If individual attribute values (<i>value . . .</i>) are specified, then only these are removed from the attribute. Removal of the last value of an attribute entails removal of the attribute as well. The format of <i>identifier</i> is <code>FN_ID_STRING</code> unless the <code>-O</code> or <code>-U</code> option is given.</li> <li>-L        If the composite name is bound to an XFN link, manipulate the attributes associated with the object pointed to by the link. If <code>-L</code> is not used, the attributes associated with the XFN link are manipulated.</li> <li>-m        Modify the values of the attribute identified by <i>identifier</i> associated with the object named by <i>composite_name</i>. <i>old_value</i> is replaced by <i>new_value</i> in the specified attribute. Other attributes and values associated with <i>composite_name</i> are not affected. The format of <i>identifier</i> is <code>FN_ID_STRING</code> unless the <code>-O</code> or <code>-U</code> option is given.</li> <li>-O        The format of <i>identifier</i> is <code>FN_ID_ISO_OID_STRING</code>, an ASN.1 dot-separated integer list string.</li> </ul> |

- s        Add in supersede mode. If an attribute with the same identifier as *identifier* already exists, remove *all* its values, and replace with *value*. If this option is omitted, the resulting values for the specified attribute is a union of the existing values and *value*.
- U        The format of *identifier* is FN\_ID\_DCE\_UUID, a DCE UUID in string form.

**OPERANDS**    The following operand is supported:

*composite\_name*                    An FNS named object.

## EXAMPLES

**Adding**    The -a option is used for adding attributes and values. This following command replaces the value of the `shoesize` attribute of `user/jane` with the value `7.5`:

```
eg% fnattr user/jane -as shoesize 7.5
```

The following command adds the value `Chameleo` to the `project` attribute of `user/jane`:

```
eg% fnattr user/jane -a project Chameleo
```

**Deleting**    The -d option is used for deleting attributes and values. The following command deletes all the attributes associated with `user/jane`:

```
eg% fnattr user/jane -d
```

The following command deletes the attribute `shoesize` associated with `user/jane`:

```
eg% fnattr user/jane -d shoesize
```

The following command deletes the attribute value `old_project` from the `projects` attribute associated with `user/jane`:

```
eg% fnattr user/jane -d projects old_project
```

**Modifying**    The -m option is for modifying an attribute value. The following command replaces the value `Chameleo` by `Dungeon` in the `projects` attribute associated with `user/jane`:

```
eg% fnattr user/jane -m projects Chameleo Dungeon
```

## fnattr(1)

The following command is an example of unsuccessful modification attempts. The user executing this command does not have permission to update `user/jane`'s attributes but is allowed to *add* new attributes. Executing the command will add the attribute `hatsize` but will not delete `shoesize` or modify `dresssize` because `-d shoesize` will fail and cause the command to stop:

```
eg% fnattr user/jane -a hatsize medium -d shoesize -m dresssize 5
6
```

**Listing** No options are required to list attributes and their values. The following command lists all the attributes associated with `user/jane`:

```
eg% fnattr user/jane
```

The following command lists the values of the `project` attribute of `user/jane`:

```
eg% fnattr user/jane project
```

The following command lists the values of the `project` and `shoesize` attributes of `user/jane`:

```
eg% fnattr user/jane project shoesize
```

**EXIT STATUS** 0           Operation was successful.

1           Operation failed.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWfns         |

**SEE ALSO** `fnlookup(1)`, `attributes(5)`, `fns(5)`

**NOTES** Built-in attributes, such as `onc_unix_passwd` for users, cannot be updated using the `fnattr` command. Their contents are affected by updates to the underlying naming service, such as NIS+ or NIS.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>NAME</b>        | fnbind – Bind a reference to an FNS name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>SYNOPSIS</b>    | <p><b>fnbind</b> [-s] [-v] [-L] <i>name new_name</i></p> <p><b>fnbind</b> -r [-s] [-v] <i>new_name</i> [-O   -U] <i>ref_type</i> { [-O   -U] <i>addr_type</i> [-c   -x] <i>addr_contents</i> }...</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | The fnbind utility binds the reference named by <i>name</i> to the name <i>new_name</i> . The second synopsis of fnbind (uses the -r option) allows the binding of <i>new_name</i> to the reference constructed using arguments supplied in the command line.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-s Bind to <i>new_name</i> even if it is already bound. If this option is omitted, fnbind fails if <i>new_name</i> is already bound.</li> <li>-v Display the reference being bound to <i>new_name</i>.</li> <li>-L Create an XFN link using <i>name</i> and bind it to <i>new_name</i>.</li> <li>-r Create a reference using <i>ref_type</i> as the reference's type, and one or more pairs of <i>addr_type</i> and <i>addr_contents</i> as the reference's list of addresses, and bind this reference to <i>new_name</i>. Unless the -O or -U options are used, FN_ID_STRING is used as the identifier format for <i>ref_type</i> and <i>addr_type</i>. Unless the -c or -x options are used, <i>addr_contents</i> is stored as an XDR-encoded string.</li> <li>-c Store <i>addr_contents</i> in the given form; do not use XDR-encoding.</li> <li>-x <i>addr_contents</i> specifies a hexadecimal string. Convert it to its hexadecimal representation and store it; do not use XDR-encoding.</li> <li>-O The identifier format is FN_ID_ISO_OID_STRING, an ASN.1 dot-separated integer list string.</li> <li>-U The identifier format is FN_ID_DCE_UUID, a DCE UUID in string form.</li> </ul> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Binding a service to a printer</p> <p>The command</p> <pre>example% fnbind -s thisorgunit/service/printer thisorgunit/service/pr</pre> <p>binds the name <i>thisorgunit/service/pr</i> to the reference named by <i>thisorgunit/service/printer</i>. Any reference bound to <i>thisorgunit/service/pr</i> is overwritten.</p> <p><b>EXAMPLE 2</b> Binding to an XFN link</p> <p>The command</p> <pre>example% fnbind -L thisorgunit/service/printer thisorgunit/service/pr</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## fnbind(1)

### **EXAMPLE 2** Binding to an XFN link *(Continued)*

binds the name `thisorgunit/service/pr` to the XFN link constructed using the name `thisorgunit/service/printer`.

### **EXAMPLE 3** Binding to an address type

The command

```
example% fnbind -r thisorgunit/service/calendar SUNW_cal \
SUNW_cal_deskset_onc staff@exodus
```

binds the name `thisorgunit/service/calendar` to the reference with reference type `SUNW_cal` and address type `SUNW_cal_deskset_onc`, and address contents of `staff@exodus`.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWfns         |

| <b>NAME</b>        | fnlist – display the names and references bound in an FNS context                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>fnlist</b> [-A v] [ <i>composite_name</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>DESCRIPTION</b> | <p>fnlist displays the names and references bound in the context of <i>composite_name</i>.</p> <p>If <i>composite_name</i> is not provided, the default initial context is displayed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-A Consult the authoritative source for information.</li> <li>-l Display the references as well as the names bound in the context of <i>composite_name</i>. Without this option, only the names are displayed.</li> <li>-v Display the references in detail. For <code>onc_fn_*</code> references, this option is useful to derive the name of the NIS+ table that stores the reference for every name bound in the context of <i>composite_name</i>.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                      |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><i>composite_name</i> An FNS named object. Composite names, like UNIX file names, depend on the subcontexts created. Examples of commands with valid <i>composite_name</i> operands are:</p> <pre style="margin-left: 40px;">eg% fnlist thisorgunit eg% fnlist thisorgunit/service eg% fnlist thisorgunit/service/printer</pre> <p>When FNS is deployed, the composite name is specific to the deployed site.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples of the fnlist command.</p> <p>In the following example, the command with no operand provides the listing with reference and address types for the initial context:</p> <pre style="margin-left: 20px;">eg% fnlist -l</pre> <p>In the following examples, where a user context is given (that is, <i>composite_name</i> = <i>user/</i>), FNS must first be deployed via <code>fncreate(1M)</code>, using one of the naming services NIS, NIS+, or files. If FNS is not deployed, there are no user contexts and the commands will fail with the "Name not found" error message.</p> <p>The following command shows the names bound in the context of <i>user/</i>:</p> <pre style="margin-left: 20px;">eg% fnlist user/</pre> <p>The following command displays the names and references bound in the context of <i>user/</i>:</p> <pre style="margin-left: 20px;">eg% fnlist -l user/</pre> |

## fnrename(1)

| <b>NAME</b>        | fnrename – rename the binding of an FNS name                                                                                                                                                                                                                       |                |                 |              |         |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <b>fnrename</b> [-s] [-v] <i>context_name old_atomic_name new_atomic_name</i>                                                                                                                                                                                      |                |                 |              |         |
| <b>DESCRIPTION</b> | fnrename renames the binding of <i>old_atomic_name</i> to <i>new_atomic_name</i> in the context of <i>context_name</i> . Both <i>old_atomic_name</i> and <i>new_atomic_name</i> must be atomic names, to be resolved in the context named by <i>context_name</i> . |                |                 |              |         |
| <b>OPTIONS</b>     | -s        Overwrite any reference already bound to <i>new_atomic_name</i> . If this option is omitted, fnrename fails if <i>new_atomic_name</i> is already bound.<br>-v        Display the binding being renamed.                                                  |                |                 |              |         |
| <b>EXAMPLES</b>    | <b>EXAMPLE 1</b> An example of the fnrename command.<br>For example, the command<br>eg% fnrename user/jsmith/service/ clendar calendar<br>binds calendar to the reference bound to clendar in the context named by user/jsmith/service/ and unbinds clendar.       |                |                 |              |         |
| <b>ATTRIBUTES</b>  | See attributes(5) for descriptions of the following attributes:                                                                                                                                                                                                    |                |                 |              |         |

| <b>NAME</b>        | fnsearch – search for FNS objects with specified attributes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>SYNOPSIS</b>    | <b>fnsearch</b> [-Allv] [-n <i>max</i> ] [-s <i>scope</i> ] <i>composite_name</i> [-a <i>ident</i> ]... [-O<br>  -U] <i>filter_expr</i> [ <i>filter_arg</i> ]...                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b> | <p>The <code>fnsearch</code> command operation displays the names and, optionally, the attributes and references of objects bound at or below <i>composite_name</i> whose attributes satisfy a given filter expression. The filter expression is given in terms of logical expressions involving the identifiers and values of the attributes and references of objects examined during the search.</p> <p>For general information about FNS, see <code>fns(5)</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"> <li>-a <i>ident</i>            Display the given attribute of each object that satisfies the filter expression. If the <code>-a</code> option is not used, all attributes are displayed. An empty <i>ident</i> (" " from the shell) indicates that no attributes are to be displayed. Multiple <code>-a</code> options may be given. The syntax of <i>ident</i> is described fully under <code>Displaying Selected Attributes</code> below.</li> <li>-A                    Consult the authoritative source(s) for information.</li> <li>-l                    Display the reference of each object that satisfies the filter expression.</li> <li>-L                    Follow XFN links during the search.</li> <li>-n <i>max</i>             Restrict the maximum number of objects displayed to the given number (a positive integer). There is no limit by default.</li> <li>-s <i>scope</i>            Set the scope of the search. <i>scope</i> is one of: <ul style="list-style-type: none"> <li>• <code>object</code>                    Only the object <i>composite_name</i> is searched.</li> <li>• <code>context</code>                   Objects bound directly to <i>composite_name</i> are searched.</li> <li>• <code>subtree</code>                    Objects bound to <i>composite_name</i> or any of its subcontexts are searched.</li> <li>• <code>constrained_subtree</code>       Like <code>subtree</code>, but the search may be restricted to a set of subcontexts defined in a context-implementation-defined manner</li> </ul> </li> </ul> |

| <b>USAGE</b>                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Simple Filter Expressions</b> | <p>The simplest form of filter expression is one that tests for the existence of an attribute. This expression is formed simply by giving the attribute's name. To search for objects having an attribute named <code>for_sale</code>, for example:</p> <pre>% fnsearch composite_name for_sale</pre> <p>Another simple filter expression is one that tests the value of a particular attribute. To find objects whose ages are less than 17:</p> <pre>% fnsearch composite_name "age &lt; 17"</pre> <p>String values are indicated by enclosing the string in single quotes. To find all <code>red</code> objects:</p> <pre>% fnsearch composite_name "color == 'red'"</pre> <p>Note that the double quotes ( <code>"</code> ) in this example are not part of the filter expression. Instead, they prevent the shell from interpreting the white-space and single quotes that <i>are</i> part of the expression.</p> |
| <b>Logical Operators</b>         | <p>Simple filter expressions may be composed using the logical operators <code>and</code>, <code>or</code>, and <code>not</code>. For example:</p> <pre>% fnsearch composite_name "age &gt;= 35 and us_citizen"</pre> <p>Parentheses may be used to group expressions:</p> <pre>% fnsearch composite_name "not (make == 'olds' and year == 1973)"</pre> <p>The precedence of operators is, in order of increasing precedence:</p> <pre>or and not relational operators (see Relational Operators below)</pre> <p>The logical operators <code>and</code> and <code>or</code> are left-associative.</p>                                                                                                                                                                                                                                                                                                                  |
| <b>Relational Operators</b>      | <p>The following are the relational operators that may be used to compare an attribute to a supplied value:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|    |                                                                                                                                                                                        |
|----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| == | True if at least one value of the attribute is equal to the supplied value.                                                                                                            |
| != | True if none of the attribute's values are equal to the supplied value.                                                                                                                |
| <  | True if at least one value of the attribute is less than the supplied value.                                                                                                           |
| <= | True if at least one value of the attribute is less than or equal to the supplied value.                                                                                               |
| >  | True if at least one value of the attribute is greater than the supplied value.                                                                                                        |
| >= | True if at least one value of the attribute is greater than or equal to the supplied value.                                                                                            |
| ~= | True if at least one value of the attribute matches the supplied value according to some context-specific approximate matching criterion. This criterion must subsume strict equality. |

Comparisons and ordering are specific to the syntax or rules of the attribute being tested.

### Displaying Selected Attributes

By default, the `fnsearch` command displays the names and all of the attributes of each object matching the search criteria. The list of attributes displayed may be restricted by using the `-a` command line option. In the following example, only the `color` and `shape` attributes of `small` objects are displayed:

```
% fnsearch composite_name -a color -a shape "size == 'small'"
```

The format of an attribute identifier is taken to be `FN_ID_STRING` (an ASCII string) by default. To name an attribute identifier that is an OSI OID or a DCE UUID, the attribute name is prefixed by `-O` or `-U`, respectively:

`-O` The identifier format is `FN_ID_ISO_OID_STRING`, an ASN.1 dot-separated integer list string.

`-U` The identifier format is `FN_ID_DCE_UUID`, a DCE UUID in string form.

For example:

```
% fnsearch composite_name -a -O 2.5.4.0 "shoe_size < 9"
```

and

```
% fnsearch composite_name -a -U 0006a446-5e97-105f-9828-8190285baa77 \
"bowling_avg > 200"
```

### Filter Arguments

Some parts of a filter expression may be replaced by a substitution token: a percent sign (%) followed by a single character. The value of this portion of the expression is then given in a filter argument that follows the filter expression, in much the same way as is done in `printf(1)`. The available substitution tokens are:

|    |            |
|----|------------|
| %a | attribute  |
| %s | string     |
| %i | identifier |

## fnsearch(1)

`%v` attribute value (the only syntax currently supported is `fn_attr_syntax_ascii`)

For example, the command:

```
% fnsearch composite_name "color == 'red'"
```

could equivalently be written:

```
% fnsearch composite_name "%a == 'red'" color
```

or:

```
% fnsearch composite_name "%a == %s" color red
```

The use of substitution tokens is helpful when writing shell scripts in which the values of the filter arguments are generated at run-time.

By default, the format of the identifier of an attribute such as the `color` attribute above is taken to be `FN_ID_STRING` (an ASCII string). Substitution tokens enable the use of OSI OIDs and DCE UUIDs instead. The filter argument is prefixed by `-O` or `-U`, with the same meaning as in the `-a` command line option described above:

`-O` The identifier format is `FN_ID_ISO_OID_STRING`, an ASN.1 dot-separated integer list string.

`-U` The identifier format is `FN_ID_DCE_UUID`, a DCE UUID in string form.

For example:

```
% fnsearch composite_name "%a -O 2.5.4.0
```

and

```
% fnsearch composite_name "%a" =='red'" \
-U 0006a446-5e97-105f-9828-8190285baa77
```

## Wildcarded Strings

A wildcarded string consists of a sequence of alternating wildcard specifiers and strings. The wildcard specifiers is denoted by the asterisk (\*) and means zero or more occurrences of any character.

Wildcarded strings are used to specify substring matches. The following are some examples of wildcarded strings and their meanings.

|                       |                                                  |
|-----------------------|--------------------------------------------------|
| <code>*</code>        | any string                                       |
| <code>'tom'</code>    | the string "tom"                                 |
| <code>'harv' *</code> | any string starting with "harv"                  |
| <code>*'ing'</code>   | any string ending with "ing"                     |
| <code>'a'*'b'</code>  | any string starting with "a" and ending with "b" |

fnsearch(1)

|                                                         |                                                                                                                                                                              |
|---------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ' <i>jo</i> '*' <i>ph</i> '*' <i>ne</i> '*' <i>er</i> ' | any string starting with "jo" and containing the substring "ph", and which contains the substring "ne" in the portion of the string following "ph", and which ends with "er" |
| %s*                                                     | any string starting with the string supplied as a filter argument                                                                                                            |
| ' <i>bix</i> '*%s                                       | any string starting with "bix" and ending with the string supplied as a filter argument                                                                                      |

**Extended Operations**

Extended operators are predicates (functions that return TRUE or FALSE) that may be freely mixed with other operators in a filter expression.

An extended operation is specified by giving the operation name as a quoted string, followed by an argument in parentheses. The following three extended operations are currently defined:

|                                             |                                                                                                       |
|---------------------------------------------|-------------------------------------------------------------------------------------------------------|
| ' <i>name</i> ' ( <i>WildcardedString</i> ) | TRUE if the name of the object matches the supplied wildcarded string.                                |
| ' <i>reftype</i> ' ( <i>Identifier</i> )    | TRUE if the reference type of the object is equal to the supplied identifier.                         |
| ' <i>addrtype</i> ' ( <i>Identifier</i> )   | TRUE if any of the address types in the reference of the object are equal to the supplied identifier. |

The following example shows a search for objects whose names start with *bill* and having IQ attributes over 80:

```
% fnsearch composite_name "'name'('bill'*) and IQ > 80"
```

**Grammar of Filter Expressions**

The complete grammar of filter expressions is given below. It is based on the grammar defined by the XFN specification (see FN\_search\_filter\_t(3XFN)).

String literals in this grammar are enclosed in double quotes; the quotes are not themselves part of the expression. Braces are used for grouping; brackets indicate optional elements. An unquoted asterisk (\*) signifies zero or more occurrences of the preceding element; a plus sign (+) signifies one or more occurrences.

|                     |   |   |                                                                                                                                                                            |
|---------------------|---|---|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>FilterExpr</i> : | : | = | [ <i>Expr</i> ]                                                                                                                                                            |
| <i>Expr</i> :       | : | = | <i>Expr</i> "or" <i>Expr</i>   <i>Expr</i> "and" <i>Expr</i>   "not" <i>Expr</i>   "(" <i>Expr</i> ")"<br>  <i>Attribute</i> [ <i>RelOp</i> <i>Value</i> ]<br>  <i>Ext</i> |
| <i>RelOp</i> :      | : | = | "=="   "!="   "<"   "<="   ">"   ">="   "~="                                                                                                                               |

## fnsearch(1)

```

Attribute : : =
 Char* | "%a"

Value : : =
 Integer | WildcardedString | "%v"

WildcardedString : : =
 "*" | String | {String "*"}+ [String]
 | {"*" String}+ [{"*"}]
 (that is, an alternating sequence of String and "*")

String : : =
 "' ' Char* "'
 | "%s"

Ext : : =
 "' name' (" WildcardedString ")"
 | "' reftype' (" Identifier ")"
 | "' addrtype' (" Identifier ")"

Identifier : : =
 "' ' Char* "'
 | "%i"

Char : : =
 an element of the Portable Character Set (ASCII)
 | a character in the repertoire
 of a string representation

```

**EXIT STATUS**

0        Operation was successful.

1        Operation failed.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWfns         |

**SEE ALSO** `printf(1)`, `FN_search_control_t(3XFN)`, `FN_search_filter_t(3XFN)`, `fn_attr_ext_search(3XFN)`, `fn_attr_search(3XFN)`, `attributes(5)`, `fns(5)`

**NOTES** If the filter expression is empty, it evaluates to TRUE (all objects satisfy it).

fnsearch(1)

If the identifier in any subexpression of the filter expression does not exist as an attribute of an object, then the innermost logical expression containing that identifier evaluates to `FALSE`.

## fnunbind(1)

**NAME** | fnunbind – unbind the reference from an FNS name

**SYNOPSIS** | **fnunbind** *composite\_name*

**DESCRIPTION** | fnunbind unbinds the reference of *composite\_name*.

For example,

```
eg% fnunbind user/jsmith/fs/
```

unbinds the reference to which the name *user/jsmith/fs/* was bound.

Note that an `fnunbind` on a name of a context will fail because such a context cannot be unbound without destroying it first with the command `fndestroy`.

**ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWfns         |

**SEE ALSO** | `fnbind(1)`, `fnlist(1)`, `fnlookup(1)`, `fnrename(1)`, `fncreate(1M)`, `fndestroy(1M)`, `attributes(5)`, `fns(5)`

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | fold – filter for folding lines                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>    | <b>fold</b> [-bs] [-w <i>width</i>   -width] [ <i>file...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>DESCRIPTION</b> | <p>The <code>fold</code> utility is a filter that will fold lines from its input files, breaking the lines to have a maximum of <i>width</i> column positions (or bytes, if the <code>-b</code> option is specified). Lines will be broken by the insertion of a NEWLINE character such that each output line (referred to later in this section as a segment) is the maximum width possible that does not exceed the specified number of column positions (or bytes). A line will not be broken in the middle of a character. The behavior is undefined if <i>width</i> is less than the number of columns any single character in the input would occupy.</p> <p>If the CARRIAGE-RETURN, BACKSPACE, or TAB characters are encountered in the input, and the <code>-b</code> option is not specified, they will be treated specially:</p> <p><b>BACKSPACE</b>                      The current count of line width will be decremented by one, although the count never will become negative. <code>fold</code> will not insert a NEWLINE character immediately before or after any BACKSPACE character.</p> <p><b>CARRIAGE-RETURN</b>                The current count of line width will be set to 0. <code>fold</code> will not insert a NEWLINE character immediately before or after any CARRIAGE-RETURN character.</p> <p><b>TAB</b>                                Each TAB character encountered will advance the column position pointer to the next tab stop. Tab stops will be at each column position <i>n</i> such that <i>n</i> modulo 8 equals 1.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-b</code>                                Count <i>width</i> in bytes rather than column positions.</p> <p><code>-s</code>                                If a segment of a line contains a blank character within the first <i>width</i> column positions (or bytes), break the line after the last such blank character meeting the width constraints. If there is no blank character meeting the requirements, the <code>-s</code> option will have no effect for that output segment of the input line.</p> <p><code>-w <i>width</i>   -width</code>                Specify the maximum line length, in column positions (or bytes if <code>-b</code> is specified). If <i>width</i> is not a positive decimal number, an error is returned. The default value is 80.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>OPERANDS</b>    | <p>The following operand is supported:</p> <p><code>file</code>                                A path name of a text file to be folded. If no <code>file</code> operands are specified, the standard input will be used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## fold(1)

**EXAMPLES** **EXAMPLE 1** Submitting a file of possibly long lines to the line printer.

An example invocation that submits a file of possibly long lines to the line printer (under the assumption that the user knows the line width of the printer to be assigned by `lp(1)`):

```
example% fold -w 132 bigfile | lp
```

### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `fold`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

### EXIT STATUS

The following exit values are returned:

0 All input files were processed successfully.

>0 An error occurred.

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**SEE ALSO** `cut(1)`, `pr(1)`, `attributes(5)`, `environ(5)`

### NOTES

`fold` and `cut(1)` can be used to create text files out of files with arbitrary line lengths. `fold` should be used when the contents of long lines need to be kept contiguous. `cut` should be used when the number of lines (or records) needs to remain constant.

`fold` is frequently used to send text files to line printers that truncate, rather than fold, lines wider than the printer is able to print (usually 80 or 132 column positions).

`fold` may not work correctly if underlining is present.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>NAME</b>        | for, foreach, repeat – shell built-in functions to repeatedly execute action(s) for a selected number of times                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>SYNOPSIS</b>    | <pre> <b>sh</b>  <b>for</b> <i>word</i> [<i>in wordlist...</i>] ; do <i>actions</i> ; done <b>csk</b>  <b>foreach</b> <i>word</i> ( <i>wordlist</i> )       [...]       <b>end</b>       <b>repeat</b> <i>count</i> <i>command</i> <b>ksh</b>  <b>for</b> <i>word</i> [<i>in wordlist...</i>] ; do <i>actions</i> ; done </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p><b>sh</b> Each time a <code>for</code> command is executed, <i>word</i> is set to the next item taken from the <i>in wordlist</i>. If <i>in wordlist . . .</i> is omitted, then the <code>for</code> command executes the <code>do actions</code> once for each positional parameter that is set. Execution ends when there are no more words in the list.</p> <p><b>csk</b> The variable <i>word</i> is successively set to each member of <i>wordlist</i>. The sequence of commands between this command and the matching <code>end</code> is executed for each new value of <i>word</i>. Both <code>foreach</code> and <code>end</code> must appear alone on separate lines.</p> <p><code>repeat</code> executes <i>command</i> repeatedly <i>count</i> times. <i>count</i> must be a number. <i>command</i> is restricted to a one-line statement.</p> <p><b>ksh</b> Each time a <code>for</code> command is executed, <i>word</i> is set to the next item taken from the <i>in wordlist</i>. If <i>in wordlist . . .</i> is omitted, then the <code>for</code> command executes the <code>do actions</code> once for each positional parameter that is set. Execution ends when there are no more words in the list.</p> <p><b>loop interrupts</b> The built-in command <code>continue</code> may be used to terminate the execution of the current iteration of a <code>for</code> or <code>foreach</code> loop, and the built-in command <code>break</code> may be used to terminate execution of a <code>for</code> or <code>foreach</code> command.</p> |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Examples using the <code>for</code> command.</p> <p>In the examples using <code>for/foreach</code>, the code counts the number of lines for each file in the current directory whose name ends with a ".c" extension. The <code>repeat</code> example prints "I will not chew gum in class" 500 times.</p> <pre> <b>sh</b>  for file in *.c ; do wc -l \$file ; done <b>csk</b>  foreach file ( *.c)       wc -l \$file       end <b>ksh</b>  for file in *.c ; do wc -l \$file ; done <b>csk</b>  The repeat command re-executes the single subsequent command for <i>count</i> number of times. </pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

for(1)

```
@ repetition = 500
repeat $repetition echo "I will not chew gum in class."
```

**ATTRIBUTES** See attributes(5) for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** break(1), csh(1), ksh(1), sh(1), attributes(5)

**NOTES** Both the Bourne shell `sh` and the Korn shell `ksh` can use the semicolon (`;`) and the carriage return interchangeably in their syntax of the `if`, `for`, and `while` built-in commands.

- NAME** | from – display the sender and date of newly-arrived mail messages
- SYNOPSIS** | `/usr/ucb/from [-s sender] [username]`
- DESCRIPTION** | The `from` utility prints out the mail header lines in your mailbox file to show you who your mail is from. If *username* is specified, then *username*'s mailbox is examined instead of your own.
- OPTIONS** | `-s sender`      Only display headers for mail sent by *sender*.
- USAGE** | See `largefile(5)` for the description of the behavior of `from` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).
- FILES** | `/var/spool/mail/*`
- ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWscpu        |

| <b>DESCRIPTION</b> | <p>The <code>ftp</code> command is the user interface to the Internet standard File Transfer Protocol (FTP). <code>ftp</code> transfers files to and from a remote network site.</p> <p>The client host with which <code>ftp</code> is to communicate may be specified on the command line. If this is done, <code>ftp</code> immediately attempts to establish a connection to an FTP server on that host; otherwise, <code>ftp</code> enters its command interpreter and awaits instructions from the user. When <code>ftp</code> is awaiting commands from the user, it displays the prompt <code>ftp&gt;</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>OPTIONS</b>     | <p>The following options may be specified at the command line, or to the command interpreter:</p> <ul style="list-style-type: none"><li>-d                    Enables debugging.</li><li>-g                    Disables filename “globbing.”</li><li>-i                    Turns off interactive prompting during multiple file transfers.</li><li>-n                    Does not attempt “auto-login” upon initial connection. If auto-login is not disabled, <code>ftp</code> checks the <code>.netrc</code> file in the user’s home directory for an entry describing an account on the remote machine. If no entry exists, <code>ftp</code> will prompt for the login name of the account on the remote machine (the default is the login name on the local machine), and, if necessary, prompts for a password and an account with which to login.</li><li>-t                    Enables packet tracing (unimplemented).</li><li>-T timeout           Enables global connection timer, specified in seconds (decimal). The timer is reset when anything is sent to the server on the control connection, and disabled while the client is prompting for user input. On the data connection, timeouts rely on TCP and may only timeout on network outages between the client and server. It may not timeout, for instance, if the server is waiting for an NFS server.</li><li>-v                    Shows all responses from the remote server, as well as report on data transfer statistics. This is turned on by default if <code>ftp</code> is running interactively with its input coming from the user’s terminal.</li></ul> <p>The following commands can be specified to the command interpreter:</p> <ul style="list-style-type: none"><li>!<br/>  [ <i>command</i> ] Runs <i>command</i> as a shell command on the local machine. If no <i>command</i> is given, invoke an interactive shell.</li></ul> |

`$ macro-name [ args ]`

Execute the macro *macro-name* that was defined with the `macdef` command. Arguments are passed to the macro unglobbed.

`account [ passwd ]`

Supplies a supplemental password required by a remote system for access to resources once a login has been successfully completed. If no argument is included, the user will be prompted for an account password in a non-echoing input mode.

`append local-file [ remote-file ]`

Appends a local file to a file on the remote machine. If *remote-file* is not specified, the local file name is used, subject to alteration by any `ntrans` or `nmap` settings. File transfer uses the current settings for “representation type”, “file structure”, and “transfer mode”.

`ascii`

Sets the “representation type” to “network ASCII”. This is the default type.

`bell`

Sounds a bell after each file transfer command is completed.

`binary`

Sets the “representation type” to “image”.

`bye`

Terminates the FTP session with the remote server and exit `ftp`. An EOF will also terminate the session and exit.

`case`

Toggles remote computer file name case mapping during `mget` commands. When `case` is on (default is off), remote computer file names with all letters in upper case are written in the local directory with the letters mapped to lower case.

`cd remote-directory`

Changes the working directory on the remote machine to *remote-directory*.

`cdup`

Changes the remote machine working directory to the parent of the current remote machine working directory.

`close`

Terminates the FTP session with the remote server, and return to the command interpreter. Any defined macros are erased.

`cr`

Toggles RETURN stripping during “network ASCII” type file retrieval. Records are denoted by a RETURN/LINEFEED sequence during “network ASCII” type file transfer. When `cr` is on (the default), RETURN characters are stripped from this sequence to conform with the UNIX system single LINEFEED record delimiter. Records on non-UNIX-system remote hosts may contain single LINEFEED characters; when an “network ASCII” type transfer is made, these LINEFEED characters may be distinguished from a record delimiter only when `cr` is off.

## ftp(1)

### `delete remote-file`

Deletes the file *remote-file* on the remote machine.

### `debug`

Toggles debugging mode. When debugging is on, `ftp` prints each command sent to the remote machine, preceded by the string `->`.

### `dir [ remote-directory ] [ local-file ]`

Prints a listing of the directory contents in the directory, *remote-directory*, and, optionally, placing the output in *local-file*. If no directory is specified, the current working directory on the remote machine is used. If no local file is specified, or *local-file* is `-`, output is sent to the terminal.

### `disconnect`

A synonym for `close`.

### `form [ format-name ]`

Sets the carriage control format subtype of the “representation type” to *format-name*. The only valid *format-name* is `non-print`, which corresponds to the default “non-print” subtype.

### `get remote-file [ local-file ]`

Retrieves the *remote-file* and store it on the local machine. If the local file name is not specified, it is given the same name it has on the remote machine, subject to alteration by the current `case`, `ntrans`, and `nmap` settings. The current settings for “representation type”, “file structure”, and “transfer mode” are used while transferring the file.

### `glob`

Toggles filename expansion, or “globbing”, for `mdelete`, `mget` and `mput`. If globbing is turned off, filenames are taken literally.

Globbing for `mput` is done as in `sh(1)`. For `mdelete` and `mget`, each remote file name is expanded separately on the remote machine, and the lists are not merged.

Expansion of a directory name is likely to be radically different from expansion of the name of an ordinary file: the exact result depends on the remote operating system and FTP server, and can be previewed by doing `mls remote-files -`.

`mget` and `mput` are not meant to transfer entire directory subtrees of files. You can do this by transferring a `tar(1)` archive of the subtree (using a “representation type” of “image” as set by the `binary` command).

### `hash`

Toggles hash-sign (#) printing for each data block transferred. The size of a data block is 8192 bytes.

### `help [ command ]`

Prints an informative message about the meaning of *command*. If no argument is given, `ftp` prints a list of the known commands.

`lcd [ directory ]`

Changes the working directory on the local machine. If no *directory* is specified, the user's home directory is used.

`ls[ remote-directory | -a1 ] [ local-file ]`

Prints an abbreviated listing of the contents of a directory on the remote machine. If *remote-directory* is left unspecified, the current working directory is used.

The `-a` option lists all entries, including those that begin with a dot (`.`), which are normally not listed. The `-l` option lists files in long format, giving mode, number of links, owner, group, size in bytes, and time of last modification for each file. If the file is a special file, the size field instead contains the major and minor device numbers rather than a size. If the file is a symbolic link, the filename is printed followed by `"->"` and the pathname of the referenced file.

If no local file is specified, or if *local-file* is `-`, the output is sent to the terminal.

`macrodef macro-name`

Defines a macro. Subsequent lines are stored as the macro *macro-name*; a null line (consecutive NEWLINE characters in a file or RETURN characters from the terminal) terminates macro input mode. There is a limit of 16 macros and 4096 total characters in all defined macros. Macros remain defined until a `close` command is executed.

The macro processor interprets `$` and `\` as special characters. A `$` followed by a number (or numbers) is replaced by the corresponding argument on the macro invocation command line. A `$` followed by an `i` signals that macro processor that the executing macro is to be looped. On the first pass, `$i` is replaced by the first argument on the macro invocation command line; on the second pass, it is replaced by the second argument, and so on. A `\` followed by any character is replaced by that character. Use the `\` to prevent special treatment of the `$`.

`mdelete remote-files`

Deletes the *remote-files* on the remote machine.

`mdir remote-files local-file`

Like `dir`, except multiple remote files may be specified. If interactive prompting is on, `ftp` will prompt the user to verify that the last argument is indeed the target local file for receiving `mdir` output.

`mget remote-files`

Expands the *remote-files* on the remote machine and do a `get` for each file name thus produced. See `glob` for details on the filename expansion. Resulting file names will then be processed according to `case`, `ntrans`, and `nmap` settings. Files are transferred into the local working directory, which can be changed with `lcd directory`; new local directories can be created with `! mkdir directory`.

`mkdir directory-name`

Makes a directory on the remote machine.

## ftp(1)

`mls remote-files local-file`

Like `ls(1)`, except multiple remote files may be specified. If interactive prompting is on, `ftp` will prompt the user to verify that the last argument is indeed the target local file for receiving `mls` output.

`mode [ mode-name ]`

Sets the “transfer mode” to *mode-name*. The only valid *mode-name* is `stream`, which corresponds to the default “stream” mode. This implementation only supports `stream`, and requires that it be specified.

`mput local-files`

Expands wild cards in the list of local files given as arguments and do a `put` for each file in the resulting list. See `glob` for details of filename expansion. Resulting file names will then be processed according to `ntrans` and `nmap` settings.

`nmap [ inpattern outpattern ]`

Sets or unsets the filename mapping mechanism. If no arguments are specified, the filename mapping mechanism is unset. If arguments are specified, remote filenames are mapped during `mput` commands and `put` commands issued without a specified remote target filename. If arguments are specified, local filenames are mapped during `mget` commands and `get` commands issued without a specified local target filename.

This command is useful when connecting to a non-UNIX-system remote host with different file naming conventions or practices. The mapping follows the pattern set by *inpattern* and *outpattern*. *inpattern* is a template for incoming filenames (which may have already been processed according to the `ntrans` and `case` settings). Variable templating is accomplished by including the sequences `$1`, `$2`, ..., `$9` in *inpattern*. Use `\` to prevent this special treatment of the `$` character. All other characters are treated literally, and are used to determine the `nmap inpattern` variable values.

For example, given *inpattern* `$1.$2` and the remote file name `mydata.data`, `$1` would have the value `mydata`, and `$2` would have the value `data`.

The *outpattern* determines the resulting mapped filename. The sequences `$1`, `$2`, ..., `$9` are replaced by any value resulting from the *inpattern* template. The sequence `$0` is replaced by the original filename. Additionally, the sequence `[ seq1 , seq2 ]` is replaced by *seq1* if *seq1* is not a null string; otherwise it is replaced by *seq2*.

For example, the command `nmap $1.$2.$3 [$1,$2] .[$2,file]` would yield the output filename `myfile.data` for input filenames `myfile.data` and `myfile.data.old`, `myfile.file` for the input filename `myfile`, and `myfile.myfile` for the input filename `.myfile`. SPACE characters may be included in *outpattern*, as in the example `nmap $1 | sed "s/ *$//" > $1`. Use the `\` character to prevent special treatment of the `$`, `[`, `]`, and `,` characters.

`ntrans [ inchars [ outchars ] ]`

Sets or unsets the filename character translation mechanism. If no arguments are specified, the filename character translation mechanism is unset. If arguments are

specified, characters in remote filenames are translated during `mput` commands and `put` commands issued without a specified remote target filename, and characters in local filenames are translated during `mget` commands and `get` commands issued without a specified local target filename.

This command is useful when connecting to a non-UNIX-system remote host with different file naming conventions or practices. Characters in a filename matching a character in *inchars* are replaced with the corresponding character in *outchars*. If the character's position in *inchars* is longer than the length of *outchars*, the character is deleted from the file name.

Only 16 characters can be translated when using the `ntrans` command under `ftp`. Use `case` (described above) if needing to convert the entire alphabet.

`open host [ port ]`

Establishes a connection to the specified *host* FTP server. An optional port number may be supplied, in which case, `ftp` will attempt to contact an FTP server at that port. If the *auto-login* option is on (default setting), `ftp` will also attempt to automatically log the user in to the FTP server.

`prompt`

Toggles interactive prompting. Interactive prompting occurs during multiple file transfers to allow the user to selectively retrieve or store files. By default, prompting is turned on. If prompting is turned off, any `mget` or `mput` will transfer all files, and any `mdelete` will delete all files.

`proxy ftp-command`

Executes an FTP command on a secondary control connection. This command allows simultaneous connection to two remote FTP servers for transferring files between the two servers. The first `proxy` command should be an `open`, to establish the secondary control connection. Enter the command `proxy ?` to see other FTP commands executable on the secondary connection.

The following commands behave differently when prefaced by `proxy`: `open` will not define new macros during the auto-login process, `close` will not erase existing macro definitions, `get` and `mget` transfer files from the host on the primary control connection to the host on the secondary control connection, and `put`, `mputd`, and `append` transfer files from the host on the secondary control connection to the host on the primary control connection.

Third party file transfers depend upon support of the `PASV` command by the server on the secondary control connection.

`put local-file[ remote-file ]`

Stores a local file on the remote machine. If *remote-file* is left unspecified, the local file name is used after processing according to any `ntrans` or `nmap` settings in naming the remote file. File transfer uses the current settings for "representation type", "file structure", and "transfer mode".

`pwd`

Prints the name of the current working directory on the remote machine.

## ftp(1)

`quit`  
A synonym for `bye`.

`quote arg1 arg2 ...`  
Sends the arguments specified, verbatim, to the remote FTP server. A single FTP reply code is expected in return. (The `remotehelp` command displays a list of valid arguments.)

`quote` should be used only by experienced users who are familiar with the FTP protocol.

`recv remote-file[ local-file]`  
A synonym for `get`.

`remotehelp [ command-name ]`  
Requests help from the remote FTP server. If a *command-name* is specified it is supplied to the server as well.

`rename from to`  
Renames the file *from* on the remote machine to have the name *to*.

`reset`  
Clear reply queue. This command re-synchronizes command/reply sequencing with the remote FTP server. Resynchronization may be necessary following a violation of the FTP protocol by the remote server.

`rmdir directory-name`  
Deletes a directory on the remote machine.

`runique`  
Toggles storing of files on the local system with unique filenames. If a file already exists with a name equal to the target local filename for a `get` or `mget` command, a `.1` is appended to the name. If the resulting name matches another existing file, a `.2` is appended to the original name. If this process continues up to `.99`, an error message is printed, and the transfer does not take place. The generated unique filename will be reported. `runique` will not affect local files generated from a shell command. The default value is off.

`send local-file [ remote-file ]`  
A synonym for `put`.

`sendport`  
Toggles the use of `PORT` commands. By default, `ftp` will attempt to use a `PORT` command when establishing a connection for each data transfer. The use of `PORT` commands can prevent delays when performing multiple file transfers. If the `PORT` command fails, `ftp` will use the default data port. When the use of `PORT` commands is disabled, no attempt will be made to use `PORT` commands for each data transfer. This is useful when connected to certain FTP implementations that ignore `PORT` commands but incorrectly indicate they have been accepted.

`status`  
Show the current status of `ftp`.

**struct** [ *struct-name* ]

Sets the file structure to *struct-name*. The only valid *struct-name* is `file`, which corresponds to the default “file” structure. The implementation only supports `file`, and requires that it be specified.

**sunique**

Toggles storing of files on remote machine under unique file names. The remote FTP server must support the `STOU` command for successful completion. The remote server will report the unique name. Default value is off.

**tenex**

Sets the “representation type” to that needed to talk to TENEX machines.

**trace**

Toggles packet tracing (unimplemented).

**type** [ *type-name* ]

Sets the “representation type” to *type-name*. The valid *type-names* are `ascii` for “network ASCII”, `binary` or `image` for “image”, and `tenex` for “local byte size” with a byte size of 8 (used to talk to TENEX machines). If no type is specified, the current type is printed. The default type is “network ASCII”.

**user** *user-name* [ *password* ] [ *account* ]

Identify yourself to the remote FTP server. If the password is not specified and the server requires it, `ftp` will prompt the user for it (after disabling local echo). If an account field is not specified, and the FTP server requires it, the user will be prompted for it. If an account field is specified, an account command will be relayed to the remote server after the login sequence is completed if the remote server did not require it for logging in. Unless `ftp` is invoked with “auto-login” disabled, this process is done automatically on initial connection to the FTP server.

**verbose**

Toggles verbose mode. In verbose mode, all responses from the FTP server are displayed to the user. In addition, if verbose mode is on, when a file transfer completes, statistics regarding the efficiency of the transfer are reported. By default, verbose mode is on if `ftp`’s commands are coming from a terminal, and off otherwise.

**? [ *command* ]**

A synonym for `help`.

Command arguments which have embedded spaces may be quoted with quote (") marks.

If any command argument which is not indicated as being optional is not specified, `ftp` will prompt for that argument.

## ABORTING A FILE TRANSFER

To abort a file transfer, use the terminal interrupt key. Sending transfers will be immediately halted. Receiving transfers will be halted by sending an FTP protocol `ABOR` command to the remote server, and discarding any further data received. The

ftp(1)

speed at which this is accomplished depends upon the remote server's support for ABOR processing. If the remote server does not support the ABOR command, an ftp> prompt will not appear until the remote server has completed sending the requested file.

The terminal interrupt key sequence will be ignored when ftp has completed any local processing and is awaiting a reply from the remote server. A long delay in this mode may result from the ABOR processing described above, or from unexpected behavior by the remote server, including violations of the ftp protocol. If the delay results from unexpected remote server behavior, the local ftp program must be killed by hand.

#### FILE NAMING CONVENTIONS

Local files specified as arguments to ftp commands are processed according to the following rules.

- 1) If the file name - is specified, the standard input (for reading) or standard output (for writing) is used.
- 2) If the first character of the file name is |, the remainder of the argument is interpreted as a shell command. ftp then forks a shell, using popen(3C) with the argument supplied, and reads (writes) from the standard output (standard input) of that shell. If the shell command includes SPACE characters, the argument must be quoted; for example " | ls -lt". A particularly useful example of this mechanism is: "dir | more".
- 3) Failing the above checks, if globbing is enabled, local file names are expanded according to the rules used in the sh(1); see the glob command. If the ftp command expects a single local file (for example, put), only the first filename generated by the globbing operation is used.
- 4) For mget commands and get commands with unspecified local file names, the local filename is the remote filename, which may be altered by a case, ntrans, or nmap setting. The resulting filename may then be altered if runique is on.
- 5) For mput commands and put commands with unspecified remote file names, the remote filename is the local filename, which may be altered by a ntrans or nmap setting. The resulting filename may then be altered by the remote server if sunique is on.

#### FILE TRANSFER PARAMETERS

The FTP specification specifies many parameters which may affect a file transfer.

The "representation type" may be one of "network ASCII", "EBCDIC", "image", or "local byte size" with a specified byte size (for PDP-10's and PDP-20's mostly). The "network ASCII" and "EBCDIC" types have a further subtype which specifies whether vertical format control (NEWLINE characters, form feeds, etc.) are to be passed through ("non-print"), provided in TELNET format ("TELNET format controls"), or provided in ASA (FORTRAN) ("carriage control (ASA)") format. ftp supports the "network ASCII" (subtype "non-print" only) and "image" types, plus "local byte size" with a byte size of 8 for communicating with TENEX machines.

The “file structure” may be one of `file` (no record structure), `record`, or `page`. `ftp` supports only the default value, which is `file`.

The “transfer mode” may be one of `stream`, `block`, or `compressed`. `ftp` supports only the default value, which is `stream`.

**USAGE** See `largefile(5)` for the description of the behavior of `ftp` when encountering files greater than or equal to 2 Gbyte ( $2^{31}$  bytes).

The `ftp` command is IPv6-enabled. See `ip6(7P)`.

**FILES** `~/.netrc`

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**SEE ALSO** `ls(1)`, `rcp(1)`, `sh(1)`, `tar(1)`, `in.ftpd(1M)`, `popen(3C)`, `ftpusers(4)`, `netrc(4)`, `attributes(5)`, `largefile(5)`, `ip6(7P)`

**NOTES** Failure to log in may arise from an explicit denial by the remote FTP server because the account is listed in `/etc/ftpusers`. See `in.ftpd(1M)` and `ftpusers(4)`.

Correct execution of many commands depends upon proper behavior by the remote server.

An error in the treatment of carriage returns in the 4.2 BSD code handling transfers with a “representation type” of “network ASCII” has been corrected. This correction may result in incorrect transfers of binary files to and from 4.2 BSD servers using a “representation type” of “network ASCII”. Avoid this problem by using the “image” type.

function(1)

**NAME** function – shell built-in command to define a function which is usable within this shell

**SYNOPSIS**

**ksh** **function** *identifier* {*list* ;}  
*identifier* ( ) {*list* ;}

**DESCRIPTION**

**ksh** **function** defines a function which is referenced by *identifier*. The body of the function is the *list* of commands between { and }.

Alternatively, omitting the **function** keyword and appending the *identifier* with a set of enclosed parentheses will accomplish the same function definition.

**ATTRIBUTES** See **attributes(5)** for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** **ksh(1)**, **attributes(5)**

|                    |                                                                                                                                                                                                             |                                                                                                            |

| <b>NAME</b>        | gcore – get core images of running processes                                                                                                                                                                |                                                                                                            |
| <b>SYNOPSIS</b>    | <b>gcore</b> [-o <i>filename</i> ] <i>process-id</i> ...                                                                                                                                                    |                                                                                                            |
| <b>DESCRIPTION</b> | The <b>gcore</b> utility creates a core image of each specified process. By default, the name of the core image file for the process whose process ID is <i>process-id</i> will be <i>core.process-id</i> . |                                                                                                            |
| <b>OPTIONS</b>     | -o <i>filename</i>                                                                                                                                                                                          | Substitutes <i>filename</i> in place of <i>core</i> as the first part of the name of the core image files. |
| <b>OPERANDS</b>    | <i>process-id</i>                                                                                                                                                                                           | process ID                                                                                                 |
| <b>EXIT STATUS</b> | 0                                                                                                                                                                                                           | On success.                                                                                                |
|                    | non-zero                                                                                                                                                                                                    | On failure, such as non-existent process ID.                                                               |

| <b>NAME</b>        | gencat – generate a formatted message catalog                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <b>gencat</b> <i>catfile msgfile...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>DESCRIPTION</b> | <p>The <code>gencat</code> command merges the message text source file(s) <i>msgfile</i> into a formatted message database <i>catfile</i>. The database <i>catfile</i> is created if it does not already exist. If <i>catfile</i> does exist, its messages are included in the new <i>catfile</i>. If set and message numbers collide, the new message-text defined in <i>msgfile</i> replaces the old message text currently contained in <i>catfile</i>. The message text source file (or set of files) input to <code>gencat</code> can contain either set and message numbers or simply message numbers, in which case the set <code>NL_SETD</code> (see <code>nl_types(3HEAD)</code>) is assumed.</p> <p><b>Message Text Source File Format</b></p> <p>The format of a message text source file is defined as follows. Note that the fields of a message text source line are separated by a single ASCII space or tab character. Any other ASCII spaces or tabs are considered as part of the subsequent field.</p> <p><i>\$set n comment</i>                      Where <i>n</i> specifies the set identifier of the following messages until the next <i>\$set</i>, <i>\$delset</i>, or end-of-file appears. <i>n</i> must be a number in the range (1–{<code>NL_SETMAX</code>}). Set identifiers within a single source file need not be contiguous. Any string following the set identifier is treated as a comment. If no <i>\$set</i> directive is specified in a message text source file, all messages are located in the default message set <code>NL_SETD</code>.</p> <p><i>\$delset n comment</i>                    Deletes message set <i>n</i> from an existing message catalog. Any string following the set number is treated as a comment. (Note: if <i>n</i> is not a valid set it is ignored.)</p> <p><i>\$comment</i>                              A line beginning with a dollar symbol <code>\$</code> followed by an ASCII space or tab character is treated as a comment.</p> <p><i>m message-text</i>                      The <i>m</i> denotes the message identifier, a number in the range (1–{<code>NL_MSGMAX</code>}). The <i>message-text</i> is stored in the message catalog with the set identifier specified by the last <i>\$set</i> directive, and with message identifier <i>m</i>. If the <i>message-text</i> is empty, and an ASCII space or tab field separator is present, an empty string is stored in the message catalog. If a message source line has a message number, but neither a field separator nor <i>message-text</i>, the existing message with that number (if any) is deleted from the catalog. Message identifiers need not be contiguous. The length of <i>message-text</i> must be in the range (0–{<code>NL_TEXTMAX</code>}).</p> <p><i>\$quote c</i>                              This line specifies an optional quote character <i>c</i>, which can be used to surround <i>message-text</i> so that trailing spaces or null (empty) messages are visible in a message source line. By default, or if an empty <i>\$quote</i></p> |

directive is supplied, no quoting of *message-text* will be recognized.

Empty lines in a message text source file are ignored.

Text strings can contain the special characters and escape sequences defined in the following table:

| Description     | Symbol | Sequence |
|-----------------|--------|----------|
| newline         | NL(LF) | \n       |
| horizontal tab  | HT     | \t       |
| vertical tab    | VT     | \v       |
| backspace       | BS     | \b       |
| carriage return | CR     | \r       |
| form feed       | FF     | \f       |
| backslash       | \      | \\       |
| bit pattern     | ddd    | \ddd     |

The escape sequence `\ddd` consists of backslash followed by 1, 2 or 3 octal digits, which are taken to specify the value of the desired character. If the character following a backslash is not one of those specified, the backslash is ignored.

Backslash followed by an ASCII newline character is also used to continue a string on the following line. Thus, the following two lines describe a single message string:

```
1 This line continues \
to the next line
```

which is equivalent to:

```
1 This line continues to the next line
```

**OPERANDS** The following operands are supported:

*catfile* A path name of the formatted message catalogue. If `-` is specified, standard output is used.

*msgfile* A path name of a message text source file. If `-` is specified for an instance of *msgfile*, standard input is used. The format of message text source files is defined in Message Text Source File Format.

gencat(1)

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `gencat`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

- 0 Successful completion.
- >0 An error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |
| CSI            | enabled         |

| <b>SYNOPSIS</b>    | <b>geniconvtbl</b> [-fnq] [-p <i>preprocessor</i> ] [-W <i>arg</i> ] [-D <i>name</i> ] [-D <i>name=def</i> ]<br>[-I <i>directory</i> ] [-U <i>name</i> ] [ <i>infile...</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>DESCRIPTION</b> | The <code>geniconvtbl</code> utility accepts code conversion rules defined in flat text file(s) and writes code conversion binary table file(s) that can be used to support user-defined <code>iconv</code> code conversions (see <code>iconv(1)</code> and <code>iconv(3C)</code> for more detail on the <code>iconv</code> code conversion).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OPTIONS</b>     | The following options are supported: <ul style="list-style-type: none"> <li>-f Overwrites output file if the output file exists.</li> <li>-n Does not generate an output file. This is useful to check the contents of the input file.</li> <li>-p <i>preprocessor</i> Uses specified <i>preprocessor</i> instead of the default preprocessor, <code>/usr/lib/cpp</code>.</li> <li>-q Quiet option. It suppresses warning and error messages.</li> <li>-W <i>arg</i> Passes the argument <i>arg</i> to the preprocessor. If this option is specified more than once, all arguments are passed to the preprocessor.</li> <li>-D<i>name</i></li> <li>-D<i>name=def</i></li> <li>-I<i>directory</i></li> <li>-U<i>name</i> <code>geniconvtbl</code> recognizes these options and passes them and their arguments to the preprocessor.</li> </ul>                                            |
| <b>OPERANDS</b>    | The following operand is supported: <ul style="list-style-type: none"> <li><i>infile</i> A path name of an input file. If no input file is specified, <code>geniconvtbl</code> reads from the standard input stream. The user can specify more than one input file if necessary.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>OUTPUT</b>      | If input is from the standard input stream, <code>geniconvtbl</code> writes output to the standard output stream. If one or more input files are specified, <code>geniconvtbl</code> reads from each input file and writes to a corresponding output file. Each of the output file names will be the same as the corresponding input file with <code>.bt</code> appended. <p>The generated output files must be moved to the following directory prior to using the code conversions at <code>iconv(1)</code> and <code>iconv(3C)</code>:</p> <pre>/usr/lib/iconv/geniconvtbl/binarytables/</pre> <p>The output file name should start with one or more printable ASCII characters as the 'fromcode' name followed by a percentage character (%), followed by one or more printable ASCII characters as the 'tocode' name, followed by the suffix '.bt'. The 'fromcode' and 'tocode'</p> |

## geniconvtbl(1)

names are used to identify the `iconv` code conversion at `iconv(1)` and `iconv_open(3C)`. The properly named output file should be placed in the directory, `/usr/lib/iconv/geniconvtbl/binarytables/`.

### EXAMPLES

#### EXAMPLE 1 Generating an iconv code conversion binary table

The following example generates a code conversion binary table with output file name `convertA2B.bt`:

```
example% geniconvtbl convertA2B
```

#### EXAMPLE 2 Generating multiple iconv code conversion binary tables

The following example generates two code conversion binary tables with output files `test1.bt` and `test2.bt`:

```
example% geniconvtbl test1 test2
```

#### EXAMPLE 3 Using another preprocessor

The following example generates a code conversion binary table once the specified preprocessor has processed the input file:

```
example% geniconvtbl -p /opt/SUNWspro/bin/cc -W -E convertB2A
```

#### EXAMPLE 4 Placing a binary table

To use the binary table created in the first example above as the engine of the conversion 'fromcode' ABC to 'tocode' DEF, become super-user and then rename it and place it like this:

```
example# mv convertA2B.bt
/usr/lib/iconv/geniconvtbl/binarytables/ABC%DEF.bt
```

### ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `geniconvtbl`: `LANG` and `LC_CTYPE`.

### EXIT STATUS

The following exit values are returned:

- |   |                                                                                                           |
|---|-----------------------------------------------------------------------------------------------------------|
| 0 | No errors occurred and the output files were successfully created.                                        |
| 1 | Command line options are not correctly used or an unknown command line option was specified.              |
| 2 | Invalid input or output file was specified.                                                               |
| 3 | Conversion rules in input files are not correctly defined.                                                |
| 4 | Conversion rule limit of input files has been reached. See NOTES section of <code>geniconvtbl(4)</code> . |
| 5 | No more system resource error.                                                                            |

6 Internal error.

| <b>NAME</b>                      | genlayouttbl – generate layout table for complex text layout                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>SYNOPSIS</b>                  | <b>genlayouttbl</b> [-o <i>outfile</i> ] [ <i>infile</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>DESCRIPTION</b>               | The <code>genlayouttbl</code> utility accepts a locale's layout definition in a flat text file and writes a binary layout table file that can be used in the complex text layout of the locale.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>OPTIONS</b>                   | The following option is supported:<br><br>-o <i>outfile</i> Writes output binary layout table to the <i>outfile</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OPERANDS</b>                  | The following operand is supported:<br><br><i>infile</i> A path name of an input file. If no input file is specified, <code>genlayouttbl</code> reads from the standard input stream.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>OUTPUT AND SYMBOLIC LINKS</b> | If no <i>outfile</i> is specified, <code>genlayouttbl</code> writes output to the standard output stream.<br><br>The generated output file must be moved to the following directory prior to the use at the system and the file name should be <code>layout.dat</code> :<br><br>/usr/lib/locale/locale/LO_LTYPE/layout.dat<br><br>The locale should also have a symbolic link, /usr/lib/locale/locale/LO_LTYPE/locale.layout.so.1, to the 32-bit Universal Multiscript Layout Engine (UMLE), /usr/lib/locale/common/LO_LTYPE/umle.layout.so.1.<br><br>For proper 64-bit platform operations, the locale should also have a symbolic link, as for instance, in 64-bit SPARC platform, /usr/lib/locale/locale/LO_LTYPE/sparcv9/locale.layout.so.1, to the 64-bit UMLE, /usr/lib/locale/common/LO_LTYPE/sparcv9/umle.layout.so.1.<br><br>The <i>locale</i> is the locale that you want to provide and to use the layout functionality you defined. |
| <b>INPUT FILE FORMAT</b>         | A layout definition file to <code>genlayouttbl</code> contains three different sections of definitions: <ul style="list-style-type: none"><li>■ Layout attribute definition</li><li>■ Bidirectional data and character type data definition</li><li>■ Shaping data definition</li></ul> For appropriate complex text layout support, all three sections need to be defined in the layout definition file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>The Lexical Conventions</b>   | The following lexical conventions are used in the layout definition:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                  |                                                                                                                                                                                                                |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NAME             | A string of characters that consists of printable ASCII characters. It includes DECIMAL and HEXADECIMAL also. <i>Examples:</i> test, a1_src, b32, 123.                                                         |
| HEXADECIMAL_BYTE | Two-digit hexadecimal number. The number starts with a hexadecimal digit followed by another hexadecimal digit. <i>Examples:</i> e0, E1, a7, fe.                                                               |
| HEXADECIMAL      | A hexadecimal number. The hexadecimal representation consists of an escape character, '0' followed by the constant 'x' or 'X' and one or more hexadecimal digits. <i>Examples:</i> 0x0, 0x1, 0x1a, 0xA, 0x1b3. |
| DECIMAL          | A decimal number, represented by one or more decimal digits. <i>Examples:</i> 0, 123, 2165.                                                                                                                    |

Each comment must start with '#'. The comment ends at the end of the line.

The following keywords are reserved:

active\_directional, active\_shape\_editing, AL, ALGORITHM\_BASIC, ALGORITHM\_IMPLICIT, AN, BN, check\_mode, context, CONTEXT\_LTR, CONTEXT\_RTL, CS, EN, END, ES, ET, FALSE, FILE\_CODE\_REPRESENTATION, implicit\_algorithm, keep, L, LAYOUT\_ATTRIBUTES, LAYOUT\_BIDI\_CHAR\_TYPE\_DATA, LAYOUT\_SHAPE\_DATA, LRE, LRO, MODE\_EDIT, MODE\_STREAM, NSM, national\_numerals, numerals, NUMERALS\_CONTEXTUAL, NUMERALS\_NATIONAL, NUMERALS\_NOMINAL, ON, orientation, ORIENTATION\_CONTEXTUAL, ORIENTATION\_LTR, ORIENTATION\_RTL, ORIENTATION\_TTBRL, ORIENTATION\_TTBRL, PDF, PROCESS\_CODE\_REPRESENTATION, PS, R, repeat\*, repeat+, RLE, RLO, S, shape\_charset, shape\_charset\_size, shape\_context\_size, swapping, SWAPPING\_NO, swapping\_pairs, SWAPPING\_YES, TEXT\_EXPLICIT, TEXT\_IMPLICIT, TEXT\_NOMINAL, TEXT\_SHAPED, text\_shaping, TEXT\_VISUAL, TRUE, type\_of\_text, WS

Additionally, the following symbols are also reserved as tokens:

( ) [ ] , : ; ... = -> +

### Layout Attribute Definition

The layout attribute definition section defines the layout attributes and their associated values.

The definition starts with a keyword, LAYOUT\_ATTRIBUTES, and ends with END LAYOUT\_ATTRIBUTES:

```
LAYOUT_ATTRIBUTES
```

## genlayouttbl(1)

```
Layout attributes here.
:
:

END LAYOUT_ATTRIBUTES
```

There are a total of eight layout attribute value trios that can be defined in this section:

- orientation
- context
- type\_of\_text
- implicit\_algorithm
- swapping
- numerals
- text\_shaping
- shape\_context\_size

Additionally, there are five layout attribute value pairs that also can be defined in this section:

- active\_directional
- active\_shape\_editing
- shape\_charset
- shape\_charset\_size
- check\_mode

Each attribute value trio will have an attribute name, an attribute value for the input buffer, and an attribute value for the output buffer, as in the following example:

```
Orientation layout attribute value trio. The input and output
attribute values are separated by a colon and the left one
is the input attribute value:
orientation ORIENTATION_LTR:ORIENTATION_LTR
```

Each attribute value pair will have an attribute name and an associated attribute value, as in the following example:

```
Shape charset attribute value pair:
shape_charset ISO8859-6
```

The orientation value trio defines the global directional text orientation. The possible values are:

|                   |                                                                  |
|-------------------|------------------------------------------------------------------|
| ORIENTATION_LTR   | Left-to-right horizontal rows that progress from top to bottom.  |
| ORIENTATION_RTL   | Right-to-left horizontal rows that progress from top to bottom.  |
| ORIENTATION_TTBRL | Top-to-bottom vertical columns that progress from right to left. |

|                        |                                                                                                                                                                                                                                                                                                                                                            |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ORIENTATION_TTBLR      | Top-to-bottom vertical columns that progress from left to right.                                                                                                                                                                                                                                                                                           |
| ORIENTATION_CONTEXTUAL | The global orientation is set according to the direction of the first significant (strong) character. If there are no strong characters in the text and the attribute is set to this value, the global orientation of the text is set according to the value of the attribute <code>context</code> . This value is meaningful only for bidirectional text. |

If no value or value trio is defined, the default is `ORIENTATION_LTR`.

The `context` value trio is meaningful only if the attribute orientation is set to `ORIENTATION_CONTEXTUAL`. It defines what orientation is assumed when no strong character appears in the text. The possible values are:

`CONTEXT_LTR`

In the absence of characters with strong directionality in the text, orientation is assumed to be left-to-right rows progressing from top to bottom.

`CONTEXT_RTL`

In the absence of characters with strong directionality in the text, orientation is assumed to be right-to-left rows progressing from top to bottom.

If no value or value trio is specified, the default is `CONTEXT_LTR`.

The `type_of_text` value trio specifies the ordering of the directional text. The possible values are:

`TEXT_VISUAL`

Code elements are provided in visually ordered segments, which can be rendered without any segment inversion.

`TEXT_IMPLICIT`

Code elements are provided in logically ordered segments. Logically ordered means that the order in which the characters are provided is the same as the order in which the characters are pronounced when reading the presented text or the order in which characters would be entered from a keyboard.

`TEXT_EXPLICIT`

Code elements are provided in logically ordered segments with a set of embedded controls. Some examples of such embedded controls from ISO/IEC 10646-1 are:

LEFT-TO-RIGHT EMBEDDING (LRE)  
 RIGHT-TO-LEFT EMBEDDING (RLE)  
 RIGHT-TO-LEFT OVERRIDE (RLO)  
 LEFT-TO-RIGHT OVERRIDE (LRO)  
 POP DIRECTIONAL FORMAT (PDF)

genlayouttbl(1)

If no value or value trio is specified, the default is `TEXT_IMPLICIT`.

The `implicit_algorithm` value trio specifies the type of bidirectional implicit algorithm used in reordering and shaping of directional or context-dependent text. The possible values are:

`ALGORITHM_IMPLICIT`

Directional code elements will be reordered using an implementation-defined implicit algorithm.

`ALGORITHM_BASIC`

Directional code elements will be reordered using a basic implicit algorithm defined in the Unicode standard.

Even though we allow two different values for the `implicit_algorithm`, since the Solaris implementation-defined implicit algorithm is based on the Unicode standard, there is no difference in behavior whether you choose `ALGORITHM_IMPLICIT` or `ALGORITHM_BASIC` for this attribute.

The default value is `ALGORITHM_IMPLICIT`.

The `swapping` value trio specifies whether symmetric swapping is applied to the text. The possible values are:

`SWAPPING_YES`

The text conforms to symmetric swapping.

`SWAPPING_NO`

The text does not conform to symmetric swapping.

If no value or value trio is specified, the default is `SWAPPING_NO`.

The `numerals` value trio specifies the shaping of numerals. The possible values are:

`NUMERALS_NOMINAL`

Nominal shaping of numerals using the Arabic numbers of the portable character set (in Solaris, ASCII digits).

`NUMERALS_NATIONAL`

National shaping of numerals based on the script of the locale. For instance, Thai digits in the Thai locale.

`NUMERALS_CONTEXTUAL`

Contextual shaping of numerals depending on the context script of surrounding text, such as Hindi numbers in Arabic text and Arabic numbers otherwise.

If no value or value trio is specified, the default is `NUMERALS_NOMINAL`.

The `text_shaping` value trio specifies the shaping; that is, choosing (or composing) the correct shape of the input or output text. The possible values are:

`TEXT_SHAPED`

The text has presentation form shapes.

TEXT\_NOMINAL

The text is in basic form.

If no value or value trio is specified, the default is TEXT\_NOMINAL for input and TEXT\_SHAPED for output.

The shape\_context\_size value trio specifies the size of the context (surrounding code elements) that must be accounted for when performing active shape editing. If not defined, the default value 0 is used for the number of surrounding code elements at both front and rear:

```
The shape_context_size for both front and rear surrounding code
elements are all zero:
shape_context_size 0:0
```

The front and rear attribute values are separated by a colon, with the front value to the left of the colon.

The active\_directional value pair specifies whether the current locale requires (bi-)directional processing. The possible values are:

TRUE

Requires (bi-)directional processing.

FALSE

Does not require (bi-)directional processing.

The active\_shape\_editing value pair specifies whether the current locale requires context-dependent shaping for presentation. The possible values are:

TRUE

Requires context-dependent shaping.

FALSE

Does not require context-dependent shaping.

The shape\_charset value pair specifies the current locale's shape charset on which the complex text layout is based. There are two different kinds of shape charset values that can be specified:

- A single shape charset
- Multiple shape charsets

For a single shape charset, it can be defined by using NAME as defined in the `Lexical Convention` section above. For multiple shape charsets, however, it should follow the syntax given below in extended BNF form:

```
multiple_shape_charset
 : charset_list
 ;

charset_list
 : charset
 | charset_list ';' charset
```

genlayouttbl(1)

```
 ;
charset : charset_name '=' charset_id
 ;
charset_name : NAME
 ;
charset_id : HEXADECIMAL_BYTE
 ;
```

For instance, the following is a valid multiple shape charsets value for the `shape_charset` attribute:

```
Multi-shape charsets:
shape_charset tis620.2533=e4;iso8859-8=e5;iso8859-6=e6
```

The `shape_charset` must be specified.

The `shape_charset_size` value pair specifies the encoding size of the current `shape_charset`. The valid value is a positive integer from 1 to 4. If the multiple shape charsets value is defined for the `shape_charset` attribute, the `shape_charset_size` must be 4.

The `shape_charset_size` must be specified.

The `check_mode` value pair specifies the level of checking of the elements in the input buffer for shaping and reordering purposes. The possible values are:

`MODE_STREAM`

The string in the input buffer is expected to have valid combinations of characters or character elements.

`MODE_EDIT`

The shaping of input text may vary depending on locale-specific validation or assumption.

When no value or value pair is not specified, the default value is `MODE_STREAM`.

### **Bidirectional Data And Character Type Data Definition**

This section defines the bidirectional and other character types that will be used in the Unicode Bidirectional Algorithm and the shaping algorithm part of the UMLE.

The definition starts with a keyword `LAYOUT_BIDI_CHAR_TYPE_DATA` and ends with `END LAYOUT_BIDI_CHAR_TYPE_DATA`:

```
LAYOUT_BIDI_CHAR_TYPE_DATA

 # Layout bidi definitions here.
 :
 :

END LAYOUT_BIDI_CHAR_TYPE_DATA
```

The bidirectional data and character type data definition should be defined for the two different kinds of text shape forms, `TEXT_SHAPED` and `TEXT_NOMINAL`, depending on the `text_shaping` attribute value and also for the two different kinds of text representations, file code representation and process code representation (that is, wide character representation):

```
LAYOUT_BIDI_CHAR_TYPE_DATA

 FILE_CODE_REPRESENTATION
 TEXT_SHAPED

 # TEXT_SHAPED bidi and character type data
 # definition in file code representation here.
 :
 :

 END TEXT_SHAPED

 TEXT_NOMINAL

 # TEXT_NOMINAL bidi and character type data
 # definition in file code representation here.
 :
 :

 END TEXT_NOMINAL
 END FILE_CODE_REPRESENTATION

 PROCESS_CODE_REPRESENTATION
 TEXT_SHAPED

 # TEXT_SHAPED bidi and character type data
 # definition in process code representation here.
 :
 :

 END TEXT_SHAPED

 TEXT_NOMINAL

 # TEXT_NOMINAL bidi and character type data
 # definition in process code representation here.
 :
 :

 END TEXT_NOMINAL
 END PROCESS_CODE_REPRESENTATION

END LAYOUT_BIDI_CHAR_TYPE_DATA
```

Each bidi and character type data definition can have the following definitions:

- Bidirectional data type definition
- `swapping_pairs` character type definition
- `national_numerals` character type definition

There are nineteen different bidirectional data types that can be defined, as in the following table:

| <b>Keyword</b> | <b>Category</b> | <b>Description</b>         |
|----------------|-----------------|----------------------------|
| L              | Strong          | Left-to-right              |
| LRE            | Strong          | Left-to-right embedding    |
| LRO            | Strong          | Left-to-right override     |
| R              | Strong          | Right-to-left              |
| AL             | Strong          | Right-to-left              |
| RLE            | Strong          | Right-to-left embedding    |
| RLO            | Strong          | Right-to-left override     |
| PDF            | Weak            | Pop directional format     |
| EN             | Weak            | European number            |
| ES             | Weak            | European number separator  |
| ET             | Weak            | European number terminator |
| AN             | Weak            | Arabic number              |
| CS             | Weak            | Common number separator    |
| PS             | Separator       | Paragraph separator        |
| S              | Separator       | Segment separator          |
| WS             | Neutral         | White space                |
| ON             | Neutral         | Other neutrals             |
| NSM            | Weak            | Non-spacing mark           |
| BN             | Weak            | Boundary neutral           |

If not defined in this section, the characters belong to the other neutrals type, ON.

Each keyword list above will be accompanied by one or more HEXADECIMAL ranges of characters that belong to the bidirectional character type. The syntax is as follows:

```

bidi_char_type : bidi_keyword ':' range_list
 ;

bidi_keyword : 'L'
 | 'LRE'
 | 'LRO'
 | 'R'
 | 'AL'
 | 'RLE'

```

```

| 'RLO'
| 'PDF'
| 'EN'
| 'ES'
| 'ET'
| 'AN'
| 'CS'
| 'PS'
| 'S'
| 'WS'
| 'ON'
| 'NSM'
| 'BN'
;

range_list : range
| range_list ',' range
;

range : HEXADECIMAL
| HEXADECIMAL '...' HEXADECIMAL
;

```

**For example:**

```

Bidi character type definitions:
L: 0x26, 0x41...0x5a, 0xc380...0xc396, 0xe285a0...0xe28682
WS: 0x20, 0xc2a0, 0xe28080...0xe28086

```

The `swapping_pairs` specifies the list of swappable characters if `SWAPPING_YES` is specified as a value at the swapping value trio. The syntax of the `swapping_pairs` is as follows:

```

swapping_pair_list : swapping_keyword ':' swap_pair_list
;

swapping_keyword : 'swapping_pairs'
;

swap_pair_list : swap_pair
| swap_pair_list ',' swap_pair
;

swap_pair : '(' HEXADECIMAL ',' HEXADECIMAL ')'

```

**For example:**

```

Swapping pair definitions:
swapping_pairs: (0x28, 0x29), (0x7b, 0x7d)

```

The `national_numerals` specifies the list of national digits that can be converted as the numerals value trio specifies. The syntax of the `national_numerals` is as follows:

## genlayouttbl(1)

```
numerals_list : numerals_keyword ':'
 numerals_list ';' contextual_range_list
 ;

numerals_keyword : 'national_numerals'
 ;

numerals_list : '(' zero ',' one ',' two ',' three ','
 four ',' five ',' six ',' seven ','
 eight ',' nine ')'

zero : HEXADECIMAL
 ;

one : HEXADECIMAL
 ;

two : HEXADECIMAL
 ;

three : HEXADECIMAL
 ;

four : HEXADECIMAL
 ;

five : HEXADECIMAL
 ;

six : HEXADECIMAL
 ;

seven : HEXADECIMAL
 ;

eight : HEXADECIMAL
 ;

nine : HEXADECIMAL
 ;

contextual_range_list
 : contextual_range
 | contextual_range_list ',' contextual_range
 ;

contextual_range : HEXADECIMAL
 | HEXADECIMAL '...' HEXADECIMAL
 ;
```

### For instance:

```
National numerals definition. The national number that will
replace Arabic number 0 to 9 is 0, 0x41, 0x42, and so on.
The contextual surrounding characters are 0x20 to 0x40 and
0x50 to 0x7f:
national_numerals:
```

```
(0x0, 0x41, 0x42, 0x43, 0x44, 0x45, 0x46, 0x47, 0x48, 0x49)
; 0x20...0x40, 0x50...0x7f
```

Unless `NUMERALS_CONTEXTUAL` is the value of the numerals attribute, the contextual range list definition is meaningless.

## Shaping Data Definition

The shaping data definition section defines the context-dependent shaping rules that will be used in the shaping algorithm of the UMLE.

The definition starts with a keyword, `LAYOUT_SHAPE_DATA`, and ends with `END LAYOUT_SHAPE_DATA`:

```
LAYOUT_SHAPE_DATA

Layout shaping data definitions here.
:
:

END LAYOUT_SHAPE_DATA
```

The shaping data definition should be defined for the two different kinds of text shape forms, `TEXT_SHAPED` and `TEXT_NOMINAL`, depending on the `text_shaping` attribute value and also for the two different kinds of text representations, file code representation and process code representation (that is, wide character representation:

```
LAYOUT_SHAPE_DATA

FILE_CODE_REPRESENTATION
TEXT_SHAPED

TEXT_SHAPED shaping data definition in file code
representation here.
:
:

END TEXT_SHAPED

TEXT_NOMINAL

TEXT_NOMINAL shaping data definition in file code
representation here.
:
:

END TEXT_NOMINAL
END FILE_CODE_REPRESENTATION

PROCESS_CODE_REPRESENTATION
TEXT_SHAPED

TEXT_SHAPED shaping data definition in process code
representation here.
:
:
```

```

 END TEXT_SHAPED

 TEXT_NOMINAL

 # TEXT NOMINAL shaping data definition in process
 # code representation here.
 :
 :

 END TEXT_NOMINAL
 END PROCESS_CODE_REPRESENTATION

END LAYOUT_SHAPE_DATA

```

Each shaping data definition consists of one or more of the shaping sequence definitions. Each shaping sequence definition is a representation of a series of state transitions triggered by an input character and the current state at each transition.

The syntax of the shaping sequence definition is as follows:

```

shaping_sequence : initial_state '+' input '->' next_state_list
 ;

initial_state : '(' ')'
 ;

input : HEXADECIMAL
 ;

next_state_list : next_state
 | next_state_list '+' input '->' next_state
 | '(' next_state_list '+' input ')' 'repeat+'
 | '(' next_state_list '+' input ')' 'repeat*'
 ;

next_state : '(' out_buffer ',' in2out ',' out2in ','
 property ')'
 ;

out_buffer : '[' out_char_list ']'
 ;

out_char_list : HEXADECIMAL
 | '(' HEXADECIMAL ')' 'repeat+'
 | out_char_list ';' HEXADECIMAL
 ;

in2out : '[' i2o_list ']'
 ;

i2o_list : DECIMAL
 | '(' DECIMAL ')' 'repeat+'
 | i2o_list ';' DECIMAL
 ;

```

```

out2in : '[' o2i_list ']'
 ;

o2i_list : DECIMAL
 | '(' DECIMAL ')' 'repeat+'
 | o2i_list ';' DECIMAL
 ;

property : '[' prop_list ']'
 ;

prop_list : HEXADECIMAL
 | '(' HEXADECIMAL ')' 'repeat+'
 | prop_list ';' HEXADECIMAL
 ;

```

For example, the following shaping sequences can be defined:

```

A simple shaping sequence:
() + 0x21 ->
([0x0021], [0], [0;0], [0x80]) + 0x22 ->
([0x0021;0x0022], [0;1], [0;0;1;1], [0x80;0x80]) + 0xc2a0 ->
([0x0021;0x0022;0xe030], [0;1;2], [0;0;1;1;2;2],
 [0x80;0x80;0x80])

A repeating shaping sequence:
() + 0x21 ->
(
 ([0x0021], [0], [0;0], [0x80]) + 0x22 ->
 ([0x0021;0x0022], [0;1], [0;0;1;1], [0x80;0x80]) + 0xc2a2
) repeat+

```

The first example shows a shaping sequence such that if 0x21, 0x22, and 0xc2a0 are the input buffer contents, it will be converted into an output buffer containing 0x0021, 0x0022, and 0xe030; an input to the output buffer containing 0, 1, and 2; an output to the input buffer containing 0, 0, 1, 1, 2, and 2; and a property buffer containing 0x80, 0x80, and 0x80.

The second example shows a repeating shaping sequence where, if the first input code element is 0x21, then the second and third input code elements are 0x22 and 0xc2a2, respectively.

**EXIT STATUS** The following exit values are returned:

- |   |                                                                                       |
|---|---------------------------------------------------------------------------------------|
| 0 | No errors occurred and the output file was successfully created.                      |
| 1 | Command line options are not correctly used or unknown command line option specified. |
| 2 | Invalid input or output file specified.                                               |
| 3 | The layout definitions not correctly defined.                                         |
| 4 | No more system resource error.                                                        |

| <b>SYNOPSIS</b>                  | <b>genmsg</b> [-abdfntx] [-c <i>message-tag</i> ] [-g <i>project-file</i> ] [-l <i>project-file</i> ]<br>[-m <i>prefix</i> ] [-M <i>suffix</i> ] [-o <i>message-file</i> ] [-p <i>preprocessor</i> ] [-s <i>set-tags</i> ] <i>file...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                |                    |               |            |                             |            |                                  |          |
| <b>DESCRIPTION</b>               | The genmsg utility extracts message strings with calls to <code>catgets(3C)</code> from source files and writes them in a format suitable for input to <code>gencat(1)</code> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                |                    |               |            |                             |            |                                  |          |
| <b>Invocation</b>                | genmsg reads one or more input files and, by default, generates a message source file whose name is composed of the first input file name with <code>.msg</code> . If the <code>-o</code> option is specified, genmsg uses the option argument for its output file.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                |                    |               |            |                             |            |                                  |          |

| gensmg main.c util.c tool.c      | main.c.msg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                |                    |               |            |                             |            |                                  |          |
| genmsg -o prog.msg mail.c util.c | prog.msg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                    |               |            |                             |            |                                  |          |
|                                  | genmsg also allows you to invoke a preprocessor to solve the dependencies of macros and define statements for the <code>catgets(3C)</code> calls.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                |                    |               |            |                             |            |                                  |          |
| <b>Auto Message Numbering</b>    | genmsg replaces message numbers with the calculated numbers based upon the project file if the message numbers are <code>-1</code> , and it generates copies of the input files with the new message numbers and a copy of the project file with the new maximum message numbers.<br><br>A project file is a database that stores a list of set numbers with their maximum message numbers. Each line in a project file is composed of a set number and its maximum message number:<br><br><i>Set_number</i> <i>Maximum_message_number</i><br><br>In a project file, a line beginning with a number sign ( <code>#</code> ) or an ASCII space is considered as a comment and ignored.<br><br>genmsg also has the reverse operation to replace all message numbers with <code>-1</code> . |                |                    |               |            |                             |            |                                  |          |
| <b>Comment Extraction</b>        | genmsg allows you to comment about messages and set numbers to inform the translator how the messages should be translated. It extracts the comment, which is surrounded with the comment indicators and has the specified tag inside the comment, from the input file and writes it with a dollar ( <code>\$</code> ) prefix in the output file. genmsg supports the C and C++ comment indicators, <code>'/*'</code> , <code>'*//'</code> , and <code>'//'</code> .                                                                                                                                                                                                                                                                                                                     |                |                    |               |            |                             |            |                                  |          |
| <b>Testing</b>                   | genmsg generates two kinds of messages for testing, prefixed messages and long messages. Prefixed messages allow you to check that your program is retrieving the messages from the message catalog. Long messages allow you to check the appearance of your window program's initial size and position.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                    |               |            |                             |            |                                  |          |

## genmsg(1)

### OPTIONS

The following options are supported:

|                        |                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -a                     | Append the output into the message file <i>message-file</i> that is specified by the -o option. If two different messages that have the same set and message number are found, the message in the specified message file is kept and the other message in the input file is discarded.                                                                                                                                                   |
| -b                     | Place the extracted comment after the corresponding message in the output file. This option changes the placement behavior of the -s or -c option.                                                                                                                                                                                                                                                                                       |
| -c <i>message-tag</i>  | Extract message comments having <i>message-tag</i> inside them from the input files and write them with a '\$' prefix as a comment in the output file.                                                                                                                                                                                                                                                                                   |
| -d                     | Include an original text of a message as a comment to be preserved along with its translations. With this option, the translator can see the original messages even after they are replaced with their translations.                                                                                                                                                                                                                     |
| -f                     | Overwrite the input files and the project file when used with the -l or -r option. With the -r option, genmsg overwrites only the input files.                                                                                                                                                                                                                                                                                           |
| -g <i>project-file</i> | Generate <i>project-file</i> that has a list of set numbers and their maximum message numbers in the input files.                                                                                                                                                                                                                                                                                                                        |
| -l <i>project-file</i> | Replace message numbers with the calculated numbers based upon <i>project-file</i> if the message numbers are -1 in the input files, and then generate copies of the input files with the new message numbers and a copy of <i>project-file</i> with the new maximum message numbers. If <i>project-file</i> is not found, genmsg uses the maximum message number in the input file as a base number and generates <i>project-file</i> . |
| -m <i>prefix</i>       | Fill in the message with <i>prefix</i> . This option is useful for testing.                                                                                                                                                                                                                                                                                                                                                              |
| -M <i>suffix</i>       | Fill in the message with <i>suffix</i> . This option is useful for testing.                                                                                                                                                                                                                                                                                                                                                              |
| -n                     | Add comment lines to the output file indicating the file name and line number in the input files where each extracted string is encountered.                                                                                                                                                                                                                                                                                             |
| -o <i>message-file</i> | Write the output to <i>message-file</i> .                                                                                                                                                                                                                                                                                                                                                                                                |
| -p <i>preprocessor</i> | Invoke <i>preprocessor</i> to preprocess macros and define statements for the catgets(3C) calls. genmsg first invokes the option argument as a preprocessor and                                                                                                                                                                                                                                                                          |

then starts the normal process against the output from the preprocessor. `genmsg` initiates this process for all the input files.

|                         |                                                                                                                                                                                                                                                                                   |
|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>-r</code>         | Replace message numbers with <code>-1</code> . This is the reverse operation of the <code>-1</code> option.                                                                                                                                                                       |
| <code>-s set-tag</code> | Extract set number comments having <code>set-tag</code> inside them from the input files and write them with a '\$' prefix as a comment in the output file. If multiple comments are specified for one set number, the first one is extracted and the rest of them are discarded. |
| <code>-t</code>         | Generate a message that is three times as long as the original message. This option is useful for testing.                                                                                                                                                                        |
| <code>-x</code>         | Suppress warning messages about message and set number range checks and conflicts.                                                                                                                                                                                                |

**OPERANDS** *file* An input source file.

**EXAMPLES** **EXAMPLE 1** Assigning message numbers and generating new files

Suppose that you have the following source and project files:

```
example% cat test.c printf(catgets(catfd, 1, -1, "line too long));
printf(catgets(catfd, 2, -1, "invalid code));example% cat proj 10
2 20
```

The command

```
example% genmsg -1 proj test.c
```

would assign the calculated message numbers based upon `proj` and generate the following files:

|                         |                      |
|-------------------------|----------------------|
| <code>test.c.msg</code> | message file         |
| <code>proj.new</code>   | updated project file |
| <code>test.c.new</code> | new source file      |

```
example% cat test.c.msg$quote "
$set 1
11 "line too long
$set 2
21 "invalid codeexample% cat proj.new1 11
2 21example% cat test.c.newprintf(catgets(catfd, 1, 11, "line too long));
printf(catgets(catfd, 2, 21, "invalid code));
```

**EXAMPLE 2** Extracting comments into a file

The command

## genmsg(1)

### EXAMPLE 2 Extracting comments into a file *(Continued)*

```
example% genmsg -s SET -c MSG test.cexample% cat test.c/* SET: tar messages */
/* MSG: don't translate "tar". */
catgets(catfd, 1, 1, "tar: tape write error");
// MSG: don't translate "tar" and "-I".
catgets(catfd, 1, 2, "tar: missing argument for -I flag");
```

would extract the comments and write them in the following output file:

```
example% cat test.c.msg$ /* SET: tar messages */
$set 1
$ /* MSG: don't translate "tar". */
1 "tar: tape write error"
$ // MSG: don't translate "tar" and "-I".
2 "tar: missing argument for -I flag"
```

### EXAMPLE 3 Generating test messages

The command

```
example% genmsg -m PRE: -M :FIX test.c
```

would generate the following messages for testing:

```
example% cat test.c.msg1 "PRE:OK:FIX"
2 "PRE:Cancel:FIX"
```

### EXAMPLE 4 Parsing a macro and writing the extracted messages

Given the following input:

```
example% example.c
#include <nl_types.h>
#define MSG1 "message1"
#define MSG2 "message2"
#define MSG3 "message3"
#define MSG(n) catgets(catd, 1, n, MSG ## n)
void
main(int argc, char **argv)
{
 nl_catd catd = catopen(argv[0], NL_CAT_LOCALE);
 (void) printf("%s0, MSG(1));
 (void) printf("%s0, MSG(2));
 (void) printf("%s0, MSG(3));
 (void) catclose(catd);
}
```

The following command:

```
example% genmsg -p "cc -E" -o example.msg example.c
```

would parse the MSG macros and write the extracted messages in `example.msg`.

### EXAMPLE 5 Assigning calculated message numbers

Suppose that you have the following header, source, and project files:

**EXAMPLE 5** Assigning calculated message numbers (Continued)

```

example% ./inc/msg.h
#define WARN_SET 1
#define ERR_SET 2
#define WARN_MSG(id, msg) catgets(catd, WARN_SET, (id), (msg))
#define ERR_MSG(id, msg) catgets(catd, ERR_SET, (id), (msg))
example% example.c
#include "msg.h"
printf("%s, WARN_MSG(-1, "Warning error");
printf("%s, ERR_MSG(-1, "Fatal error");
example % proj
1 10
2 10

```

## The command

```

example% genmsg -f -p "cc -E -I../inc" -l proj \
-o example.msg example.c

```

would assign each of the -1 message numbers a calculated number based upon `proj` and would overwrite the results to `example.c` and `proj`. Also, this command writes the extracted messages in `example.msg`.

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `genmsg`: `LC_MESSAGES` and `NLSPATH`.

**EXIT STATUS**

The following exit values are returned:

```

0 Successful completion.
>0 An error occurred.

```

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |

**SEE ALSO**

`gencat(1)`, `catgets(3C)`, `catopen(3C)`, `attributes(5)`, `environ(5)`

**NOTES**

`genmsg` does not handle pointers or valuables in the `catgets(3C)` call. For example:

```

const int set_num = 1;
extern int msg_num(const char *);
const char *msg = "Hello";
catgets(catd, set_num, msg_num(msg), msg);

```

When the auto message numbering is turned on with a preprocessor, if there are multiple -1's in the `catgets(3C)` line, `genmsg` replaces all of the -1's in the line with a calculated number. For example, given the input:

genmsg(1)

```
#define MSG(id, msg) catgets(catd, 1, (id), (msg))
if (ret == -1) printf("%s, MSG(-1, "Failed"));
```

the command

```
genmsg -l proj -p "cc -E"
```

would produce:

```
#define MSG(id, msg) catgets(catd, 1, (id), (msg))
if (ret == 1) printf("%s, MSG(1, "Failed"));
```

The workaround would be to split it into two lines as follows:

```
if (ret == -1)
 printf("%s, MSG(-1, "Failed"));
```

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                        |          |                        |           |          |                |           |          |                |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------|----------|------------------------|-----------|----------|----------------|-----------|----------|----------------|
| <b>NAME</b>        | getconf – get configuration values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                        |          |                        |           |          |                |           |          |                |
| <b>SYNOPSIS</b>    | <pre>getconf [-v <i>specification</i>] <i>system_var</i> getconf [-v <i>specification</i>] <i>path_var</i> <i>pathname</i> getconf -a</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                        |          |                        |           |          |                |           |          |                |
| <b>DESCRIPTION</b> | <p>In the first synopsis form, the <code>getconf</code> utility will write to the standard output the value of the variable specified by <i>system_var</i>, in accordance with <i>specification</i> if the <code>-v</code> option is used.</p> <p>In the second synopsis form, <code>getconf</code> will write to the standard output the value of the variable specified by <i>path_var</i> for the path specified by <i>pathname</i>, in accordance with <i>specification</i> if the <code>-v</code> option is used.</p> <p>In the third synopsis form, <code>confi g</code> will write to the standard output the names of the current system configuration variables.</p> <p>The value of each configuration variable will be determined as if it were obtained by calling the function from which it is defined to be available. The value will reflect conditions in the current operating environment.</p> |                        |          |                        |           |          |                |           |          |                |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p><code>-a</code>                               Writes the names of the current system configuration variables to the standard output.</p> <p><code>-v <i>specification</i></code>               Gives the specification which governs the selection of values for configuration variables.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                        |          |                        |           |          |                |           |          |                |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>path_var</i>                       A name of a configuration variable whose value is available from the <code>pathconf(2)</code> function. All of the values in the following table are supported:</p> <table border="0" style="margin-left: 40px;"> <tr> <td>LINK_MAX</td> <td>NAME_MAX</td> <td>POSIX_CHOWN_RESTRICTED</td> </tr> <tr> <td>MAX_CANON</td> <td>PATH_MAX</td> <td>POSIX_NO_TRUNC</td> </tr> <tr> <td>MAX_INPUT</td> <td>PIPE_BUF</td> <td>POSIX_VDISABLE</td> </tr> </table> <p><i>pathname</i>                       A path name for which the variable specified by <i>path_var</i> is to be determined.</p> <p><i>system_var</i>                      A name of a configuration variable whose value is available from <code>confstr(3C)</code> or <code>sysconf(3C)</code>. All of the values in the following table are supported:</p>    | LINK_MAX               | NAME_MAX | POSIX_CHOWN_RESTRICTED | MAX_CANON | PATH_MAX | POSIX_NO_TRUNC | MAX_INPUT | PIPE_BUF | POSIX_VDISABLE |
| LINK_MAX           | NAME_MAX                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | POSIX_CHOWN_RESTRICTED |          |                        |           |          |                |           |          |                |
| MAX_CANON          | PATH_MAX                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | POSIX_NO_TRUNC         |          |                        |           |          |                |           |          |                |

The symbol `PATH` also is recognized, yielding the same value as the `confstr()` name value `CS_PATH`.

## getconf(1)

**USAGE** See `largefile(5)` for the description of the behavior of `getconf` when encountering files greater than or equal to 2 Gbyte (  $2^{31}$  bytes).

**EXAMPLES** **EXAMPLE 1** Writing the value of a variable  
This example illustrates the value of `{NGROUPS_MAX}`:

```
example% getconf NGROUPS_MAX
```

**EXAMPLE 2** Writing the value of a variable for a specific directory

This example illustrates the value of `NAME_MAX` for a specific directory:

```
example% getconf NAME_MAX /usr
```

**EXAMPLE 3** Dealing with unspecified results

This example shows how to deal more carefully with results that might be unspecified:

```
if value=$(getconf PATH_MAX /usr); then
 if ["$value" = "undefined"]; then
 echo PATH_MAX in /usr is infinite.
 else
 echo PATH_MAX in /usr is $value.
 fi
else
 echo Error in getconf.
fi
```

Note that

```
sysconf(_SC_POSIX_C_BIND);
```

and

```
system("getconf POSIX2_C_BIND");
```

in a C program could give different answers. The `sysconf` call supplies a value that corresponds to the conditions when the program was either compiled or executed, depending on the implementation; the `system` call to `getconf` always supplies a value corresponding to conditions when the program is executed.

**ENVIRONMENT VARIABLES** See `environ(5)` for descriptions of the following environment variables that affect the execution of `getconf`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

**EXIT STATUS** The following exit values are returned:

|    |                                                                                                   |
|----|---------------------------------------------------------------------------------------------------|
| 0  | The specified variable is valid and information about its current state was written successfully. |
| >0 | An error occurred.                                                                                |

getconf(1)

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>NAME</b>        | getfacl – display discretionary file information                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>SYNOPSIS</b>    | <b>getfacl</b> [-ad] <i>file...</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>DESCRIPTION</b> | <p>For each argument that is a regular file, special file, or named pipe, <code>getfacl</code> displays the owner, the group, and the Access Control List (ACL). For each directory argument, <code>getfacl</code> displays the owner, the group, and the ACL and/or the default ACL. Only directories contain default ACLs.</p> <p><code>getfacl</code> may be executed on a file system that does not support ACLs. It reports the ACL based on the base permission bits.</p> <p>With no options specified, <code>getfacl</code> displays the filename, the file owner, the file group owner, and both the ACL and the default ACL, if it exists.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <ul style="list-style-type: none"><li>-a        Display the filename, the file owner, the file group owner, and the ACL of the file.</li><li>-d        Display the filename, the file owner, the file group owner, and the default ACL of the file, if it exists.</li></ul>                                                                                                                                                                                                                                                                                                                                 |
| <b>OPERANDS</b>    | <p>The following operands are supported:</p> <p><i>file</i>        The path name of a regular file, special file, or named pipe.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>OUTPUT</b>      | <p>The format for ACL output is as follows:</p> <pre># file: filename # owner: uid # group: gid user::perm user:uid:perm group::perm group:gid:perm mask:perm other:perm default:user::perm default:user:uid:perm default:group::perm default:group:gid:perm default:mask:perm default:other:perm</pre> <p>When multiple files are specified on the command line, a blank line separates the ACLs for each file.</p> <p>The ACL entries are displayed in the order in which they are evaluated when an access check is performed. The default ACL entries that may exist on a directory have no effect on access checks.</p>                            |

The first three lines display the filename, the file owner, and the file group owner. Note that when only the `-d` option is specified and the file has no default ACL, only these three lines are displayed.

The user entry without a user ID indicates the permissions that are granted to the file owner. One or more additional user entries indicate the permissions that are granted to the specified users.

The group entry without a group ID indicates the permissions that are granted to the file group owner. One or more additional group entries indicate the permissions that are granted to the specified groups.

The mask entry indicates the ACL mask permissions. These are the maximum permissions allowed to any user entries except the file owner, and to any group entries, including the file group owner. These permissions restrict the permissions specified in other entries.

The other entry indicates the permissions that are granted to others.

The default entries may exist only for directories, and indicate the default entries that are added to a file created within the directory.

The `uid` is a login name or a user ID if there is no entry for the `uid` in the system password file, `/etc/passwd`. The `gid` is a group name or a group ID if there is no entry for the `gid` in the system group file, `/etc/group`. The `perm` is a three character string composed of the letters representing the separate discretionary access rights: `r` (read), `w` (write), `x` (execute/search), or the place holder character `-`. The `perm` is displayed in the following order: `rwX`. If a permission is not granted by an ACL entry, the place holder character appears.

If you use the `chmod(1)` command to change the file group owner permissions on a file with ACL entries, both the file group owner permissions and the ACL mask are changed to the new permissions. Be aware that the new ACL mask permissions may change the effective permissions for additional users and groups who have ACL entries on the file.

In order to indicate that the ACL mask restrict an ACL entry, `getfacl` displays an additional tab character, pound sign ("`#`"), and the actual permissions granted, following the entry.

## EXAMPLES **EXAMPLE 1** Displaying file information

Given file "foo", with an ACL six entries long, the command

```
host% getfacl foo
```

would print:

```
file: foo
owner: shea
group: staff
```

## getfacl(1)

### EXAMPLE 1 Displaying file information *(Continued)*

```
user::rwx
user:spy: - - -
user:mookie:r - -
group::r - -
mask::rw -
other:: - - -
```

### EXAMPLE 2 Displaying information after chmod command

Continue with the above example, after "chmod 700 foo" was issued:

```
host% getfacl foo
```

would print:

```
file: foo
owner: shea
group: staff
user::rwx
user:spy: - - -
user:mookie:r - - #effective: - - -
group:: - - -
mask:: - - -
other:: - - -
```

### EXAMPLE 3 Displaying information when ACL contains default entries

Given directory "doo", with an ACL containing default entries, the command

```
host% getfacl -d doo
```

would print:

```
file: doo
owner: shea
group: staff
default:user::rwx
default:user:spy: - - -
default:user:mookie:r - -
default:group::r - -
default:mask:: - - -
default:other:: - - -
```

|              |             |                      |
|--------------|-------------|----------------------|
| <b>FILES</b> | /etc/passwd | system password file |
|              | /etc/group  | group file           |

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE      | ATTRIBUTE VALUE |
|---------------------|-----------------|
| Availability        | SUNWcsu         |
| Interface Stability | Evolving        |

**SEE ALSO** `chmod(1)`, `ls(1)`, `setfacl(1)`, `acl(2)`, `aclsort(3SEC)`, `group(4)`, `passwd(4)`, `attributes(5)`

**NOTES** The output from `getfacl` is in the correct format for input to the `setfacl -f` command. If the output from `getfacl` is redirected to a file, the file may be used as input to `setfacl`. In this way, a user may easily assign one file's ACL to another file.

getfrm(1F)

**NAME** getfrm – returns the current frameID number

**SYNOPSIS** `getfrm`

**DESCRIPTION** `getfrm` returns the current frameID number. The frameID number is a number assigned to the frame by FMLI and displayed flush left in the frame's title bar. If a frame is closed its frameID number may be reused when a new frame is opened. `getfrm` takes no arguments.

**EXAMPLES** **EXAMPLE 1** A sample of the `getfrm` command.

If a menu whose frameID is 3 defines an item to have this `action` descriptor:

```
action=open text stdtext 'getfrm'
```

the text frame defined in the definition file `stdtext` would be passed the argument 3 when it is opened.

**NOTES** It is not a good idea to use `getfrm` in a backquoted expression coded on a line by itself. Stand-alone backquoted expressions are evaluated before any descriptors are parsed, thus the frame is not yet fully current, and may not have been assigned a frameID number.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `attributes(5)`

| <b>NAME</b>        | getitems – returns a list of currently marked menu items                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                |                 |              |         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|-----------------|--------------|---------|
| <b>SYNOPSIS</b>    | <b>getitems</b> [ <i>delimiter_string</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |         |
| <b>DESCRIPTION</b> | The <code>getitems</code> function returns the value of <code>lininfo</code> if defined, else it returns the value of the name descriptor, for all currently marked menu items. Each value in the list is delimited by <i>delimiter_string</i> . The default value of <i>delimiter_string</i> is newline.                                                                                                                                                                                                                                                                                                                                                                                                   |                |                 |              |         |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> A sample output of <code>getitems</code> command.</p> <p>The <code>done</code> descriptor in the following menu definition file executes <code>getitems</code> when the user presses ENTER (note that the menu is multiselect):</p> <pre>Menu="Example" multiselect=TRUE done='getitems ":"   message' name="Item 1" action='message "You selected item 1"' name="Item 2" lininfo="This is item 2" action='message "You selected item 2"' name="Item 3" action='message "You selected item 3"'</pre> <p>If a user marked all three items in this menu, pressing ENTER would cause the following string to be displayed on the message line:</p> <pre>Item 1:This is item 2:Item 3</pre> |                |                 |              |         |
| <b>NOTES</b>       | Because <code>lininfo</code> is defined for the second menu item, its value is displayed instead of the value of the name descriptor.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                |                 |              |         |

getopt(1)

**NAME** getopt – parse command options

**SYNOPSIS** `set - - `getopt optstring $ * ``

**DESCRIPTION** The `getopts` command supersedes `getopt`. For more information, see **NOTES** below.

`getopt` is used to break up options in command lines for easy parsing by shell procedures and to check for legal options. *optstring* is a string of recognized option letters; see `getopt(3C)`. If a letter is followed by a colon, the option is expected to have an argument which may or may not be separated from it by white space. The special option `-` is used to delimit the end of the options. If it is used explicitly, `getopt` recognizes it; otherwise, `getopt` generates it; in either case, `getopt` places it at the end of the options. The positional parameters (`$1 $2 . . .`) of the shell are reset so that each option is preceded by a `-` and is in its own positional parameter; each option argument is also parsed into its own positional parameter.

**EXAMPLES** **EXAMPLE 1** Processing the arguments for a command.

The following code fragment shows how one might process the arguments for a command that can take the options `a` or `b`, as well as the option `o`, which requires an argument:

```
set - - `getopt abo: $*`
if [$? != 0]
then
 echo $USAGE
 exit 2
fi
for i in $*
do
 case $i in
 - a | - b) FLAG=$i; shift;;
 - o) OARG=$2; shift 2;;
 - -) shift; break;;
 esac
done
```

This code accepts any of the following as equivalent:

```
cmd - aoarg filename1 filename2
cmd - a - o arg filename1 filename2
cmd - oarg - a filename1 filename2
cmd - a - oarg - - filename1 filename2
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DIAGNOSTICS</b> | getopt prints an error message on the standard error when it encounters an option letter not included in <i>optstring</i> .                                                                                                                                                                                                                                                                                                                                                                             |
| <b>NOTES</b>       | getopt will not be supported in the next major release. For this release a conversion tool has been provided, <code>getoptcvt</code> . For more information about <code>getopts</code> and <code>getoptcvt</code> , see <code>getopts(1)</code> .                                                                                                                                                                                                                                                       |
|                    | Reset <code>optind</code> to 1 when rescanning the options.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|                    | getopt does not support the part of Rule 8 of the command syntax standard (see <code>intro(1)</code> ) that permits groups of option-arguments following an option to be separated by white space and quoted. For example,                                                                                                                                                                                                                                                                              |
|                    | <code>cmd - a - b - o "xxx z yy" filename</code> is not handled correctly. To correct this deficiency, use the <code>getopts</code> command in place of <code>getopt</code> .                                                                                                                                                                                                                                                                                                                           |
|                    | If an option that takes an option-argument is followed by a value that is the same as one of the options listed in <i>optstring</i> (referring to the earlier <code>EXAMPLES</code> section, but using the following command line: <code>cmd - o - a filename</code> , <code>getopt</code> always treats as an option-argument to <code>-o</code> ; it never recognizes <code>-a</code> as an option. For this case, the <code>for</code> loop in the example shifts past the <i>filename</i> argument. |

| <b>NAME</b>        | getoptcvt – convert to getopt to parse command options                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>SYNOPSIS</b>    | <pre>/usr/lib/getoptcvt [-b] filename<br/><br/>/usr/lib/getoptcvt</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>DESCRIPTION</b> | <p><code>/usr/lib/getoptcvt</code> reads the shell script in <i>filename</i>, converts it to use <code>getopts</code> instead of <code>getopt</code>, and writes the results on the standard output.</p> <p><code>getopts</code> is a built-in Bourne shell command used to parse positional parameters and to check for valid options. See <code>sh(1)</code>. It supports all applicable rules of the command syntax standard (see Rules 3-10, <code>intro(1)</code>). It should be used in place of the <code>getopt</code> command. (See the <b>NOTES</b> section below.) The syntax for the shell's built-in <code>getopts</code> command is:</p> <pre>getopts optstring name [ argument . . . ]</pre> <p><i>optstring</i> must contain the option letters the command using <code>getopts</code> will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which must be separated from it by white space.</p> <p>Each time it is invoked, <code>getopts</code> places the next option in the shell variable <i>name</i> and the index of the next argument to be processed in the shell variable <code>OPTIND</code>. Whenever the shell or a shell script is invoked, <code>OPTIND</code> is initialized to 1.</p> <p>When an option requires an option-argument, <code>getopts</code> places it in the shell variable <code>OPTARG</code>.</p> <p>If an illegal option is encountered, <code>?</code> will be placed in <i>name</i>.</p> <p>When the end of options is encountered, <code>getopts</code> exits with a non-zero exit status. The special option <code>—</code> may be used to delimit the end of the options.</p> <p>By default, <code>getopts</code> parses the positional parameters. If extra arguments (<i>argument . . .</i>) are given on the <code>getopts</code> command line, <code>getopts</code> parses them instead.</p> <p>So that all new commands will adhere to the command syntax standard described in <code>intro(1)</code>, they should use <code>getopts</code> or <code>getopt</code> to parse positional parameters and check for options that are valid for that command (see the <b>NOTES</b> section below).</p> |
| <b>OPTIONS</b>     | <p><code>-b</code> Make the converted script portable to earlier releases of the UNIX system. <code>/usr/lib/getoptcvt</code> modifies the shell script in <i>filename</i> so that when the resulting shell script is executed, it determines at run time whether to invoke <code>getopts</code> or <code>getopt</code>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>EXAMPLES</b>    | <p><b>EXAMPLE 1</b> Processing the arguments for a command.</p> <p>The following fragment of a shell program shows how one might process the arguments for a command that can take the options <code>a</code> or <code>b</code>, as well as the option <code>o</code>, which requires an option-argument:</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**EXAMPLE 1** Processing the arguments for a command. (Continued)

```
while getopts abo: c
do
 case $c in
 a | b) FLAG=$c;;
 o) OARG=$OPTARG;;
 \?) echo $USAGE
 exit 2;;
 esac
done
shift `expr $OPTIND - 1`
```

This code accepts any of the following as equivalent:

```
cmd - a - b - o "xxx z yy" filename
cmd - a - b - o "xxx z yy" - filename
cmd - ab - o xxx,z,yy filename
cmd - ab - o "xxx z yy" filename
cmd - o xxx,z,yy b a filename
```

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

**SEE ALSO** `intro(1)`, `sh(1)`, `shell_builtins(1)`, `getopt(3C)`, `attributes(5)`

**DIAGNOSTICS** `getopts` prints an error message on the standard error when it encounters an option letter not included in *optstring*.

**NOTES** Although the following command syntax rule (see `intro(1)`) relaxations are permitted under the current implementation, they should not be used because they may not be supported in future releases of the system. As in the **EXAMPLES** section above, `a` and `b` are options, and the option `o` requires an option-argument. The following example violates Rule 5: options with option-arguments must not be grouped with other options:

```
example% cmd - abxxxx filename
```

The following example violates Rule 6: there must be white space after an option that takes an option-argument:

```
example% cmd - ab oxxx filename
```

getoptcvt(1)

Changing the value of the shell variable `OPTIND` or parsing different sets of arguments may lead to unexpected results.

|                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Any of the following identifies the end of options: the special option <code>--</code>, finding an argument that does not begin with a <code>-</code>, or encountering an error.</p> |

## getopts(1)

The shell variables `OPTIND` and `OPTARG` are local to the caller of `getopts` and are not exported by default.

The shell variable specified by the *name* operand, `OPTIND` and `OPTARG` affect the current shell execution environment.

If the application sets `OPTIND` to the value 1, a new set of parameters can be used: either the current positional parameters or new *arg* values. Any other attempt to invoke `getopts` multiple times in a single shell execution environment with parameters (positional parameters or *arg* operands) that are not the same in all invocations, or with an `OPTIND` value modified to be a value other than 1, produces unspecified results.

**sh** `getopts` is a built-in Bourne shell command used to parse positional parameters and to check for valid options. See `sh(1)`. It supports all applicable rules of the command syntax standard (see Rules 3-10, `intro(1)`). It should be used in place of the `getopt` command.

*optstring* must contain the option letters the command using `getopts` will recognize; if a letter is followed by a colon, the option is expected to have an argument, or group of arguments, which must be separated from it by white space.

Each time it is invoked, `getopts` places the next option in the shell variable *name* and the index of the next argument to be processed in the shell variable `OPTIND`. Whenever the shell or a shell script is invoked, `OPTIND` is initialized to 1.

When an option requires an option-argument, `getopts` places it in the shell variable `OPTARG`.

If an illegal option is encountered, `?` will be placed in *name*.

When the end of options is encountered, `getopts` exits with a non-zero exit status. The special option `-` may be used to delimit the end of the options.

By default, `getopts` parses the positional parameters. If extra arguments (*argument* . . .) are given on the `getopts` command line, `getopts` parses them instead.

`/usr/lib/getoptcvt` reads the shell script in *filename*, converts it to use `getopts` instead of `getopt`, and writes the results on the standard output.

So that all new commands will adhere to the command syntax standard described in `intro(1)`, they should use `getopts` or `getopt` to parse positional parameters and check for options that are valid for that command.

Examples:

The following fragment of a shell program shows how one might process the arguments for a command that can take the options `a` or `b`, as well as the option `o`, which requires an option-argument:

```

while getopts abo: c
do
 case $c in
 a | b) FLAG=$c;;
 o) OARG=$OPTARG;;
 \?) echo $USAGE
 exit 2;;
 esac
done
shift `expr $OPTIND - 1`

```

This code accepts any of the following as equivalent:

```

cmd - a - b - o "xxx z yy" filename
cmd - a - b - o "xxx z yy" -- filename
cmd - ab - o xxx,z,yy filename
cmd - ab - o "xxx z yy" filename
cmd - o xxx,z,yy - b - a filename

```

getopts prints an error message on the standard error when it encounters an option letter not included in *optstring*.

Although the following command syntax rule (see [intro\(1\)](#)) relaxations are permitted under the current implementation, they should not be used because they may not be supported in future releases of the system. As in the [EXAMPLES](#) section above, *a* and *b* are options, and the option *o* requires an option-argument.

The following example violates Rule 5: options with option-arguments must not be grouped with other options:

```
example% cmd - abxxxx filename
```

The following example violates Rule 6: there must be white space after an option that takes an option-argument:

```
example% cmd - ab oxxx filename
```

Changing the value of the shell variable `OPTIND` or parsing different sets of arguments may lead to unexpected results.

**ksh** Checks *arg* for legal options. If *arg* is omitted, the positional parameters are used. An option argument begins with a + or a -. An option not beginning with + or - or the argument - ends the options. *optstring* contains the letters that `getopts` recognizes. If a letter is followed by a :, that option is expected to have an argument. The options can be separated from the argument by blanks.

`getopts` places the next option letter it finds inside variable *name* each time it is invoked with a + prepended when *arg* begins with a +. The index of the next *arg* is stored in `OPTIND`. The option argument, if any, gets stored in `OPTARG`.

## getopts(1)

A leading `:` in *optstring* causes `getopts` to store the letter of an invalid option in `OPTARG`, and to set *name* to `?` for an unknown option and to `:` when a required option is missing. Otherwise, `getopts` prints an error message. The exit status is non-zero when there are no more options.

For a further discussion of the Korn shell's `getopts` built-in command, see the previous discussion in the Bourne shell, `sh`, section of this manpage.

**OPERANDS** The following operands are supported:

|                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>optstring</i> | A string containing the option characters recognised by the utility invoking <code>getopts</code> . If a character is followed by a colon, the option will be expected to have an argument, which should be supplied as a separate argument. Applications should specify an option character and its option-argument as separate arguments, but <code>getopts</code> will interpret the characters following an option character requiring arguments as an argument whether or not this is done. An explicit null option-argument need not be recognised if it is not supplied as a separate argument when <code>getopts</code> is invoked; see <code>getopt(3C)</code> . The characters question-mark and colon must not be used as option characters by an application. The use of other option characters that are not alphanumeric produces unspecified results. If the option-argument is not supplied as a separate argument from the option character, the value in <code>OPTARG</code> will be stripped of the option character and the <code>-</code> . The first character in <i>optstring</i> will determine how <code>getopts</code> will behave if an option character is not known or an option-argument is missing. |
| <i>name</i>      | The name of a shell variable that will be set by the <code>getopts</code> utility to the option character that was found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

The `getopts` utility by default will parse positional parameters passed to the invoking shell procedure. If *arg s* are given, they will be parsed instead of the positional parameters.

**USAGE** Since `getopts` affects the current shell execution environment, it is generally provided as a shell regular built-in. If it is called in a subshell or separate utility execution environment, such as one of the following:

```
(getopts abc value "$@")
nohup getopts ...
find . - exec getopts ... \;
```

it will not affect the shell variables in the caller's environment.

Note that shell functions share `OPTIND` with the calling shell even though the positional parameters are changed. Functions that want to use `getopts` to parse their arguments will usually want to save the value of `OPTIND` on entry and restore it before returning. However, there will be cases when a function will want to change `OPTIND` for the calling shell.

**EXAMPLES**    **EXAMPLE 1** Parsing and displaying arguments>

The following example script parses and displays its arguments:

```
aflag=
bflag=
while getopts ab: name
do
 case $name in
 a) aflag=1;;
 b) bflag=1
 bval="$OPTARG";;
 ?) printf "Usage: %s: [-a] [-b value] args\n" $0
 exit 2;;
 esac
done
if [! -z "$aflag"]; then
 printf "Option -a specified\n"
fi
if [! -z "$bflag"]; then
 printf 'Option -b "%s" specified\n' "$bval"
fi
shift $((OPTIND - 1))
printf "Remaining arguments are: %s\n" "$@"
```

**ENVIRONMENT VARIABLES**

See `environ(5)` for descriptions of the following environment variables that affect the execution of `getopts`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`OPTIND`            This variable is used by `getopts` as the index of the next argument to be processed.

**EXIT STATUS**

The following exit values are returned:

0            An option, specified or unspecified by *optstring*, was found.

>0          The end of options was encountered or an error occurred.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO**

`intro(1)`, `getopt(1)`, `getoptcvt(1)`, `ksh(1)`, `sh(1)`, `getopt(3C)`, `attributes(5)`, `environ(5)`

## getopts(1)

### DIAGNOSTICS

Whenever an error is detected and the first character in the *optstring* operand is not a colon ( : ), a diagnostic message will be written to standard error with the following information in an unspecified format:

- The invoking program name will be identified in the message. The invoking program name will be the value of the shell special parameter 0 at the time the `getopts` utility is invoked. A name equivalent to:

```
basename "$0"
may be used.
```

- If an option is found that was not specified in *optstring*, this error will be identified and the invalid option character will be identified in the message.
- If an option requiring an option-argument is found, but an option-argument is not found, this error will be identified and the invalid option character will be identified in the message.

|                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |

| <b>NAME</b>                             | gettext – retrieve text string from message database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |
| <b>SYNOPSIS</b>                         | <pre>gettext [-d <i>textdomain</i>   --domain=<i>textdomain</i>] [<i>textdomain</i>] <i>msgid</i> gettext -s [-e] [-n] [-d <i>textdomain</i>   --domain=<i>textdomain</i>] <i>msgid</i>...</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>                      | <p>The <code>gettext</code> utility retrieves a translated text string corresponding to string <i>msgid</i> from a message object generated with <code>msgfmt(1)</code>. The message object name is derived from the optional argument <i>textdomain</i> if present, otherwise from the <code>TEXTDOMAIN</code> environment. If no domain is specified, or if a corresponding string cannot be found, <code>gettext</code> prints <i>msgid</i>.</p> <p>Ordinarily, <code>gettext</code> looks for its message object in <code>/usr/lib/locale/<i>lang</i>/LC_MESSAGES</code> where <i>lang</i> is the locale name. If present, the <code>TEXTDOMAINDIR</code> environment variable replaces the pathname component up to <i>lang</i>.</p> <p>This command interprets C escape sequences such as <code>\t</code> for tab. Use <code>\\</code> to print a backslash. To produce a message on a line of its own, either enter <code>\n</code> at the end of <i>msgid</i>, or use this command in conjunction with <code>printf(1)</code>.</p> <p>When used with the <code>-s</code> option, <code>gettext</code> behaves like <code>echo(1)</code>. But it does not simply copy its arguments to standard output. Instead, those messages found in the selected catalog are translated.</p> |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |
| <b>OPTIONS</b>                          | <p>The following options are supported:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><code>-d <i>textdomain</i></code></td> <td></td> </tr> <tr> <td style="padding-right: 20px;"><code>--domain=<i>textdomain</i></code></td> <td>Retrieves translated messages from the domain <i>textdomain</i>, if <i>textdomain</i> is not specified as an operand.</td> </tr> <tr> <td style="padding-right: 20px;"><code>-e</code></td> <td>Enables expansion of some escape sequences if used with the <code>-s</code> option.</td> </tr> <tr> <td style="padding-right: 20px;"><code>-n</code></td> <td>Suppresses trailing newline if used with the <code>-s</code> option.</td> </tr> <tr> <td style="padding-right: 20px;"><code>-s</code></td> <td>Behaves like <code>echo(1)</code> (see <b>DESCRIPTION</b> above). If the <code>-s</code> option is specified, no expansion of C escape sequences is performed and a newline character is appended to the output, by default.</td> </tr> </table>                                                                                                                                                                                                                                              | <code>-d <i>textdomain</i></code> |                                                                                                                                                    | <code>--domain=<i>textdomain</i></code> | Retrieves translated messages from the domain <i>textdomain</i> , if <i>textdomain</i> is not specified as an operand. | <code>-e</code> | Enables expansion of some escape sequences if used with the <code>-s</code> option. | <code>-n</code> | Suppresses trailing newline if used with the <code>-s</code> option. | <code>-s</code> | Behaves like <code>echo(1)</code> (see <b>DESCRIPTION</b> above). If the <code>-s</code> option is specified, no expansion of C escape sequences is performed and a newline character is appended to the output, by default. |
| <code>-d <i>textdomain</i></code>       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |
| <code>--domain=<i>textdomain</i></code> | Retrieves translated messages from the domain <i>textdomain</i> , if <i>textdomain</i> is not specified as an operand.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |

| <code>-n</code>                         | Suppresses trailing newline if used with the <code>-s</code> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |
| <code>-s</code>                         | Behaves like <code>echo(1)</code> (see <b>DESCRIPTION</b> above). If the <code>-s</code> option is specified, no expansion of C escape sequences is performed and a newline character is appended to the output, by default.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |
| <b>OPERANDS</b>                         | <p>The following operands are supported:</p> <table border="0" style="margin-left: 20px;"> <tr> <td style="padding-right: 20px;"><i>textdomain</i></td> <td>A domain name used to retrieve the messages. This overrides the specification by the <code>-d</code> or <code>--domain</code> options, if present.</td> </tr> <tr> <td style="padding-right: 20px;"><i>msgid</i></td> <td>A key to retrieve the localized message.</td> </tr> </table>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       | <i>textdomain</i>                 | A domain name used to retrieve the messages. This overrides the specification by the <code>-d</code> or <code>--domain</code> options, if present. | <i>msgid</i>                            | A key to retrieve the localized message.                                                                               |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |
| <i>textdomain</i>                       | A domain name used to retrieve the messages. This overrides the specification by the <code>-d</code> or <code>--domain</code> options, if present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |

| <code>LC_MESSAGES</code>                | Specifies messaging locale, and if present overrides <code>LANG</code> for messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                                   |                                                                                                                                                    |                                         |                                                                                                                        |                 |                                                                                     |                 |                                                                      |                 |                                                                                                                                                                                                                              |

## gettext(1)

TEXTDOMAIN Specifies the text domain name, which is identical to the message object filename without .mo suffix.

TEXTDOMAINDIR Specifies the pathname to the message database. If present, replaces /usr/lib/locale.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

**SEE ALSO** `echo(1)`, `msgfmt(1)`, `printf(1)`, `gettext(3C)`, `setlocale(3C)`, `attributes(5)`

**NOTES** This is the shell equivalent of the library routine `gettext(3C)`.

|                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>NAME</b>                  | gettxt – retrieve a text string from a message database                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>SYNOPSIS</b>              | <b>gettxt</b> <i>msgfile</i> : <i>msgnum</i> [ <i>dflt_msg</i> ]                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>DESCRIPTION</b>           | <p>gettxt retrieves a text string from a message file in the directory <code>/usr/lib/locale/locale/LC_MESSAGES</code>. The directory name <i>locale</i> corresponds to the language in which the text strings are written; see <code>setlocale(3C)</code>.</p> <p><i>msgfile</i>            Name of the file in the directory <code>/usr/lib/locale/locale/LC_MESSAGES</code> to retrieve <i>msgnum</i> from. The name of <i>msgfile</i> can be up to 14 characters in length, but may not contain either <code>\0</code> (null) or the ASCII code for <code>/</code> (slash) or <code>:</code> (colon).</p> <p><i>msgnum</i>            Sequence number of the string to retrieve from <i>msgfile</i>. The strings in <i>msgfile</i> are numbered sequentially from 1 to <i>n</i>, where <i>n</i> is the number of strings in the file.</p> <p><i>dflt_msg</i>            Default string to be displayed if gettxt fails to retrieve <i>msgnum</i> from <i>msgfile</i>. Nongraphic characters must be represented as alphabetic escape sequences.</p> <p>The text string to be retrieved is in the file <i>msgfile</i>, created by the <code>mkmsgs(1)</code> utility and installed under the directory <code>/usr/lib/locale/locale/LC_MESSAGES</code>. You control which directory is searched by setting the environment variable <code>LC_MESSAGES</code>. If <code>LC_MESSAGES</code> is not set, the environment variable <code>LANG</code> will be used. If <code>LANG</code> is not set, the files containing the strings are under the directory <code>/usr/lib/locale/C/LC_MESSAGES</code>.</p> <p>If gettxt fails to retrieve a message in the requested language, it will try to retrieve the same message from <code>/usr/lib/locale/C/LC_MESSAGES/ msgfile</code>. If this also fails, and if <i>dflt_msg</i> is present and non-null, then it will display the value of <i>dflt_msg</i>; if <i>dflt_msg</i> is not present or is null, then it will display the string <code>Message not found!!</code>.</p> |
| <b>EXAMPLES</b>              | <p><b>EXAMPLE 1</b> The environment variables <code>LANG</code> and <code>LC_MESSAGES</code>.</p> <p>If the environment variables <code>LANG</code> or <code>LC_MESSAGES</code> have not been set to other than their default values, the following example:</p> <pre>example% gettxt UX:10 "hello world\n"</pre> <p>will try to retrieve the 10th message from <code>/usr/lib/locale/C/UX/msgfile</code>. If the retrieval fails, the message "hello world," followed by a newline, will be displayed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>ENVIRONMENT VARIABLES</b> | <p>See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of gettxt: <code>LC_CTYPE</code> and <code>LC_MESSAGES</code>.</p> <p><code>LC_CTYPE</code>            Determines how gettxt handles characters. When <code>LC_CTYPE</code> is set to a valid value, gettxt can display and handle text and filenames containing valid</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## gettext(1)

characters for that locale. `gettext` can display and handle Extended Unix Code (EUC) characters where any individual character can be 1, 2, or 3 bytes wide. `gettext` can also handle EUC characters of 1, 2, or more column widths. In the "C" locale, only characters from ISO 8859-1 are valid.

`LC_MESSAGES`

Determines how diagnostic and informative messages are presented. This includes the language and style of the messages, and the correct form of affirmative and negative responses. In the "C" locale, the messages are presented in the default form found in the program itself (in most cases, U.S. English).

### FILES

`/usr/lib/locale/C/LC_MESSAGES/*`  
default message files created by `mkmsgs(1)`

`/usr/lib/locale/locale/LC_MESSAGES/*`  
message files for different languages created by `mkmsgs(1)`

### ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWloc         |
| CSI            | Enabled         |

### SEE ALSO

**NAME** glob – shell built-in function to expand a word list

**SYNOPSIS**

**cs**h **glob** *wordlist*

**DESCRIPTION**

**cs**h glob performs filename expansion on *wordlist*. Like `echo(1)`, but no ‘\’ escapes are recognized. Words are delimited by null characters in the output.

**ATTRIBUTES**

See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |

| <b>DESCRIPTION</b> | <p>The <code>gprof</code> utility produces an execution profile of a program. The effect of called routines is incorporated in the profile of each caller. The profile data is taken from the call graph profile file that is created by programs compiled with the <code>-xpg</code> option of <code>cc(1)</code>, or by the <code>-pg</code> option with other compilers, or by setting the <code>LD_PROFILE</code> environment variable for shared objects. See <code>ld.so.1(1)</code>. These compiler options also link in versions of the library routines which are compiled for profiling. The symbol table in the executable image file <i>image-file</i> (<code>a.out</code> by default) is read and correlated with the call graph profile file <i>profile-file</i> (<code>gmon.out</code> by default).</p> <p>First, execution times for each routine are propagated along the edges of the call graph. Cycles are discovered, and calls into a cycle are made to share the time of the cycle. The first listing shows the functions sorted according to the time they represent, including the time of their call graph descendants. Below each function entry is shown its (direct) call-graph children and how their times are propagated to this function. A similar display above the function shows how this function's time and the time of its descendants are propagated to its (direct) call-graph parents.</p> <p>Cycles are also shown, with an entry for the cycle as a whole and a listing of the members of the cycle and their contributions to the time and call counts of the cycle.</p> <p>Next, a flat profile is given, similar to that provided by <code>prof(1)</code>. This listing gives the total execution times and call counts for each of the functions in the program, sorted by decreasing time. Finally, an index is given, which shows the correspondence between function names and call-graph profile index numbers.</p> <p>A single function may be split into subfunctions for profiling by means of the <code>MARK</code> macro. See <code>prof(5)</code>.</p> <p>Beware of quantization errors. The granularity of the sampling is shown, but remains statistical at best. It is assumed that the time for each execution of a function can be expressed by the total time for the function divided by the number of times the function is called. Thus the time propagated along the call-graph arcs to parents of that function is directly proportional to the number of times that arc is traversed.</p> <p>The profiled program must call <code>exit(2)</code> or return normally for the profiling information to be saved in the <code>gmon.out</code> file.</p> |
| <b>OPTIONS</b>     | <p>The following options are supported:</p> <p>-a                      Suppress printing statically declared functions. If this option is given, all relevant information about the static function (for instance, time samples, calls to other functions, calls from other functions) belongs to the function loaded just before the static function in the <code>a.out</code> file.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -b                      | Brief. Suppress descriptions of each field in the profile.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| -c                      | Discover the static call-graph of the program by a heuristic which examines the text space of the object file. Static-only parents or children are indicated with call counts of 0. Note that for dynamically linked executables, the linked shared objects' text segments are not examined.                                                                                                                                                                                                                                                                                                                                                                             |
| -C                      | Demangle C++ symbol names before printing them out.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| -D                      | Produce a profile file <code>gmon.sum</code> that represents the difference of the profile information in all specified profile files. This summary profile file may be given to subsequent executions of <code>gprof</code> (also with <code>-D</code> ) to summarize profile data across several runs of an <code>a.out</code> file. See also the <code>-s</code> option.<br><br>As an example, suppose function A calls function B $n$ times in profile file <code>gmon.sum</code> , and $m$ times in profile file <code>gmon.out</code> . With <code>-D</code> , a new <code>gmon.sum</code> file will be created showing the number of calls from A to B as $n-m$ . |
| -e <i>function-name</i> | Suppress printing the graph profile entry for routine <i>function-name</i> and all its descendants (unless they have other ancestors that are not suppressed). More than one <code>-e</code> option may be given. Only one <i>function-name</i> may be given with each <code>-e</code> option.                                                                                                                                                                                                                                                                                                                                                                           |
| -E <i>function-name</i> | Suppress printing the graph profile entry for routine <i>function-name</i> (and its descendants) as <code>-e</code> , below, and also exclude the time spent in <i>function-name</i> (and its descendants) from the total and percentage time computations. More than one <code>-E</code> option may be given. For example:<br><br><code>'-E mcount -E mcleanup'</code><br><br>is the default.                                                                                                                                                                                                                                                                           |
| -f <i>function-name</i> | Print the graph profile entry only for routine <i>function-name</i> and its descendants. More than one <code>-f</code> option may be given. Only one <i>function-name</i> may be given with each <code>-f</code> option.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| -F <i>function-name</i> | Print the graph profile entry only for routine <i>function-name</i> and its descendants (as <code>-f</code> , below) and also use only the times of the printed routines in total                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## gprof(1)

|                              |                                                                                                                                                                               | time and percentage computations. More than one <code>-F</code> option may be given. Only one <i>function-name</i> may be given with each <code>-F</code> option. The <code>-F</code> option overrides the <code>-E</code> option.                                                                                                                                                                                                                                                                |                |                 |              |           |

|                              | <code>-l</code>                                                                                                                                                               | Suppress the reporting of graph profile entries for all local symbols. This option would be the equivalent of placing all of the local symbols for the specified executable image on the <code>-E</code> exclusion list.                                                                                                                                                                                                                                                                          |                |                 |              |           |
|                              | <code>-n</code>                                                                                                                                                               | Limits the size of flat and graph profile listings to the top <code>n</code> offending functions.                                                                                                                                                                                                                                                                                                                                                                                                 |                |                 |              |           |
|                              | <code>-s</code>                                                                                                                                                               | Produce a profile file <code>gmon.sum</code> which represents the sum of the profile information in all of the specified profile files. This summary profile file may be given to subsequent executions of <code>gprof</code> (also with <code>-s</code> ) to accumulate profile data across several runs of an <code>a.out</code> file. See also the <code>-D</code> option.                                                                                                                     |                |                 |              |           |
|                              | <code>-z</code>                                                                                                                                                               | Display routines which have zero usage (as indicated by call counts and accumulated time). This is useful in conjunction with the <code>-c</code> option for discovering which routines were never called. Note that this has restricted use for dynamically linked executables, since shared object text space will not be examined by the <code>-c</code> option.                                                                                                                               |                |                 |              |           |
| <b>ENVIRONMENT VARIABLES</b> | <code>PROFDIR</code>                                                                                                                                                          | If this environment variable contains a value, place profiling output within that directory, in a file named <i>pid.programname</i> . <i>pid</i> is the process ID and <i>programname</i> is the name of the program being profiled, as determined by removing any path prefix from the <code>argv[0]</code> with which the program was called. If the variable contains a null value, no profiling output is produced. Otherwise, profiling output is placed in the file <code>gmon.out</code> . |                |                 |              |           |

| <b>NOTES</b>            | <p>If the executable image has been stripped and has no symbol table (<i>.symtab</i>), then gprof will read the dynamic symbol table (<i>.dyntab</i>), if present. If the dynamic symbol table is used, then only the information for the global symbols will be available, and the behavior will be identical to the -a option.</p> <p>LD_LIBRARY_PATH must not contain /usr/lib as a component when compiling a program for profiling. If LD_LIBRARY_PATH contains /usr/lib, the program will not be linked correctly with the profiling versions of the system libraries in /usr/lib/libp.</p> <p>The times reported in successive identical runs may show variances because of varying cache-hit ratios that result from sharing the cache with other processes. Even if a program seems to be the only one using the machine, hidden background or asynchronous processes may blur the data. In rare cases, the clock ticks initiating recording of the program counter may "beat" with loops in a program, grossly distorting measurements. Call counts are always recorded precisely, however.</p> <p>Only programs that call exit or return from main are guaranteed to produce a profile file, unless a final call to monitor is explicitly coded.</p> <p>Functions such as mcount(), _mcount(), moncontrol(), _moncontrol(), monitor(), and _monitor() may appear in the gprof report. These functions are part of the profiling implementation and thus account for some amount of the runtime overhead. Since these functions are not present in an unprofiled application, time accumulated and call counts for these functions may be ignored when evaluating the performance of an application.</p> |
| <b>64-bit profiling</b> | <p>64-bit profiling may be used freely with dynamically linked executables, and profiling information is collected for the shared objects if the objects are compiled for profiling. Care must be applied to interpret the profile output, since it is possible for symbols from different shared objects to have the same name. If name duplication occurs in the profile output, the module id prefix before the symbol name in the symbol index listing can be used to identify the appropriate module for the symbol.</p> <p>When using the -s or -D option to sum multiple profile files, care must be taken not to mix 32-bit profile files with 64-bit profile files.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## gprof(1)

image is sampled. This means that all time spent outside of the "main" object, that is, time spent in a shared object, will not be included in the profile summary; the total time reported for the program may be less than the total time used by the program.

Because the time spent in a shared object cannot be accounted for, the use of shared objects should be minimized whenever a program is profiled with `gprof`. If desired, the program should be linked to the profiled version of a library (or to the standard archive version if no profiling version is available), instead of the shared object to get profile information on the functions of a library. Versions of profiled libraries may be supplied with the system in the `/usr/lib/libp` directory. Refer to compiler driver documentation on profiling.

Consider an extreme case. A profiled program dynamically linked with the shared C library spends 100 units of time in some `libc` routine, say, `malloc()`. Suppose `malloc()` is called only from routine B and B consumes only 1 unit of time. Suppose further that routine A consumes 10 units of time, more than any other routine in the "main" (profiled) portion of the image. In this case, `gprof` will conclude that most of the time is being spent in A and almost no time is being spent in B. From this it will be almost impossible to tell that the greatest improvement can be made by looking at routine B and not routine A. The value of the profiler in this case is severely degraded; the solution is to use archives as much as possible for profiling.

**BUGS** Parents which are not themselves profiled will have the time of their profiled children propagated to them, but they will appear to be spontaneously invoked in the call-graph listing, and will not have their time propagated further. Similarly, signal catchers, even though profiled, will appear to be spontaneous (although for more obscure reasons). Any profiled children of signal catchers should have their times propagated properly, unless the signal catcher was invoked during the execution of the profiling routine, in which case all is lost.

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>DESCRIPTION</b> | graph with no options takes pairs of numbers from the standard input as abscissas and ordinates of a graph. Successive points are connected by straight lines. The standard output from graph contains plotting instructions suitable for input to plot(1B) or to the command lpr -g (see lpr(1B)).<br><br>If the coordinates of a point are followed by a nonnumeric string, that string is printed as a label beginning on the point. Labels may be surrounded with quotes ". . .", in which case they may be empty or contain blanks and numbers; labels never contain NEWLINE characters.<br><br>A legend indicating grid range is produced with a grid unless the -s option is present.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>OPTIONS</b>     | Each option is recognized as a separate argument. If a specified lower limit exceeds the upper limit, the axis is reversed.<br><br>-a <i>spacing</i> [ <i>start</i> ]<br>Supply abscissas automatically (they are missing from the input); <i>spacing</i> is the spacing (default 1). <i>start</i> is the starting point for automatic abscissas (default 0 or lower limit given by -x).<br><br>-b<br>Break (disconnect) the graph after each label in the input.<br><br>-c <i>string</i><br><i>String</i> is the default label for each point.<br><br>-g <i>gridstyle</i><br><i>Gridstyle</i> is the grid style: 0 no grid, 1 frame with ticks, 2 full grid (default).<br><br>-l <i>label</i><br><i>label</i> is label for graph.<br><br>-m <i>connectmode</i><br>Mode (style) of connecting lines: 0 disconnected, 1 connected (default). Some devices give distinguishable line styles for other small integers.<br><br>-s<br>Save screen, do not erase before plotting.<br><br>-x [ <i>l</i> ] <i>lower</i> [ <i>upper</i> [ <i>spacing</i> ] ]<br>If <i>l</i> is present, <i>x</i> axis is logarithmic. <i>lower</i> and <i>upper</i> are lower (and upper) <i>x</i> limits. <i>spacing</i> , if present, is grid spacing on <i>x</i> axis. Normally these quantities are determined automatically. |

## graph(1)

-y [ 1 ] *lower* [ *upper* [ *spacing* ] ]

If 1 is present, *y* axis is logarithmic. *lower* and *upper* are lower (and upper) *y* limits. *spacing*, if present, is grid spacing on *y* axis. Normally these quantities are determined automatically.

-h *fraction*  
*fraction* of space for height.

-w *fraction*  
*fraction* of space for width.

-r *fraction*  
*fraction* of space to move right before plotting.

-u *fraction*  
*fraction* of space to move up before plotting.

-t  
Transpose horizontal and vertical axes. Option -x now applies to the vertical axis.

**ATTRIBUTES** See `attributes(5)` for descriptions of the following attributes:

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWesu         |

**SEE ALSO** `lpr(1B)`, `plot(1B)`, `spline(1)`, `plot(3PLOT)`, `attributes(5)`

**BUGS** `graph` stores all points internally and drops those for which there is no room.

Segments that run out of bounds are dropped, not windowed.

Logarithmic axes may not be reversed.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>DESCRIPTION</b>        | <p>The <code>grep</code> utility searches text files for a pattern and prints all lines that contain that pattern. It uses a compact non-deterministic algorithm.</p> <p>Be careful using the characters <code>\$</code>, <code>*</code>, <code>[</code>, <code>^</code>, <code> </code>, <code>(</code>, <code>)</code>, and <code>\</code> in the <i>pattern_list</i> because they are also meaningful to the shell. It is safest to enclose the entire <i>pattern_list</i> in single quotes <code>'...'</code>.</p> <p>If no files are specified, <code>grep</code> assumes standard input. Normally, each line found is copied to standard output. The file name is printed before each line found if there is more than one input file.</p>                                                                                                                                                                                                                                    |
| <b>/usr/bin/grep</b>      | The <code>/usr/bin/grep</code> utility uses limited regular expressions like those described on the <code>regex(5)</code> manual page to match the patterns.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>/usr/xpg4/bin/grep</b> | The options <code>-E</code> and <code>-F</code> affect the way <code>/usr/xpg4/bin/grep</code> interprets <i>pattern_list</i> . If <code>-E</code> is specified, <code>/usr/xpg4/bin/grep</code> interprets <i>pattern_list</i> as a full regular expression (see <code>-E</code> for description). If <code>-F</code> is specified, <code>grep</code> interprets <i>pattern_list</i> as a fixed string. If neither are specified, <code>grep</code> interprets <i>pattern_list</i> as a basic regular expression as described on <code>regex(5)</code> manual page.                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>OPTIONS</b>            | <p>The following options are supported for both <code>/usr/bin/grep</code> and <code>/usr/xpg4/bin/grep</code>:</p> <ul style="list-style-type: none"> <li>-b      Precede each line by the block number on which it was found. This can be useful in locating block numbers by context (first block is 0).</li> <li>-c      Print only a count of the lines that contain the pattern.</li> <li>-h      Prevents the name of the file containing the matching line from being appended to that line. Used when searching multiple files.</li> <li>-i      Ignore upper/lower case distinction during comparisons.</li> <li>-l      Print only the names of files with matching lines, separated by NEWLINE characters. Does not repeat the names of files when the pattern is found more than once.</li> <li>-n      Precede each line by its line number in the file (first line is 1).</li> <li>-s      Suppress error messages about nonexistent or unreadable files.</li> </ul> |

## grep(1)

|                           |                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                           | -v                     | Print all lines except those that contain the pattern.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                           | -w                     | Search for the expression as a word as if surrounded by \< and \>.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>/usr/xpg4/bin/grep</b> |                        | The following options are supported for /usr/xpg4/bin/grep only:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|                           | -e <i>pattern_list</i> | Specify one or more patterns to be used during the search for input. Patterns in <i>pattern_list</i> must be separated by a NEWLINE character. A null pattern can be specified by two adjacent newline characters in <i>pattern_list</i> . Unless the -E or -F option is also specified, each pattern will be treated as a basic regular expression. Multiple -e and -f options are accepted by grep. All of the specified patterns are used when matching lines, but the order of evaluation is unspecified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                           | -E                     | Match using full regular expressions. Treat each pattern specified as a full regular expression. If any entire full regular expression pattern matches an input line, the line will be matched. A null full regular expression matches every line. Each pattern will be interpreted as a full regular expression as described on the <code>regex(5)</code> manual page, except for \< and \>, and including: <ol style="list-style-type: none"><li>1. A full regular expression followed by + that matches one or more occurrences of the full regular expression.</li><li>2. A full regular expression followed by ? that matches 0 or 1 occurrences of the full regular expression.</li><li>3. Full regular expressions separated by   or by a new-line that match strings that are matched by any of the expressions.</li><li>4. A full regular expression that may be enclosed in parentheses ( ) for grouping.</li></ol> The order of precedence of operators is [ ], then * ? +, then concatenation, then   and new-line. |
|                           | -f <i>pattern_file</i> | Read one or more patterns from the file named by the path name <i>pattern_file</i> . Patterns in <i>pattern_file</i> are terminated by a NEWLINE character. A null pattern can be specified by an empty line in <i>pattern_file</i> . Unless the -E or -F option is also specified, each pattern will be treated as a basic regular expression.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|                           | -F                     | Match using fixed strings. Treat each pattern specified as a string instead of a regular expression. If an input line contains any of the patterns as a contiguous sequence of bytes, the line will be matched. A null string matches every line. See <code>fgrep(1)</code> for more information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|                           | -q                     | Quiet. Do not write anything to the standard output, regardless of matching lines. Exit with zero status if an input line is selected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                           | -x                     | Consider only input lines that use all characters in the line to match an entire fixed string or regular expression to be matching                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                            | <i>file</i> A path name of a file to be searched for the patterns. If no <i>file</i> operands are specified, the standard input will be used.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>/usr/bin/grep</b>       | <i>pattern</i> Specify a pattern to be used during the search for input.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>/usr/xpg4/bin/grep</b>  | <i>pattern</i> Specify one or more patterns to be used during the search for input. This operand is treated as if it were specified as <i>-epattern_list</i> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>USAGE</b>               | <p>The <i>-epattern_list</i> option has the same effect as the <i>pattern_list</i> operand, but is useful when <i>pattern_list</i> begins with the hyphen delimiter. It is also useful when it is more convenient to provide multiple patterns as separate arguments.</p> <p>Multiple <i>-e</i> and <i>-f</i> options are accepted and <code>grep</code> will use all of the patterns it is given while matching input text lines. (Note that the order of evaluation is not specified. If an implementation finds a null string as a pattern, it is allowed to use that pattern first, matching every line, and effectively ignore any other patterns.)</p> <p>The <i>-q</i> option provides a means of easily determining whether or not a pattern (or string) exists in a group of files. When searching several files, it provides a performance improvement (because it can quit as soon as it finds the first match) and requires less care by the user in choosing the set of files to supply as arguments (because it will exit zero if it finds a match even if <code>grep</code> detected an access or read error on earlier file operands).</p> |
| <b>Large File Behavior</b> | See <code>largefile(5)</code> for the description of the behavior of <code>grep</code> when encountering files greater than or equal to 2 Gbyte (2 <sup>31</sup> bytes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>EXAMPLES</b>            | <p><b>EXAMPLE 1</b> Finding all uses of a word</p> <p>To find all uses of the word "Posix" (in any case) in the file <code>text.mm</code>, and write with line numbers:</p> <pre>example% /usr/bin/grep -i -n posix text.mm</pre> <p><b>EXAMPLE 2</b> Finding all empty lines</p> <p>To find all empty lines in the standard input:</p> <pre>example% /usr/bin/grep ^\$</pre> <p>or</p> <pre>example% /usr/bin/grep -v .</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## grep(1)

**EXAMPLE 2** Finding all empty lines (Continued)

**EXAMPLE 3** Finding lines containing strings

Both of the following commands print all lines containing strings abc or def or both:

```
example% /usr/xpg4/bin/grep -E 'abc def'
```

```
example% /usr/xpg4/bin/grep -F 'abc def'
```

**EXAMPLE 4** Finding lines with matching strings

Both of the following commands print all lines matching exactly abc or def:

```
example% /usr/xpg4/bin/grep -E '^abc$ ^def$'
```

```
example% /usr/xpg4/bin/grep -F -x 'abc def'
```

### ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of grep: LC\_COLLATE, LC\_CTYPE, LC\_MESSAGES, and NLSPATH.

### EXIT STATUS

The following exit values are returned:

- 0 One or more matches were found.
- 1 No matches were found.
- 2 Syntax errors or inaccessible files (even if matches were found).

### ATTRIBUTES

See attributes(5) for descriptions of the following attributes:

#### /usr/bin/grep

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWcsu         |
| CSI            | enabled         |

#### /usr/xpg4/bin/grep

| ATTRIBUTE TYPE | ATTRIBUTE VALUE |
|----------------|-----------------|
| Availability   | SUNWxcu4        |
| CSI            | enabled         |

### SEE ALSO

egrep(1), fgrep(1), sed(1), sh(1), attributes(5), environ(5), largefile(5), regex(5), regexp(5), XPG4(5)

### NOTES

#### /usr/bin/grep

Lines are limited only by the size of the available virtual memory. If there is a line with embedded nulls, grep will only match up to the first null; if it matches, it will print the entire line.

**/usr/xpg4/bin/grep**

The results are unspecified if input files contain lines longer than `LINE_MAX` bytes or contain binary data. `LINE_MAX` is defined in `/usr/include/limits.h`.

## groups(1)

- NAME** | groups – print group membership of user
- SYNOPSIS** | **groups** [*user...*]
- DESCRIPTION** | The command `groups` prints on standard output the groups to which you or the optionally specified user belong. Each user belongs to a group specified in `/etc/passwd` and possibly to other groups as specified in `/etc/group`. Note that `/etc/passwd` specifies the numerical ID (`gid`) of the group. The `groups` command converts `gid` to the group name in the output.
- EXAMPLES** | The output takes the following form:
- ```
example% groups tester01 tester02
tester01 : staff
tester02 : staff
example%
```
- FILES** | `/etc/passwd`
`/etc/group`
- ATTRIBUTES** | See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO | `group(4)`, `passwd(4)`, `attributes(5)`

NAME	groups – display a user’s group memberships				
SYNOPSIS	<code>/usr/ucb/groups</code> [<i>user...</i>]				
DESCRIPTION	With no arguments, <code>groups</code> displays the groups to which you belong; else it displays the groups to which the user belongs. Each user belongs to a group specified in the password file <code>/etc/passwd</code> and possibly to other groups as specified in the file <code>/etc/group</code> . If you do not own a file but belong to the group which it is owned by then you are granted group access to the file.				
FILES	<code>/etc/passwd</code> <code>/etc/group</code>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWscpu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWscpu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWscpu				
SEE ALSO	<code>getgroups(2)</code> , <code>attributes(5)</code>				
NOTES	This command is obsolete.				

grpck(1B)

NAME grpck – check group database entries

SYNOPSIS /usr/etc/grpck [filename]

DESCRIPTION The grpck utility checks that a file in group(4) does not contain any errors; it checks the /etc/group file by default.

FILES /etc/group

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO groups(1), group(4), passwd(4), attributes(5)

DIAGNOSTICS

Too many/few fields
An entry in the group file does not have the proper number of fields.

No group name
The group name field of an entry is empty.

Bad character(s) in group name
The group name in an entry contains characters other than lower-case letters and digits.

Invalid GID
The group ID field in an entry is not numeric or is greater than 65535.

Null login name
A login name in the list of login names in an entry is null.

Logname not found in password file
A login name in the list of login names in an entry is not in the password file.

Line too long
A line (including the newline character) in the group file exceeds the maximum length of 512 characters.

Duplicate logname entry
A login name appears more than once in the list of login names for a group file entry.

Out of memory
The program cannot allocate memory in order to continue.

Maximum groups exceeded for logname
A login name's group membership exceeds the maximum, NGROUPS_MAX.

NAME	hash, rehash, unhash, hashstat – evaluate the internal hash table of the contents of directories
SYNOPSIS	<pre>/usr/bin/hash [<i>utility</i>]</pre> <pre>/usr/bin/hash [-r]</pre>
sh	hash [-r] [<i>name...</i>]
cs	rehash
	unhash
	hashstat
ksh	hash [<i>name...</i>]
DESCRIPTION	
/usr/bin/hash	<p>The <code>/usr/bin/hash</code> utility affects the way the current shell environment remembers the locations of utilities found. Depending on the arguments specified, it adds utility locations to its list of remembered locations or it purges the contents of the list. When no arguments are specified, it reports on the contents of the list.</p> <p>Utilities provided as built-ins to the shell are not reported by hash.</p>
sh	<p>For each <i>name</i>, the location in the search path of the command specified by <i>name</i> is determined and remembered by the shell. The <code>-r</code> option to the <code>hash</code> built-in causes the shell to forget all remembered locations. If no arguments are given, <code>hash</code> provides information about remembered commands. The <i>Hits</i> column of output is the number of times a command has been invoked by the shell process. The <i>Cost</i> column of output is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the <i>Hits</i> information. <i>Cost</i> will be incremented when the recalculation is done.</p>
cs	<p><code>rehash</code> recomputes the internal hash table of the contents of directories listed in the <code>path</code> environmental variable to account for new commands added.</p> <p><code>unhash</code> disables the internal hash table.</p> <p><code>hashstat</code> prints a statistics line indicating how effective the internal hash table has been at locating commands (and avoiding execs). An <code>exec</code> is attempted for each component of the <i>path</i> where the hash function indicates a possible hit and in each component that does not begin with a <code>' / '</code>.</p>
ksh	<p>For each <i>name</i>, the location in the search path of the command specified by <i>name</i> is determined and remembered by the shell. If no arguments are given, <code>hash</code> provides information about remembered commands.</p>
OPERANDS	The following operand is supported by hash:

hash(1)

utility The name of a utility to be searched for and added to the list of remembered locations.

OUTPUT The standard output of hash is used when no arguments are specified. Its format is unspecified, but includes the pathname of each utility in the list of remembered locations for the current shell environment. This list consists of those utilities named in previous hash invocations that have been invoked, and may contain those invoked and found through the normal command search process.

ENVIRONMENT VARIABLES See `environ(5)` for descriptions of the following environment variables that affect the execution of hash: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`PATH` Determine the location of *utility*.

EXIT STATUS The following exit values are returned by hash:

0 Successful completion.

>0 An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

TYPE	VALUE
Availability	SUNWcsu

NAME	head – display first few lines of files
SYNOPSIS	head [-number -n <i>number</i>] [<i>filename</i> ...]
DESCRIPTION	<p>The head utility copies the first <i>number</i> of lines of each <i>filename</i> to the standard output. If no <i>filename</i> is given, head copies lines from the standard input. The default value of <i>number</i> is 10 lines.</p> <p>When more than one file is specified, the start of each file will look like:</p> <pre>==> filename <==</pre> <p>Thus, a common way to display a set of short files, identifying each one, is:</p> <pre>example% head -9999 filename1 filename2 . . .</pre>
OPTIONS	<p>The following options are supported:</p> <p><i>-n number</i> The first <i>number</i> lines of each input file will be copied to standard output. The <i>number</i> option-argument must be a positive decimal integer.</p> <p><i>-number</i> The <i>number</i> argument is a positive decimal integer with the same effect as the <i>-n number</i> option.</p> <p>If no options are specified, head will act as if <i>-n 10</i> had been specified.</p>
OPERANDS	<p>The following operand is supported:</p> <p><i>file</i> A path name of an input file. If no <i>file</i> operands are specified, the standard input will be used.</p>
USAGE	See <code>largefile(5)</code> for the description of the behavior of head when encountering files greater than or equal to 2 Gbyte (2 ³¹ bytes).
EXAMPLES	<p>EXAMPLE 1 Writing the first ten lines of all files</p> <p>To write the first ten lines of all files (except those with a leading period) in the directory:</p> <pre>example% head *</pre>
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of head: LC_CTYPE, LC_MESSAGES, and NLSPATH.
EXIT STATUS	<p>The following exit values are returned:</p> <p>0 Successful completion.</p> <p>>0 An error occurred.</p>

head(1)

NAME	history, fc – process command history list
SYNOPSIS	<pre> /usr/bin/fc [first [last]] /usr/bin/fc -l [-nr] [first [last]] /usr/bin/fc -s [old = new] [first] </pre>
cs	history [-hr] [n]
ks	fc -e - [old = new] [command] fc [-e <i>ename</i>] [-nlr] [first [last]]
DESCRIPTION	
/usr/bin/fc	<p>The <code>fc</code> utility lists or edits and reexecutes, commands previously entered to an interactive <code>sh</code>.</p> <p>The command history list references commands by number. The first number in the list is selected arbitrarily. The relationship of a number to its command will not change except when the user logs in and no other process is accessing the list, at which time the system may reset the numbering to start the oldest retained command at another number (usually 1). When the number reaches the value in <code>HISTSIZE</code> or 128 (whichever is greater), the shell may wrap the numbers, starting the next command with a lower number (usually 1). However, despite this optional wrapping of numbers, <code>fc</code> will maintain the time-ordering sequence of the commands. For example, if four commands in sequence are given the numbers 32 766, 32 767, 1 (wrapped), and 2 as they are executed, command 32 767 is considered the command previous to 1, even though its number is higher.</p> <p>When commands are edited (when the <code>-l</code> option is not specified), the resulting lines will be entered at the end of the history list and then reexecuted by <code>sh</code>. The <code>fc</code> command that caused the editing will not be entered into the history list. If the editor returns a non-zero exit status, this will suppress the entry into the history list and the command reexecution. Any command-line variable assignments or redirection operators used with <code>fc</code> will affect both the <code>fc</code> command itself as well as the command that results, for example:</p> <pre>fc -s -- -1 2>/dev/nullreinvokes the previous command, suppressing standard error for both fc and the previous command.</pre>
cs	<p>Display the history list; if <i>n</i> is given, display only the <i>n</i> most recent events.</p> <p><code>-r</code> Reverse the order of printout to be most recent first rather than oldest first.</p> <p><code>-h</code> Display the history list without leading numbers. This is used to produce files suitable for sourcing using the <code>-h</code> option to the <code>cs</code> built-in command, <code>source(1)</code>.</p> <p>History Substitution</p>

history(1)

History substitution allows you to use words from previous command lines in the command line you are typing. This simplifies spelling corrections and the repetition of complicated commands or arguments. Command lines are saved in the history list, the size of which is controlled by the `history` variable. The `history` shell variable may be set to the maximum number of command lines that will be saved in the history file; i.e.:

```
set history = 200
```

will allow the history list to keep track of the most recent 200 command lines. If not set, the C shell saves only the most recent command.

A history substitution begins with a `!` (although you can change this with the `histchars` variable) and may occur anywhere on the command line; history substitutions do not nest. The `!` can be escaped with `\` to suppress its special meaning.

Input lines containing history substitutions are echoed on the terminal after being expanded, but before any other substitutions take place or the command gets executed.

Event Designators:

An event designator is a reference to a command line entry in the history list.

<code>!</code>	Start a history substitution, except when followed by a space character, tab, newline, = or (.
<code>!!</code>	Refer to the previous command. By itself, this substitution repeats the previous command.
<code>!n</code>	Refer to command line <i>n</i> .
<code>!-n</code>	Refer to the current command line minus <i>n</i> .
<code>!str</code>	Refer to the most recent command starting with <i>str</i> .
<code>!?str?</code>	Refer to the most recent command containing <i>str</i> .
<code>!?str? additional</code>	Refer to the most recent command containing <i>str</i> and append <i>additional</i> to that referenced command.
<code>!{command} additional</code>	Refer to the most recent command beginning with <i>command</i> and append <i>additional</i> to that referenced command.
<code>^previous_word^replacement^</code>	Repeat the previous command line replacing the string <i>previous_word</i> with the string <i>replacement</i> . This is equivalent to the history substitution:

history(1)

`! : s / previous_word / replacement / .` To re-execute a specific previous command AND make such a substitution, say, re-executing command #6,

`! : 6 s / previous_word / replacement / .`

Word Designators:

A ':' (colon) separates the event specification from the word designator. It can be omitted if the word designator begins with a ^, \$, *, - or %. If the word is to be selected from the previous command, the second ! character can be omitted from the event specification. For instance, !!:1 and !:1 both refer to the first word of the previous command, while !!\$ and !\$ both refer to the last word in the previous command. Word designators include:

#	The entire command line typed so far.
0	The first input word (command).
<i>n</i>	The <i>n</i> 'th argument.
^	The first argument, that is, 1.
\$	The last argument.
%	The word matched by (the most recent) ?s search.
<i>x-y</i>	A range of words; - <i>y</i> abbreviates 0- <i>y</i> .
*	All the arguments, or a null value if there is just one word in the event.
<i>x</i> *	Abbreviates <i>x</i> -\$.
<i>x</i> -	Like <i>x</i> * but omitting word \$.

Modifiers:

After the optional word designator, you can add a sequence of one or more of the following modifiers, each preceded by a :.

h	Remove a trailing pathname component, leaving the head.
r	Remove a trailing suffix of the form '.xxx', leaving the basename.
e	Remove all but the suffix, leaving the extension.

`s / oldchars / replacements /` Substitute *replacements* for *oldchars*. *oldchars* is a string that may contain embedded blank spaces, whereas *previous_word* in the event designator

history(1)

^oldchars^replacements^ may not.

- t Remove all leading pathname components, leaving the tail.
- & Repeat the previous substitution.
- g Apply the change to the first occurrence of a match in each word, by prefixing the above (for example, *g&*).
- p Print the new command but do not execute it.
- q Quote the substituted words, escaping further substitutions.
- x Like *q*, but break into words at each space character, tab or newline.

Unless preceded by a *g*, the modification is applied only to the first string that matches *oldchars*; an error results if no string matches.

The left-hand side of substitutions are not regular expressions, but character strings. Any character can be used as the delimiter in place of */*. A backslash quotes the delimiter character. The character *&*, in the right hand side, is replaced by the text from the left-hand-side. The *&* can be quoted with a backslash. A null *oldchars* uses the previous string either from a *oldchars* or from a contextual scan string *s* from *! ? s*. You can omit the rightmost delimiter if a newline immediately follows *replacements*; the rightmost *?* in a context scan can similarly be omitted.

Without an event specification, a history reference refers either to the previous command, or to a previous history reference on the command line (if any).

ksh Using *fc*, in the form of

fc -e - [old=new] [command], the *command* is re-executed after the substitution *old=new* is performed. If there is not a *command* argument, the most recent command typed at this terminal is executed.

Using *fc* in the form of

fc [-e name] [-nlr] [first [last]], a range of commands from *first* to *last* is selected from the last HISTSIZE commands that were typed at the terminal. The arguments *first* and *last* may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the *-l* flag is selected, the commands are listed on standard output. Otherwise, the editor program *-e name* is invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the

variable FCEDIT (default /bin/ed) is used as the editor. When editing is complete, the edited command(s) is executed. If *last* is not specified then it will be set to *first*. If *first* is not specified the default is the previous command for editing and -16 for listing. The flag -r reverses the order of the commands and the flag -n suppresses command numbers when listing. (See ksh(1) for more about command line editing.)

HISTFILE If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history.

HISTSIZE If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is 128.

Command Re-entry:

The text of the last HISTSIZE (default 128) commands entered from a terminal device is saved in a history file. The file \$HOME/.sh_history is used if the HISTFILE variable is not set or if the file it names is not writable. A shell can access the commands of all *interactive* shells which use the same named HISTFILE. The special command fc is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to fc then the value of the variable FCEDIT is used. If FCEDIT is not defined then /bin/ed is used. The edited command(s) is printed and re-executed upon leaving the editor. The editor name - is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form *old=new* can be used to modify the command before execution. For example, if r is aliased to `fc -e -` then typing `r bad=good c` will re-execute the most recent command which starts with the letter c, replacing the first occurrence of the string bad with the string good.

Using the fc built-in command within a compound command will cause the whole command to disappear from the history file.

OPTIONS The following options are supported:

-e *editor* Use the editor named by *editor* to edit the commands. The *editor* string is a utility name, subject to search via the PATH variable. The value in the FCEDIT variable is used as a default when -e is not specified. If FCEDIT is null or unset, ed will be used as the editor.

-l (The letter ell.) List the commands rather than invoking an editor on them. The commands will be written in the sequence indicated by the *first* and *last* operands, as affected by -r, with each command preceded by the command number.

-n Suppress command numbers when listing with -l.

history(1)

`-r` Reverse the order of the commands listed (with `-1`) or edited (with neither `-1` nor `-s`).

`-s` Re-execute the command without invoking an editor.

OPERANDS The following operands are supported:

first
last

Select the commands to list or edit. The number of previous commands that can be accessed is determined by the value of the `HISTSIZE` variable. The value of *first* or *last* or both will be one of the following:

`[+]number` A positive number representing a command number; command numbers can be displayed with the `-1` option.

`-number` A negative decimal number representing the command that was executed *number* of commands previously. For example, `-1` is the immediately previous command.

string A string indicating the most recently entered command that begins with that string. If the *old=new* operand is not also specified with `-s`, the string form of the *first* operand cannot contain an embedded equal sign.

When the synopsis form with `-s` is used:

- If *first* is omitted, the previous command will be used. For the synopsis forms without `-s` :
- If *last* is omitted, *last* defaults to the previous command when `-1` is specified; otherwise, it defaults to *first*.
- If *first* and *last* are both omitted, the previous 16 commands will be listed or the previous single command will be edited (based on the `-1` option).
- If *first* and *last* are both present, all of the commands from *first* to *last* will be edited (without `-1`) or listed (with `-1`). Editing multiple commands will be accomplished by presenting to the editor all of the commands at one time, each command starting on a new line. If *first* represents a newer command than *last*, the commands will be listed or edited in reverse sequence, equivalent to using `-r` . For example, the following commands on the first line are equivalent to the corresponding commands on the second:

```
fc -r 10 20      fc    30 40
fc    20 10      fc -r 40 30
```

- When a range of commands is used, it will not be an error to specify *first* or *last* values that are not in the history list; `fc` will substitute the value representing the oldest or newest command in the list, as appropriate. For example, if there are only ten commands in the history list, numbered 1 to 10:

```
fc -1
fc 1 99
```

will list and edit, respectively, all ten commands.

old=new Replace the first occurrence of string *old* in the commands to be reexecuted by the string *new*.

OUTPUT When the `-l` option is used to list commands, the format of each command in the list is as follows:

```
"%d\t%s\n", <line number>, <command>
```

If both the `-l` and `-n` options are specified, the format of each command is:

```
"\t%s\n", <command>
```

If the *command* consists of more than one line, the lines after the first are displayed as:

```
"\t%s\n", <continued-command>
```

EXAMPLES **EXAMPLE 1** Using `history` and `fc`

csh	ksh
% history	\$ fc -l
1 cd /etc	1 cd /etc
2 vi passwd	2 vi passwd
3 date	3 date
4 cd	4 cd
5 du .	5 du .
6 ls -t	6 ls -t
7 history	7 fc -l
% !d	\$ fc -e - d
du .	du .
262 ./SCCS	262 ./SCCS
336 .	336 .
% !da	\$ fc -e - da
Thu Jul 21 17:29:56 PDT 1994	Thu Jul 21 17:29:56 PDT 1994
%	\$ alias \!='fc -e -'

history(1)

EXAMPLE 1 Using history and fc (Continued)

```
% !!                               $ !
  date                               alias = 'fc -e -'
Thu Jul 21 17:29:56 PDT 1994
```

ENVIRONMENT VARIABLES

See environ(5) for descriptions of the following environment variables that affect the execution of fc: LC_CTYPE, LC_MESSAGES, and NLSPATH.

FCEDIT This variable, when expanded by the shell, determines the default value for the *e editor* option's *editor* option-argument. If FCEDIT is null or unset, *ed* will be used as the editor.

HISTFILE Determine a pathname naming a command history file. If the HISTFILE variable is not set, the shell may attempt to access or create a file *.sh_history* in the user's home directory. If the shell cannot obtain both read and write access to, or create, the history file, it will use an unspecified mechanism that allows the history to operate properly. (References to history "file" in this section are understood to mean this unspecified mechanism in such cases.) fc may choose to access this variable only when initializing the history file; this initialization will occur when fc or sh first attempt to retrieve entries from, or add entries to, the file, as the result of commands issued by the user, the file named by the ENV variable, or a system startup file such as */etc/profile*. (The initialization process for the history file can be dependent on the system startup files, in that they may contain commands that will effectively preempt the user's settings of HISTFILE and HISTSIZE. For example, function definition commands are recorded in the history file, unless the *set -o nolog* option is set. If the system administrator includes function definitions in some system startup file called before the ENV file, the history file will be initialized before the user gets a chance to influence its characteristics.) The variable HISTFILE is accessed initially when the shell is invoked. Any changes to HISTFILE will not take effect until another shell is invoked.

HISTSIZE Determine a decimal number representing the limit to the number of previous commands that are accessible. If this variable is unset, an unspecified default greater than or equal to 128 will be used. The variable HISTSIZE is accessed initially when the shell is invoked. Any changes to HISTSIZE will not take effect until another shell is invoked.

EXIT STATUS

The following exit values are returned:

0 Successful completion of the listing.
>0 An error occurred.

history(1)

Otherwise, the exit status will be that of the commands executed by `fc`.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`csh(1)`, `ed(1)`, `ksh(1)`, `set(1)`, `set(1F)`, `sh(1)`, `source(1)`, `attributes(5)`, `environ(5)`

hostid(1)

NAME hostid – print the numeric identifier of the current host

SYNOPSIS `/usr/bin/hostid`

DESCRIPTION The `hostid` command prints the identifier of the current host in hexadecimal. This numeric value is likely to differ when `hostid` is run on a different machine.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `sysinfo(2)`, `gethostid(3C)`, `attributes(5)`

NAME hostname – set or print name of current host system

SYNOPSIS `/usr/bin/hostname` [*name-of-host*]

DESCRIPTION The `hostname` command prints the name of the current host, as given before the login prompt. The super-user can set the hostname by giving an argument.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

iconv(1)

NAME	iconv – code set conversion utility
SYNOPSIS	iconv -f <i>fromcode</i> -t <i>toctype</i> [<i>file...</i>]
DESCRIPTION	<p>The iconv utility converts the characters or sequences of characters in <i>file</i> from one code set to another and writes the results to standard output. If no conversion exists for a particular character, it is converted to the underscore <code>_</code> in the target code set.</p> <p>The list of supported conversions and the locations of the associated conversion tables are provided in the iconv(5) manual page.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-f <i>fromcode</i> Identifies the input code set.-t <i>toctype</i> Identifies the output code set.
OPERANDS	<p>The following operands are supported:</p> <ul style="list-style-type: none"><i>file</i> A path name of the input file to be translated. If <i>file</i> is omitted, the standard input is used.
EXAMPLES	<p>EXAMPLE 1 Converting and storing files</p> <p>The following example converts the contents of file <code>mail1</code> from code set <code>8859</code> to <code>646fr</code> and stores the results in file <code>mail.local</code>:</p> <pre>example% iconv -f 8859 -t 646fr mail1 > mail.local</pre>
ENVIRONMENT VARIABLES	See environ(5) for descriptions of the following environment variables that affect the execution of iconv : <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .
EXIT STATUS	<p>The following exit values are returned:</p> <ul style="list-style-type: none">0 Successful completion.1 An error has occurred.
FILES	<ul style="list-style-type: none"><code>/usr/lib/iconv/*.so</code> conversion modules<code>/usr/lib/iconv/*.t</code> conversion tables<code>/usr/lib/iconv/iconv_data</code> list of conversions supported by conversion tables<code>/usr/lib/iconv/geniconvtbl/binarytables/*.bt</code> conversion binary tables

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `geniconvtbl(1)`, `iconv(3C)`, `geniconvtbl(4)`, `attributes(5)`, `environ(5)`, `iconv(5)`, `iconv_unicode(5)`

NOTES The `iconv` utility can use conversion modules (`/usr/lib/iconv/*.so`), conversion tables (`/usr/lib/iconv/*.t`), or conversion binary tables (`/usr/lib/iconv/geniconvtbl/binarytables/*.bt`) to do the code set conversion. The `iconv` utility uses `iconv_open(3C)` to see if a particular code set conversion is available in the `iconv(3C)` function. `iconv_open(3C)` first tries to find out if there is a conversion binary table and then if there is a conversion module. If neither is available in your system, `iconv_open(3C)` will return a failure code. Then, finally, `iconv` will search for a conversion table.

Refer to the `/usr/share/man/man5/iconv_locale.5` manual page in the Asian localized releases for information on which code set conversions are supported. For example, the command

```
example% man -s 5 iconv_ja
```

would display the manual page describing the code set conversions that are supported for the Japanese locale.

Notice that the `iconv_locale.5` manual page may not exist in your system, depending on which locale you chose to install during the system installation.

if(1)

NAME	if, test – evaluate condition(s) or make execution of actions dependent upon the evaluation of condition(s)
SYNOPSIS	<pre>/usr/bin/test [<i>condition</i>] <i>condition</i></pre>
sh	<pre>if <i>condition</i> ; then <i>action</i> ; fi if <i>condition</i> ; then <i>action</i> ; else <i>action2</i> ; fi if <i>condition</i> ; then <i>action</i> ; elif <i>condition2</i> ; then <i>action2</i> ;... ; fi if <i>condition</i> ; then <i>action</i> ; elif <i>condition2</i> ; then <i>action2</i> ;... ; else <i>action3</i> ; fi test <i>condition</i> [<i>condition</i>]</pre>
csh	<pre>if (<i>condition</i>) then <i>action</i> else if (<i>condition2</i>) then <i>action2</i> else <i>action3</i> endif if (<i>condition</i>) [<i>action</i>]</pre>
ksh	<pre>if <i>condition</i> ; then <i>action</i> ; fi if <i>condition</i> ; then <i>action</i> ; else <i>action2</i> ; fi if <i>condition</i> ; then <i>action</i> ; elif <i>condition2</i> ; then <i>action2</i> ;... ; fi if <i>condition</i> ; then <i>action</i> ; elif <i>condition2</i> ; then <i>action2</i> ;... ; else <i>action3</i> ; fi test <i>condition</i> [<i>condition</i>]</pre>
DESCRIPTION	
/usr/bin/test	<p>The <code>test</code> utility evaluates the <i>condition</i> and indicates the result of the evaluation by its exit status. An exit status of zero indicates that the condition evaluated as true and an exit status of 1 indicates that the condition evaluated as false.</p> <p>In the second form of the utility, which uses [] rather than <code>test</code>, the square brackets must be separate arguments and <i>condition</i> is optional.</p>

See `largefile(5)` for the description of the behavior of `test` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

sh The *condition* following `if` is executed and, if it returns a 0 exit status, the *action* following the first `then` is executed. Otherwise, the *condition2* following `elif` is executed and, if its value is 0, the *action2* following the next `then` is executed. Failing the `if` and `elif` *conditions*, the `else` *action3* is executed. If no `else` *action* or `then` *action* is executed, the `if` command returns a 0 exit status. Any number of `elif` . . . `then` . . . branching pairs are allowed, but only one `else`.

`test` evaluates the condition *condition* and, if its value is true, sets exit status to 0; otherwise, a non-zero (false) exit status is set; `test` also sets a non-zero exit status if there are no arguments. When permissions are tested, the effective user ID of the process is used.

All operators, flags, and brackets (brackets used as shown in the second SYNOPSIS line) must be separate arguments to the `test` command; normally these items are separated by spaces.

Primitives:

The following primitives are used to construct *condition*:

<code>-r filename</code>	True if <i>filename</i> exists and is readable.
<code>-w filename</code>	True if <i>filename</i> exists and is writable.
<code>-x filename</code>	True if <i>filename</i> exists and is executable.
<code>-f filename</code>	True if <i>filename</i> exists and is a regular file. Alternatively, if <code>/usr/bin/sh</code> users specify <code>/usr/ucb</code> before <code>/usr/bin</code> in their <code>PATH</code> environment variable, then <code>test</code> will return true if <i>filename</i> exists and is (not-a-directory). This is also the default for <code>/usr/bin/csh</code> users.
<code>-d filename</code>	True if <i>filename</i> exists and is a directory.
<code>-h filename</code>	True if <i>filename</i> exists and is a symbolic link. With all other primitives (except <code>-L filename</code>), the symbolic links are followed by default.
<code>-c filename</code>	True if <i>filename</i> exists and is a character special file.
<code>-b filename</code>	True if <i>filename</i> exists and is a block special file.
<code>-p filename</code>	True if <i>filename</i> exists and is a named pipe (fifo).
<code>-u filename</code>	True if <i>filename</i> exists and its set-user- ID bit is set.
<code>-g filename</code>	True if <i>filename</i> exists and its set-group- ID bit is set.
<code>-k filename</code>	True if <i>filename</i> exists and its sticky bit is set.
<code>-s filename</code>	True if <i>filename</i> exists and has a size greater than zero.

if(1)

<code>-t [<i>fildev</i>]</code>	True if the open file whose file descriptor number is <i>fildev</i> (1 by default) is associated with a terminal device.
<code>-z <i>s1</i></code>	True if the length of string <i>s1</i> is zero.
<code>-n <i>s1</i></code>	True if the length of the string <i>s1</i> is non-zero.
<code><i>s1</i> = <i>s2</i></code>	True if strings <i>s1</i> and <i>s2</i> are identical.
<code><i>s1</i> != <i>s2</i></code>	True if strings <i>s1</i> and <i>s2</i> are not identical.
<code><i>s1</i></code>	True if <i>s1</i> is not the null string.
<code><i>n1</i> -eq <i>n2</i></code>	True if the integers <i>n1</i> and <i>n2</i> are algebraically equal.
<code><i>n1</i> -ne <i>n2</i></code>	True if the integers <i>n1</i> and <i>n2</i> are not algebraically equal.
<code><i>n1</i> -gt <i>n2</i></code>	True if the integer <i>n1</i> is algebraically greater than the integer <i>n2</i> .
<code><i>n1</i> -ge <i>n2</i></code>	True if the integer <i>n1</i> is algebraically greater than or equal to the integer <i>n2</i> .
<code><i>n1</i> -lt <i>n2</i></code>	True if the integer <i>n1</i> is algebraically less than the integer <i>n2</i> .
<code><i>n1</i> -le <i>n2</i></code>	True if the integer <i>n1</i> is algebraically less than or equal to the integer <i>n2</i> .
<code>-L <i>filename</i></code>	True if <i>filename</i> exists and is a symbolic link. With all other primitives (except <code>-h <i>filename</i></code>), the symbolic links are followed by default.

Operators:

These primaries may be combined with the following operators:

<code>!</code>	Unary negation operator.
<code>-a</code>	Binary <i>and</i> operator.
<code>-o</code>	Binary <i>or</i> operator (<code>-a</code> has higher precedence than <code>-o</code>).
<code>(<i>condition</i>)</code>	Parentheses for grouping. Notice also that parentheses are meaningful to the shell and, therefore, must be quoted.

The `not-a-directory` alternative to the `-f` option is a transition aid for BSD applications and may not be supported in future releases.

The `-L` option is a migration aid for users of other shells which have similar options and may not be supported in future releases.

If you test a file you own (the `-r -w` or `-x` tests), but the permission tested does not have the *owner* bit set, a non-zero (false) exit status will be returned even though the file may have the *group* or *other* bit set for that permission. The correct exit status will be set if you are super-user.

The `=` and `!=` operators have a higher precedence than the `-r` through `-n` operators, and `=` and `!=` always expect arguments; therefore, `=` and `!=` cannot be used with the `-r` through `-n` operators.

If more than one argument follows the `-r` through `-n` operators, only the first argument is examined; the others are ignored, unless a `-a` or a `-o` is the second argument.

csh With the multi-line form of `if`:

if *condition* is true, the *action* up to the first `else` or `then` is executed. Otherwise, if `else if` *condition2* is true, the *action2* between the `else if` and the following `else` or `then` is executed. Otherwise, the *action3* between the `else` and the `endif` is executed.

The `if` must appear alone on its input line or after an `else`. Only one `endif` is needed, but it is required. The words `else` and `endif` must be the first nonwhite characters on a line. Any number of `else if . . . then . . .` branching pairs are allowed, but only one `else`.

With the one-line form of `if`, there are no `else`, `then`, or `endif` keywords: if the specified *condition* evaluates to true, the single *action* with arguments is executed. Variable substitution on *action* happens early, at the same time it does for the rest of the `if` command. *action* must be a simple command, not a pipeline, a command list, or a parenthesized command list. Note that I/O redirection occurs even if *condition* is false, when *action* is not executed (this is a bug).

ksh The *condition* following `if` is executed and, if it returns an exit status of 0, the *action* following the first `then` is executed. Otherwise, the *condition2* following `elif` is executed and, if its value is 0, the *action2* following the next `then` is executed. Failing that, the `else` *action3* is executed. If no `else` *action* or `then` *action* is executed, then the `if` command returns an exit status of 0. Any number of `elif . . . then . . .` branching pairs are allowed, but only one `else`.

For a description of the `test` built-in, see the `ksh(1)` sections Conditional Expressions and Arithmetic Evaluation as well as the `(sh)` Bourne shell's `test` built-in above.

[*condition*] evaluates file attributes, string comparisons, and compound "and" or "or" conditions.

OPERANDS

All operators and elements of primaries must be presented as separate arguments to the `test` utility.

The following primaries can be used to construct *condition*:

`-a file` True, if *file* exists.

if(1)

<code>-b file</code>	True if <i>file</i> exists and is a block special file.
<code>-c file</code>	True if <i>file</i> exists and is a character special file.
<code>-d file</code>	True if <i>file</i> exists and is a directory.
<code>-e file</code>	True if <i>file</i> exists.
<code>-f file</code>	True if <i>file</i> exists and is a regular file.
<code>-g file</code>	True if <i>file</i> exists and its set group ID flag is set.
<code>-k file</code>	True, if <i>file</i> exists and is has its sticky bit set.
<code>-n string</code>	True if the length of <i>string</i> is non-zero.
<code>-o option</code>	True, if option named <i>option</i> is on.
<code>-p file</code>	True if <i>file</i> is a named pipe (FIFO).
<code>-r file</code>	True if <i>file</i> exists and is readable.
<code>-s file</code>	True if <i>file</i> exists and has a size greater than zero.
<code>-t file_descriptor</code>	True if the file whose file descriptor number is <i>file_descriptor</i> is open and is associated with a terminal.
<code>-u file</code>	True if <i>file</i> exists and its set-user-ID flag is set.
<code>-w file</code>	True if <i>file</i> exists and is writable. True will indicate only that the write flag is on. The <i>file</i> will not be writable on a read-only file system even if this test indicates true.
<code>-x file</code>	True if <i>file</i> exists and is executable. True will indicate only that the execute flag is on. If <i>file</i> is a directory, true indicates that <i>file</i> can be searched.
<code>-z string</code>	True if the length of string <i>string</i> is zero.
<code>-L file</code>	True, if <i>file</i> exists and is a symbolic link.
<code>-O file</code>	True, if <i>file</i> exists and is owned by the effective user ID of this process.
<code>-G file</code>	True, if <i>file</i> exists and its group matches the effective group ID of this process.
<code>-S file</code>	True, if <i>file</i> exists and is a socket.
<code>file1 -nt file2</code>	True, if <i>file1</i> exists and is newer than <i>file2</i> .
<code>file1 -ot file2</code>	True, if <i>file1</i> exists and is older than <i>file2</i> .
<code>file1 -ef file2</code>	True, if <i>file1</i> and <i>file2</i> exist and refer to the same file.
<code>string</code>	True if the string <i>string</i> is not the null string.
<code>string = pattern</code>	True, if <i>string</i> matches <i>pattern</i> .

<code>string != pattern</code>	True, if <i>string</i> does not match <i>pattern</i> .
<code>string1=string2</code>	True if the strings <i>string1</i> and <i>string2</i> are identical.
<code>string1! =string2</code>	True if the strings <i>string1</i> and <i>string2</i> are not identical.
<code>string1 < string2</code>	True, if <i>string1</i> comes before <i>string2</i> based on ASCII value of their characters.
<code>string1 > string2</code>	True, if <i>string1</i> comes after <i>string2</i> based on ASCII value of their characters.
<code>n1 -eq n2</code>	True if the integers <i>n1</i> and <i>n2</i> are algebraically equal.
<code>n1 -ne n2</code>	True if the integers <i>n1</i> and <i>n2</i> are not algebraically equal.
<code>n1 -gt n2</code>	True if the integer <i>n1</i> is algebraically greater than the integer <i>n2</i> .
<code>n1 -ge n2</code>	True if the integer <i>n1</i> is algebraically greater than or equal to the integer <i>n2</i> .
<code>n1 -lt n2</code>	True if the integer <i>n1</i> is algebraically less than the integer <i>n2</i> .
<code>n1 -le n2</code>	True if the integer <i>n1</i> is algebraically less than or equal to the integer <i>n2</i> .

These primaries can be combined with the following operator:

`!condition` True if *condition* is false.

The primaries with two elements of the form:

`-primary_operator primary_operand` are known as *unary primaries*. The primaries with three elements in either of the two forms:

`primary_operand -primary_operator primary_operand`

`primary_operand primary_operator primary_operand` are known as *binary primaries*.

The algorithm for determining the precedence of the operators and the return value that will be generated is based on the number of arguments presented to `test`. (However, when using the `[. . .]` form, the right-bracket final argument will not be counted in this algorithm.)

In the following list, \$1, \$2, \$3 and \$4 represent the arguments presented to `test`.

0 arguments: Exit false (1).

1 argument: Exit true (0) if \$1 is not null; otherwise, exit false.

2 arguments:

- If \$1 is `!`, exit true if \$2 is null, false if \$2 is not null.

if(1)

- If \$1 is a unary primary, exit true if the unary test is true, false if the unary test is false.
- Otherwise, produce unspecified results.

3 arguments:

- If \$2 is a binary primary, perform the binary test of \$1 and \$3.
- If \$1 is !, negate the two-argument test of \$2 and \$3.
- Otherwise, produce unspecified results.

4 arguments:

- If \$1 is !, negate the three-argument test of \$2, \$3, and \$4.
- Otherwise, the results are unspecified.

USAGE

Scripts should be careful when dealing with user-supplied input that could be confused with primaries and operators. Unless the application writer knows all the cases that produce input to the script, invocations like:

```
test "$1" -a "$2"should be written as:
```

```
test "$1" && test "$2"to avoid problems if a user supplied values such as $1 set to ! and $2 set to the null string. That is, in cases where maximal portability is of concern, replace:
```

```
test expr1 -a expr2with:
```

```
test expr1 && test expr2and replace:
```

```
test expr1 -o expr2with:
```

```
test expr1 | | test expr2but note that, in test, -a has higher precedence than -o while && and | | have equal precedence in the shell.
```

Parentheses or braces can be used in the shell command language to effect grouping.

Parentheses must be escaped when using `sh`; for example:

```
test \( expr1 -a expr2 \) -o expr3This command is not always portable outside XSI-conformant systems. The following form can be used instead:
```

```
( test expr1 && test expr2 ) | | test expr3The two commands:
```

```
test "$1"
```

```
test ! "$1"could not be used reliably on some historical systems. Unexpected results would occur if such a string condition were used and $1 expanded to !, ( or a known unary primary. Better constructs are:
```

```
test -n "$1"
```

```
test -z "$1"respectively.
```

Historical systems have also been unreliable given the common construct:

```
test "$response" = "expected string"One of the following is a more reliable form:
```

```
test "$response" = "expected string"
test "expected string" = "$response"
```

Note that the second form assumes that `expected string` could not be confused with any unary primary. If `expected string` starts with `-`, `(`, `!` or even `=`, the first form should be used instead. Using the preceding rules without the marked extensions, any of the three comparison forms is reliable, given any input. (However, note that the strings are quoted in all cases.)

Because the string comparison binary primaries, `=` and `!=`, have a higher precedence than any unary primary in the `>4` argument case, unexpected results can occur if arguments are not properly prepared. For example, in

```
test -d $1 -o -d $2
```

If `$1` evaluates to a possible directory name of `=`, the first three arguments are considered a string comparison, which causes a syntax error when the second `-d` is encountered. One of the following forms prevents this; the second is preferred:

```
test \( -d "$1" \) -o \( -d "$2" \)
test -d "$1" | | test -d "$2"
test "$1" = "bat" -a "$2" = "ball"
```

Syntax errors will occur if `$1` evaluates to `(` or `!`. One of the following forms prevents this; the third is preferred:

```
test "X$1" = "Xbat" -a "X$2" = "Xball"
test "$1" = "bat" && test "$2" = "ball"
test "X$1" = "Xbat" && test "X$2" = "Xball"
```

EXAMPLES

In the `if` command examples, three conditions are tested, and if all three evaluate as true or successful, then their validities are written to the screen. The 3 tests are:

- if a variable set to 1 is greater than 0,
- if a variable set to 2 is equal to 2, and
- if the word "root" is included in the text file `/etc/passwd`.

/usr/bin/test

EXAMPLE 1 Using `/usr/bin/test`

Perform a `mkdir` if a directory does not exist:

```
test ! -d tempdir && mkdir tempdir
```

Wait for a file to become non-readable:

```
while test -r thefile
do
```

if(1)

```
        sleep 30
done
echo 'thefile' is no longer readable'
```

Perform a command if the argument is one of three strings (two variations):

```
if [ "$1" = "pear" ] || [ "$1" = "grape" ] || [ "$1" = "apple" ]
then
    command
fi
case "$1" in
    pear|grape|apple) command;;
esac
```

The test built-in

The two forms of the test built-in follow the Bourne shell's if example.

EXAMPLE 2 Using the sh built-in

```
ZERO=0 ONE=1 TWO=2 ROOT=root

if [ $ONE -gt $ZERO ]

[ $TWO -eq 2 ]

grep $ROOT /etc/passwd >&1 > /dev/null # discard output

then

    echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is a user-name
    in the password file"

else

    echo "At least one of the three test conditions is false"

fi
```

EXAMPLE 3 Using the test built-in

Examples of the test built-in:

```
test `grep $ROOT /etc/passwd >&1 /dev/null` # discard output

echo $? # test for success
[ `grep nosuchname /etc/passwd >&1 /dev/null` ]

echo $? # test for failure
```

csh EXAMPLE 4 Using the csh built-in

```
@ ZERO = 0; @ ONE = 1; @ TWO = 2; set ROOT = root
grep $ROOT /etc/passwd >&1 /dev/null # discard output
# $status must be tested for immediately following grep
if ( "$status" == "0" && $ONE > $ZERO && $TWO == 2 ) then
```

EXAMPLE 4 Using the csh built-in (Continued)

```

        echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is a user-name
            in the password file"
    endif

```

ksh **EXAMPLE 5** Using the ksh built-in

```

ZERO=0 ONE=1 TWO=$((ONE+ONE)) ROOT=root
if ((ONE > ZERO))          # arithmetical comparison
[[ $TWO = 2 ]]            # string comparison
[ `grep $ROOT /etc/passwd >&1 /dev/null` ] # discard output
then
    echo "$ONE is greater than 0, $TWO equals 2, and $ROOT is a user-name
        in the password file"

else
    echo "At least one of the three test conditions is false"
fi

```

The Korn shell will also accept the syntax of both the `if` command and the `test` command of the Bourne shell.

When using the brackets (`[]`) within `if` commands, you must separate both inside ends of the brackets from the inside characters with a space.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `test`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

```

0          condition evaluated to true.
1          condition evaluated to false or condition was missing.
>1        An error occurred.

```

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `csh(1)`, `ksh(1)`, `sh(1)`, `test(1B)`, `attributes(5)`, `environ(5)`, `largefile(5)`

NOTES

Both the Bourne shell, `sh`, and the Korn shell, `ksh`, can use the semicolon and the carriage return interchangeably in their syntax of the `if`, `for`, and `while` built-in commands.

indicator(1F)

NAME indicator – display application specific alarms and/or the "working" indicator

SYNOPSIS **indicator** [-b *n*] [-c *column*] [-l *length*] [-o] [-w] [*string...*]

DESCRIPTION The *indicator* function displays application specific alarms or the "working" indicator, or both, on the FMLI banner line. The argument *string* is a string to be displayed on the banner line, and should always be the last argument given. Note that *string* is not automatically cleared from the banner line.

OPTIONS

- b*n* The -b option rings the terminal bell *n* times, where *n* is an integer from 1 to 10. The default value is 1. If the terminal has no bell, the screen is flashed instead, if possible.
- c *column* The -c option defines the column of the banner line at which to start the indicator string. The argument *column* must be an integer from 0 to DISPLAYW-1. If the -c option is not used, *column* defaults to 0.
- l *length* The -l option defines the maximum length of the string displayed. If *string* is longer than *length* characters, it will be truncated. The argument *length* must be an integer from 1 to DISPLAYW. If the -l option is not used, *length* defaults to DISPLAYW. Note that if *string* doesn't fit it will be truncated.
- o The -o option causes *indicator* to duplicate its output to *stdout*.
- w The -w option turns on the "working" indicator.

EXAMPLES

EXAMPLE 1 A sample output of the *indicator* command.

When the value entered in a form field is invalid, the following use of *indicator* will ring the bell three times and display the word *WRONG* starting at column 1 of the banner line.

```
invalidmsg=`indicator -b 3 -c 1 "WRONG"`
```

To clear the indicator after telling the user the entry is wrong:

```
invalidmsg=`indicator -b 9 -c 1 "WRONG"; sleep 3;
indicator -c 1 "      "`
```

In this example the value of *invalidmsg* (in this case the default value *Input is not valid*), still appears on the FMLI message line.

ATTRIBUTES See *attributes(5)* for descriptions of the following attributes:

NAME	indxbib – create an inverted index to a bibliographic database				
SYNOPSIS	indxbib <i>database-file</i> ...				
DESCRIPTION	<p>indxbib makes an inverted index to the named <i>database-file</i> (which must reside within the current directory), typically for use by <code>lookbib(1)</code> and <code>refer(1)</code>. A <i>database</i> contains bibliographic references (or other kinds of information) separated by blank lines.</p> <p>A bibliographic reference is a set of lines, constituting fields of bibliographic information. Each field starts on a line beginning with a '%', followed by a key-letter, then a blank, and finally the contents of the field, which may continue until the next line starting with '%'.</p> <p>indxbib is a shell script that calls two programs: <code>/usr/lib/refer/mkey</code> and <code>/usr/lib/refer/inv</code>. <code>mkey</code> truncates words to 6 characters, and maps upper case to lower case. It also discards words shorter than 3 characters, words among the 100 most common English words, and numbers (dates) < 1000 or > 2099. These parameters can be changed.</p> <p>indxbib creates an entry file (with a <code>.ia</code> suffix), a posting file (<code>.ib</code>), and a tag file (<code>.ic</code>), in the working directory.</p>				
FILES	<pre> /usr/lib/refer/mkey /usr/lib/refer/inv x.ia entry file x.ib posting file x.ic tag file x.ig reference file </pre>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th>ATTRIBUTE TYPE</th> <th>ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWdoc</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWdoc
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWdoc				
SEE ALSO	<code>addbib(1)</code> , <code>lookbib(1)</code> , <code>refer(1)</code> , <code>roffbib(1)</code> , <code>sortbib(1)</code> , <code>attributes(5)</code>				
BUGS	<p>All dates should probably be indexed, since many disciplines refer to literature written in the 1800s or earlier.</p> <p>indxbib does not recognize pathnames.</p>				

install(1B)

NAME	install – install files												
SYNOPSIS	<pre>/usr/ucb/install [-cs] [-g group] [-m mode] [-o owner] filename1 filename2 /usr/ucb/install [-cs] [-g group] [-m mode] [-o owner] filename... directory /usr/ucb/install -d [-g group] [-m mode] [-o owner] directory</pre>												
DESCRIPTION	<p>install is used within makefiles to copy new versions of files into a destination directory and to create the destination directory itself.</p> <p>The first two forms are similar to the cp(1) command with the addition that executable files can be stripped during the copy and the owner, group, and mode of the installed file(s) can be given.</p> <p>The third form can be used to create a destination directory with the required owner, group and permissions.</p> <p>Note: install uses no special privileges to copy files from one place to another. The implications of this are:</p> <ul style="list-style-type: none">■ You must have permission to read the files to be installed.■ You must have permission to copy into the destination file or directory.■ You must have permission to change the modes on the final copy of the file if you want to use the -m option to change modes.■ You must be superuser if you want to specify the ownership of the installed file with -o. If you are not the super-user, or if -o is not in effect, the installed file will be owned by you, regardless of who owns the original.												
OPTIONS	<table><tr><td>-c</td><td>Copy files. In fact <i>install</i> <i>always</i> copies files, but the -c option is retained for backwards compatibility with old shell scripts that might otherwise break.</td></tr><tr><td>-d</td><td>Create a directory. Missing parent directories are created as required as in <i>mkdir -p</i>. If the directory already exists, the owner, group and mode will be set to the values given on the command line.</td></tr><tr><td>-s</td><td>Strip executable files as they are copied.</td></tr><tr><td>-g <i>group</i></td><td>Set the group ownership of the installed file or directory. (staff by default.)</td></tr><tr><td>-m <i>mode</i></td><td>Set the mode for the installed file or directory. (0755 by default.)</td></tr><tr><td>-o <i>owner</i></td><td>If run as root, set the ownership of the installed file to the user-ID of <i>owner</i>.</td></tr></table>	-c	Copy files. In fact <i>install</i> <i>always</i> copies files, but the -c option is retained for backwards compatibility with old shell scripts that might otherwise break.	-d	Create a directory. Missing parent directories are created as required as in <i>mkdir -p</i> . If the directory already exists, the owner, group and mode will be set to the values given on the command line.	-s	Strip executable files as they are copied.	-g <i>group</i>	Set the group ownership of the installed file or directory. (staff by default.)	-m <i>mode</i>	Set the mode for the installed file or directory. (0755 by default.)	-o <i>owner</i>	If run as root, set the ownership of the installed file to the user-ID of <i>owner</i> .
-c	Copy files. In fact <i>install</i> <i>always</i> copies files, but the -c option is retained for backwards compatibility with old shell scripts that might otherwise break.												
-d	Create a directory. Missing parent directories are created as required as in <i>mkdir -p</i> . If the directory already exists, the owner, group and mode will be set to the values given on the command line.												
-s	Strip executable files as they are copied.												
-g <i>group</i>	Set the group ownership of the installed file or directory. (staff by default.)												
-m <i>mode</i>	Set the mode for the installed file or directory. (0755 by default.)												
-o <i>owner</i>	If run as root, set the ownership of the installed file to the user-ID of <i>owner</i> .

ipcrm(1)

NAME	ipcrm – remove a message queue, semaphore set, or shared memory ID				
SYNOPSIS	ipcrm [-m <i>shm</i> id] [-q <i>msg</i> id] [-s <i>sem</i> id] [-M <i>shm</i> key] [-Q <i>msg</i> key] [-S <i>sem</i> key]				
DESCRIPTION	ipcrm removes one or more messages, semaphores, or shared memory identifiers.				
OPTIONS	<p>The identifiers are specified by the following options:</p> <p>-m <i>shm</i>id Remove the shared memory identifier <i>shm</i>id from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.</p> <p>-q <i>msg</i>id Remove the message queue identifier <i>msg</i>id from the system and destroy the message queue and data structure associated with it.</p> <p>-s <i>sem</i>id Remove the semaphore identifier <i>sem</i>id from the system and destroy the set of semaphores and data structure associated with it.</p> <p>-M <i>shm</i>key Remove the shared memory identifier, created with key <i>shm</i>key, from the system. The shared memory segment and data structure associated with it are destroyed after the last detach.</p> <p>-Q <i>msg</i>key Remove the message queue identifier, created with key <i>msg</i>key, from the system and destroy the message queue and data structure associated with it.</p> <p>-S <i>sem</i>key Remove the semaphore identifier, created with key <i>sem</i>key, from the system and destroy the set of semaphores and data structure associated with it.</p> <p>The details of the removes are described in <code>msgctl(2)</code>, <code>shmctl(2)</code>, and <code>semctl(2)</code>. Use the <code>ipcs</code> command to find the identifiers and keys.</p>				
ENVIRONMENT VARIABLES	See <code>environ(5)</code> for descriptions of the following environment variables that affect the execution of <code>ipcrm</code> : <code>LANG</code> , <code>LC_ALL</code> , <code>LC_CTYPE</code> , <code>LC_MESSAGES</code> , and <code>NLSPATH</code> .

NAME	ipcs – report inter-process communication facilities status
SYNOPSIS	<pre> /usr/bin/ipcs [-aAbcimopqst] [-C <i>corefile</i>] [-N <i>namelist</i>] /usr/xpg4/bin/ipcs [-aAbcimopqst] [-C <i>corefile</i>] [-N <i>namelist</i>] </pre>
DESCRIPTION	<p>The utility <code>ipcs</code> prints information about active inter-process communication facilities. The information that is displayed is controlled by the options supplied. Without options, information is printed in short format for message queues, shared memory, and semaphores that are currently active in the system.</p>
<code>/usr/xpg4/bin/ipcs</code>	See NOTES.
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -m Prints information about active shared memory segments. -q Prints information about active message queues. -s Prints information about active semaphores. <p>If <code>-m</code>, <code>-q</code>, or <code>-s</code> are specified, information about only those indicated is printed. If none of these three is specified, information about all three is printed subject to these options:</p> <ul style="list-style-type: none"> -a Uses all XCU5 print options. (This is a shorthand notation for <code>-b</code>, <code>-c</code>, <code>-o</code>, <code>-p</code>, and <code>-t</code>.) -A Uses all print options. (This is a shorthand notation for <code>-b</code>, <code>-c</code>, <code>-i</code>, <code>-o</code>, <code>-p</code>, and <code>-t</code>.) -b Prints information on biggest allowable size: maximum number of bytes in messages on queue for message queues, size of segments for shared memory, and number of semaphores in each set for semaphores. See below for meaning of columns in a listing. -c Prints creator's login name and group name. See below. -C <i>corefile</i> Uses the file <i>corefile</i> in place of <code>/dev/mem</code> and <code>/dev/kmem</code>. Use a core dump obtained from <code>savecore(1M)</code> in place of <code>/dev/mem</code> and <code>/dev/kmem</code>. Without the <code>-C</code> option (default), the running system image is used. -i Prints number of ISM attaches to shared memory segments. -N <i>namelist</i> Uses the file <i>namelist</i> in place of <code>/dev/ksyms</code>. -o Prints information on outstanding usage: number of messages on queue and total number of bytes in messages on queue for message queues and number of processes attached to shared memory segments. -p Prints process number information: process ID of last process to send a message, process ID of last process to receive a message on

ipcs(1)

message queues, process ID of creating process, and process ID of last process to attach or detach on shared memory segments. See below.

-t Prints time information: time of the last control operation that changed the access permissions for all facilities, time of last `msgsnd(2)` and last `msgrcv(2)` on message queues, time of last `shmat(2)` and last `shmdt(2)` on shared memory (see `shmop(2)`), time of last `semop(2)` on semaphores. See below.

The column headings and the meaning of the columns in an `ipcs` listing are given below; the letters in parentheses indicate the options that cause the corresponding heading to appear; "all" means that the heading always appears. Note: These options only determine what information is provided for each facility; they do not determine which facilities are listed.

T (all)	Type of the facility: q message queue m shared memory segment s semaphore
ID (all)	The identifier for the facility entry.
KEY (all)	The key used as an argument to <code>msgget(2)</code> , <code>semget(2)</code> , or <code>shmget(2)</code> to create the facility entry. (Note: The key of a shared memory segment is changed to <code>IPC_PRIVATE</code> when the segment has been removed until all processes attached to the segment detach it.)
MODE (all)	The facility access modes and flags: The mode consists of 11 characters that are interpreted as follows. The first two characters are: R A process is waiting on a <code>msgrcv(2)</code> . S A process is waiting on a <code>msgsnd(2)</code> . D The associated shared memory segment has been removed. It will disappear when the last process attached to the segment detaches it. (Note: If the shared memory segment identifier is removed via an <code>IPC_RMID</code> call to <code>shmctl(2)</code> before the process has detached from the segment with <code>shmdt(2)</code> , the segment is no longer visible to <code>ipcs</code> and it will not appear in the <code>ipcs</code> output.)

C The associated shared memory segment is to be cleared when the first attach is executed.

- The corresponding special flag is not set.

The next nine characters are interpreted as three sets of three bits each. The first set refers to the owner's permissions; the next to permissions of others in the user-group of the facility entry; and the last to all others. Within each set, the first character indicates permission to read, the second character indicates permission to write or alter the facility entry, and the last character is currently unused.

The permissions are indicated as follows:

r Read permission is granted.

w Write permission is granted.

a Alter permission is granted.

- The indicated permission is not granted.

OWNER (all)

The login name of the owner of the facility entry.

GROUP (all)

The group name of the group of the owner of the facility entry.

CREATOR (a,A,c)

The login name of the creator of the facility entry.

CGROUP (a,A,c)

The group name of the group of the creator of the facility entry.

CBYTES (a,A,o)

The number of bytes in messages currently outstanding on the associated message queue.

QNUM (a,A,o)

The number of messages currently outstanding on the associated message queue.

QBYTES (a,A,b)

The maximum number of bytes allowed in messages outstanding on the associated message queue.

LSPID (a,A,p)

The process ID of the last process to send a message to the associated queue.

LRPID (a,A,p)

The process ID of the last process to receive a message from the associated queue.

STIME (a,A,t)

The time the last message was sent to the associated queue.

ipcs(1)

RTIME (a,A,t)	The time the last message was received from the associated queue.
CTIME (a,A,t)	The time when the associated entry was created or changed.
ISMATCH (a,i)	The number of ISM attaches to the associated shared memory segments.
NATCH (a,A,o)	The number of processes attached to the associated shared memory segment.
SEGSZ (a,A,b)	The size of the associated shared memory segment.
CPID (a,A,p)	The process ID of the creator of the shared memory entry.
LPID (a,A,p)	The process ID of the last process to attach or detach the shared memory segment.
ATIME (a,A,t)	The time the last attach was completed to the associated shared memory segment.
DTIME (a,A,t)	The time the last detach was completed on the associated shared memory segment.
NSEMS (a,A,b)	The number of semaphores in the set associated with the semaphore entry.
NSEMS (a,A,b,t)	(For /usr/xpg4/bin/ipcs) The number of semaphores in the set associated with the semaphore entry.
OTIME (a,A,t)	The time the last semaphore operation was completed on the set associated with the semaphore entry.

ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `ipcs`: `LANG`, `LC_ALL`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

`TZ` Determine the timezone for the time strings written by `ipcs`.

FILES

<code>/etc/group</code>	group names
<code>/etc/passwd</code>	user names
<code>/dev/mem</code>	memory
<code>/dev/ksyms</code>	system namelist

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWipc (32-bit)

ATTRIBUTE TYPE	ATTRIBUTE VALUE
	SUNWipcx (64-bit)

SEE ALSO `ipcrm(1)`, `savecore(1M)`, `msgget(2)`, `msgrcv(2)`, `msgsnd(2)`, `semget(2)`, `semop(2)`, `shmctl(2)`, `shmget(2)`, `shmop(2)`, `attributes(5)`, `environ(5)`

NOTES If the user specifies either the `-C` or `-N` flag, the real and effective UID/GID is set to the real UID/GID of the user invoking `ipcs`.

Things can change while `ipcs` is running; the information it gives is guaranteed to be accurate only when it was retrieved.

When the corresponding facility is not installed or has not been used since the last reboot, `/usr/xpg4/bin/ipcs` will report

`"%s facility not in system.\n", facility` while `/usr/bin/ipcs` will report

`"%s facility is inactive.\n", facility` where `facility` is "Message Queue", "Shared Memory", or "Semaphore", as appropriate.

isainfo(1)

NAME	isainfo – describe instruction set architectures
SYNOPSIS	isainfo [-v] [-b -n -k]
DESCRIPTION	<p>The <code>isainfo</code> utility is used to identify various attributes of the instruction set architectures supported on the currently running system. Among the questions it can answer are whether 64-bit applications are supported, or whether the running kernel uses 32-bit or 64-bit device drivers.</p> <p>When invoked with no flags, <code>isainfo</code> prints the name(s) of the native instruction sets for applications supported by the current version of the operating system. These will be a subset of the list returned by <code>isalist(1)</code>. The subset corresponds to the basic applications environments supported by the currently running system.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-b Prints the number of bits in the address space of the native instruction set.-k Prints the name of the instruction set(s) used by the operating system kernel components such as device drivers and STREAMS modules.-n Prints the name of the native instruction set used by portable applications supported by the current version of the operating system.-v Prints more detailed information about the other options.
EXAMPLES	<p>EXAMPLE 1 Invoking <code>isainfo</code> on a 32-bit IA platform</p> <pre>example% isainfo -v 32-bit i386 applications example% isainfo -k i386</pre> <p>EXAMPLE 2 Invoking <code>isainfo</code> on a system running the 32-bit operating system on a 64-bit SPARC processor</p> <pre>example% isainfo -n sparc example% isainfo -v 32-bit sparc applications example% isainfo -kv 32-bit sparc kernel modules</pre> <p>EXAMPLE 3 Invoking <code>isainfo</code> on the same hardware platform (that is, a 64-bit SPARC processor) running the 64-bit operating system</p> <pre>example% isainfosparcv9 sparc example% isainfo -n sparcv9 example% isainfo -v 64-bit sparcv9 applications 32-bit sparc applications example% isainfo -kv 64-bit sparcv9 kernel modules</pre>

EXAMPLE 3 Invoking isainfo on the same hardware platform (that is, a 64-bit SPARC processor) running the 64-bit operating system (Continued)

EXIT STATUS Non-zero Flags are not specified correctly, or the command is unable to recognize attributes of the system on which it is running. An error message is printed to stderr.

ATTRIBUTES See attributes(5) for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO isalist(1), uname(1), psrinfo(1M), sysinfo(2), attributes(5), isalist(5)

isalist(1)

NAME isalist – display the native instruction sets executable on this platform

SYNOPSIS **isalist**

DESCRIPTION **isalist** prints the names of the native instruction sets executable on this platform on the standard output, as returned by the `SI_ISALIST` command of `sysinfo(2)`.

The names are space-separated and are ordered in the sense of best performance. That is, earlier-named instruction sets may contain more instructions than later-named instruction sets; a program that is compiled for an earlier-named instruction sets will most likely run faster on this machine than the same program compiled for a later-named instruction set.

Programs compiled for instruction sets that do not appear in the list will most likely experience performance degradation or not run at all on this machine.

The instruction set names known to the system are listed in `isalist(5)`. These names may or may not match predefined names or compiler options in the C language compilation system,

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

NAME	jobs, fg, bg, stop, notify – control process execution
SYNOPSIS	<pre> sh jobs [-p -l] [% <i>job_id</i>...] jobs -x <i>command</i> [<i>arguments</i>] fg [% <i>job_id</i>...] bg [% <i>job_id</i>...] stop % <i>job_id</i>... stop <i>pid</i>... csh jobs [-l] fg [% <i>job_id</i>] bg [% <i>job_id</i>...] notify [% <i>job_id</i>]... stop % <i>job_id</i>... stop <i>pid</i>... ksh jobs [-lnp] [% <i>job_id</i>...] fg [% <i>job_id</i>...] bg [% <i>job_id</i>...] stop % <i>job_id</i>... stop <i>pid</i>...</pre>
DESCRIPTION	<p>sh When Job Control is enabled, the Bourne shell built-in <code>jobs</code> reports all jobs that are stopped or executing in the background. If <code>%<i>job_id</i></code> is omitted, all jobs that are stopped or running in the background will be reported. The following options will modify/enhance the output of <code>jobs</code>:</p> <ul style="list-style-type: none"> -l Report the process group ID and working directory of the jobs. -p Report only the process group ID of the jobs. -x Replace any <code><i>job_id</i></code> found in <code><i>command</i></code> or <code><i>arguments</i></code> with the corresponding process group ID, and then execute <code><i>command</i></code> passing it <code><i>arguments</i></code>. <p>When the shell is invoked as <code>jsh</code>, Job Control is enabled in addition to all of the functionality described previously for <code>sh</code>. Typically Job Control is enabled for the interactive shell only. Non-interactive shells typically do not benefit from the added functionality of Job Control.</p>

jobs(1)

With Job Control enabled every command or pipeline the user enters at the terminal is called a *job_id*. All jobs exist in one of the following states: foreground, background or stopped. These terms are defined as follows: 1) a job in the foreground has read and write access to the controlling terminal; 2) a job in the background is denied read access and has conditional write access to the controlling terminal (see `stty(1)`); 3) a stopped job is a job that has been placed in a suspended state, usually as a result of a `SIGTSTP` signal (see `signal(3HEAD)`).

Every job that the shell starts is assigned a positive integer, called a *job_id number* which is tracked by the shell and will be used as an identifier to indicate a specific job. Additionally the shell keeps track of the *current* and *previous* jobs. The *current job* is the most recent job to be started or restarted. The *previous job* is the first non-current job.

The acceptable syntax for a Job Identifier is of the form:

`%job_id`

where, *job_id* may be specified in any of the following formats:

<code>%</code> or <code>+</code>	for the current job
<code>-</code>	for the previous job
<code>?<string></code>	specify the job for which the command line uniquely contains <i>string</i> .
<code>n</code>	for job number <i>n</i> , where <i>n</i> is a job number
<code>pref</code>	where <i>pref</i> is a unique prefix of the command name (for example, if the command <code>ls -l</code> name were running in the background, it could be referred to as <code>%ls</code>); <i>pref</i> cannot contain blanks unless it is quoted.

When Job Control is enabled, `fg` resumes the execution of a stopped job in the foreground, also moves an executing background job into the foreground. If `%job_id` is omitted the current job is assumed.

When Job Control is enabled, `bg` resumes the execution of a stopped job in the background. If `%job_id` is omitted the current job is assumed.

`stop` stops the execution of a background job(s) by using its *job_id*, or of any process by using its *pid*; see `ps(1)`.

csh The C shell built-in, `jobs`, without an argument, lists the active jobs under job control.

`-l` List process IDs, in addition to the normal information.

The shell associates a numbered *job_id* with each command sequence to keep track of those commands that are running in the background or have been stopped with TSTP signals (typically CTRL-Z). When a command or command sequence (semicolon separated list) is started in the background using the & metacharacter, the shell displays a line with the job number in brackets and a list of associated process numbers:

```
[1] 1234
```

To see the current list of jobs, use the `jobs` built-in command. The job most recently stopped (or put into the background if none are stopped) is referred to as the *current* job and is indicated with a '+'. The previous job is indicated with a '-'; when the current job is terminated or moved to the foreground, this job takes its place (becomes the new current job).

To manipulate jobs, refer to the `bg`, `fg`, `kill`, `stop`, and `%` built-in commands.

A reference to a job begins with a '%'. By itself, the percent-sign refers to the current job.

<code>% %+ %%</code>	The current job.
<code>%-</code>	The previous job.
<code>%j</code>	Refer to job <i>j</i> as in: 'kill -9 %j'. <i>j</i> can be a job number, or a string that uniquely specifies the command line by which it was started; 'fg %vi' might bring a stopped <code>vi</code> job to the foreground, for instance.
<code>??string</code>	Specify the job for which the command line uniquely contains <i>string</i> .

A job running in the background stops when it attempts to read from the terminal. Background jobs can normally produce output, but this can be suppressed using the 'stty tostop' command.

`fg` brings the current or specified *job_id* into the foreground.

`bg` runs the current or specified jobs in the background.

`stop` stops the execution of a background job(s) by using its *job_id*, or of any process by using its *pid*; see `ps(1)`.

`notify` will notify the user asynchronously when the status of the current job or specified jobs changes.

ksh `jobs` displays the status of the jobs that were started in the current shell environment. When `jobs` reports the termination status of a job, the shell removes its process ID from the list of those "known in the current shell execution environment."

jobs(1)

job_id specifies the jobs for which the status is to be displayed. If no *job_id* is given, the status information for all jobs will be displayed.

The following options will modify/enhance the output of `jobs`:

- l (The letter ell.) Provide more information about each job listed. This information includes the job number, current job, process group ID, state and the command that formed the job.
- n Display only jobs that have stopped or exited since last notified.
- p Displays only the process IDs for the process group leaders of the selected jobs.

By default, `jobs` displays the status of all the stopped jobs, running background jobs, and all jobs whose status has changed and have not been reported by the shell.

If the `monitor` option of the `set` command is turned on, an interactive shell associates a job with each pipeline. It keeps a table of current jobs, printed by the `jobs` command, and assigns them small integer numbers. When a job is started asynchronously with `&`, the shell prints a line which looks like:

```
[1] 1234
```

indicating that the job, which was started asynchronously, was job number 1 and had one (top-level) process, whose process id was 1234.

If you are running a job and wish to do something else you may hit the key `^Z` (CTRL-Z) which sends a `STOP` signal to the current job. The shell will then normally indicate that the job has been 'Stopped' (see `OUTPUT` below), and print another prompt. You can then manipulate the state of this job, putting it in the background with the `bg` command, or run some other commands and then eventually bring the job back into the foreground with the foreground command `fg`. A `^Z` takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.

There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

<i>%number</i>	The job with the given number.
<i>%string</i>	Any job whose command line begins with <i>string</i> ; works only in the interactive mode when the history file is active.
<i>%?string</i>	Any job whose command line contains <i>string</i> ; works only in the interactive mode when the history file is active.
<i>%%</i>	Current job.
<i>%+</i>	Equivalent to <i>%%</i> .
<i>%-</i>	Previous job.

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work. When the monitor mode is on, each background job that completes triggers any trap set for CHLD. When you try to leave the shell while jobs are running or stopped, you will be warned that 'You have stopped (running) jobs.' You may use the `jobs` command to see what they are. If you do this or immediately try to exit again, the shell will not warn you a second time, and the stopped jobs will be terminated.

`fg` will move a background job from the current environment into the foreground. Using `fg` to place a job in the foreground will remove its process ID from the list of those "known in the current shell execution environment." The `fg` command is available only on systems that support job control. If *job_id* is not specified, the current job is brought into the foreground.

`bg` resumes suspended jobs from the current environment by running them as background jobs. If the job specified by *job_id* is already a running background job, `bg` has no effect and will exit successfully. Using `bg` to place a job into the background causes its process ID to become "known in the current shell execution environment", as if it had been started as an asynchronous list. The `bg` command is available only on systems that support job control. If *job_id* is not specified, the current job is placed in the background.

`stop` stops the execution of a background job(s) by using its *job_id*, or of any process by using its *pid*; see `ps(1)`.

OUTPUT If the `-p` option is specified, the output consists of one line for each process ID:

```
"%d\n" , <"process ID">
```

Otherwise, if the `-l` option is not specified, the output is a series of lines of the form:

```
" [%d] %c %s %s\n" , <job-number> , <current> , <state> , <command>
```

where the fields are as follows:

<current> The character `+` identifies the job that would be used as a default for the `fg` or `bg` commands; this job can also be specified using the *job_id* `%+` or `%%` . The character `-` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the *job_id* `%-` . For other jobs, this field is a space character. At most one job can be identified with `+` and at most one job can be identified with `-`. If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job.

jobs(1)

<code><job-number></code>	A number that can be used to identify the process group to the <code>wait</code> , <code>fg</code> , <code>bg</code> , and <code>kill</code> utilities. Using these utilities, the job can be identified by prefixing the job number with <code>%</code> .																
<code><state></code>	One of the following strings (in the POSIX Locale): <table><tr><td>Running</td><td>Indicates that the job has not been suspended by a signal and has not exited.</td></tr><tr><td>Done</td><td>Indicates that the job completed and returned exit status zero.</td></tr><tr><td>Done(<i>code</i>)</td><td>Indicates that the job completed normally and that it exited with the specified non-zero exit status, <i>code</i>, expressed as a decimal number.</td></tr><tr><td>Stopped</td><td></td></tr><tr><td>Stopped (SIGTSTP)</td><td>Indicates that the job was suspended by the SIGTSTP signal.</td></tr><tr><td>Stopped (SIGSTOP)</td><td>Indicates that the job was suspended by the SIGSTOP signal.</td></tr><tr><td>Stopped (SIGTTIN)</td><td>Indicates that the job was suspended by the SIGTTIN signal.</td></tr><tr><td>Stopped (SIGTTOU)</td><td>Indicates that the job was suspended by the SIGTTOU signal.</td></tr></table> The implementation may substitute the string <code>Suspended</code> in place of <code>Stopped</code> . If the job was terminated by a signal, the format of <code>state</code> is unspecified, but it will be visibly distinct from all of the other <code>state</code> formats shown here and will indicate the name or description of the signal causing the termination.	Running	Indicates that the job has not been suspended by a signal and has not exited.	Done	Indicates that the job completed and returned exit status zero.	Done(<i>code</i>)	Indicates that the job completed normally and that it exited with the specified non-zero exit status, <i>code</i> , expressed as a decimal number.	Stopped		Stopped (SIGTSTP)	Indicates that the job was suspended by the SIGTSTP signal.	Stopped (SIGSTOP)	Indicates that the job was suspended by the SIGSTOP signal.	Stopped (SIGTTIN)	Indicates that the job was suspended by the SIGTTIN signal.	Stopped (SIGTTOU)	Indicates that the job was suspended by the SIGTTOU signal.
Running	Indicates that the job has not been suspended by a signal and has not exited.																
Done	Indicates that the job completed and returned exit status zero.																
Done(<i>code</i>)	Indicates that the job completed normally and that it exited with the specified non-zero exit status, <i>code</i> , expressed as a decimal number.																
Stopped																	
Stopped (SIGTSTP)	Indicates that the job was suspended by the SIGTSTP signal.																
Stopped (SIGSTOP)	Indicates that the job was suspended by the SIGSTOP signal.																
Stopped (SIGTTIN)	Indicates that the job was suspended by the SIGTTIN signal.																
Stopped (SIGTTOU)	Indicates that the job was suspended by the SIGTTOU signal.																
<code><command></code>	The associated command that was given to the shell.																

If the `-l` option is specified, a field containing the process group ID is inserted before the `state` field. Also, more processes in a process group may be output on separate lines, using only the process ID and `command` fields.

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `jobs`, `fg`, and `bg`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned for `jobs`, `fg`, and `bg`:

0	Successful completion.
>0	An error occurred.

jobs(1)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO `csh(1)`, `kill(1)`, `ksh(1)`, `ps(1)`, `sh(1)`, `stop(1)`, `shell_builtins(1)`, `stty(1)`, `wait(1)`, `signal(3HEAD)`, `attributes(5)`, `environ(5)`

join(1)

NAME	join – relational database operator														
SYNOPSIS	<pre>join [-a <i>filename</i> -v <i>filename</i>] [-1 <i>fieldnumber</i>] [-2 <i>fieldnumber</i>] [-o <i>list</i>] [-e <i>string</i>] [-t <i>char</i>] <i>file1</i> <i>file2</i> join [-a <i>filename</i>] [-j <i>fieldnumber</i>] [-j1 <i>fieldnumber</i>] [-j2 <i>fieldnumber</i>] [-o <i>list</i>] [-e <i>string</i>] [-t <i>char</i>] <i>file1</i> <i>file2</i></pre>														
DESCRIPTION	<p>The <code>join</code> command forms, on the standard output, a join of the two relations specified by the lines of <i>file1</i> and <i>file2</i>.</p> <p>There is one line in the output for each pair of lines in <i>file1</i> and <i>file2</i> that have identical join fields. The output line normally consists of the common field, then the rest of the line from <i>file1</i>, then the rest of the line from <i>file2</i>. This format can be changed by using the <code>-o</code> option (see below). The <code>-a</code> option can be used to add unmatched lines to the output. The <code>-v</code> option can be used to output only unmatched lines.</p> <p>The default input field separators are blank, tab, or new-line. In this case, multiple separators count as one field separator, and leading separators are ignored. The default output field separator is a blank.</p> <p>If the input files are not in the appropriate collating sequence, the results are unspecified.</p>														
OPTIONS	<p>Some of the options below use the argument <i>filename</i>. This argument should be a 1 or a 2 referring to either <i>file1</i> or <i>file2</i>, respectively.</p> <table><tr><td><code>-a <i>filename</i></code></td><td>In addition to the normal output, produce a line for each unpairable line in file <i>filename</i>, where <i>filename</i> is 1 or 2. If both <code>-a 1</code> and <code>-a 2</code> are specified, all unpairable lines will be output.</td></tr><tr><td><code>-e <i>string</i></code></td><td>Replace empty output fields with <i>string</i>.</td></tr><tr><td><code>-j <i>fieldnumber</i></code></td><td>Equivalent to <code>-1<i>fieldnumber</i> -2<i>fieldnumber</i></code>.</td></tr><tr><td><code>-j1 <i>fieldnumber</i></code></td><td>Equivalent to <code>-1<i>fieldnumber</i></code>.</td></tr><tr><td><code>-j2 <i>fieldnumber</i></code></td><td>Equivalent to <code>-2<i>fieldnumber</i></code> Fields are numbered starting with 1.</td></tr><tr><td><code>-o <i>list</i></code></td><td>Each output line includes the fields specified in <i>list</i>. Fields selected by <i>list</i> that do not appear in the input will be treated as empty output fields. (See the <code>-e</code> option.) Each element of which has the either the form <i>filename</i>.<i>fieldnumber</i>, or 0, which represents the <code>join</code> field. The common field is not printed unless specifically requested.</td></tr><tr><td><code>-t <i>char</i></code></td><td>Use character <i>char</i> as a separator. Every appearance of <i>char</i> in a line is significant. The character <i>char</i> is used as the field separator for both input and output. With this</td></tr></table>	<code>-a <i>filename</i></code>	In addition to the normal output, produce a line for each unpairable line in file <i>filename</i> , where <i>filename</i> is 1 or 2. If both <code>-a 1</code> and <code>-a 2</code> are specified, all unpairable lines will be output.	<code>-e <i>string</i></code>	Replace empty output fields with <i>string</i> .	<code>-j <i>fieldnumber</i></code>	Equivalent to <code>-1<i>fieldnumber</i> -2<i>fieldnumber</i></code> .	<code>-j1 <i>fieldnumber</i></code>	Equivalent to <code>-1<i>fieldnumber</i></code> .	<code>-j2 <i>fieldnumber</i></code>	Equivalent to <code>-2<i>fieldnumber</i></code> Fields are numbered starting with 1.	<code>-o <i>list</i></code>	Each output line includes the fields specified in <i>list</i> . Fields selected by <i>list</i> that do not appear in the input will be treated as empty output fields. (See the <code>-e</code> option.) Each element of which has the either the form <i>filename</i> . <i>fieldnumber</i> , or 0, which represents the <code>join</code> field. The common field is not printed unless specifically requested.	<code>-t <i>char</i></code>	Use character <i>char</i> as a separator. Every appearance of <i>char</i> in a line is significant. The character <i>char</i> is used as the field separator for both input and output. With this
<code>-a <i>filename</i></code>	In addition to the normal output, produce a line for each unpairable line in file <i>filename</i> , where <i>filename</i> is 1 or 2. If both <code>-a 1</code> and <code>-a 2</code> are specified, all unpairable lines will be output.														
<code>-e <i>string</i></code>	Replace empty output fields with <i>string</i> .														
<code>-j <i>fieldnumber</i></code>	Equivalent to <code>-1<i>fieldnumber</i> -2<i>fieldnumber</i></code> .														
<code>-j1 <i>fieldnumber</i></code>	Equivalent to <code>-1<i>fieldnumber</i></code> .														
<code>-j2 <i>fieldnumber</i></code>	Equivalent to <code>-2<i>fieldnumber</i></code> Fields are numbered starting with 1.														
<code>-o <i>list</i></code>	Each output line includes the fields specified in <i>list</i> . Fields selected by <i>list</i> that do not appear in the input will be treated as empty output fields. (See the <code>-e</code> option.) Each element of which has the either the form <i>filename</i> . <i>fieldnumber</i> , or 0, which represents the <code>join</code> field. The common field is not printed unless specifically requested.														
<code>-t <i>char</i></code>	Use character <i>char</i> as a separator. Every appearance of <i>char</i> in a line is significant. The character <i>char</i> is used as the field separator for both input and output. With this														

option specified, the collating term should be the same as `sort` without the `-b` option.

- `-v filename` Instead of the default output, produce a line only for each unpairable line in *filename*, where *filename* is 1 or 2. If both `-v 1` and `-v 2` are specified, all unpairable lines will be output.
- `-1 fieldnumber` Join on the *fieldnumber*th field of file 1. Fields are decimal integers starting with 1.
- `-2 fieldnumber` Join on the *fieldnumber*th field of file 2. Fields are decimal integers starting with 1.

OPERANDS The following operands are supported:

file1

file2 A path name of a file to be joined. If either of the *file1* or *file2* operands is `-`, the standard input is used in its place.

file1 and *file2* must be sorted in increasing collating sequence as determined by `LC_COLLATE` on the fields on which they are to be joined, normally the first in each line (see `sort(1)`).

USAGE See `largefile(5)` for the description of the behavior of `join` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXAMPLES **EXAMPLE 1** Using `join`

The following command line will join the password file and the group file, matching on the numeric group ID, and outputting the login name, the group name and the login directory. It is assumed that the files have been sorted in ASCII collating sequence on the group ID fields.

```
example% join -j1 4-j2 3 -o 1.1 2.1 1.6 -t:/etc/passwd /etc/group
```

EXAMPLE 2 Using the `-o` option

the `-o 0` field essentially selects the union of the join fields. For example, given file `phone`:

```
!Name      Phone Number
Don        +1 123-456-7890
Hal        +1 234-567-8901
Yasushi    +2 345-678-9012
```

and file `fax`:

```
!Name      Fax Number
Don        +1 123-456-7899
Keith     +1 456-789-0122
```

join(1)

EXAMPLE 2 Using the -o option *(Continued)*

```
Yasushi          +2 345-678-9011
```

where the large expanses of white space are meant to each represent a single tab character), the command:

```
example% join -t"<tab>" -a 1 -a 2 -e '(unknown)' -o 0,1.2,2.2 phone fax
would produce
```

!Name	Phone Number	Fax Number
Don	+1 123-456-7890	+1 123-456-7899
Hal	+1 234-567-8901	(unknown)
Keith	(unknown)	+1 456-789-012
Yasushi	+2 345-678-9012	+2 345-678-9011

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `join`: `LC_CTYPE`, `LC_MESSAGES`, `LC_COLLATE`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0 All input files were output successfully.
>0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	Enabled

SEE ALSO

`awk(1)`, `comm(1)`, `sort(1)`, `uniq(1)`, `attributes(5)`, `environ(5)`, `largefile(5)`

NOTES

With default field separation, the collating sequence is that of `sort -b`; with `-t`, the sequence is that of a plain sort.

The conventions of the `join`, `sort`, `comm`, `uniq`, and `awk` commands are wildly incongruous.

NAME	kbd – manipulate the state of keyboard, or display the type of keyboard, or change the default keyboard abort sequence effect
SYNOPSIS	<pre> kbd [-r] [-t] [-a enable disable alternate] [-c on off] [-d keyboard device] kbd [-i] [-d keyboard device] </pre>
DESCRIPTION	The kbd utility manipulates the state of the keyboard, or displays the keyboard type, or allows the default keyboard abort sequence effect to be changed. The abort sequence also applies to serial console devices. The kbd utility sets the /dev/kbd default keyboard device.
EXTENDED DESCRIPTION	<p>The -i option reads and processes default values for the keyclick and keyboard abort settings from the /etc/default/kbd keyboard default file. Only keyboards that support a clicker respond to the -c option. To turn clicking on by default, add or change the value of the KEYCLICK variable in the /etc/default/kbd file to:</p> <pre>KEYCLICK=on</pre> <p>Next, run the command <code>kbd -i</code> to change the setting. Valid settings for the KEYCLICK variable are <code>on</code> and <code>off</code>; all other values are ignored. If the KEYCLICK variable is not specified in the default file, the setting is unchanged.</p> <p>The keyboard abort sequence effect (L1-A or STOP-A on the keyboard, and BREAK on the serial console input device on most systems) can only be changed by a superuser using the -a option. The system can be configured to ignore the keyboard abort sequence or trigger on the standard or alternate sequence.</p> <p>A BREAK condition that originates from an erroneous electrical signal cannot be distinguished from one deliberately sent by remote DCE. As a remedy, use the -a option with Alternate Break to switch break interpretation. Due to the risk of incorrect sequence interpretation, binary protocols such as PPP, SLIP, and others should not be run over the serial console port when Alternate Break sequence is in effect. The Alternate Break sequence has no effect on the keyboard abort. For more information on the Alternate Break sequence, see zs(7D), se(7D), and asy(7D).</p> <p>On many systems, the default effect of the keyboard abort sequence is to suspend the operating system and enter the debugger or the monitor. Some systems feature key switches with a secure position. On these systems, setting the key switch to the secure position overrides any software default set with this command.</p> <p>To permanently change the software default effect of the keyboard abort sequence, first add or change the value of the KEYBOARD_ABORT variable in the /etc/default/kbd file to:</p> <pre>KEYBOARD_ABORT=disable</pre> <p>Next, run the command <code>kbd -i</code> to change the setting. Valid settings are <code>enable</code>, <code>disable</code>, and <code>alternate</code>; all other values are ignored. If the variable is not specified in the default file, the setting is unchanged.</p>

kbd(1)

To set the abort sequence to the hardware BREAK, set the value of the `KEYBOARD_ABORT` variable in the `/etc/default/kbd` file to:

```
KEYBOARD_ABORT=enable
```

To change the current setting, run the command `kbd -i`. To set the abort sequence to the Alternate Break character sequence, first set the current value of the `KEYBOARD_ABORT` variable in the `/etc/default/kbd` file to:

```
KEYBOARD_ABORT=alternate
```

Next, run the command `kbd -i` to change the setting. When the Alternate Break sequence is in effect, only serial console devices are affected.

OPTIONS

The `kbd` utility supports the following options:

`-i`

Set keyboard defaults from the keyboard default file. With the exception of `-d keyboard device`, this option cannot be used with any other option. The `-i` option instructs the keyboard command to read and process keyclick and keyboard abort default values from the `/etc/default/kbd` file. The `-i` option can only be used by a superuser.

`-r`

Reset the keyboard as if power-up

`-t`

Return the type of the keyboard being used

`-c on/off state`

Turn the clicking of the keyboard on or off.

on Enable clicking

off Disable clicking

`-a enable/disable/alternate state`

Enable, disable, or alternate the keyboard abort sequence effect. By default, a keyboard abort sequence (typically Stop-A or L1-A on the keyboard and BREAK on the serial console device) suspends the operating system on most systems. The default keyboard behavior can be changed using this option. The `-a` option can only be used by a superuser.

enable Enable the default effect of the keyboard abort sequence (suspend the operating system and enter the debugger or the monitor)

disable Disable the default/alternate effect and ignore keyboard abort sequences

alternate Enable the alternate effect of the keyboard abort sequences (suspend the operating system and enter the debugger or the monitor) upon receiving the Alternate Break character sequence on the console. The Alternate Break sequence is defined by the drivers `zs(7D)`, `se(7D)`, `asy(7D)`. Due to a risk of incorrect sequence interpretation, binary protocols cannot be run over the serial console port when this value is used.

`-d` *keyboard device*

Specify the keyboard device being set. The default setting is `/dev/kbd`.

EXAMPLES **EXAMPLE 1** Displaying the keyboard type

To display the keyboard type:

```
example% kbd -ttype 4 Sun keyboardexample%
```

EXAMPLE 2 Setting keyboard defaults

To set the keyboard defaults as specified in the keyboard default file:

```
example# kbd -iexample#
```

FILES	<code>/etc/rcS</code>	shell script containing commands necessary to get the system to single-user mode
	<code>/dev/kbd</code>	keyboard device file
	<code>/etc/default/kbd</code>	keyboard default file containing software defaults for keyboard configurations.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Architecture	SPARC
Availability	SUNWcsu

SEE ALSO `loadkeys(1)`, `kadb(1M)`, `keytables(4)`, `attributes(5)`, `kb(7M)`, `zs(7D)`, `se(7D)`, `asy(7D)`

NOTES Some server systems have key switches with a *secure* key position that can be read by system software. This key position overrides the normal default of the keyboard abort sequence effect and changes the default so the effect is disabled. When the key switch is in the *secure* position on these systems, the keyboard abort sequence effect cannot be overridden by the software default, which is settable with the `kbd` utility.

Currently, there is no way to determine the state of the keyboard click setting.

kdestroy(1)

NAME	kdestroy – destroy Kerberos tickets				
SYNOPSIS	<code>/usr/bin/kdestroy [-q] [-c <i>cache_name</i>]</code>				
DESCRIPTION	<p>The <code>kdestroy</code> utility destroys the user's active Kerberos authorization tickets by writing zeros to the specified credentials cache that contains them. If the credentials cache is not specified, the default credentials cache is destroyed. If the credentials cache does not exist, <code>kdestroy</code> displays a message to that effect.</p> <p>After overwriting the cache, <code>kdestroy</code> removes the cache from the system. The utility displays a message indicating the success or failure of the operation. If <code>kdestroy</code> is unable to destroy the cache, it will warn you by making your terminal beep.</p> <p>If desired, you can place the <code>kdestroy</code> command in your <code>.logout</code> file so that your tickets are destroyed automatically when you logout.</p>				
OPTIONS	<p>The following options are supported:</p> <table><tr><td><code>-c <i>cache_name</i></code></td><td>Uses <i>cache_name</i> as the credentials (ticket) cache name and location. If this option is not used, the default cache name and location are used.</td></tr><tr><td><code>-q</code></td><td>Runs quietly. Your terminal will not beep when <code>kdestroy</code> fails to destroy the tickets.</td></tr></table>	<code>-c <i>cache_name</i></code>	Uses <i>cache_name</i> as the credentials (ticket) cache name and location. If this option is not used, the default cache name and location are used.	<code>-q</code>	Runs quietly. Your terminal will not beep when <code>kdestroy</code> fails to destroy the tickets.
<code>-c <i>cache_name</i></code>	Uses <i>cache_name</i> as the credentials (ticket) cache name and location. If this option is not used, the default cache name and location are used.				
<code>-q</code>	Runs quietly. Your terminal will not beep when <code>kdestroy</code> fails to destroy the tickets.				
ENVIRONMENT VARIABLES	<p><code>kdestroy</code> uses the following environment variable:</p> <table><tr><td><code>KRB5CCNAME</code></td><td>Location of the credentials (ticket) cache.</td></tr></table>	<code>KRB5CCNAME</code>	Location of the credentials (ticket) cache.		
<code>KRB5CCNAME</code>	Location of the credentials (ticket) cache.				
FILES	<table><tr><td><code>/tmp/krb5cc_<i>uid</i></code></td><td>Default credentials cache (<i>uid</i> is the decimal UID of the user).</td></tr></table>	<code>/tmp/krb5cc_<i>uid</i></code>	Default credentials cache (<i>uid</i> is the decimal UID of the user).		
<code>/tmp/krb5cc_<i>uid</i></code>	Default credentials cache (<i>uid</i> is the decimal UID of the user).				
ATTRIBUTES	<p>See <code>attributes(5)</code> for descriptions of the following attributes:</p> <table border="1"><thead><tr><th>ATTRIBUTE TYPE</th><th>ATTRIBUTE VALUE</th></tr></thead><tbody><tr><td>Availability</td><td>SUNWcsu</td></tr></tbody></table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu
ATTRIBUTE TYPE	ATTRIBUTE VALUE				
Availability	SUNWcsu				
SEE ALSO	<code>kinit(1)</code> , <code>klist(1)</code> , <code>attributes(5)</code> , <code>SEAM(5)</code>				
BUGS	Only the tickets in the specified credentials cache are destroyed. Separate ticket caches are used to hold root instance and password changing tickets. These files should probably be destroyed too, or all of a user's tickets should be kept in a single credential cache.				
AUTHORS	Steve Miller, MIT Project Athena/Digital Equipment Corporation; Clifford Neuman, MIT Project Athena Bill Sommerfeld, MIT Project Athena				

NAME	kerberos – introduction to the Kerberos system
DESCRIPTION	<p>The Kerberos system authenticates individual users in a network environment. After authenticating yourself to Kerberos, you can use the <code>kerberos</code> authentication option of network services such as NFS. In addition, in some environments you can use network utilities such as <code>rlogin(1)</code>, <code>rcp(1)</code>, and <code>rsh(1)</code> without having to present passwords to remote hosts and without having to bother with <code>.rhosts</code> files. See your system administrator for more information about Kerberos support at your site.</p> <p>Before you can use Kerberos, you must be registered as a user in the Kerberos database. You can use the <code>kinit(1)</code> command to find out your status. This command tries to log you into the Kerberos system. <code>kinit</code> will prompt you for a username and password. Enter your username and password. If the utility lets you login without giving you a message, you have already been registered.</p> <p>If you enter your username and <code>kinit</code> responds with this message:</p> <pre>Principal unknown (kerberos)</pre> <p>you haven't been registered as a Kerberos user. See your system administrator.</p> <p>A Kerberos name contains three parts. The first is the <i>principal name</i>, which is usually a user's or service's name. The second is the <i>instance</i>, which in the case of a user is usually NULL. Some users may have privileged instances, however, such as <code>root</code> or <code>admin</code>. In the case of a service, the instance is the name of the machine on which it runs; that is, there can be an NFS service running on the machine ABC, which is different from the NFS service running on the machine XYZ. The third part of a Kerberos name is the <i>realm</i>. The realm corresponds to the Kerberos service providing authentication for the principal. For example, at MIT there is a Kerberos running at the Laboratory for Computer Science and one running at Project Athena.</p> <p>When writing a Kerberos name, the principal name is separated from the instance (if not NULL) by a period, and the realm (if not the local realm) follows, preceded by an "@" sign. The following are examples of valid Kerberos names:</p> <pre>billb jis.admin srz@lcs.mit.edu treese.root@athena.mit.edu</pre> <p>When you authenticate yourself with Kerberos, typically through the <code>kinit</code> command, Kerberos gives you an initial Kerberos <i>ticket</i>. (A Kerberos ticket is an encrypted protocol message that provides authentication.) Kerberos uses this ticket for network utilities such as NFS, <code>rlogin</code> and <code>rcp</code>. The ticket transactions are done transparently, so you do not have to worry about their management.</p> <p>Note, however, that tickets expire. Privileged tickets, such as <code>root</code> instance tickets, expire in a few minutes, while tickets that carry more ordinary privileges may be good for several hours or a day, depending on the installation's policy. If your login session extends beyond the time limit, you will have to re-authenticate yourself to Kerberos to get new tickets. Use the <code>kinit</code> command to re-authenticate yourself.</p>

kerberos(1)

If you use the `kinit` command to get your tickets, you can use the `kdestroy(1)` command to destroy your tickets before you end your login session. For more information about the `kinit` and `kdestroy` commands, see the `kinit(1)` and `kdestroy(1)` manual pages.

Currently, Kerberos supports NFS and other RPC network services using the `AUTH_KERB` authentication type. In some environments, the following network services are also supported: `rlogin`, `rsh`, and `rcp`. Other services are being worked on, such as the pop mail system, but are not yet available.

SEE ALSO `kdestroy(1)`, `kinit(1)`, `klist(1)`, `kerbd(1M)`,

BUGS Kerberos will not do authentication forwarding. In other words, if you use `rlogin` to login to a remote host, you cannot use Kerberos services from that host until you authenticate yourself explicitly on that host. Although you may need to authenticate yourself on the remote host, be aware that when you do so, `rlogin` sends your password across the network in clear text.

AUTHORS Steve Miller, MIT Project Athena/Digital Equipment Corporation

Clifford Neuman, MIT Project Athena

The following people helped out on various aspects of the system:

Jeff Schiller designed and wrote the administration server and its user interface, `kadmin`. He also wrote the `dbm` version of the database management system.

Mark Colan developed the Kerberos versions of `rlogin`, `rsh`, and `rcp`, as well as contributing work on the servers.

John Ostlund developed the Kerberos versions of `passwd` and `userreg`.

Stan Zandarotti pioneered Kerberos in a foreign realm (LCS), and made many contributions based on that experience.

Many people contributed code and/or useful ideas. These include, Jim Aspnes, Bob Baldwin, John Barba, Richard Basch, Jim Bloom, Bill Bryant, Rob French, Dan Geer, David Jedlinsky, John Kohl, John Kubiatawicz, Bob McKie, Brian Murphy, Ken Raeburn, Chris Reed, Jon Rochlis, Mike Shanzer, Bill Sommerfeld, Jennifer Steiner, Ted Ts'o, and Win Treese.

RESTRICTIONS COPYRIGHT 1985,1986 Massachusetts Institute of Technology

NAME	keylogin – decrypt and store secret key with keyserv				
SYNOPSIS	<code>/usr/bin/keylogin [-r]</code>				
DESCRIPTION	<p>The <code>keylogin</code> command prompts for a password, and uses it to decrypt the user's secret key. The key may be found in the <code>/etc/publickey</code> file (see <code>publickey(4)</code>) or the NIS map "publickey.byname" or the NIS+ table "cred.org_dir" in the user's home domain. The sources and their lookup order are specified in the <code>/etc/nsswitch.conf</code> file. See <code>nsswitch.conf(4)</code>. Once decrypted, the user's secret key is stored by the local key server process, <code>keyserv(1M)</code>. This stored key is used when issuing requests to any secure RPC services, such as NFS or NIS+. The program <code>keylogout(1)</code> can be used to delete the key stored by <code>keyserv</code>.</p> <p><code>keylogin</code> will fail if it cannot get the caller's key, or the password given is incorrect. For a new user or host, a new key can be added using <code>newkey(1M)</code>, <code>nisaddcred(1M)</code>, or <code>nisclient(1M)</code>.</p> <p>If multiple authentication mechanisms are configured for the system, each of the configured mechanism's secret key will be decrypted and stored by <code>keyserv(1M)</code>. See <code>nisauthconf(1M)</code> for information on configuring multiple authentication mechanisms.</p>				
OPTIONS	<p><code>-r</code> Update the <code>/etc/.rootkey</code> file. This file holds the unencrypted secret key of the superuser. Only the superuser may use this option. It is used so that processes running as superuser can issue authenticated requests without requiring that the administrator explicitly run <code>keylogin</code> as superuser at system startup time. See <code>keyserv(1M)</code>. The <code>-r</code> option should be used by the administrator when the host's entry in the <code>publickey</code> database has changed, and the <code>/etc/.rootkey</code> file has become out-of-date with respect to the actual key pair stored in the <code>publickey</code> database. The permissions on the <code>/etc/.rootkey</code> file are such that it may be read and written by the superuser but by no other user on the system.</p> <p>If multiple authentication mechanisms are configured for the system, each of the configured mechanism's secret keys will be stored in the <code>/etc/.rootkey</code> file.</p>				
FILES	<code>/etc/.rootkey</code> superuser's secret key				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:				
	<table border="1"> <thead> <tr> <th style="text-align: center;">ATTRIBUTE TYPE</th> <th style="text-align: center;">ATTRIBUTE VALUE</th> </tr> </thead> <tbody> <tr> <td>Availability</td> <td>SUNWcsu</td> </tr> </tbody> </table>	ATTRIBUTE TYPE	ATTRIBUTE VALUE	Availability	SUNWcsu

keylogout(1)

NAME	keylogout – delete stored secret key with keyserver				
SYNOPSIS	<code>/usr/bin/keylogout [-f]</code>				
DESCRIPTION	<p>keylogout deletes the key stored by the key server process <code>keyserv(1M)</code>. Further access to the key is revoked; however, current session keys may remain valid until they expire or are refreshed.</p> <p>Deleting the keys stored by <code>keyserv</code> will cause any background jobs or scheduled <code>at(1)</code> jobs that need secure RPC services to fail. Since only one copy of the key is kept on a machine, it is a bad idea to place a call to this command in your <code>.logout</code> file since it will affect other sessions on the same machine.</p> <p>If multiple NIS+ authentication mechanisms are configured for the system, then all keys stored by the key server process will be deleted, including keys that are no longer configured.</p>				
OPTIONS	<p><code>-f</code> Force keylogout to delete the secret key for the superuser. By default, keylogout by the superuser is disallowed because it would break all RPC services, such as NFS, that are started by the superuser.</p>				
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NAME	kill – terminate or signal processes
SYNOPSIS	<pre> /usr/bin/kill -s <i>signal</i> <i>pid</i>... /usr/bin/kill -l [<i>exit_status</i>] /usr/bin/kill [-<i>signal</i>] <i>pid</i>... </pre>
DESCRIPTION	<p>The <code>kill</code> utility sends a signal to the process or processes specified by each <i>pid</i> operand.</p> <p>For each <i>pid</i> operand, the <code>kill</code> utility will perform actions equivalent to the <code>kill(2)</code> function called with the following arguments:</p> <ol style="list-style-type: none"> 1. The value of the <i>pid</i> operand will be used as the <i>pid</i> argument. 2. The <i>sig</i> argument is the value specified by the <code>-s</code> option, or by <code>SIGTERM</code>, if none of these options is specified. <p>The signaled process must belong to the current user unless the user is the super-user.</p> <p>See NOTES for descriptions of the shell built-in versions of <code>kill</code>.</p>
OPTIONS	<p>The following options are supported:</p> <p><code>-l</code> (The letter ell.) Write all values of <i>signal</i> supported by the implementation, if no operand is given. If an <i>exit_status</i> operand is given and it is a value of the <code>?</code> shell special parameter and <code>wait</code> corresponding to a process that was terminated by a signal, the <i>signal</i> corresponding to the signal that terminated the process will be written. If an <i>exit_status</i> operand is given and it is the unsigned decimal integer value of a signal number, the <i>signal</i> corresponding to that signal will be written. Otherwise, the results are unspecified.</p> <p><code>-s <i>signal</i></code> Specify the signal to send, using one of the symbolic names defined in the <code><signal.h></code> description. Values of <i>signal</i> will be recognized in a case-independent fashion, without the <code>SIG</code> prefix. In addition, the symbolic name <code>0</code> will be recognized, representing the signal value zero. The corresponding signal will be sent instead of <code>SIGTERM</code>.</p>
OPERANDS	<p>The following operands are supported:</p> <p><i>pid</i> One of the following:</p> <ol style="list-style-type: none"> 1. A decimal integer specifying a process or process group to be signaled. The process or processes selected by positive, negative and zero values of the <i>pid</i> operand will be as described for the <code>kill</code> function. If process number <code>0</code> is specified, all processes in the process group are signaled. If the first <i>pid</i> operand is negative, it should be preceded by <code>--</code> to keep it from being interpreted as an option.

kill(1)

2. A job control job ID that identifies a background process group to be signaled. The job control job ID notation is applicable only for invocations of `kill` in the current shell execution environment.

Note the job control job ID type of *pid* is available only on systems supporting the job control option.

exit_status A decimal integer specifying a signal number or the exit status of a process terminated by a signal.

USAGE Process numbers can be found by using `ps(1)`.

The job control job ID notation is not required to work as expected when `kill` is operating in its own utility execution environment. In either of the following examples:

```
nohup kill %1 &  
system( "kill %1");
```

`kill` operates in a different environment and will not share the shell's understanding of job numbers.

OUTPUT When the `-l` option is not specified, the standard output will not be used.

When the `-l` option is specified, the symbolic name of each signal will be written in the following format:

```
"%s%c" , <signal> , <separator>
```

where the *<signal>* is in upper-case, without the SIG prefix, and the *<separator>* will be either a newline character or a space character. For the last signal written, *<separator>* will be a newline character.

When both the `-l` option and *exit_status* operand are specified, the symbolic name of the corresponding signal will be written in the following format:

```
"%s\n" , <signal>
```

EXAMPLES **EXAMPLE 1** Examples of the `kill` command.

Any of the commands:

```
kill -9 100 -165  
kill -s kill 100 -165  
kill -s KILL 100 -165
```

sends the SIGKILL signal to the process whose process ID is 100 and to all processes whose process group ID is 165, assuming the sending process has permission to send that signal to the specified processes, and that they exist.

EXAMPLE 1 Examples of the kill command. (Continued)

To avoid an ambiguity of an initial negative number argument specifying either a signal number or a process group, the former will always be the case. Therefore, to send the default signal to a process group (for example, 123), an application should use a command similar to one of the following:

```
kill -TERM -123
kill -- -123
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `kill`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

- 0 At least one matching process was found for each *pid* operand, and the specified signal was successfully processed for at least one matching process.
- >0 An error occurred.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu
CSI	enabled

SEE ALSO

`csh(1)`, `jobs(1)`, `ksh(1)`, `ps(1)`, `sh(1)`, `shell_builtins(1)`, `wait(1)`, `kill(2)`, `signal(3C)`, `attributes(5)`, `environ(5)`, `signal(3HEAD)`

NOTES

- sh** The Bourne shell, `sh`, has a built-in version of `kill` to provide the functionality of the `kill` command for processes identified with a *jobid*. The `sh` syntax is:

```
kill [ -sig ] [ pid ] [ %job ] ...
kill -l
```

- csh** The C-shell, `csh`, also has a built-in `kill` command, whose syntax is:

```
kill [-sig] [pid] [%job] ...
```

`kill -l`The `csh kill` built-in sends the `TERM` (terminate) signal, by default, or the signal specified, to the specified process ID, the *job* indicated, or the current *job*. Signals are either given by number or by

name. There is no default. Typing `kill` does not send a signal to the current job. If the signal being sent is `TERM` (terminate) or `HUP` (hangup), then the job or process is sent a `CONT` (continue) signal as well.

kill(1)

-l List the signal names that can be sent.

ksh The ksh `kill`'s syntax is:

```
kill [-sig] [pid] [%job] ...
```

`kill -l`The ksh `kill` sends either the `TERM` (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in `signal(3HEAD)` stripped of the prefix "SIG"). If the signal being sent is `TERM` (terminate) or `HUP` (hangup), then the job or process will be sent a `CONT` (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. In the second form, `kill -l`, the signal numbers and names are listed.

NAME	kinit – obtain and cache Kerberos ticket-granting ticket
SYNOPSIS	<code>/usr/bin/kinit [-fpRv] [-c <i>cache_name</i>] [-k [-t <i>keytab_file</i>]] [-l <i>lifetime</i>] [-r <i>renewable_life</i>] [-s <i>start_time</i>] [-S <i>service_name</i>] [<i>principal</i>]</code>
DESCRIPTION	<p>The <code>kinit</code> command is used to obtain and cache an initial ticket-granting ticket (credential) for <i>principal</i>. This ticket is used for authentication by the Kerberos system. Notice that only users with Kerberos principals can use the Kerberos system. For information about Kerberos principals, see <code>SEAM(5)</code>.</p> <p>When you use <code>kinit</code> without options, the utility prompts for your <i>principal</i> and Kerberos password, and tries to authenticate your login with the local Kerberos server. The <i>principal</i> can be specified on the command line if desired.</p> <p>If Kerberos authenticates the login attempt, <code>kinit</code> retrieves your initial ticket-granting ticket and puts it in the ticket cache. By default your ticket will be stored in the file <code>/tmp/krb5cc_<i>uid</i></code>, where <i>uid</i> specifies your user identification number. Tickets expire after a specified lifetime, after which <code>kinit</code> must be run again. Any existing contents of the cache are destroyed by <code>kinit</code>.</p> <p>The <code>kdestroy(1)</code> command may be used to destroy any active tickets before you end your login session.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> <code>-c <i>cache_name</i></code> Use <i>cache_name</i> as the credentials (ticket) cache name and location. If this option is not used, the default cache name and location are used. <code>-f</code> Requests forwardable tickets. <code>-k [-t <i>keytab_file</i>]</code> Requests a host ticket, obtained from a key in the local host's <i>keytab</i> file. The name and location of the <i>keytab</i> file may be specified with the <code>-t <i>keytab_file</i></code> option; otherwise the default name and location will be used. <code>-l <i>lifetime</i></code> Requests a ticket with the lifetime <i>lifetime</i>. If the <code>-l</code> option is not specified, the default ticket lifetime (configured by each site) is used. Specifying a ticket lifetime longer than the maximum ticket lifetime (configured by each site) results in a ticket with the maximum lifetime. See the <code>Time Formats</code> section for the valid time duration formats that you can specify for <i>lifetime</i>. <code>-p</code> Requests proxiable tickets. <code>-r <i>renewable_life</i></code> Requests renewable tickets, with a total lifetime of <i>renewable_life</i>. See the <code>Time Formats</code> section for the valid time duration formats that you can specify for <i>renewable_life</i>.

kinit(1)

- R Requests renewal of the ticket-granting ticket. Notice that an expired ticket cannot be renewed, even if the ticket is still within its renewable life.
- s *start_time* Requests a postdated ticket, valid starting at *start_time*. Postdated tickets are issued with the *invalid* flag set, and need to be fed back to the KDC before use. See the Time Formats section for either the valid absolute time or time duration formats that you can specify for *start_time*. *kinit* attempts to match an absolute time first before trying to match a time duration.
- S *service_name* Specifies an alternate service name to use when getting initial tickets.
- v Requests that the ticket granting ticket in the cache (with the *invalid* flag set) be passed to the KDC for validation. If the ticket is within its requested time range, the cache is replaced with the validated ticket.

Time Formats

The following absolute time formats can be used for the -s *start_time* option. The examples are based on the date and time of July 2, 1999, 1:35:30 p.m.

Absolute Time Format	Example
<i>yyymmddhhmm[ss]</i>	990702133530
<i>hhmm[ss]</i>	133530
<i>yy.mm.dd.hh.mm.ss</i>	99:07:02:13:35:30
<i>hh:mm[:ss]</i>	13:35:30
<i>ldate:ltime</i>	07-07-99:13:35:30
<i>dd-month-yyyy:hh:mm[:ss]</i>	02-july-1999:13:35:30

Variable	Description
<i>dd</i>	day
<i>hh</i>	hour (24-hour clock)
<i>mm</i>	minutes
<i>ss</i>	seconds
<i>yy</i>	year within century (0-68 is 2000 to 2068; 69-99 is 1969 to 1999)
<i>yyyy</i>	year including century

Variable	Description
<i>month</i>	locale's full or abbreviated month name
<i>ldate</i>	locale's appropriate date representation
<i>ltime</i>	locale's appropriate time representation

The following time duration formats can be used for the *-l lifetime*, *-x renewable_life*, and *-sstart_time* options. The examples are based on the time duration of 14 days, 7 hours, 5 minutes, and 30 seconds.

Time Duration Format	Example
#d	14d
#h	7h
#m	5m
#s	30s
#d#h#m#s	14d7h5m30s
#h#m[#s]	7h5m30s
<i>days-hh:mm:ss</i>	14-07:05:30
<i>hours:mm[:ss]</i>	7:05:30

Delimiter	Description
d	number of days
h	number of hours
m	number of minutes
s	number of seconds

Variable	Description
#	number
<i>days</i>	number of days
<i>hours</i>	number of hours
<i>hh</i>	hour (24-hour clock)
<i>mm</i>	minutes

kinit(1)

Variable	Description
ss	seconds

ENVIRONMENT VARIABLES

kinit uses the following environment variable:

KRB5CCNAME	Location of the credentials (ticket) cache.
FILES /tmp/krb5cc_ <i>uid</i>	Default credentials cache (<i>uid</i> is the decimal UID of the user).
/etc/krb5/krb5.keytab	Default location for the local host's keytab file.

NAME	klist – list currently held Kerberos tickets
SYNOPSIS	<code>/usr/bin/klist [-e] [[-c] [cache_name] [-f] [-s]] [-k [-t] [keytab_file] [-K]]</code>
DESCRIPTION	<p>The <code>klist</code> utility prints the name of the credentials cache, the identity of the principal that the tickets are for (as listed in the ticket file), and the principal names of all Kerberos tickets currently held by the user, along with the issue and expiration time for each authenticator. Principal names are listed in the form <code>name/instance@realm</code>, with the <code>'/'</code> omitted if the instance is not included, and the <code>'@'</code> omitted if the realm is not included.</p> <p>If <code>cache_file</code> or <code>keytab_name</code> is not specified, <code>klist</code> will display the credentials in the default credentials cache or keytab files as appropriate. By default your ticket will be stored in the file <code>/tmp/krb5cc_uid</code>, where <code>uid</code> is the current user-ID of the user.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none"> -e Displays the encryption types of the session key and the ticket for each credential in the credential cache, or each key in the keytab file. -c [cache_name] Lists tickets held in a credentials cache. This is the default if neither -c nor -k is specified. -f Shows the flags present in the credentials, using the following abbreviations: <ul style="list-style-type: none"> F Forwardable f forwarded P Proxiable p proxy D postDateable d postdated R Renewable I Initial i invalid -s Causes <code>klist</code> to run silently (produce no output), but to still set the exit status according to whether it finds the credentials cache. The exit status is <code>'0'</code> if <code>klist</code> finds a credentials cache, and <code>'1'</code> if it does not. -k [keytab_file] List keys held in a keytab file. -t Displays the time entry timestamps for each keytab entry in the keytab file.

klist(1)

-K Displays the value of the encryption key in each keytab entry in the keytab file.

ENVIRONMENT VARIABLES

klist uses the following environment variable:

KRB5CCNAME Location of the credentials (ticket) cache.

FILES

/tmp/krb5cc_*uid* Default credentials cache (*uid* is the decimal UID of the user).

/etc/krb5/krb5.keytab Default location for the local host's keytab file.

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO

`kdestroy(1)`, `kinit(1)`, `attributes(5)`, `SEAM(5)`

BUGS

When reading a file as a service key file, very little error checking is performed.

NAME	kpasswd – change a user’s Kerberos password						
SYNOPSIS	<code>/usr/bin/kpasswd</code> [<i>principal</i>]						
DESCRIPTION	<p>The <code>kpasswd</code> command is used to change a Kerberos principal’s password. <code>kpasswd</code> prompts for the current Kerberos password, which is used to obtain a <code>changepw</code> ticket from the KDC for the user’s Kerberos realm. If <code>kpasswd</code> successfully obtains the <code>changepw</code> ticket, the user is prompted twice for the new password, and the password is changed.</p> <p>If the principal is governed by a policy that specifies the length and/or number of character classes required in the new password, the new password must conform to the policy. (The five character classes are lower case, upper case, numbers, punctuation, and all other characters.)</p>						
OPERANDS	<p>The following operand is supported:</p> <p><i>principal</i> change the password for the Kerberos principal <i>principal</i>. Otherwise, the principal is derived from the identity of the user invoking the <code>kpasswd</code> command.</p>						
FILES	<p><code>/tmp/ovsec_adm.xxxxxx</code> temporary credentials cache for the lifetime of the password changing operation. (<i>xxxxxx</i> is a random string.)</p>						
ATTRIBUTES	See <code>attributes(5)</code> for descriptions of the following attributes:

NOTES	<p>Kerberos privacy support must be installed on the local machine for <code>kpasswd</code> to work. <code>kpasswd</code> requires that the Kerberos GSS plug-in module with privacy support be installed on the local machine. Currently this is only available on the Solaris encryption kit CD (due to import/export restrictions on DES for encryption purposes). This support is in <code>SUNWk5pk</code> and <code>SUNWk5pu</code> packages.</p>						
BUGS	If <code>kpasswd</code> is suspended, the <code>changepw</code> tickets may not be destroyed.						

ksh(1)

NAME	ksh, rksh – KornShell, a standard/restricted command and programming language
SYNOPSIS	<pre>/usr/bin/ksh [+ abCefhikmnoqrstuvx] [+ o option...] [arg...] /usr/bin/ksh -c [+ abCefhikmnoqrstuvx] [+ o option...] command_string [command_name [arg...]] /usr/xpg4/bin/sh [+ abCefhikmnoqrstuvx] [+ o option...] [arg...] /usr/xpg4/bin/sh -c [+ abCefhikmnoqrstuvx] [+ o option...] command_string [command_name [arg...]] /usr/bin/rksh [+ abCefhikmnoqrstuvx] [+ o option...] [arg...] /usr/bin/rksh -c [+ abCefhikmnoqrstuvx] [+ o option...] command_string [command_name [arg...]]</pre>
DESCRIPTION	<p>The <code>/usr/xpg4/bin/sh</code> utility is a standards compliant shell. This utility provides all the functionality of <code>/usr/bin/ksh</code>, except in cases discussed below where differences in behavior exist. See Arithmetic Expansions section for details.</p> <p><code>/usr/bin/ksh</code> is a command and programming language that executes commands read from a terminal or a file. <code>rksh</code> is a restricted version of the command interpreter <code>ksh</code>; it is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. See Invocation below for the meaning of arguments to the shell.</p>
Definitions	<p>A <i>metacharacter</i> is one of the following characters:</p> <pre>; & () < > NEWLINE SPACE TAB</pre> <p>A <i>blank</i> is a TAB or a SPACE. An <i>identifier</i> is a sequence of letters, digits, or underscores starting with a letter or underscore. Identifiers are used as names for <i>functions</i> and <i>variables</i>. A <i>word</i> is a sequence of <i>characters</i> separated by one or more non-quoted <i>metacharacters</i>.</p> <p>A <i>command</i> is a sequence of characters in the syntax of the shell language. The shell reads each command and carries out the desired action either directly or by invoking separate utilities. A <i>special-command</i> is a command that is carried out by the shell without creating a separate process. Except for documented side effects, most special commands can be implemented as separate utilities.</p>
Commands	<p>A <i>simple-command</i> is a sequence of blank-separated words which may be preceded by a variable assignment list. (See Environment below.) The first word specifies the name of the command to be executed. Except as specified below, the remaining words are passed as arguments to the invoked command. The command name is passed as argument 0 (see <code>exec(2)</code>). The <i>value</i> of a simple-command is its exit status if it terminates normally. If it terminates abnormally due to receipt of a signal, the <i>value</i> is the signal number plus 128. See <code>signal(3HEAD)</code> for a list of signal values. Obviously, normal exit status values 129 to 255 cannot be distinguished from abnormal exit caused by receiving signal numbers 1 to 127.</p>

A *pipeline* is a sequence of one or more *commands* separated by `|`. The standard output of each command but the last is connected by a `pipe(2)` to the standard input of the next command. Each command is run as a separate process; the shell waits for the last command to terminate. The exit status of a pipeline is the exit status of the last command.

A *list* is a sequence of one or more *pipelines* separated by `;`, `&`, `&&`, or `| |`, and optionally terminated by `;`, `&`, or `|&`. Of these five symbols, `;`, `&`, and `|&` have equal precedence, which is lower than that of `&&` and `| |`. The symbols `&&` and `| |` also have equal precedence. A semicolon (`;`) causes sequential execution of the preceding pipeline; an ampersand (`&`) causes asynchronous execution of the preceding pipeline (that is, the shell does *not* wait for that pipeline to finish). The symbol `|&` causes asynchronous execution of the preceding command or pipeline with a two-way pipe established to the parent shell.

The standard input and output of the spawned command can be written to and read from by the parent shell using the `-p` option of the special commands `read` and `print` described in Special Commands. The symbol `&&` (`| |`) causes the *list* following it to be executed only if the preceding pipeline returns 0 (or a non-zero) value. An arbitrary number of new-lines may appear in a *list*, instead of a semicolon, to delimit a command.

A *command* is either a *simple-command* or one of the following. Unless otherwise stated, the value returned by a command is that of the last simple-command executed in the command.

`for identifier [in word ...] ; do list ; done`

Each time a `for` command is executed, *identifier* is set to the next *word* taken from the *in word* list. If *in word ...* is omitted, then the `for` command executes the `do list` once for each positional parameter that is set (see Parameter Substitution below). Execution ends when there are no more words in the list.

`select identifier [in word ...] ; do list ; done`

A `select` command prints to standard error (file descriptor 2), the set of *words*, each preceded by a number. If *in word ...* is omitted, then the positional parameters are used instead (see Parameter Substitution below). The PS3 prompt is printed and a line is read from the standard input. If this line consists of the number of one of the listed *words*, then the value of the variable *identifier* is set to the *word* corresponding to this number. If this line is empty the selection list is printed again. Otherwise the value of the variable *identifier* is set to NULL. (See Blank Interpretation about NULL). The contents of the line read from standard input is saved in the shell variable `REPLY`. The *list* is executed for each selection until a `break` or EOF is encountered. If the `REPLY` variable is set to NULL by the execution of *list*, then the selection list is printed before displaying the PS3 prompt for the next selection.

`case word in [pattern [| pattern]) list ;;] ... esac`

A `case` command executes the *list* associated with the first *pattern* that matches *word*. The form of the patterns is the same as that used for file-name generation (see File Name Generation below).

ksh(1)

```
if list ; then list ; [ elif list ; then list ; ... ] [ else list ; ] fi
```

The *list* following `if` is executed and, if it returns an exit status of 0, the *list* following the first `then` is executed. Otherwise, the *list* following `elif` is executed and, if its value is 0, the *list* following the next `then` is executed. Failing that, the `else list` is executed. If no `else list` or `then list` is executed, then the `if` command returns 0 exit status.

```
while list ; do list ; done
```

```
until list ; do list ; done
```

A `while` command repeatedly executes the `while list` and, if the exit status of the last command in the `do list` is 0, executes the `do list`; otherwise the loop terminates. If no commands in the `do list` are executed, then the `while` command returns 0 exit status. `until` may be used in place of `while` to negate the loop termination test.

```
(list)
```

Execute *list* in a separate environment. Notice that if two adjacent open parentheses are needed for nesting, a space must be inserted to avoid arithmetic evaluation as described below.

```
{list}
```

list is simply executed. Notice that, unlike the metacharacters `(` and `)`, `{` and `}` are *reserved words* and must occur at the beginning of a line or after a `;` in order to be recognized.

```
[ expression ]
```

Evaluates *expression* and returns 0 exit status when *expression* is true. See Conditional Expressions below, for a description of *expression*.

```
function identifier { list ; }
```

```
identifier ( ) { list ; }
```

Define a function which is referenced by *identifier*. The body of the function is the *list* of commands between `{` and `}`. (See Functions below).

```
time pipeline
```

The *pipeline* is executed and the elapsed time as well as the user and system time are printed to standard error.

The following reserved words are only recognized as the first word of a command and when not quoted:

```
!          if      then    else    elif    fi      case
esac      for     while   until  do      done    {  }
function  select  time    [[ ]]
```

Comments A word beginning with `#` causes that word and all the following characters up to a new-line to be ignored.

Aliasing The first word of each command is replaced by the text of an alias if an alias for this word has been defined. An alias name consists of any number of characters excluding metacharacters, quoting characters, file expansion characters, parameter and command substitution characters, and `=`. The replacement string can contain any valid shell script including the metacharacters listed above. The first word of each command

in the replaced text, other than any that are in the process of being replaced, will be tested for aliases. If the last character of the alias value is a *blank* then the word following the alias will also be checked for alias substitution. Aliases can be used to redefine special builtin commands but cannot be used to redefine the reserved words listed above. Aliases can be created, listed, and exported with the `alias` command and can be removed with the `unalias` command. Exported aliases remain in effect for scripts invoked by name, but must be reinitialized for separate invocations of the shell (see *Invocation* below). To prevent infinite loops in recursive aliasing, if the shell is not currently processing an alias of the same name, the word will be replaced by the value of the alias; otherwise, it will not be replaced.

Aliasing is performed when scripts are read, not while they are executed. Therefore, for an alias to take effect, the `alias` definition command has to be executed before the command which references the alias is read.

Aliases are frequently used as a short hand for full path names. An option to the aliasing facility allows the value of the alias to be automatically set to the full pathname of the corresponding command. These aliases are called *tracked* aliases. The value of a *tracked* alias is defined the first time the corresponding command is looked up and becomes undefined each time the `PATH` variable is reset. These aliases remain *tracked* so that the next subsequent reference will redefine the value. Several tracked aliases are compiled into the shell. The `-h` option of the `set` command makes each referenced command name into a tracked alias.

The following *exported aliases* are compiled into (and built-in to) the shell but can be unset or redefined:

```
autoload='typeset -fu'
false='let 0'
functions='typeset -f'
hash='alias -t'
history='fc -l'
integer='typeset -i'
nohup='nohup '
r='fc -e -'
true=':'
type='whence -v'
```

An example concerning trailing blank characters and reserved words follows. If the user types:

```
$ alias foo="/bin/ls "
$ alias while="/"
```

the effect of executing:

```
$ while true
> do
> echo "Hello, World"
> done
```

is a never-ending sequence of `Hello, World` strings to the screen. However, if the user types:

ksh(1)

```
$ foo while
```

the result will be an `ls` listing of `/`. Since the alias substitution for `foo` ends in a space character, the next word is checked for alias substitution. The next word, `while`, has also been aliased, so it is substituted as well. Since it is not in the proper position as a command word, it is not recognized as a reserved word.

If the user types:

```
$ foo; while
```

`while` retains its normal reserved-word properties.

Tilde Substitution

After alias substitution is performed, each word is checked to see if it begins with an unquoted `~`. If it does, then the word up to a `/` is checked to see if it matches a user name. If a match is found, the `~` and the matched login name are replaced by the login directory of the matched user. This is called a *tilde* substitution. If no match is found, the original text is left unchanged. A `~` by itself, or in front of a `/`, is replaced by `$HOME`. A `~` followed by a `+` or `-` is replaced by `$PWD` and `$OLDPWD`, respectively.

In addition, *tilde* substitution is attempted when the value of a *variable assignment* begins with a `~`.

Tilde Expansion

A *tilde-prefix* consists of an unquoted tilde character at the beginning of a word, followed by all of the characters preceding the first unquoted slash in the word, or all the characters in the word if there is no slash. In an assignment, multiple tilde-prefixes can be used: at the beginning of the word (that is, following the equal sign of the assignment), following any unquoted colon or both. A tilde-prefix in an assignment is terminated by the first unquoted colon or slash. If none of the characters in the tilde-prefix are quoted, the characters in the tilde-prefix following the tilde are treated as a possible login name from the user database.

A portable login name cannot contain characters outside the set given in the description of the `LOGNAME` environment variable. If the login name is null (that is, the tilde-prefix contains only the tilde), the tilde-prefix will be replaced by the value of the variable `HOME`. If `HOME` is unset, the results are unspecified. Otherwise, the tilde-prefix will be replaced by a pathname of the home directory associated with the login name obtained using the `getpwnam` function. If the system does not recognize the login name, the results are undefined.

Tilde expansion generally occurs only at the beginning of words, but an exception based on historical practice has been included:

```
PATH=/posix/bin:~dgk/bin
```

is eligible for tilde expansion because tilde follows a colon and none of the relevant characters is quoted. Consideration was given to prohibiting this behavior because any of the following are reasonable substitutes:

```
PATH=$(printf %s ~karels/bin : ~bostic/bin)
for Dir in ~maat/bin ~srb/bin .
do
```

```
PATH=${PATH:+$PATH:}$Dir
done
```

With the first command, explicit colons are used for each directory. In all cases, the shell performs tilde expansion on each directory because all are separate words to the shell.

Notice that expressions in operands such as:

```
make -k mumble LIBDIR=~chet/lib
```

do not qualify as shell variable assignments and tilde expansion is not performed (unless the command does so itself, which `make` does not).

The special sequence `$~` has been designated for future implementations to evaluate as a means of forcing tilde expansion in any word.

Because of the requirement that the word not be quoted, the following are not equivalent; only the last will cause tilde expansion:

```
\~h1j/  ~h\1j/  ~"h1j"/  ~h1j\ /  ~h1j/
```

The results of giving tilde with an unknown login name are undefined because the KornShell `~+` and `~-` constructs make use of this condition, but, in general it is an error to give an incorrect login name with tilde. The results of having `HOME` unset are unspecified because some historical shells treat this as an error.

Command Substitution

The standard output from a *command* enclosed in parenthesis preceded by a dollar sign (that is, `$(command)`) or a pair of grave accents (`` ``) may be used as part or all of a word; trailing new-lines are removed. In the second (archaic) form, the string between the quotes is processed for special quoting characters before the command is executed. (See `Quoting` below.) The command substitution `$(cat file)` can be replaced by the equivalent but faster `$(<file)`. Command substitution of most special commands that do not perform input/output redirection are carried out without creating a separate process.

Command substitution allows the output of a command to be substituted in place of the command name itself. Command substitution occurs when the command is enclosed as follows:

```
$(command)
```

or (backquoted version):

```
`command`
```

The shell will expand the command substitution by executing *command* in a subshell environment and replacing the command substitution (the text of *command* plus the enclosing `$()` or backquotes) with the standard output of the command, removing sequences of one or more newline characters at the end of the substitution. Embedded

ksh(1)

newline characters before the end of the output will not be removed; however, they may be treated as field delimiters and eliminated during field splitting, depending on the value of IFS and quoting that is in effect.

Within the backquoted style of command substitution, backslash shall retain its literal meaning, except when followed by:

```
$ ` \
```

(dollar-sign, backquote, backslash). The search for the matching backquote is satisfied by the first backquote found without a preceding backslash. During this search, if a non-escaped backquote is encountered within a shell comment, a here-document, an embedded command substitution of the $\$(command)$ form, or a quoted string, undefined results occur. A single- or double-quoted string that begins, but does not end, within the `' . . .'` sequence produces undefined results.

With the $\$(command)$ form, all characters following the open parenthesis to the matching closing parenthesis constitute the *command*. Any valid shell script can be used for *command*, except:

- A script consisting solely of redirections produces unspecified results.
- See the restriction on single subshells described below.

The results of command substitution will not be field splitting and pathname expansion processed for further tilde expansion, parameter expansion, command substitution or arithmetic expansion. If a command substitution occurs inside double-quotes, it will not be performed on the results of the substitution.

Command substitution can be nested. To specify nesting within the backquoted version, the application must precede the inner backquotes with backslashes; for example:

```
\`command``
```

The $\$()$ form of command substitution solves a problem of inconsistent behavior when using backquotes. For example:

Command	Output
<code>echo `\\$x`</code>	<code> \\$x</code>
<code>echo 'echo `\\$x`'</code>	<code> \$x</code>
<code>echo \$(echo `\\$x`)</code>	<code> \\$x</code>

Additionally, the backquoted syntax has historical restrictions on the contents of the embedded command. While the new $\$()$ form can process any kind of valid embedded script, the backquoted form cannot handle some valid scripts that include backquotes. For example, these otherwise valid embedded scripts do not work in the left column, but do work on the right:

echo `	echo \$(
cat <<eof	cat <<eof
a here-doc with `	a here-doc with)
eof	eof
`)
echo `	echo \$(
echo abc # a comment with `	echo abc # a comment with)
`)
echo `	echo \$(
echo '''	echo `)`
`)

Because of these inconsistent behaviors, the backquoted variety of command substitution is not recommended for new applications that nest command substitutions or attempt to embed complex scripts.

If the command substitution consists of a single subshell, such as:

```
$( command )
```

a portable application must separate the \$ (and (into two tokens (that is, separate them with white space). This is required to avoid any ambiguities with arithmetic expansion.

Arithmetic Expansion

An arithmetic expression enclosed in double parentheses preceded by a dollar sign (\$(*arithmetic-expression*)) is replaced by the value of the arithmetic expression within the double parenthesis. Arithmetic expansion provides a mechanism for evaluating an arithmetic expression and substituting its value. The format for arithmetic expansion is as follows:

```
$(expression)
```

The expression is treated as if it were in double-quotes, except that a double-quote inside the expression is not treated specially. The shell will expand all tokens in the expression for parameter expansion, command substitution and quote removal.

Next, the shell will treat this as an arithmetic expression and substitute the value of the expression. The arithmetic expression will be processed according to the rules of the ISO C with the following exceptions:

- Only integer arithmetic is required.

ksh(1)

- The `sizeof()` operator and the prefix and postfix `++` and `--` operators are not required.
- Selection, iteration, and jump statements are not supported.
- `/usr/bin/ksh` and `/usr/bin/rksh` treat prefix 0 through 9 as decimal constants. See the examples below.

Command	Result in <code>/bin/ksh</code>	Result in <code>/usr/xpg4/bin/sh</code>
<code>echo \$((010+10))</code>	20	18
<code>echo \$((010+10))</code>	29	error
<code>[10 -le \$((011))]</code>	true	false

As an extension, the shell may recognize arithmetic expressions beyond those listed. If the expression is invalid, the expansion will fail and the shell will write a message to standard error indicating the failure.

A simple example using arithmetic expansion:

```
# repeat a command 100 times
x=100
while [ $x -gt 0 ]
do
    command
    x=$((x-1))
done
```

Process Substitution

This feature is available in SunOS and only on versions of the UNIX operating system that support the `/dev/fd` directory for naming open files. Each command argument of the form `<(list)` or `>(list)` will run process `list` asynchronously connected to some file in `/dev/fd`. The name of this file will become the argument to the command. If the form with `>` is selected, then writing on this file will provide input for `list`. If `<` is used, then the file passed as an argument will contain the output of the `list` process. For example,

```
paste <(cut -f1 file1) <(cut -f3 file2) | tee >(process1) >(process2)
```

`cut`s fields 1 and 3 from the files `file1` and `file2`, respectively, pastes the results together, and sends it to the processes `process1` and `process2`, as well as putting it onto the standard output. Note that the file, which is passed as an argument to the command, is a UNIX pipe(2) so programs that expect to `lseek(2)` on the file will not work.

Parameter Substitution

A *parameter* is an *identifier*, one or more digits, or any of the characters `*`, `@`, `#`, `?`, `-`, `$`, and `!`. A *variable* (a *parameter* denoted by an *identifier*) has a *value* and zero or more *attributes*. *variables* can be assigned *values* and *attributes* by using the `typeset` special command. The attributes supported by the shell are described later with the `typeset` special command. Exported variables pass values and attributes to the environment.

The shell supports a one-dimensional array facility. An element of an array variable is referenced by a *subscript*. A *subscript* is denoted by a [, followed by an *arithmetic expression* (see Arithmetic Evaluation below) followed by a]. To assign values to an array, use `set -A name value . . .`. The *value* of all subscripts must be in the range of 0 through 4095. Arrays need not be declared. Any reference to a variable with a valid subscript is legal and an array will be created if necessary. Referencing an array without a subscript is equivalent to referencing the element 0. If an array *identifier* with subscript * or @ is used, then the value for each of the elements is substituted (separated by a field separator character).

The *value* of a *variable* may be assigned by writing:

```
name=value [ name=value ] . . .
```

If the integer attribute, `-i`, is set for *name*, the *value* is subject to arithmetic evaluation as described below.

Positional parameters, parameters denoted by a number, may be assigned values with the `set` special command. Parameter \$0 is set from argument zero when the shell is invoked. If *parameter* is one or more digits then it is a positional parameter. A positional parameter of more than one digit must be enclosed in braces.

Parameter Expansion

The format for parameter expansion is as follows:

```
${expression}
```

where *expression* consists of all characters until the matching }. Any } escaped by a backslash or within a quoted string, and characters in embedded arithmetic expansions, command substitutions and variable expansions, are not examined in determining the matching }.

The simplest form for parameter expansion is:

```
${parameter}
```

The value, if any, of *parameter* will be substituted.

The parameter name or symbol can be enclosed in braces, which are optional except for positional parameters with more than one digit or when *parameter* is followed by a character that could be interpreted as part of the name. The matching closing brace will be determined by counting brace levels, skipping over enclosed quoted strings and command substitutions.

If the parameter name or symbol is not enclosed in braces, the expansion will use the longest valid name whether or not the symbol represented by that name exists. When the shell is scanning its input to determine the boundaries of a name, it is not bound by its knowledge of what names are already defined. For example, if F is a defined shell variable, the command:

ksh(1)

```
echo $Fred
```

does not echo the value of `$F` followed by `red`; it selects the longest possible valid name, `Fred`, which in this case might be unset.

If a parameter expansion occurs inside double-quotes:

- Pathname expansion will not be performed on the results of the expansion.
- Field splitting will not be performed on the results of the expansion, with the exception of `@`.

In addition, a parameter expansion can be modified by using one of the following formats. In each case that a value of *word* is needed (based on the state of *parameter*, as described below), *word* will be subjected to tilde expansion, parameter expansion, command substitution and arithmetic expansion. If *word* is not needed, it will not be expanded. The `}` character that delimits the following parameter expansion modifications is determined as described previously in this section and in `dquote`. (For example, `${foo-bar}xyz` would result in the expansion of `foo` followed by the string `xyz` if `foo` is set, else the string `barxyz`).

<code>\${parameter:-word}</code>	Use Default Values. If <i>parameter</i> is unset or null, the expansion of <i>word</i> will be substituted; otherwise, the value of <i>parameter</i> will be substituted.
<code>\${parameter:=word}</code>	Assign Default Values. If <i>parameter</i> is unset or null, the expansion of <i>word</i> will be assigned to <i>parameter</i> . In all cases, the final value of <i>parameter</i> will be substituted. Only variables, not positional parameters or special parameters, can be assigned in this way.
<code>\${parameter:?word}</code>	Indicate Error if Null or Unset. If <i>parameter</i> is unset or null, the expansion of <i>word</i> (or a message indicating it is unset if <i>word</i> is omitted) will be written to standard error and the shell will exit with a non-zero exit status. Otherwise, the value of <i>parameter</i> will be substituted. An interactive shell need not exit.
<code>\${parameter:+word}</code>	Use Alternative Value. If <i>parameter</i> is unset or null, null will be substituted. Otherwise, the expansion of <i>word</i> will be substituted.

In the parameter expansions shown previously, use of the colon in the format results in a test for a parameter that is unset or null. Omission of the colon results in a test for a parameter that is only unset. The following table summarizes the effect of the colon:

	parameter set and not null	parameter set and null	parameter unset
<code>\${parameter:-word}</code>	substitute <i>parameter</i>	substitute <i>word</i>	substitute <i>word</i>
<code>\${parameter-word}</code>	substitute <i>parameter</i>	substitute null	substitute <i>word</i>
<code>\${parameter:=word}</code>	substitute <i>parameter</i>	assign <i>word</i>	assign <i>word</i>
<code>\${parameter=word}</code>	substitute <i>parameter</i>	substitute <i>parameter</i>	assign null
<code>\${parameter:?word}</code>	substitute <i>parameter</i>	error, exit	error, exit
<code>\${parameter?word}</code>	substitute <i>parameter</i>	substitute null	error, exit
<code>\${parameter:+word}</code>	substitute <i>word</i>	substitute null	substitute null
<code>\${parameter+word}</code>	substitute <i>word</i>	substitute <i>word</i>	substitute null

In all cases shown with “substitute”, the expression is replaced with the value shown. In all cases shown with “assign” *parameter* is assigned that value, which also replaces the expression.

`${#parameter}` String Length. The length in characters of the value of *parameter*. If *parameter* is * or @, then all the positional parameters, starting with \$1, are substituted (separated by a field separator character).

The following four varieties of parameter expansion provide for substring processing. In each case, pattern matching notation (see `patmat`), rather than regular expression notation, will be used to evaluate the patterns. If *parameter* is * or @, then all the positional parameters, starting with \$1, are substituted (separated by a field separator character). Enclosing the full parameter expansion string in double-quotes will not cause the following four varieties of pattern characters to be quoted, whereas quoting characters within the braces will have this effect.

`${parameter%word}` Remove Smallest Suffix Pattern. The *word* will be expanded to produce a pattern. The parameter expansion then will result in *parameter*, with the smallest portion of the suffix matched by the *pattern* deleted.

`${parameter%%word}` Remove Largest Suffix Pattern. The *word* will be expanded to produce a pattern. The parameter expansion then will result in *parameter*, with the largest portion of the suffix matched by the *pattern* deleted.

ksh(1)

`${parameter#word}` Remove Smallest Prefix Pattern. The *word* will be expanded to produce a pattern. The parameter expansion then will result in *parameter*, with the smallest portion of the prefix matched by the *pattern* deleted.

`${parameter##word}` Remove Largest Prefix Pattern. The *word* will be expanded to produce a pattern. The parameter expansion then will result in *parameter*, with the largest portion of the prefix matched by the *pattern* deleted.

Examples:

`${parameter:-word}`

In this example, `ls` is executed only if `x` is null or unset. (The `$(ls)` command substitution notation is explained in Command Substitution above.)

```
$(x:-$(ls))
```

`${parameter:=word}`

```
unset X
echo ${X:=abc}
abc
```

`${parameter:?word}`

```
unset posix
echo ${posix:?}
sh: posix: parameter null or not set
```

`${parameter:+word}`

```
set a b c
echo ${3:+posix}
posix
```

`${#parameter}`

```
HOME=/usr/posix
echo ${#HOME}
10
```

`${parameter%word}`

```
x=file.c
echo ${x%.c}.o
file.o
```

`${parameter%%word}`

```
x=posix/src/std
echo ${x%%/*}
posix
```

```

${parameter#word}

```

```

x=$HOME/src/cmd
echo ${x#$HOME}

Parameters Set by Shell

The following parameters are automatically set by the shell:

#	The number of positional parameters in decimal.
-	Flags supplied to the shell on invocation or by the <code>set</code> command.
?	The decimal value returned by the last executed command.
\$	The process number of this shell.
_	Initially, the value of <code>_</code> is an absolute pathname of the shell or script being executed as passed in the <i>environment</i> . Subsequently it is assigned the last argument of the previous command. This parameter is not set for commands which are asynchronous. This parameter is also used to hold the name of the matching <code>MAIL</code> file when checking for mail.
!	The process number of the last background command invoked.
ERRNO	The value of <code>errno</code> as set by the most recently failed system call. This value is system dependent and is intended for debugging purposes.
LINENO	The line number of the current line within the script or function being executed.
OLDPWD	The previous working directory set by the <code>cd</code> command.
OPTARG	The value of the last option argument processed by the <code>getopts</code> special command.
OPTIND	The index of the last option argument processed by the <code>getopts</code> special command.
PPID	The process number of the parent of the shell.
PWD	The present working directory set by the <code>cd</code> command.
RANDOM	Each time this variable is referenced, a random integer, uniformly distributed between 0 and 32767, is generated. The sequence of random numbers can be initialized by assigning a numeric value to <code>RANDOM</code> .
REPLY	This variable is set by the <code>select</code> statement and by the <code>read</code> special command when no arguments are supplied.

ksh(1)

Variables Used by Shell

SECONDS	Each time this variable is referenced, the number of seconds since shell invocation is returned. If this variable is assigned a value, then the value returned upon reference will be the value that was assigned plus the number of seconds since the assignment.
The following variables are used by the shell:	
CDPATH	The search path for the <code>cd</code> command.
COLUMNS	If this variable is set, the value is used to define the width of the edit window for the shell edit modes and for printing <code>select</code> lists.
EDITOR	If the value of this variable ends in <code>emacs</code> , <code>gmacs</code> , or <code>vi</code> and the <code>VISUAL</code> variable is not set, then the corresponding option (see the <code>set</code> special command below) will be turned on.
ENV	<p>This variable, when the shell is invoked, is subjected to parameter expansion by the shell and the resulting value is used as a pathname of a file containing shell commands to execute in the current environment. The file need not be executable. If the expanded value of <code>ENV</code> is not an absolute pathname, the results are unspecified. <code>ENV</code> will be ignored if the user's real and effective user IDs or real and effective group IDs are different.</p> <p>This variable can be used to set aliases and other items local to the invocation of a shell. The file referred to by <code>ENV</code> differs from <code>\$HOME/.profile</code> in that <code>.profile</code> is typically executed at session startup, whereas the <code>ENV</code> file is executed at the beginning of each shell invocation. The <code>ENV</code> value is interpreted in a manner similar to a dot script, in that the commands are executed in the current environment and the file needs to be readable, but not executable. However, unlike dot scripts, no <code>PATH</code> searching is performed. This is used as a guard against Trojan Horse security breaches.</p>
FCEDIT	The default editor name for the <code>fc</code> command.
FPATH	The search path for function definitions. By default, the <code>FPATH</code> directories are searched after the <code>PATH</code> variable. If an executable file is found, then it is read and executed in the current environment. <code>FPATH</code> is searched before <code>PATH</code> when a function with the <code>-u</code> attribute is referenced. The preset alias <code>autoload</code> causes a function with the <code>-u</code> attribute to be created.
IFS	Internal field separators, normally <code>space</code> , <code>tab</code> , and <code>new-line</code> that are used to separate command words which result from command or parameter substitution and for separating words with the special command <code>read</code> . The first character of the <code>IFS</code> variable is used to separate arguments for the <code>\$*</code> substitution (See <code>Quoting</code> below).

HISTFILE	If this variable is set when the shell is invoked, then the value is the pathname of the file that will be used to store the command history. (See Command <code>re-entry</code> below.)
HISTSIZE	If this variable is set when the shell is invoked, then the number of previously entered commands that are accessible by this shell will be greater than or equal to this number. The default is 128.
HOME	The default argument (home directory) for the <code>cd</code> command.
LC_ALL	This variable provides a default value for the <code>LC_*</code> variables.
LC_COLLATE	This variable determines the behavior of range expressions, equivalence classes and multi-byte character collating elements within pattern matching.
LC_CTYPE	Determines how the shell handles characters. When <code>LC_CTYPE</code> is set to a valid value, the shell can display and handle text and filenames containing valid characters for that locale. If <code>LC_CTYPE</code> (see <code>environ(5)</code>) is not set in the environment, the operational behavior of the shell is determined by the value of the <code>LANG</code> environment variable. If <code>LC_ALL</code> is set, its contents are used to override both the <code>LANG</code> and the other <code>LC_*</code> variables.
LC_MESSAGES	This variable determines the language in which messages should be written.
LANG	Provide a default value for the internationalization variables that are unset or null. If any of the internationalization variables contains an invalid setting, the utility will behave as if none of the variables had been defined.
LINENO	This variable is set by the shell to a decimal number representing the current sequential line number (numbered starting with 1) within a script or function before it executes each command. If the user unsets or resets <code>LINENO</code> , the variable may lose its special meaning for the life of the shell. If the shell is not currently executing a script or function, the value of <code>LINENO</code> is unspecified.
LINES	If this variable is set, the value is used to determine the column length for printing <code>select</code> lists. Select lists will print vertically until about two-thirds of <code>LINES</code> lines are filled.
MAIL	If this variable is set to the name of a mail file <i>and</i> the <code>MAILPATH</code> variable is not set, then the shell informs the user of arrival of mail in the specified file.
MAILCHECK	This variable specifies how often (in seconds) the shell will check for changes in the modification time of any of the files specified by the <code>MAILPATH</code> or <code>MAIL</code> variables. The default value is 600 seconds. When the time has elapsed the shell will check before issuing the next prompt.

ksh(1)

MAILPATH	A colon (:) separated list of file names. If this variable is set, then the shell informs the user of any modifications to the specified files that have occurred within the last MAILCHECK seconds. Each file name can be followed by a ? and a message that will be printed. The message will undergo parameter substitution with the variable \$_ defined as the name of the file that has changed. The default message is you have mail in \$_.
NLSPATH	Determine the location of message catalogues for the processing of LC_MESSAGES.
PATH	The search path for commands (see Execution below). The user may not change PATH if executing under rksh (except in .profile).
PPID	This variable is set by the shell to the decimal process ID of the process that invoked the shell. In a subshell, PPID will be set to the same value as that of the parent of the current shell. For example, echo \$PPID and (echo \$PPID) would produce the same value.
PS1	The value of this variable is expanded for parameter substitution to define the primary prompt string which by default is "\$ ". The character ! in the primary prompt string is replaced by the command number (see Command Re-entry below). Two successive occurrences of ! will produce a single ! when the prompt string is printed.
PS2	Secondary prompt string, by default "> ".
PS3	Selection prompt string used within a select loop, by default "#? ".
PS4	The value of this variable is expanded for parameter substitution and precedes each line of an execution trace. If omitted, the execution trace prompt is "+ ".
SHELL	The pathname of the shell is kept in the environment. At invocation, if the basename of this variable is rsh, rksh, or krsh, then the shell becomes restricted.
TMOUT	If set to a value greater than zero, the shell will terminate if a command is not entered within the prescribed number of seconds after issuing the PS1 prompt. (Notice that the shell can be compiled with a maximum bound for this value which cannot be exceeded.)
VISUAL	If the value of this variable ends in emacs, gmacs, or vi, then the corresponding option (see Special Command set below) will be turned on.

The shell gives default values to PATH, PS1, PS2, PS3, PS4, MAILCHECK, FCEDIT, TMOUT, and IFS, while HOME, SHELL, ENV, and MAIL are not set at all by the shell (although HOME is set by login(1)). On some systems MAIL and SHELL are also set by login.

Blank Interpretation

After parameter and command substitution, the results of substitutions are scanned for the field separator characters (those found in IFS) and split into distinct arguments where such characters are found. Explicit null arguments (" ") or (' ') are retained. Implicit null arguments (those resulting from *parameters* that have no values) are removed.

File Name Generation

Following substitution, each command *word* is scanned for the characters *, ?, and [unless the -f option has been set. If one of these characters appears, the word is regarded as a *pattern*. The word is replaced with lexicographically sorted file names that match the pattern. If no file name is found that matches the pattern, the word is left unchanged. When a *pattern* is used for file name generation, the character period (.) at the start of a file name or immediately following a /, as well as the character / itself, must be matched explicitly. A file name beginning with a period will not be matched with a pattern with the period inside parentheses. That is, ls .@(r*) would locate a file named .restore, but ls @(.r*) would not. In other instances of pattern matching, the / and . are not treated specially.

* Matches any string, including the null string.

? Matches any single character.

[. . .] Matches any one of the enclosed characters. A pair of characters separated by – matches any character lexically between the pair, inclusive. If the first character following the opening "[" is a "!", then any character not enclosed is matched. A – can be included in the character set by putting it as the first or last character.

A *pattern-list* is a list of one or more patterns separated from each other with a |. Composite patterns can be formed with one or more of the following:

? (*pattern-list*) Optionally matches any one of the given patterns.

* (*pattern-list*) Matches zero or more occurrences of the given patterns.

+ (*pattern-list*) Matches one or more occurrences of the given patterns.

@ (*pattern-list*) Matches exactly one of the given patterns.

! (*pattern-list*) Matches anything, except one of the given patterns.

Quoting

Each of the *metacharacters* listed above (see Definitions) has a special meaning to the shell and causes termination of a word unless quoted. A character may be *quoted* (that is, made to stand for itself) by preceding it with a \ . The pair \ NEWLINE is removed. All characters enclosed between a pair of single quote marks (' ') are quoted. A single quote cannot appear within single quotes. Inside double quote marks

ksh(1)

	<p>(" "), parameter and command substitution occur and \ quotes the characters \ , ' , " , and \$. The meaning of \$* and @\$ is identical when not quoted or when used as a parameter assignment value or as a file name. However, when used as a command argument, \$* is equivalent to ``\$1\$d \$2d . . . '' , where <i>d</i> is the first character of the IFS variable, whereas @\$ is equivalent to \$1 \$2 . . . Inside grave quote marks (` `), \ quotes the characters \ , ' , and \$. If the grave quotes occur within double quotes, then \ also quotes the character " .</p> <p>The special meaning of reserved words or aliases can be removed by quoting any character of the reserved word. The recognition of function names or special command names listed below cannot be altered by quoting them.</p>						
Arithmetic Evaluation	<p>An ability to perform integer arithmetic is provided with the special command <code>let</code>. Evaluations are performed using <i>long</i> arithmetic. Constants are of the form [<i>base#</i>] <i>n</i> where <i>base</i> is a decimal number between two and thirty-six representing the arithmetic base and <i>n</i> is a number in that base. If <i>base</i> is omitted then base 10 is used.</p> <p>An arithmetic expression uses the same syntax, precedence, and associativity of expression as the C language. All the integral operators, other than ++, --, ?:, and , are supported. Variables can be referenced by name within an arithmetic expression without using the parameter substitution syntax. When a variable is referenced, its value is evaluated as an arithmetic expression.</p> <p>An internal integer representation of a <i>variable</i> can be specified with the <code>-i</code> option of the <code>typeset</code> special command. Arithmetic evaluation is performed on the value of each assignment to a variable with the <code>-i</code> attribute. If you do not specify an arithmetic base, the first assignment to the variable determines the arithmetic base. This base is used when parameter substitution occurs.</p> <p>Since many of the arithmetic operators require quoting, an alternative form of the <code>let</code> command is provided. For any command which begins with a ((, all the characters until a matching)) are treated as a quoted expression. More precisely, ((. . .)) is equivalent to <code>let " . . . "</code>.</p>						
Prompting	<p>When used interactively, the shell prompts with the parameter expanded value of PS1 before reading a command. If at any time a new-line is typed and further input is needed to complete a command, then the secondary prompt (that is, the value of PS2) is issued.</p>						
Conditional Expressions	<p>A <i>conditional expression</i> is used with the [[compound command to test attributes of files and to compare strings. Word splitting and file name generation are not performed on the words between [[and]] . Each expression can be constructed from one or more of the following unary or binary expressions:</p> <table border="0"><tr><td>-a <i>file</i></td><td>True, if <i>file</i> exists.</td></tr><tr><td>-b <i>file</i></td><td>True, if <i>file</i> exists and is a block special file.</td></tr><tr><td>-c <i>file</i></td><td>True, if <i>file</i> exists and is a character special file.</td></tr></table>	-a <i>file</i>	True, if <i>file</i> exists.	-b <i>file</i>	True, if <i>file</i> exists and is a block special file.	-c <i>file</i>	True, if <i>file</i> exists and is a character special file.
-a <i>file</i>	True, if <i>file</i> exists.						
-b <i>file</i>	True, if <i>file</i> exists and is a block special file.						
-c <i>file</i>	True, if <i>file</i> exists and is a character special file.						

<code>-d file</code>	True, if <i>file</i> exists and is a directory.
<code>-e file</code>	True, if <i>file</i> exists.
<code>-f file</code>	True, if <i>file</i> exists and is an ordinary file.
<code>-g file</code>	True, if <i>file</i> exists and is has its setgid bit set.
<code>-k file</code>	True, if <i>file</i> exists and is has its sticky bit set.
<code>-n string</code>	True, if length of <i>string</i> is non-zero.
<code>-o option</code>	True, if option named <i>option</i> is on.
<code>-p file</code>	True, if <i>file</i> exists and is a fifo special file or a pipe.
<code>-r file</code>	True, if <i>file</i> exists and is readable by current process.
<code>-s file</code>	True, if <i>file</i> exists and has size greater than zero.
<code>-t fildes</code>	True, if file descriptor number <i>fildes</i> is open and associated with a terminal device.
<code>-u file</code>	True, if <i>file</i> exists and has its setuid bit set.
<code>-w file</code>	True, if <i>file</i> exists and is writable by current process.
<code>-x file</code>	True, if <i>file</i> exists and is executable by current process. If <i>file</i> exists and is a directory, then the current process has permission to search in the directory.
<code>-z string</code>	True, if length of <i>string</i> is zero.
<code>-L file</code>	True, if <i>file</i> exists and is a symbolic link.
<code>-O file</code>	True, if <i>file</i> exists and is owned by the effective user id of this process.
<code>-G file</code>	True, if <i>file</i> exists and its group matches the effective group id of this process.
<code>-S file</code>	True, if <i>file</i> exists and is a socket.
<code>file1 -nt file2</code>	True, if <i>file1</i> exists and is newer than <i>file2</i> .
<code>file1 -ot file2</code>	True, if <i>file1</i> exists and is older than <i>file2</i> .
<code>file1 -ef file2</code>	True, if <i>file1</i> and <i>file2</i> exist and refer to the same file.
<code>string</code>	True if the string <i>string</i> is not the null string.
<code>string = pattern</code>	True, if <i>string</i> matches <i>pattern</i> .
<code>string != pattern</code>	True, if <i>string</i> does not match <i>pattern</i> .
<code>string1=string2</code>	True if the strings <i>string1</i> and <i>string2</i> are identical.
<code>string1! =string2</code>	True if the strings <i>string1</i> and <i>string2</i> are not identical.

ksh(1)

<i>string1</i> < <i>string2</i>	True, if <i>string1</i> comes before <i>string2</i> based on strings interpreted as appropriate to the locale setting for category LC_COLLATE.
<i>string1</i> > <i>string2</i>	True, if <i>string1</i> comes after <i>string2</i> based on strings interpreted as appropriate to the locale setting for category LC_COLLATE.
<i>exp1</i> -eq <i>exp2</i>	True, if <i>exp1</i> is equal to <i>exp2</i> .
<i>exp1</i> -ne <i>exp2</i>	True, if <i>exp1</i> is not equal to <i>exp2</i> .
<i>exp1</i> -lt <i>exp2</i>	True, if <i>exp1</i> is less than <i>exp2</i> .
<i>exp1</i> -gt <i>exp2</i>	True, if <i>exp1</i> is greater than <i>exp2</i> .
<i>exp1</i> -le <i>exp2</i>	True, if <i>exp1</i> is less than or equal to <i>exp2</i> .
<i>exp1</i> -ge <i>exp2</i>	True, if <i>exp1</i> is greater than or equal to <i>exp2</i> .

In each of the above expressions, if *file* is of the form */dev/fd/n*, where *n* is an integer, then the test is applied to the open file whose descriptor number is *n*.

A compound expression can be constructed from these primitives by using any of the following, listed in decreasing order of precedence.

(<i>expression</i>)	True, if <i>expression</i> is true. Used to group expressions.
! <i>expression</i>	True if <i>expression</i> is false.
<i>expression1</i> && <i>expression2</i>	True, if <i>expression1</i> and <i>expression2</i> are both true.
<i>expression1</i> <i>expression2</i>	True, if either <i>expression1</i> or <i>expression2</i> is true.

Input/Output

Before a command is executed, its input and output may be redirected using a special notation interpreted by the shell. The following may appear anywhere in a simple-command or may precede or follow a *command* and are *not* passed on to the invoked command. Command and parameter substitution occur before *word* or *digit* is used except as noted below. File name generation occurs only if the pattern matches a single file, and blank interpretation is not performed.

< <i>word</i>	Use file <i>word</i> as standard input (file descriptor 0).
> <i>word</i>	Use file <i>word</i> as standard output (file descriptor 1). If the file does not exist then it is created. If the file exists, and the <code>noclobber</code> option is on, this causes an error; otherwise, it is truncated to zero length.
> <i>word</i>	Sames as >, except that it overrides the <code>noclobber</code> option.

<code>>>word</code>	Use file <i>word</i> as standard output. If the file exists, output is appended to it (by first seeking to the EOF). Otherwise, the file is created.
<code><>word</code>	Open file <i>word</i> for reading and writing as standard input.
<code><< [-] word</code>	The shell input is read up to a line that is the same as <i>word</i> , or to an EOF. No parameter substitution, command substitution, or file name generation is performed on <i>word</i> . The resulting document, called a <i>here-document</i> , becomes the standard input. If any character of <i>word</i> is quoted, no interpretation is placed upon the characters of the document. Otherwise, parameter and command substitution occur, <code>\NEWLINE</code> is ignored, and <code>\</code> must be used to quote the characters <code>\</code> , <code>\$</code> , <code>`</code> , and the first character of <i>word</i> . If <code>-</code> is appended to <code><<</code> , then all leading tabs are stripped from <i>word</i> and from the document.
<code><&digit</code>	The standard input is duplicated from file descriptor <i>digit</i> (see <code>dup(2)</code>). Similarly for the standard output using <code>>&digit</code> .
<code><&-</code>	The standard input is closed. Similarly for the standard output using <code>>&-</code> .
<code><&p</code>	The input from the co-process is moved to standard input.
<code>>&p</code>	The output to the co-process is moved to standard output.

If one of the above is preceded by a digit, then the file descriptor number referred to is that specified by the digit (instead of the default 0 or 1). For example:

```
... 2>&1
```

means file descriptor 2 is to be opened for writing as a duplicate of file descriptor 1.

The order in which redirections are specified is significant. The shell evaluates each redirection in terms of the (*file descriptor*, *file*) association at the time of evaluation. For example:

```
... 1>fname 2>&1
```

first associates file descriptor 1 with file *fname*. It then associates file descriptor 2 with the file associated with file descriptor 1 (that is, *fname*). If the order of redirections were reversed, file descriptor 2 would be associated with the terminal (assuming file descriptor 1 had been) and then file descriptor 1 would be associated with file *fname*.

ksh(1)

If a command is followed by `&` and job control is not active, then the default standard input for the command is the empty file `/dev/null`. Otherwise, the environment for the execution of a command contains the file descriptors of the invoking shell as modified by input/output specifications.

Environment

The *environment* (see `environ(5)`) is a list of name-value pairs that is passed to an executed program in the same way as a normal argument list. The names must be *identifiers* and the values are character strings. The shell interacts with the environment in several ways. On invocation, the shell scans the environment and creates a variable for each name found, giving it the corresponding value and marking it *export*. Executed commands inherit the environment. If the user modifies the values of these variables or creates new ones, using the `export` or `typeset -x` commands, they become part of the environment. The environment seen by any executed command is thus composed of any name-value pairs originally inherited by the shell, whose values may be modified by the current shell, plus any additions which must be noted in `export` or `typeset -x` commands.

The environment for any *simple-command* or *function* may be augmented by prefixing it with one or more variable assignments. A variable assignment argument is a word of the form *identifier=value*. Thus:

```
TERM=450 cmd args
```

and

```
(export TERM; TERM=450; cmd args)
```

are equivalent (as far as the above execution of *cmd* is concerned, except for special commands listed below that are preceded with an asterisk).

If the `-k` flag is set, *all* variable assignment arguments are placed in the environment, even if they occur after the command name. The following first prints `a=b c` and then `c`:

```
echo a=b c
set -k echo
a=b c
```

This feature is intended for use with scripts written for early versions of the shell and its use in new scripts is strongly discouraged. It is likely to disappear someday.

Functions

The `function` reserved word, described in the `Commands` section above, is used to define shell functions. Shell functions are read in and stored internally. Alias names are resolved when the function is read. Functions are executed like commands with the arguments passed as positional parameters. (See `Execution` below.)

Functions execute in the same process as the caller and share all files and present working directory with the caller. Traps caught by the caller are reset to their default action inside the function. A trap condition that is not caught or ignored by the function causes the function to terminate and the condition to be passed on to the caller.

A trap on `EXIT` set inside a function is executed after the function completes in the environment of the caller. This is true only for non-POSIX-style functions, that is, functions declared as

```
function func
as opposed to POSIX-style functions, declared as
func ()
```

Ordinarily, variables are shared between the calling program and the function. However, the `typeset` special command used within a function defines local variables whose scope includes the current function and all functions it calls.

The special command `return` is used to return from function calls. Errors within functions return control to the caller.

The names of all functions can be listed with `typeset+f`. `typeset -f` lists all function names as well as the text of all functions. `typeset -f function-names` lists the text of the named functions only. Functions can be undefined with the `-f` option of the `unset` special command.

Ordinarily, functions are `unset` when the shell executes a shell script. The `-xf` option of the `typeset` command allows a function to be exported to scripts that are executed without a separate invocation of the shell. Functions that need to be defined across separate invocations of the shell should be specified in the `ENV` file with the `-xf` option of `typeset`.

Function Definition Command

A function is a user-defined name that is used as a simple command to call a compound command with new positional parameters. A function is defined with a *function definition command*.

The format of a function definition command is as follows:

```
fname () compound-command[io-redirect . . .]
```

The function is named `fname`; it must be a name. An implementation may allow other characters in a function name as an extension. The implementation will maintain separate name spaces for functions and variables.

The `()` in the function definition command consists of two operators. Therefore, intermixing blank characters with the `fname`, `(`, and `)` is allowed, but unnecessary.

The argument *compound-command* represents a compound command.

ksh(1)

When the function is declared, none of the expansions in `wordexp` will be performed on the text in *compound-command* or *io-redirect*; all expansions will be performed as normal each time the function is called. Similarly, the optional *io-redirect* redirections and any variable assignments within *compound-command* will be performed during the execution of the function itself, not the function definition.

When a function is executed, it will have the syntax-error and variable-assignment properties described for the special built-in utilities.

The *compound-command* will be executed whenever the function name is specified as the name of a simple command. The operands to the command temporarily will become the positional parameters during the execution of the *compound-command*; the special parameter `#` will also be changed to reflect the number of operands. The special parameter `0` will be unchanged. When the function completes, the values of the positional parameters and the special parameter `#` will be restored to the values they had before the function was executed. If the special built-in `return` is executed in the *compound-command*, the function will complete and execution will resume with the next command after the function call.

An example of how a function definition can be used wherever a simple command is allowed:

```
# If variable i is equal to "yes",
# define function foo to be ls -l
#
[ "$i" = yes ] && foo() {
    ls -l
}
```

The exit status of a function definition will be `0` if the function was declared successfully; otherwise, it will be greater than zero. The exit status of a function invocation will be the exit status of the last command executed by the function.

Jobs If the `monitor` option of the `set` command is turned on, an interactive shell associates a `job` with each pipeline. It keeps a table of current jobs, printed by the `jobs` command, and assigns them small integer numbers. When a job is started asynchronously with `&`, the shell prints a line which looks like:

```
[1] 1234
```

indicating that the `job`, which was started asynchronously, was job number `1` and had one (top-level) process, whose process id was `1234`.

If you are running a job and wish to do something else you may press the key `^Z` (Control-Z) which sends a `STOP` signal to the current job. The shell will then normally indicate that the job has been '`Stopped`', and print another prompt. You can then manipulate the state of this job, putting it in the background with the `bg` command, or run some other commands and then eventually bring the job back into the foreground with the foreground command `fg`. A `^Z` takes effect immediately and is like an interrupt in that pending output and unread input are discarded when it is typed.

A job being run in the background will stop if it tries to read from the terminal. Background jobs are normally allowed to produce output, but this can be disabled by giving the command `"stty tostop"`. If you set this tty option, then background jobs will stop when they try to produce output as they do when they try to read input.

There are several ways to refer to jobs in the shell. A job can be referred to by the process id of any process of the job or by one of the following:

<code>%number</code>	The job with the given number.
<code>%string</code>	Any job whose command line begins with <i>string</i> .
<code>%?string</code>	Any job whose command line contains <i>string</i> .
<code>%%</code>	Current job.
<code>%+</code>	Equivalent to <code>%%</code> .
<code>%-</code>	Previous job.

The shell learns immediately whenever a process changes state. It normally informs you whenever a job becomes blocked so that no further progress is possible, but only just before it prints a prompt. This is done so that it does not otherwise disturb your work.

When the monitor mode is on, each background job that completes triggers any trap set for CHLD.

When you try to leave the shell while jobs are running or stopped, you will be warned with the message, 'You have stopped (running) jobs.' You may use the `jobs` command to see what they are. If you do this or immediately try to exit again, the shell will not warn you a second time, and the stopped jobs will be terminated. If you have `nohup`'ed jobs running when you attempt to logout, you will be warned with the message:

```
You have jobs running.
```

You will then need to logout a second time to actually logout. However, your background jobs will continue to run.

Signals The `INT` and `QUIT` signals for an invoked command are ignored if the command is followed by `&` and the `monitor` option is not active. Otherwise, signals have the values inherited by the shell from its parent (but see also the `trap` special command below).

Execution Each time a command is executed, the above substitutions are carried out. If the command name matches one of the `Special Commands` listed below, it is executed within the current shell process. Next, the command name is checked to see if it matches one of the user defined functions. If it does, the positional parameters are saved and then reset to the arguments of the `function` call. When the `function` completes or issues a `return`, the positional parameter list is restored and any trap set on `EXIT` within the function is executed. The value of a `function` is the value of the

ksh(1)

last command executed. A function is also executed in the current shell process. If a command name is not a `special` command or a user defined function, a process is created and an attempt is made to execute the command via `exec(2)`.

The shell variable `PATH` defines the search path for the directory containing the command. Alternative directory names are separated by a colon (:). The default path is `/bin:/usr/bin:` (specifying `/bin`, `/usr/bin`, and the current directory in that order). The current directory can be specified by two or more adjacent colons, or by a colon at the beginning or end of the path list. If the command name contains a / then the search path is not used. Otherwise, each directory in the path is searched for an executable file. If the file has execute permission but is not a directory or an `a.out` file, it is assumed to be a file containing shell commands. A sub-shell is spawned to read it. All non-exported aliases, functions, and variables are removed in this case. A parenthesized command is executed in a sub-shell without removing non-exported quantities.

**Command
Re-entry**

The text of the last `HISTSIZE` (default 128) commands entered from a terminal device is saved in a `history` file. The file `$HOME/.sh_history` is used if the `HISTFILE` variable is not set or if the file it names is not writable. A shell can access the commands of all *interactive* shells which use the same named `HISTFILE`. The special command `fc` is used to list or edit a portion of this file. The portion of the file to be edited or listed can be selected by number or by giving the first character or characters of the command. A single command or range of commands can be specified. If you do not specify an editor program as an argument to `fc` then the value of the variable `FCEDIT` is used. If `FCEDIT` is not defined, then `/bin/ed` is used. The edited command(s) is printed and re-executed upon leaving the editor. The editor name `-` is used to skip the editing phase and to re-execute the command. In this case a substitution parameter of the form `old=new` can be used to modify the command before execution. For example, if `r` is aliased to `'fc -e -'` then typing `'r bad=good c'` will re-execute the most recent command which starts with the letter `c`, replacing the first occurrence of the string `bad` with the string `good`.

**In-line Editing
Option**

Normally, each command line entered from a terminal device is simply typed followed by a new-line (RETURN or LINEFEED). If either the `emacs`, `gmacs`, or `vi` option is active, the user can edit the command line. To be in either of these edit modes set the corresponding option. An editing option is automatically selected each time the `VISUAL` or `EDITOR` variable is assigned a value ending in either of these option names.

The editing features require that the user's terminal accept RETURN as carriage return without line feed and that a space must overwrite the current character on the screen.

The editing modes implement a concept where the user is looking through a window at the current line. The window width is the value of `COLUMNS` if it is defined, otherwise 80. If the window width is too small to display the prompt and leave at least 8 columns to enter input, the prompt is truncated from the left. If the line is longer than the window width minus two, a mark is displayed at the end of the window to

notify the user. As the cursor moves and reaches the window boundaries the window will be centered about the cursor. The mark is a > if the line extends on the right side of the window, < if the line extends on the left, and * if the line extends on both sides of the window.

The search commands in each edit mode provide access to the history file. Only strings are matched, not patterns, although a leading caret (^) in the string restricts the match to begin at the first character in the line.

emacs Editing Mode

This mode is entered by enabling either the `emacs` or `gmacs` option. The only difference between these two modes is the way they handle ^T. To edit, move the cursor to the point needing correction and then insert or delete characters or words as needed. All the editing commands are control characters or escape sequences. The notation for control characters is caret (^) followed by the character. For example, ^F is the notation for control F. This is entered by depressing 'f' while holding down the CTRL (control) key. The SHIFT key is *not* depressed. (The notation ^? indicates the DEL (delete) key.)

The notation for escape sequences is M- followed by a character. For example, M-f (pronounced Meta f) is entered by depressing ESC (ascii 033) followed by 'f'. (M-F would be the notation for ESC followed by SHIFT (capital) 'F'.)

All edit commands operate from any place on the line (not just at the beginning). Neither the RETURN nor the LINEFEED key is entered after edit commands except when noted.

^F	Move cursor forward (right) one character.
M-f	Move cursor forward one word. (The emacs editor's idea of a word is a string of characters consisting of only letters, digits and underscores.)
^B	Move cursor backward (left) one character.
M-b	Move cursor backward one word.
^A	Move cursor to start of line.
^E	Move cursor to end of line.
^] <i>char</i>	Move cursor forward to character <i>char</i> on current line.
M-^] <i>char</i>	Move cursor backward to character <i>char</i> on current line.
^X^X	Interchange the cursor and mark.
<i>erase</i>	(User defined erase character as defined by the <code>stty(1)</code> command, usually ^H or #.) Delete previous character.
^D	Delete current character.
M-d	Delete current word.
M-^H	(Meta-backspace) Delete previous word.

ksh(1)

M-h	Delete previous word.
M-^?	(Meta-DEL) Delete previous word (if your interrupt character is ^? (DEL, the default) then this command will not work).
^T	Transpose current character with next character in <code>emacs</code> mode. Transpose two previous characters in <code>gmacs</code> mode.
^C	Capitalize current character.
M-c	Capitalize current word.
M-l	Change the current word to lower case.
^K	Delete from the cursor to the end of the line. If preceded by a numerical parameter whose value is less than the current cursor position, then delete from given position up to the cursor. If preceded by a numerical parameter whose value is greater than the current cursor position, then delete from cursor up to given cursor position.
^W	Kill from the cursor to the mark.
M-p	Push the region from the cursor to the mark on the stack.
<i>kill</i>	(User defined kill character as defined by the <code>stty(1)</code> command, usually ^G or @.) Kill the entire current line. If two <i>kill</i> characters are entered in succession, all kill characters from then on cause a line feed (useful when using paper terminals).
^Y	Restore last item removed from line. (Yank item back to the line.)
^L	Line feed and print current line.
^@	(null character) Set mark.
M-space	(Meta space) Set mark.
J	(New line) Execute the current line.
M	(Return) Execute the current line.
<i>eof</i>	End-of-file character, normally ^D, is processed as an End-of-file only if the current line is null.
^P	Fetch previous command. Each time ^P is entered the previous command back in time is accessed. Moves back one line when not on the first line of a multi-line command.
M-<	Fetch the least recent (oldest) history line.
M->	Fetch the most recent (youngest) history line.
^N	Fetch next command line. Each time ^N is entered the next command line forward in time is accessed.

^R <i>string</i>	Reverse search history for a previous command line containing <i>string</i> . If a parameter of zero is given, the search is forward. <i>string</i> is terminated by a RETURN or NEW LINE. If <i>string</i> is preceded by a ^, the matched line must begin with <i>string</i> . If <i>string</i> is omitted, then the next command line containing the most recent <i>string</i> is accessed. In this case a parameter of zero reverses the direction of the search.
^O	Operate. Execute the current line and fetch the next line relative to current line from the history file.
M- <i>digits</i>	(Escape) Define numeric parameter, the digits are taken as a parameter to the next command. The commands that accept a parameter are ^F, ^B, <i>erase</i> , ^C, ^D, ^K, ^R, ^P, ^N, ^], M-. , M-^], M-_, M-b, M-c, M-d, M-f, M-h, M-l and M-^H.
M- <i>letter</i>	Soft-key. Your alias list is searched for an alias by the name <i>_letter</i> and if an alias of this name is defined, its value will be inserted on the input queue. The <i>letter</i> must not be one of the above meta-functions.
M- [<i>letter</i>	Soft-key. Your alias list is searched for an alias by the name <i>__letter</i> and if an alias of this name is defined, its value will be inserted on the input queue. The can be used to program functions keys on many terminals.
M-.	The last word of the previous command is inserted on the line. If preceded by a numeric parameter, the value of this parameter determines which word to insert rather than the last word.
M-__	Same as M-..
M-*	An asterisk is appended to the end of the word and a file name expansion is attempted.
M-ESC	File name completion. Replaces the current word with the longest common prefix of all filenames matching the current word with an asterisk appended. If the match is unique, a / is appended if the file is a directory and a space is appended if the file is not a directory.
M-=	List files matching current word pattern if an asterisk were appended.
^U	Multiply parameter of next command by 4.
\	Escape next character. Editing characters, the user's erase, kill and interrupt (normally ^?) characters may be entered in a command line or in a search string if preceded by a \ . The \ removes the next character's editing features (if any).
^V	Display version of the shell.

ksh(1)

	M-#	Insert a # at the beginning of the line and execute it. This causes a comment to be inserted in the history file.
vi Editing Mode		<p>There are two typing modes. Initially, when you enter a command you are in the <i>input</i> mode. To edit, enter <i>control</i> mode by typing ESC (033) and move the cursor to the point needing correction and then insert or delete characters or words as needed. Most control commands accept an optional repeat <i>count</i> prior to the command.</p> <p>When in <i>vi</i> mode on most systems, canonical processing is initially enabled and the command will be echoed again if the speed is 1200 baud or greater and it contains any control characters or less than one second has elapsed since the prompt was printed. The ESC character terminates canonical processing for the remainder of the command and the user can then modify the command line. This scheme has the advantages of canonical processing with the type-ahead echoing of raw mode.</p> <p>If the option <i>viraw</i> is also set, the terminal will always have canonical processing disabled. This mode is implicit for systems that do not support two alternate end of line delimiters, and may be helpful for certain terminals.</p>
Input Edit Commands		<p>By default the editor is in input mode.</p> <p><i>erase</i> (User defined erase character as defined by the <i>stty(1)</i> command, usually ^H or #.) Delete previous character.</p> <p>^W Delete the previous blank separated word.</p> <p>^D Terminate the shell.</p> <p>^V Escape next character. Editing characters and the user's erase or kill characters may be entered in a command line or in a search string if preceded by a ^v. The ^v removes the next character's editing features (if any).</p> <p>\ Escape the next <i>erase</i> or <i>kill</i> character.</p>
Motion Edit Commands		<p>These commands will move the cursor.</p> <p>[<i>count</i>]l Cursor forward (right) one character.</p> <p>[<i>count</i>]w Cursor forward one alpha-numeric word.</p> <p>[<i>count</i>]W Cursor to the beginning of the next word that follows a blank.</p> <p>[<i>count</i>]e Cursor to end of word.</p> <p>[<i>count</i>]E Cursor to end of the current blank delimited word.</p> <p>[<i>count</i>]h Cursor backward (left) one character.</p> <p>[<i>count</i>]b Cursor backward one word.</p> <p>[<i>count</i>]B Cursor to preceding blank separated word.</p> <p>[<i>count</i>] Cursor to column <i>count</i>.</p>

	[<i>count</i>]E <i>c</i>	Find the next character <i>c</i> in the current line.
	[<i>count</i>]F <i>c</i>	Find the previous character <i>c</i> in the current line.
	[<i>count</i>]t <i>c</i>	Equivalent to E followed by h.
	[<i>count</i>]T <i>c</i>	Equivalent to F followed by l.
	[<i>count</i>];	Repeats <i>count</i> times, the last single character find command, E, F, t, or T.
	[<i>count</i>],	Reverses the last single character find command <i>count</i> times.
	0	Cursor to start of line.
	^	Cursor to first non-blank character in line.
	\$	Cursor to end of line.
	%	Moves to balancing (,) , { , } , [, or] . If cursor is not on one of the above characters, the remainder of the line is searched for the first occurrence of one of the above characters first.
Search Edit Commands	These commands access your command history.	
	[<i>count</i>]k	Fetch previous command. Each time <i>k</i> is entered the previous command back in time is accessed.
	[<i>count</i>]-	Equivalent to k.
	[<i>count</i>]j	Fetch next command. Each time <i>j</i> is entered, the next command forward in time is accessed.
	[<i>count</i>]+	Equivalent to j.
	[<i>count</i>]G	The command number <i>count</i> is fetched. The default is the least recent history command.
	/ <i>string</i>	Search backward through history for a previous command containing <i>string</i> . <i>string</i> is terminated by a RETURN or NEWLINE. If <i>string</i> is preceded by a ^, the matched line must begin with <i>string</i> . If <i>string</i> is NULL, the previous string will be used.
	? <i>string</i>	Same as / except that search will be in the forward direction.
	n	Search for next match of the last pattern to / or ? commands.
	N	Search for next match of the last pattern to / or ?, but in reverse direction. Search history for the <i>string</i> entered by the previous / command.
Text Modification Edit Commands	These commands will modify the line.	
	a	Enter input mode and enter text after the current character.
	A	Append text to the end of the line. Equivalent to \$a.

ksh(1)

<code>[count]c</code> <i>motion</i> <code>c</code> <code>[count]</code> <i>motion</i>	Delete current character through the character that <i>motion</i> would move the cursor to and enter input mode. If <i>motion</i> is <code>c</code> , the entire line will be deleted and input mode entered.
<code>C</code>	Delete the current character through the end of line and enter input mode. Equivalent to <code>c\$</code> .
<code>[count]s</code>	Delete <i>count</i> characters and enter input mode.
<code>S</code>	Equivalent to <code>cc</code> .
<code>D</code>	Delete the current character through the end of line. Equivalent to <code>d\$</code> .
<code>[count]d</code> <i>motion</i> <code>d</code> <code>[count]</code> <i>motion</i>	Delete current character through the character that <i>motion</i> would move to. If <i>motion</i> is <code>d</code> , the entire line will be deleted.
<code>i</code>	Enter input mode and insert text before the current character.
<code>I</code>	Insert text before the beginning of the line. Equivalent to <code>0i</code> .
<code>[count]P</code>	Place the previous text modification before the cursor.
<code>[count]p</code>	Place the previous text modification after the cursor.
<code>R</code>	Enter input mode and replace characters on the screen with characters you type overlay fashion.
<code>[count]rc</code>	Replace the <i>count</i> character(s) starting at the current cursor position with <i>c</i> , and advance the cursor.
<code>[count]x</code>	Delete current character.
<code>[count]X</code>	Delete preceding character.
<code>[count].</code>	Repeat the previous text modification command.
<code>[count]~</code>	Invert the case of the <i>count</i> character(s) starting at the current cursor position and advance the cursor.
<code>[count]_</code>	Causes the <i>count</i> word of the previous command to be appended and input mode entered. The last word is used if <i>count</i> is omitted.
<code>*</code>	Causes an <code>*</code> to be appended to the current word and file name generation attempted. If no match is found, it rings the bell. Otherwise, the word is replaced by the matching pattern and input mode is entered.

Other Edit Commands	\	Filename completion. Replaces the current word with the longest common prefix of all filenames matching the current word with an asterisk appended. If the match is unique, a / is appended if the file is a directory and a space is appended if the file is not a directory.
	Miscellaneous commands.	
	[<i>count</i>]y <i>motion</i>	Yank current character through character that <i>motion</i> would move the cursor to and puts them into the delete buffer. The text and cursor are unchanged.
	y[<i>count</i>] <i>motion</i>	Yank current character through character that <i>motion</i> would move the cursor to and puts them into the delete buffer. The text and cursor are unchanged.
	Y	Yanks from current position to end of line. Equivalent to y\$.
	u	Undo the last text modifying command.
	U	Undo all the text modifying commands performed on the line.
	[<i>count</i>]v	Returns the command <code>fc -e</code> <code>\$(VISUAL:-\$(EDITOR:-vi))</code> <i>count</i> in the input buffer. If <i>count</i> is omitted, then the current line is used.
	^L	Line feed and print current line. Has effect only in control mode.
	J	(New line) Execute the current line, regardless of mode.
M	(Return) Execute the current line, regardless of mode.	
#	If the first character of the command is a #, then this command deletes this # and each # that follows a newline. Otherwise, sends the line after inserting a # in front of each line in the command. Useful for causing the current line to be inserted in the history as a comment and removing comments from previous comment commands in the history file.	
=	List the file names that match the current word if an asterisk were appended it.	
@ <i>letter</i>	Your alias list is searched for an alias by the name <u><i>letter</i></u> and if an alias of this name is defined, its value will be inserted on the input queue for processing.	
Special Commands	The following <i>simple-commands</i> are executed in the shell process. Input/Output redirection is permitted. Unless otherwise indicated, the output is written on file descriptor 1 and the exit status, when there is no syntax error, is 0. Commands that are preceded by one or two * (asterisks) are treated specially in the following ways:	

ksh(1)

1. Variable assignment lists preceding the command remain in effect when the command completes.
 2. I/O redirections are processed after variable assignments.
 3. Errors cause a script that contains them to abort.
 4. Words, following a command preceded by ****** that are in the format of a variable assignment, are expanded with the same rules as a variable assignment. This means that tilde substitution is performed after the = sign and word splitting and file name generation are not performed.
- *** : [*arg* . . .]
The command only expands parameters.
- *** . *file* [*arg* . . .]
Read the complete *file* then execute the commands. The commands are executed in the current shell environment. The search path specified by `PATH` is used to find the directory containing *file*. If any arguments *arg* are given, they become the positional parameters. Otherwise the positional parameters are unchanged. The exit status is the exit status of the last command executed.
- **** alias [-tx] [*name*[=*value*]] . . .
alias with no arguments prints the list of aliases in the form *name=value* on standard output. An *alias* is defined for each name whose *value* is given. A trailing space in *value* causes the next word to be checked for alias substitution. The -t flag is used to set and list tracked aliases. The value of a tracked alias is the full pathname corresponding to the given *name*. The value becomes undefined when the value of `PATH` is reset but the aliases remained tracked. Without the -t flag, for each *name* in the argument list for which no *value* is given, the name and value of the alias is printed. The -x flag is used to set or print *exported aliases*. An *exported alias* is defined for scripts invoked by name. The exit status is non-zero if a *name* is given, but no value, and no alias has been defined for the *name*.
- bg [%*job*. . .]
This command is only on systems that support job control. Puts each specified *job* into the background. The current job is put in the background if *job* is not specified. See "Jobs" section above for a description of the format of *job*.
- *** break [*n*]
Exit from the enclosed for, while, until, or select loop, if any. If *n* is specified then break *n* levels.
- *** continue [*n*]
Resume the next iteration of the enclosed for, while, until, or select loop. If *n* is specified then resume at the *n*-th enclosed loop.
- cd [*arg*]
cd *old new*
This command can be in either of two forms. In the first form it changes the current directory to *arg*. If *arg* is - the directory is changed to the previous directory. The shell variable `HOME` is the default *arg*. The variable `PWD` is set to the current directory. The shell variable `CDPATH` defines the search path for the directory

containing *arg*. Alternative directory names are separated by a colon (:). The default path is null (specifying the current directory). Notice that the current directory is specified by a null path name, which can appear immediately after the equal sign or between the colon delimiters anywhere else in the path list. If *arg* begins with a / then the search path is not used. Otherwise, each directory in the path is searched for *arg*.

The second form of `cd` substitutes the string *new* for the string *old* in the current directory name, `PWD` and tries to change to this new directory. The `cd` command may not be executed by `rksh`.

`command [-p] [command_name] [argument . . .]`

`command [-v -V] command_name`

The `command` utility causes the shell to treat the arguments as a simple command, suppressing the shell function lookup. The `-p` flag performs the command search using a default value for `PATH` that is guaranteed to find all of the standard utilities. The `-v` flag writes a string to standard output that indicates the pathname or command that will be used by the shell, in the current shell execution environment, to invoke *command_name*. The `-V` flag writes a string to standard output that indicates how the name given in the *command_name* operand will be interpreted by the shell, in the current shell execution environment.

`echo [arg . . .]`

See `echo(1)` for usage and description.

* `eval [arg . . .]`

The arguments are read as input to the shell and the resulting command(s) executed.

* `exec [arg . . .]`

If *arg* is given, the command specified by the arguments is executed in place of this shell without creating a new process. Input/output arguments may appear and affect the current process. If no arguments are given the effect of this command is to modify file descriptors as prescribed by the input/output redirection list. In this case, any file descriptor numbers greater than 2 that are opened with this mechanism are closed when invoking another program.

* `exit [n]`

Causes the calling shell or shell script to exit with the exit status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the exit status is that of the last command executed. When `exit` occurs when executing a trap, the last command refers to the command that executed before the trap was invoked. An EOF will also cause the shell to exit except for a shell which has the `ignoreeof` option (See `set` below) turned on.

** `export [name[=value]] . . .`

The given *names* are marked for automatic export to the environment of subsequently-executed commands.

`fc [-e ename] [-nlr] [first [last]]`

`fc -e - [old=new] [command]`

ksh(1)

In the first form, a range of commands from *first* to *last* is selected from the last HISTSIZE commands that were typed at the terminal. The arguments *first* and *last* may be specified as a number or as a string. A string is used to locate the most recent command starting with the given string. A negative number is used as an offset to the current command number. If the -1 flag is selected, the commands are listed on standard output. Otherwise, the editor program *ename* is invoked on a file containing these keyboard commands. If *ename* is not supplied, then the value of the variable FCEDIT (default /bin/ed) is used as the editor. When editing is complete, the edited command(s) is executed. If *last* is not specified then it will be set to *first*. If *first* is not specified the default is the previous command for editing and -16 for listing. The flag -r reverses the order of the commands and the flag -n suppresses command numbers when listing. In the second form the *command* is re-executed after the substitution *old=new* is performed. If there is not a *command* argument, the most recent command typed at this terminal is executed.

fg [%*job*. . .]

This command is only on systems that support job control. Each *job* specified is brought to the foreground. Otherwise, the current job is brought into the foreground. See "Jobs" section above for a description of the format of *job*.

getopts *optstring name* [*arg* . . .]

Checks *arg* for legal options. If *arg* is omitted, the positional parameters are used. An option argument begins with a + or a -. An option not beginning with + or - or the argument - ends the options. *optstring* contains the letters that *getopts* recognizes. If a letter is followed by a :, that option is expected to have an argument. The options can be separated from the argument by blanks.

getopts places the next option letter it finds inside variable *name* each time it is invoked with a + prepended when *arg* begins with a +. The index of the next *arg* is stored in OPTIND. The option argument, if any, gets stored in OPTARG.

A leading : in *optstring* causes *getopts* to store the letter of an invalid option in OPTARG, and to set *name* to ? for an unknown option and to : when a required option is missing. Otherwise, *getopts* prints an error message. The exit status is non-zero when there are no more options. See *getoptcv*(1) for usage and description.

hash [*name* . . .]

For each *name*, the location in the search path of the command specified by *name* is determined and remembered by the shell. The -r option causes the shell to forget all remembered locations. If no arguments are given, information about remembered commands is presented. *Hits* is the number of times a command has been invoked by the shell process. *Cost* is a measure of the work required to locate a command in the search path. If a command is found in a "relative" directory in the search path, after changing to that directory, the stored location of that command is recalculated. Commands for which this will be done are indicated by an asterisk (*) adjacent to the *hits* information. *Cost* will be incremented when the recalculation is done.

`jobs [-lnp] [%job ...]`

Lists information about each given job; or all active jobs if *job* is omitted. The `-l` flag lists process ids in addition to the normal information. The `-n` flag displays only jobs that have stopped or exited since last notified. The `-p` flag causes only the process group to be listed. See "Jobs" section above and `jobs(1)` for a description of the format of *job*.

`kill [-sig] %job ...`

`kill [-sig] pid ...`

`kill -l`

Sends either the TERM (terminate) signal or the specified signal to the specified jobs or processes. Signals are either given by number or by names (as given in `signal(3HEAD)` stripped of the prefix "SIG" with the exception that SIGCHD is named CHLD). If the signal being sent is TERM (terminate) or HUP (hangup), then the job or process will be sent a CONT (continue) signal if it is stopped. The argument *job* can be the process id of a process that is not a member of one of the active jobs. See Jobs for a description of the format of *job*. In the second form, `kill -l`, the signal numbers and names are listed.

`let arg ...`

Each *arg* is a separate *arithmetic expression* to be evaluated. See the Arithmetic Evaluation section above, for a description of arithmetic expression evaluation.

The exit status is 0 if the value of the last expression is non-zero, and 1 otherwise.

`login argument ...`

Equivalent to `'exec login argument. ...'` See `login(1)` for usage and description.

`*newgrp [arg ...]`

Equivalent to `exec /bin/newgrp arg ...`

`print [-Rnrpsu[n]] [arg ...]`

The shell output mechanism. With no flags or with flag `-` or `-`, the arguments are printed on standard output as described by `echo(1)`. The exit status is 0, unless the output file is not open for writing.

`-n` Suppress NEWLINE from being added to the output.

`-R | -r` Raw mode. Ignore the escape conventions of `echo`. The `-R` option will print all subsequent arguments and options other than `-n`.

`-p` Write the arguments to the pipe of the process spawned with `| &` instead of standard output.

`-s` Write the arguments to the history file instead of standard output.

`-u [n]` Specify a one digit file descriptor unit number *n* on which the output will be placed. The default is 1.

`pwd`

Equivalent to `print -r - $PWD`.

ksh(1)

`read [-prsu[n]] [name?prompt] [name . . .]`

The shell input mechanism. One line is read and is broken up into fields using the characters in IFS as separators. The escape character, (`\`), is used to remove any special meaning for the next character and for line continuation. In raw mode, `-r`, the `\` character is not treated specially. The first field is assigned to the first *name*, the second field to the second *name*, etc., with leftover fields assigned to the last *name*. The `-p` option causes the input line to be taken from the input pipe of a process spawned by the shell using `|&`. If the `-s` flag is present, the input will be saved as a command in the history file. The flag `-u` can be used to specify a one digit file descriptor unit *n* to read from. The file descriptor can be opened with the `exec` special command. The default value of *n* is 0. If *name* is omitted then `REPLY` is used as the default *name*. The exit status is 0 unless the input file is not open for reading or an EOF is encountered. An EOF with the `-p` option causes cleanup for this process so that another can be spawned. If the first argument contains a `?`, the remainder of this word is used as a *prompt* on standard error when the shell is interactive. The exit status is 0 unless an EOF is encountered.

`** readonly [name[=value]] . . .`

The given *names* are marked `readonly` and these names cannot be changed by subsequent assignment.

`* return [n]`

Causes a shell function or `'.'` script to return to the invoking script with the return status specified by *n*. The value will be the least significant 8 bits of the specified status. If *n* is omitted then the return status is that of the last command executed. If return is invoked while not in a function or a `'.'` script, then it is the same as an `exit`.

`set [±abCefhkmnopstuvx] [±o option] . . . [±A name] [arg . . .]`

The flags for this command have meaning as follows:

- `-A` Array assignment. Unset the variable *name* and assign values sequentially from the list *arg*. If `+A` is used, the variable *name* is not unset first.
- `-a` All subsequent variables that are defined are automatically exported.
- `-b` Causes the shell to notify the user asynchronously of background job completions. The following message will be written to standard error:

```
" [%d] %c %s%s\n", <job-number>, <current>, <status>, <job-name>
```

where the fields are as follows:

`<current>` The character `+` identifies the job that would be used as a default for the `fg` or `bg` utilities; this job can also be specified using the `job_id %+` or `%s`. The character `-` identifies the job that would become the default if the current default job were to exit; this job can also be specified using the `job_id %-`. For other jobs, this

field is a space character. At most one job can be identified with + and at most one job can be identified with -. If there is any suspended job, then the current job will be a suspended job. If there are at least two suspended jobs, then the previous job will also be a suspended job.

<i><job-number></i>	A number that can be used to identify the process group to the <code>wait</code> , <code>fg</code> , <code>bg</code> , and <code>kill</code> utilities. Using these utilities, the job can be identified by prefixing the job number with <code>%</code> .
<i><status></i>	Unspecified.
<i><job-name></i>	Unspecified.

When the shell notifies the user a job has been completed, it may remove the job's process ID from the list of those known in the current shell execution environment. Asynchronous notification will not be enabled by default.

- C Prevent existing files from being overwritten by the shell's `>` redirection operator. The `>|` redirection operator will override this `noclobber` option for an individual file.
- e If a command has a non-zero exit status, execute the ERR trap, if set, and exit. This mode is disabled while reading profiles.
- f Disables file name generation.
- h Each command becomes a tracked alias when first encountered.
- k All variable assignment arguments are placed in the environment for a command, not just those that precede the command name.
- m Background jobs will run in a separate process group and a line will print upon completion. The exit status of background jobs is reported in a completion message. On systems with job control, this flag is turned on automatically for interactive shells.
- n Read commands and check them for syntax errors, but do not execute them. Ignored for interactive shells.
- o The following argument can be one of the following option names:

<code>allexport</code>	Same as <code>-a</code> .
<code>errexit</code>	Same as <code>-e</code> .
<code>bgnice</code>	All background jobs are run at a lower priority. This is the default mode.
<code>emacs</code>	Puts you in an emacs style in-line editor for command entry.

ksh(1)

<code>gmacs</code>	Puts you in a <code>gmacs</code> style in-line editor for command entry.
<code>ignoreeof</code>	The shell will not exit on EOF. The command <code>exit</code> must be used.
<code>keyword</code>	Same as <code>-k</code> .
<code>markdirs</code>	All directory names resulting from file name generation have a trailing <code>/</code> appended.
<code>monitor</code>	Same as <code>-m</code> .
<code>noclobber</code>	Prevents redirection <code>></code> from truncating existing files. Require <code>> </code> to truncate a file when turned on. Equivalent to <code>-C</code> .
<code>noexec</code>	Same as <code>-n</code> .
<code>noglob</code>	Same as <code>-f</code> .
<code>nolog</code>	Do not save function definitions in history file.
<code>notify</code>	Equivalent to <code>-b</code> .
<code>nounset</code>	Same as <code>-u</code> .
<code>privileged</code>	Same as <code>-p</code> .
<code>verbose</code>	Same as <code>-v</code> .
<code>trackall</code>	Same as <code>-h</code> .
<code>vi</code>	Puts you in insert mode of a <code>vi</code> style in-line editor until you hit escape character <code>033</code> . This puts you in control mode. A return sends the line.
<code>viraw</code>	Each character is processed as it is typed in <code>vi</code> mode.
<code>xtrace</code>	Same as <code>-x</code> .

If no option name is supplied, the current option settings are printed.

<code>-p</code>	Disables processing of the <code>\$HOME/.profile</code> file and uses the file <code>/etc/suid_profile</code> instead of the <code>ENV</code> file. This mode is on whenever the effective uid is not equal to the real uid, or when the effective gid is not equal to the real gid. Turning this off causes the effective uid and gid to be set to the real uid and gid.
<code>-s</code>	Sort the positional parameters lexicographically.
<code>-t</code>	Exit after reading and executing one command.
<code>-u</code>	Treat unset parameters as an error when substituting.
<code>-v</code>	Print shell input lines as they are read.

- x Print commands and their arguments as they are executed.
 - Turns off -x and -v flags and stops examining arguments for flags.
 - Do not change any of the flags; useful in setting \$1 to a value beginning with -. If no arguments follow this flag then the positional parameters are unset.
- Using + rather than - causes these flags to be turned off. These flags can also be used upon invocation of the shell. The current set of flags may be found in \$-. Unless -A is specified, the remaining arguments are positional parameters and are assigned, in order, to \$1 \$2 If no arguments are given, the names and values of all variables are printed on the standard output.
- * shift [*n*]
 The positional parameters from \$*n*+1 \$*n*+1 . . . are renamed \$1 . . . , default *n* is 1. The parameter *n* can be any arithmetic expression that evaluates to a non-negative number less than or equal to \$#.
- stop%*jobid* . . .
- stop *pid* . . .
 stop stops the execution of a background job(s) by using its *jobid*, or of any process by using its *pid*. (see ps(1)).
- suspend
 Stops the execution of the current shell (but not if it is the login shell).
- test *expression*
 Evaluate conditional expressions. See Conditional Expressions section above and test(1) for usage and description.
- * times
 Print the accumulated user and system times for the shell and for processes run from the shell.
- * trap [*arg sig* . . .]
arg is a command to be read and executed when the shell receives signal(s) *sig*. *arg* is scanned once when the trap is set and once when the trap is taken. *sig* can be specified as a signal number or signal name. trap commands are executed in order of signal number. Any attempt to set a trap on a signal number that was ignored on entry to the current shell is ineffective.
- If *arg* is -, the shell will reset each *sig* to the default value. If *arg* is null (' '), the shell will ignore each specified *sig* if it arises. Otherwise, *arg* will be read and executed by the shell when one of the corresponding *sigs* arises. The action of the trap will override a previous action (either default action or one explicitly set). The value of \$? after the trap action completes will be the value it had before the trap was invoked.

ksh(1)

sig can be `EXIT`, `0` (equivalent to `EXIT`) or a signal specified using a symbolic name, without the `SIG` prefix, for example, `HUP`, `INT`, `QUIT`, `TERM`. If *sig* is `0` or `EXIT` and the `trap` statement is executed inside the body of a function, then the command *arg* is executed after the function completes. If *sig* is `0` or `EXIT` for a `trap` set outside any function, the command *arg* is executed on exit from the shell. If *sig* is `ERR`, *arg* will be executed whenever a command has a non-zero exit status. If *sig* is `DEBUG`, *arg* will be executed after each command.

The environment in which the shell executes a trap on `EXIT` will be identical to the environment immediately after the last command executed before the trap on `EXIT` was taken.

Each time the trap is invoked, *arg* will be processed in a manner equivalent to `eval "$arg"`.

Signals that were ignored on entry to a non-interactive shell cannot be trapped or reset, although no error need be reported when attempting to do so. An interactive shell may reset or catch signals ignored on entry. Traps will remain in place for a given shell until explicitly changed with another `trap` command.

When a subshell is entered, traps are set to the default args. This does not imply that the `trap` command cannot be used within the subshell to set new traps.

The `trap` command with no arguments will write to standard output a list of commands associated with each *sig*. The format is:

```
trap -- %s %s . . . <arg>, <sig> . . .
```

The shell will format the output, including the proper use of quoting, so that it is suitable for reinput to the shell as commands that achieve the same trapping results. For example:

```
save_traps=$(trap)
. . .
eval "$save_traps"
```

If the trap name or number is invalid, a non-zero exit status will be returned; otherwise, `0` will be returned. For both interactive and non-interactive shells, invalid signal names or numbers will not be considered a syntax error and will not cause the shell to abort.

Traps are not processed while a job is waiting for a foreground process. Thus, a trap on `CHLD` won't be executed until the foreground job terminates.

`type name . . .`

For each *name*, indicate how it would be interpreted if used as a command name.

**** typeset [`±HLRZfilrtux`[*n*]] [*name*[=*value*]] . . .**

Sets attributes and values for shell variables and functions. When `typeset` is invoked inside a function, a new instance of the variables *name* is created. The variables *value* and `type` are restored when the function completes. The following list of attributes may be specified:

- H This flag provides UNIX to host-name file mapping on non-UNIX machines.
- L Left justify and remove leading blanks from *value*. If *n* is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment. When the variable is assigned to, it is filled on the right with blanks or truncated, if necessary, to fit into the field. Leading zeros are removed if the -Z flag is also set. The -R flag is turned off.
- R Right justify and fill with leading blanks. If *n* is non-zero it defines the width of the field, otherwise it is determined by the width of the value of first assignment. The field is left filled with blanks or truncated from the end if the variable is reassigned. The -L flag is turned off.
- Z Right justify and fill with leading zeros if the first non-blank character is a digit and the -L flag has not been set. If *n* is non-zero it defines the width of the field; otherwise, it is determined by the width of the value of first assignment.
- f The names refer to function names rather than variable names. No assignments can be made and the only other valid flags are -t, -u, and -x. The flag -t turns on execution tracing for this function. The flag -u causes this function to be marked undefined. The FPATH variable will be searched to find the function definition when the function is referenced. The flag -x allows the function definition to remain in effect across shell procedures invoked by name.
- i Parameter is an integer. This makes arithmetic faster. If *n* is non-zero it defines the output arithmetic base; otherwise, the first assignment determines the output base.
- l All upper-case characters are converted to lower-case. The upper-case flag, -u is turned off.
- r The given *names* are marked `readonly` and these names cannot be changed by subsequent assignment.
- t Tags the variables. Tags are user definable and have no special meaning to the shell.
- u All lower-case characters are converted to upper-case characters. The lower-case flag, -l is turned off.
- x The given *names* are marked for automatic export to the environment of subsequently-executed commands.

The -i attribute can not be specified along with -R, -L, -Z, or -f.

ksh(1)

Using + rather than - causes these flags to be turned off. If no *name* arguments are given but flags are specified, a list of *names* (and optionally the *values*) of the *variables* which have these flags set is printed. (Using + rather than - keeps the values from being printed.) If no *names* and flags are given, the *names* and *attributes* of all *variables* are printed.

`ulimit [-HSacdfnstv] [limit]`

Set or display a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value *unlimited*. The H and S flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the H or S options is specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case the soft limit is printed unless H is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- a Lists all of the current resource limits.
- c The number of 512-byte blocks on the size of core dumps.
- d The number of K-bytes on the size of the data area.
- f The number of 512-byte blocks on files written by child processes (files of any size may be read).
- n The number of file descriptors plus 1.
- s The number of K-bytes on the size of the stack area.
- t The number of seconds to be used by each process.
- v The number of K-bytes for virtual memory.

If no option is given, -f is assumed.

`umask [-S] [mask]`

The user file-creation mask is set to *mask* (see `umask(2)`). *mask* can either be an octal number or a symbolic value as described in `chmod(1)`. If a symbolic value is given, the new umask value is the complement of the result of applying *mask* to the complement of the previous umask value. If *mask* is omitted, the current value of the mask is printed. The -S flag produces symbolic output.

`unalias name . . .`

The *aliases* given by the list of *names* are removed from the *alias* list.

`unset [-f] name . . .`

The variables given by the list of *names* are unassigned, that is, their values and attributes are erased. `readonly` variables cannot be unset. If the -f, flag is set, then the names refer to *function* names. Unsetting `ERRNO`, `LINENO`, `MAILCHECK`, `OPTARG`, `OPTIND`, `RANDOM`, `SECONDS`, `TMOU`T, and `_` removes their special meaning even if they are subsequently assigned to.

* wait [*job*]

Wait for the specified *job* and report its termination status. If *job* is not given then all currently active child processes are waited for. The exit status from this command is that of the process waited for. See `Jobs` for a description of the format of *job*.

whence [-pv] *name* . . .

For each *name*, indicate how it would be interpreted if used as a command name.

The -v flag produces a more verbose report.

The -p flag does a path search for *name* even if *name* is an alias, a function, or a reserved word.

Invocation

If the shell is invoked by `exec(2)`, and the first character of argument zero (`$0`) is `-`, then the shell is assumed to be a login shell and commands are read from `/etc/profile` and then from either `.profile` in the current directory or `$HOME/.profile`, if either file exists. Next, commands are read from the file named by performing parameter substitution on the value of the environment variable `ENV` if the file exists. If the `-s` flag is not present and *arg* is, then a path search is performed on the first *arg* to determine the name of the script to execute. The script *arg* must have read permission and any `setuid` and `setgid` settings will be ignored. If the script is not found on the path, *arg* is processed as if it named a builtin command or function. Commands are then read as described below; the following flags are interpreted by the shell when it is invoked:

- c Read commands from the *command_string* operand. Set the value of special parameter 0 from the value of the *command_name* operand and the positional parameters (`$1`, `$2`, and so on) in sequence from the remaining *arg* operands. No commands will be read from the standard input.
- s If the `-s` flag is present or if no arguments remain, commands are read from the standard input. Shell output, except for the output of the Special Commands listed above, is written to file descriptor 2.
- i If the `-i` flag is present or if the shell input and output are attached to a terminal (as told by `ioctl(2)`), then this shell is *interactive*. In this case, `TERM` is ignored (so that `kill 0` does not kill an interactive shell) and `INTR` is caught and ignored (so that `wait` is interruptible). In all cases, `QUIT` is ignored by the shell.
- r If the `-r` flag is present the shell is a restricted shell.

The remaining flags and arguments are described under the `set` command above.

rksh Only

`rksh` is used to set up login names and execution environments whose capabilities are more controlled than those of the standard shell. The actions of `rksh` are identical to those of `ksh`, except that the following are disallowed:

- changing directory (see `cd(1)`)
- setting the value of `SHELL`, `ENV`, or `PATH`
- specifying path or command names containing `/`

ksh(1)

- redirecting output (>, >|, <>, and >>)
- changing group (see `newgrp(1)`).

The restrictions above are enforced after `.profile` and the `ENV` files are interpreted.

When a command to be executed is found to be a shell procedure, `rksh` invokes `ksh` to execute it. Thus, it is possible to provide to the end-user shell procedures that have access to the full power of the standard shell, while imposing a limited menu of commands; this scheme assumes that the end-user does not have write and execute permissions in the same directory.

The net effect of these rules is that the writer of the `.profile` has complete control over user actions, by performing guaranteed setup actions and leaving the user in an appropriate directory (probably *not* the login directory).

The system administrator often sets up a directory of commands (that is, `/usr/rbin`) that can be safely invoked by `rksh`.

ERRORS

Errors detected by the shell, such as syntax errors, cause the shell to return a non-zero exit status. Otherwise, the shell returns the exit status of the last command executed (see also the `exit` command above). If the shell is being used non-interactively then execution of the shell file is abandoned. Run time errors detected by the shell are reported by printing the command or function name and the error condition. If the line number that the error occurred on is greater than one, then the line number is also printed in square brackets (`[]`) after the command or function name.

For a non-interactive shell, an error condition encountered by a special built-in or other type of utility will cause the shell to write a diagnostic message to standard error and exit as shown in the following table:

Error	Special Built-in	Other Utilities
Shell language syntax error	will exit	will exit
Utility syntax error (option or operand error)	will exit	will not exit
Redirection error	will exit	will not exit
Variable assignment error	will exit	will not exit
Expansion error	will exit	will exit
Command not found	n/a	may exit
Dot script not found	will exit	n/a

An expansion error is one that occurs when the shell expansions are carried out (for example, `${x!y}`, because `!` is not a valid operator); an implementation may treat these as syntax errors if it is able to detect them during tokenization, rather than during expansion.

If any of the errors shown as “will (may) exit” occur in a subshell, the subshell will (may) exit with a non-zero status, but the script containing the subshell will not exit because of the error.

In all of the cases shown in the table, an interactive shell will write a diagnostic message to standard error without exiting.

USAGE See `largefile(5)` for the description of the behavior of `ksh` and `rksh` when encountering files greater than or equal to 2 Gbyte (2^{31} bytes).

EXIT STATUS Each command has an exit status that can influence the behavior of other shell commands. The exit status of commands that are not utilities is documented in this section. The exit status of the standard utilities is documented in their respective sections.

If a command is not found, the exit status will be 127. If the command name is found, but it is not an executable utility, the exit status will be 126. Applications that invoke utilities without using the shell should use these exit status values to report similar errors.

If a command fails during word expansion or redirection, its exit status will be greater than zero.

When reporting the exit status with the special parameter `?`, the shell will report the full eight bits of exit status available. The exit status of a command that terminated because it received a signal will be reported as greater than 128.

WARNINGS The use of `setuid` shell scripts is *strongly* discouraged.

NOTES If a command which is a *tracked alias* is executed, and then a command with the same name is installed in a directory in the search path before the directory where the original command was found, the shell will continue to `exec` the original command. Use the `-t` option of the `alias` command to correct this situation.

Some very old shell scripts contain a `^` as a synonym for the pipe character `|`.

Using the `fc` built-in command within a compound command will cause the whole command to disappear from the history file.

The built-in command `. file` reads the whole file before any commands are executed. Therefore, `alias` and `unalias` commands in the file will not apply to any functions defined in the file.

When the shell executes a shell script that attempts to execute a non-existent command interpreter, the shell returns an erroneous diagnostic message that the shell script file does not exist.

- NAME** | ksrvtgt – fetch and store Kerberos ticket-granting ticket using a service key
- SYNOPSIS** | `/usr/bin/ksrvtgt name instance [[realm] srotab]`
- DESCRIPTION** | ksrvtgt retrieves a ticket-granting ticket with a lifetime of five minutes for the principal `name.instance@realm` (or `name.instance@localrealm` if `realm` is not supplied on the command line), decrypts the response using the service key found in the file `srotab` (or in `/etc/srvtab` if `srotab` is not specified on the command line), and stores the ticket in the standard ticket cache.
- This command is intended primarily for use in shell scripts and other batch-type facilities.
- DIAGNOSTICS** | Generic kerberos failure (`kfailure`) can indicate a whole range of problems, the most common of which is the inability to read the service key file.
- FILES** | `/etc/krb.conf` to get the name of the local realm.
`/tmp/tktuid` The default ticket file.
`/etc/srvtab` The default service key file.

ktutil(1)

NAME	ktutil – Kerberos keytab maintenance utility														
SYNOPSIS	<code>/usr/bin/ktutil</code>														
DESCRIPTION	The <code>ktutil</code> command is an interactive command-line interface utility for managing the keylist in keytab files. You must read in a keytab's keylist before you can manage it. Also, the user running the <code>ktutil</code> command must have read/write permissions on the keytab. For example, if a keytab is owned by root, which it typically is, <code>ktutil</code> must be run as root to have the appropriate permissions.														
COMMANDS	<table border="0" style="width: 100%;"> <tr> <td style="padding-right: 20px;"><code>clear_list, clear</code></td> <td>Clears the current keylist.</td> </tr> <tr> <td><code>read_kt file, rkt file</code></td> <td>Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read.</td> </tr> <tr> <td><code>write_kt file, wkt file</code></td> <td>Writes the current keylist to a keytab <i>file</i>. You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file.</td> </tr> <tr> <td><code>delete_entry number, delent number</code></td> <td>Deletes an entry from the current keylist. Specify the entry by the keylist slot number.</td> </tr> <tr> <td><code>list, l</code></td> <td>Lists the current keylist.</td> </tr> <tr> <td><code>list_request, lr</code></td> <td>Lists available requests (commands).</td> </tr> <tr> <td><code>quit, exit, q</code></td> <td>Exits utility.</td> </tr> </table>	<code>clear_list, clear</code>	Clears the current keylist.	<code>read_kt file, rkt file</code>	Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read.	<code>write_kt file, wkt file</code>	Writes the current keylist to a keytab <i>file</i> . You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file.	<code>delete_entry number, delent number</code>	Deletes an entry from the current keylist. Specify the entry by the keylist slot number.	<code>list, l</code>	Lists the current keylist.	<code>list_request, lr</code>	Lists available requests (commands).	<code>quit, exit, q</code>	Exits utility.
<code>clear_list, clear</code>	Clears the current keylist.														
<code>read_kt file, rkt file</code>	Reads a keytab into the current keylist. You must specify a keytab <i>file</i> to read.														
<code>write_kt file, wkt file</code>	Writes the current keylist to a keytab <i>file</i> . You must specify a keytab file to write. If the keytab file already exists, the current keylist is appended to the existing keytab file.														
<code>delete_entry number, delent number</code>	Deletes an entry from the current keylist. Specify the entry by the keylist slot number.														
<code>list, l</code>	Lists the current keylist.														
<code>list_request, lr</code>	Lists available requests (commands).														
<code>quit, exit, q</code>	Exits utility.														
EXAMPLES	<p>EXAMPLE 1 Deleting a principal from a file</p> <p>The following example deletes the <code>host/denver@ACME.com</code> principal from the <code>/etc/krb5/krb5.keytab</code> file. Notice that if you want to delete an entry from an existing keytab, you must first write the keylist to a temporary keytab and then overwrite the existing keytab with the the temporary keytab. This is because the <code>wkt</code> command actually appends the current keylist to an existing keytab, so you can't use it to overwrite a keytab.</p> <pre>example# /usr/krb5/bin/ktutil ktutil: rkt /etc/krb5/krb5.keytab ktutil: list slot KVNO Principal ----- 1 8 host/vail@ACME.COM 2 5 host/denver@ACME.COM ktutil:delent 2 ktutil:l slot KVNO Principal ----- 1 8 host/vail@ACME.COM ktutil:wkt /tmp/krb5.keytab ktutil:q example# mv /tmp/krb5.keytab /etc/krb5/krb5.keytab</pre>

last(1)

NAME	last – display login and logout information about users and terminals
SYNOPSIS	last [-a] [-n <i>number</i> -number] [-f <i>filename</i>] [<i>name</i> <i>tty</i> ...]
DESCRIPTION	<p>The <code>last</code> command looks in the <code>/var/adm/wtmpx</code> file, which records all logins and logouts, for information about a user, a terminal, or any group of users and terminals. Arguments specify names of users or terminals of interest. If multiple arguments are given, the information applicable to any of the arguments is printed. For example, <code>last root console</code> lists all of root's sessions, as well as all sessions on the console terminal. <code>last</code> displays the sessions of the specified users and terminals, most recent first, indicating the times at which the session began, the duration of the session, and the terminal on which the session took place. <code>last</code> also indicates whether the session is continuing or was cut short by a reboot.</p> <p>The pseudo-user <code>reboot</code> logs in when the system reboots. Thus,</p> <pre>last reboot</pre> <p>will give an indication of mean time between reboots.</p> <p><code>last</code> with no arguments displays a record of all logins and logouts, in reverse order.</p> <p>If <code>last</code> is interrupted, it indicates how far the search has progressed in <code>/var/adm/wtmpx</code>. If interrupted with a quit signal (generated by a CTRL-<code>\</code>), <code>last</code> indicates how far the search has progressed, and then continues the search.</p>
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-a Displays the hostname in the last column.-f <i>filename</i> Uses <i>filename</i> as the name of the accounting file instead of <code>/var/adm/wtmpx</code>.-n <i>number</i> -<i>number</i> Limits the number of entries displayed to that specified by <i>number</i>. These options are identical; the -<i>number</i> option is provided as a transition tool only and will be removed in future releases.
ENVIRONMENT VARIABLES	Date and time format is based on locale specified by the <code>LC_ALL</code> , <code>LC_TIME</code> , or <code>LANG</code> environments, in that order of priority.
FILES	<code>/var/adm/wtmpx</code> accounting file

lastcomm(1)

NAME	lastcomm – display the last commands executed, in reverse order
SYNOPSIS	lastcomm [-f <i>file</i>] [-x] [<i>command-name</i>] ... [<i>user-name</i>] ... [<i>terminal-name</i>] ...
DESCRIPTION	<p>The <code>lastcomm</code> command gives information on previously executed commands. <code>lastcomm</code> with no arguments displays information about all the commands recorded during the current accounting file's lifetime. If called with arguments, <code>lastcomm</code> only displays accounting entries with a matching <i>command-name</i>, <i>user-name</i>, or <i>terminal-name</i>. If extended process accounting is active (see <code>acctadm(1M)</code>) and is recording the appropriate data items, <code>lastcomm</code> attempts to take data from the current extended process accounting file. If standard process accounting is active, <code>lastcomm</code> takes data from the current standard accounting file (see <code>acct(2)</code>).</p> <p>If <i>terminal-name</i> is '- -', there was no controlling TTY for the process. The process was probably executed during boot time. If <i>terminal-name</i> is '??', the controlling TTY could not be decoded into a printable name.</p> <p>For each process entry, <code>lastcomm</code> displays the following items of information:</p> <ul style="list-style-type: none">■ The command name under which the process was called.■ One or more flags indicating special information about the process. The flags have the following meanings:<ul style="list-style-type: none">F The process performed a <code>fork</code> but not an <code>exec</code>.S The process ran as a set-user-id program.■ The name of the user who ran the process.■ The terminal which the user was logged in on at the time (if applicable).■ The amount of CPU time used by the process (in seconds).■ The date and time the process exited.
OPTIONS	<p>The following options are supported:</p> <p>-f <i>file</i> Uses <i>file</i> as the source of accounting data. <i>file</i> may be either an extended process accounting file or a standard process accounting file.</p> <p>-x Uses the currently active extended process accounting file. If extended processing accounting is inactive, no output will be produced.</p>
EXAMPLES	<p>EXAMPLE 1 Listing executions of named commands</p> <p>The command</p> <pre>example% lastcomm a.out root term/01</pre> <p>produces a listing of all the executions of commands named <code>a.out</code> by user <code>root</code> while using the terminal <code>term/01</code>.</p>

EXAMPLE 2 Listing all user commands

The command

```
example% lastcomm root
```

produces a listing of all the commands executed by user root.

FILES /var/adm/pacct standard accounting file
/var/adm/exacct/proc extended accounting file

ld(1)

NAME	ld – link-editor for object files
SYNOPSIS	<pre>/usr/ccs/bin/ld [-64] [-a -r] [-b] [-c name] [-C] [-G] [-i] [-m] [-s] [-t] [-V] [-B direct] [-B dynamic static] [-B group] [-B local] [-B eliminate] [-B reduce] [-B symbolic] [-d y n] [-D token] [-e epsym] [-F name -f name] [-h name] [-I name] [-L path] [-l x] [-M mapfile] [-N string] [-o outfile] [-p auditlib] [-P auditlib] [-Q y n] [-R path] [-S supportlib] [-u symname] [-Y P,dirlist] [-z absexec] [-z alleextract defaultextract weakextract] [-z combrelloc] [-z defs nodefs] [-z endfiltee] [-z finiarray=function] [-z groupperm nogroupperm] [-z ignore record] [-z initarray=function] [-z initfirst] [-z interpose] [-z lazyload nolazyload] [-z loadfltr] [-z muldefs] [-z nodelete] [-z nodefaultlib] [-z nodlopen] [-z nodump] [-z nopartial] [-z noversion] [-z now] [-z origin] [-z preinitarray=function] [-z redlocsym] [-z text textwarn textoff] filename...</pre>
DESCRIPTION	<p>The ld command combines relocatable object files, performs relocation, and resolves external symbols. ld operates in two modes, static or dynamic, as governed by the -d option. In static mode, -dn, relocatable object files given as arguments are combined to produce an executable object file. If the -r option is specified, relocatable object files are combined to produce one relocatable object file. In dynamic mode, -dy, the default, relocatable object files given as arguments are combined to produce an executable object file that will be linked at execution with any shared object files given as arguments. If the -G option is specified, relocatable object files are combined to produce a shared object. In all cases, the output of ld is left in a .out by default.</p> <p>If any argument is a library, ld searches exactly once at the point it encounters the library in the argument list. The library may be either a relocatable archive or a shared object. For an archive library, ld loads only those routines that define an unresolved external reference. ld searches the archive library symbol table sequentially with as many passes as are necessary to resolve external references that can be satisfied by library members. See ar(3HEAD). Thus, the order of members in the library is functionally unimportant, unless multiple library members exist that define the same external symbol.</p> <p>A shared object consists of an indivisible, whole unit, that has been generated by a previous link-edit of one or more input files. When the link-editor processes a shared object, the entire contents of the shared object become a logical part of the resulting output file image. The shared object is not physically copied during the link-edit as its actual inclusion is deferred until process execution. This logical inclusion means that all symbol entries defined in the shared object are made available to the link-editing process.</p> <p>No command-line option is required to distinguish 32-bit or 64-bit objects. The link-editor uses the ELF class of the first input relocatable file it sees to govern the mode in which it will operate. Intermixing 32-bit and 64-bit objects is not permitted. See also the -64 option.</p>

OPTIONS The following options are supported:

-64

Creates a 64-bit object. By default, the class of the object being generated is determined from the first ELF object processed from the command line. This option is useful when creating an object directly with `ld` whose input is solely from a `mapfile` (see the `-M` option) or an archive library.

-a

In static mode only, produces an executable object file; gives errors for undefined references. This is the default behavior for static mode. `-a` may not be used with the `-r` option.

-b

In dynamic mode only, does no special processing for relocations that reference symbols in shared objects. Without the `-b` option, the link-editor creates special position-independent relocations for references to functions defined in shared objects and arranges for data objects defined in shared objects to be copied into the memory image of an executable by the runtime linker.

The `-b` option is intended for specialized dynamic objects and is not recommended for general use. Its use suppresses all specialized processing required to insure an object's shareability, and may even prevent the relocation of 64-bit executables.

-B direct

Establishes direct binding information by recording the relationship between each symbol reference and the dependency that provides the definition. The runtime linker uses this information to search directly for the symbol in the associated object rather than to carry out its default symbol search. Direct binding information can only be established to dependencies specified with the `link-edit`. Thus, you should use the `-z defs` option. Objects that wish to interpose on symbols in a direct binding environment should identify themselves as interposers with the `-z interpose` option. The use of `-B direct` enables `-z lazyload` for all dependencies.

-B dynamic | static

Options governing library inclusion. `-B dynamic` is valid in dynamic mode only. These options may be specified any number of times on the command line as toggles: if the `-B static` option is given, no shared objects will be accepted until `-B dynamic` is seen. See also the `-l` option.

-B eliminate

Causes any global symbols not assigned to a version definition to be eliminated from the symbol table. This option achieves the same symbol elimination as the *auto-elimination* directive available as part of a *mapfile* version definition.

-B group

Establishes a shared object and its dependencies as a group. Objects within the group will be bound to other members of the group at runtime. The runtime processing of an object containing this flag mimics that which occurs if the object is

ld(1)

added to a process using `dlopen(3DL)` with the `RTLD_GROUP` mode. An object that has an explicit dependency on a object identified as a `group`, will itself become a member of the group.

As the group must be self contained, use of the `-B group` option also asserts the `-z defs` option.

`-B local`

Causes any global symbols, not assigned to a version definition, to be reduced to local. Version definitions can be supplied via a *mapfile* and indicate the global symbols that should remain visible in the generated object. This option achieves the same symbol reduction as the *auto-reduction* directive available as part of a *mapfile* version definition and may be useful when combining versioned and non-versioned relocatable objects.

`-B reduce`

When generating a relocatable object, causes the reduction of symbolic information defined by any version definitions. Version definitions can be supplied via a *mapfile* to indicate the global symbols that should remain visible in the generated object. When a relocatable object is generated, by default version definitions are only recorded in the output image. The actual reduction of symbolic information will be carried out when the object itself is used in the construction of a dynamic executable or shared object. This option is applied automatically when dynamic executable or shared object is created.

`-B symbolic`

In dynamic mode only. When building a shared object, binds references to global symbols to their definitions, if available, within the object. Normally, references to global symbols within shared objects are not bound until runtime, even if definitions are available, so that definitions of the same symbol in an executable or other shared object can override the object's own definition. `ld` will issue warnings for undefined symbols unless `-z defs` overrides.

The `-B symbolic` option is intended for specialized dynamic objects and is not recommended for general use. To reduce the runtime relocation overhead of an object, the creation of a version definition is recommended.

`-c name`

Records the configuration file *name* for use at runtime. Configuration files may be employed to alter default search paths, provide a directory cache and provide alternative object dependencies. See `crle(1)`.

`-C`

Demangles C++ symbol names displayed in diagnostic messages.

`-d y | n`

When `-d y`, the default, is specified, `ld` uses dynamic linking; when `-d n` is specified, `ld` uses static linking. See also `-B dynamic|static`.

`-D token,token,...`

Prints debugging information, as specified by each *token*, to the standard error. The special token `help` indicates the full list of tokens available.

- e *epsym*
Sets the entry point address for the output file to be that of the symbol *epsym*.
- f *name*
Useful only when building a shared object. Specifies that the symbol table of the shared object is used as an auxiliary filter on the symbol table of the shared object specified by *name*. Multiple instances of this option are allowed. This option may not be combined with the -F option.
- F *name*
Useful only when building a shared object. Specifies that the symbol table of the shared object is used as a filter on the symbol table of the shared object specified by *name*. Multiple instances of this option are allowed. This option may not be combined with the -f option.
- G
In dynamic mode only, produces a shared object. Undefined symbols are allowed.
- h *name*
In dynamic mode only, when building a shared object, records *name* in the object's dynamic section. *name* will be recorded in executables that are linked with this object rather than the object's UNIX System file name. Accordingly, *name* will be used by the runtime linker as the name of the shared object to search for at runtime.
- i
Ignores LD_LIBRARY_PATH. This option is useful when an LD_LIBRARY_PATH setting is in effect to influence the runtime library search, which would interfere with the link-editing being performed.
- I *name*
When building an executable, uses *name* as the path name of the interpreter to be written into the program header. The default in static mode is no interpreter; in dynamic mode, the default is the name of the runtime linker, ld.so.1(1). Either case may be overridden by -I *name*. *exec(2)* will load this interpreter when it loads *a.out* and will pass control to the interpreter rather than to *a.out* directly.
- l *x*
Searches a library *libx.so* or *libx.a*, the conventional names for shared object and archive libraries, respectively. In dynamic mode, unless the -B *static* option is in effect, *ld* searches each directory specified in the library search path for a *libx.so* or *libx.a* file. The directory search stops at the first directory containing either. *ld* chooses the file ending in *.so* if -l*x* expands to two files with names of the form *libx.so* and *libx.a*. If no *libx.so* is found, then *ld* accepts *libx.a*. In static mode, or when the -B *static* option is in effect, *ld* selects only the file ending in *.a*. *ld* searches a library when it encounters its name, so the placement of -l is significant.
- L *path*
Adds *path* to the library search directories. *ld* searches for libraries first in any directories specified by the -L options and then in the standard directories. This option is useful only if it precedes the -l options to which it applies on the

ld(1)

command line. The environment variable `LD_LIBRARY_PATH` may be used to supplement the library search path (see `LD_LIBRARY_PATH` below).

`-m`

Produces a memory map or listing of the input/output sections, together with any non-fatal multiply-defined symbols, on the standard output.

`-M mapfile`

Reads *mapfile* as a text file of directives to `ld`. This option may be specified multiple times. If *mapfile* is a directory, then all regular files, as defined by `stat(2)`, within the directory will be processed. See *Linker and Libraries Guide* for a description of mapfiles. There are mapfiles in `/usr/lib/ld` that show the default layout of programs as well as mapfiles for linking 64-bit programs above or below 4 gigabytes. See the FILES section below.

`-N string`

This option causes a `DT_NEEDED` entry to be added to the *.dynamic* section of the object being built. The value of the `DT_NEEDED` string will be the *string* specified on the command line. This option is position dependent, and the `DT_NEEDED` *.dynamic* entry will be relative to the other dynamic dependencies discovered on the link-edit line.

`-o outfile`

Produces an output object file named *outfile*. The name of the default object file is `a.out`.

`-p auditlib`

Identifies an audit library, *auditlib*, that is used to audit this object at runtime. Any shared object identified as requiring auditing of itself has this requirement inherited by any object specifying this shared object as a dependency (see `-P` option).

`-P auditlib`

Identifies an audit library, *auditlib*, that is used to audit this object's dependencies at runtime. Dependency auditing can also be inherited from dependencies identified as requiring auditing (see `-p` option).

`-Q y | n`

Under `-Q y`, an `ident` string is added to the *.comment* section of the output file to identify the version of the link-editor used to create the file. This results in multiple `ld ident`s when there have been multiple linking steps, such as when using `ld -r`. This is identical with the default action of the `cc` command. `-Q n` suppresses version identification.

`-r`

Combines relocatable object files to produce one relocatable object file. `ld` will not complain about unresolved references. This option cannot be used in dynamic mode or with `-a`.

`-R path`

A colon-separated list of directories used to specify library search directories to the runtime linker. If present and not `NULL`, it is recorded in the output object file and

passed to the runtime linker. Multiple instances of this option are concatenated together with each *path* separated by a colon.

-s

Strips symbolic information from the output file. Any debugging information, that is *.debug*, *.line*, and *.stab* sections, and their associated relocation entries will be removed. Except for relocatable files or shared objects, the symbol table and string table sections will also be removed from the output object file.

-S *supportlib*

The shared object *supportlib* is loaded with the link-editor and given information regarding the linking process. Support shared objects may also be supplied using the `SGS_SUPPORT` environment variable. See *Linker and Libraries Guide* for more details.

-t

Turns off the warning for multiply-defined symbols that have different sizes or alignments.

-u *symname*

Enters *symname* as an undefined symbol in the symbol table. This is useful for loading entirely from an archive library, since initially the symbol table is empty, and an unresolved reference is needed to force the loading of the first routine. The placement of this option on the command line is significant; it must be placed before the library that will define the symbol.

-V

Outputs a message giving information about the version of ld being used.

-Y *P*, *dirlist*

Changes the default directories used for finding libraries. *dirlist* is a colon-separated path list.

-z *absexec*

Useful only when building a dynamic executable. Specifies that references to external absolute symbols should be resolved immediately instead of being left for resolution at runtime. In very specialized circumstances, this option removes text relocations that can result in excessive swap space demands by an executable.

-z *allextract* | *defaultextract* | *weakextract*

Alters the extraction criteria of objects from any archives that follow. By default, archive members are extracted to satisfy undefined references and to promote tentative definitions with data definitions. Weak symbol references do not trigger extraction. Under *-z allextract*, all archive members are extracted from the archive. Under *-z weakextract*, weak references trigger archive extraction. *-z defaultextract* provides a means of returning to the default following use of the former extract options.

-z *combrelloc*

Combines multiple relocation sections. Reduces overhead when objects are loaded into memory.

ld(1)

- z `defs`
Forces a fatal error if any undefined symbols remain at the end of the link. This is the default when an executable is built. It is also useful when building a shared object to assure that the object is self-contained, that is, that all its symbolic references are resolved internally.
- z `endfiltee`
Marks a filtee so that when processed by a filter it terminates any further filtee searches by the filter.
- z `finiarray=function`
Appends an entry to the `.finiarray` section of the object being built. If no `.finiarray` section is present, one is created. The new entry is initialized to point to *function*. See *Linker and Libraries Guide* for more details.
- z `groupperm | nogroupperm`
Assigns, or deassigns each dependency that follows to a unique group. Assigning a dependency to a group has the same effect as if the dependency had been built using the `-B group` option.
- z `ignore | record`
Ignores, or records, dynamic dependencies that are not referenced as part of the `link-edit`. By default, `-z record` is in effect.
- z `initarray=function`
Appends an entry to the `.initarray` section of the object being built. If no `.initarray` section is present, one is created. The new entry is initialized to point to *function*. See *Linker and Libraries Guide* for more details.
- z `initfirst`
Marks the object so that its runtime initialization occurs before the runtime initialization of any other objects brought into the process at the same time. In addition, the object runtime finalization will occur after the runtime finalization of any other objects removed from the process at the same time. This option is only meaningful when building a shared object.
- z `interpose`
Marks the object as an interposer. When direct bindings are in effect (see `-B direct`), the runtime linker will search for symbols in any interposers before the object associated to the direct binding.
- z `lazyload | nolazyload`
Enables or disables the marking of dynamic dependencies to be lazily loaded. Dynamic dependencies which are marked `lazyload` will not be loaded at initial process start-up, but instead will be delayed until the first binding to the object is made.
- z `loadfltr`
Marks the object to require that when building a filter, its filtees be processed immediately at runtime. Normally, filter processing is delayed until a symbol

reference is bound to the filter. The runtime processing of an object that contains this flag mimics that which occurs if the `LD_LOADFLTR` environment variable is in effect. See `ld.so.1(1)`.

-z muldefs

Allows multiple symbol definitions. By default, multiple symbol definitions that occur between relocatable objects will result in a fatal error condition. This option suppresses the error condition and allows the first symbol definition to be taken.

-z nodefs

Allows undefined symbols. This is the default when a shared object is built. When used with executables, the behavior of references to such undefined symbols is unspecified.

-z nodelete

Marks the object as non-deletable at runtime. The runtime processing of an object that contains this flag mimics that which occurs if the object is added to a process using `dlopen(3DL)` with the `RTLD_NODELETE` mode.

-z nodefaultlib

Marks the object so that the runtime default library search path (used after any `LD_LIBRARY_PATH` or *runpaths*) is ignored. This option implies that all dependencies of the object can be satisfied from its *runpath*.

-z nodlopen

Marks the object as not available to `dlopen(3DL)`, either as the object specified by the `dlopen()`, or as any form of dependency required by the object specified by the `dlopen()`. This option is only meaningful when building a shared object.

-z nodump

Marks the object as not available to `dldump(3DL)`.

-z nopartial

If there are any partially initialized symbols in the input relocatable object files, the partially initialized symbols are expanded when the output file is generated.

-z noversion

Does not record any versioning sections. Any version sections or associated *.dynamic* section entries will not be generated in the output image.

-z now

Marks the object to override the runtime linker's default mode and require non-lazy runtime binding. This is similar to adding the object to the process by using `dlopen(3DL)` with the `RTLD_NOW` mode, or setting the `LD_BIND_NOW` environment variable in effect. See `ld.so.1(1)`.

-z origin

Marks the object as requiring immediate `$ORIGIN` processing at runtime.

-z preinitarray=*function*

Appends an entry to the *.preinitarray* section of the object being built. If no *.preinitarray* section is present, one is created. The new entry is initialized to point to *function*. See *Linker and Libraries Guide* for more details.

ld(1)

**ENVIRONMENT
VARIABLES**

- z redlocsym
Eliminates all local symbols except for the SECT symbols from the symbol table SHT_SYMTAB. All relocations that refer to local symbols will be updated to refer to the corresponding SECT symbol.
- z text
In dynamic mode only, forces a fatal error if any relocations against non-writable, allocatable sections remain.
- z textoff
In dynamic mode only, allows relocations against all allocatable sections, including non-writable ones. This is the default when building a shared object.
- z textwarn
In dynamic mode only, lists a warning if any relocations against non-writable, allocatable sections remain. This is the default when building an executable.

LD_LIBRARY_PATH A list of directories in which to search for libraries specified with the `-l` option. Multiple directories are separated by a colon. In the most general case, it will contain two directory lists separated by a semicolon:

dirlist1;dirlist2

If `ld` is called with any number of occurrences of `-L`, as in:

`ld . . . -Lpath1 . . . -Lpathn . . .`

then the search path ordering is:

dirlist1 path1 . . . pathn dirlist2 LIBPATH

When the list of directories does not contain a semicolon, it is interpreted as *dirlist2*.

The `LD_LIBRARY_PATH` environment variable also affects the runtime linkers searching for dynamic dependencies.

This environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to 32-bit or 64-bit processes and overrides any non-suffixed version of the environment variable that may be in effect.

LD_OPTIONS A default set of options to `ld`. `LD_OPTIONS` is interpreted by `ld` just as though its value had been placed on the command line, immediately following the name used to invoke `ld`, as in:

`ld $LD_OPTIONS . . . other-arguments . . .`

LD_RUN_PATH An alternative mechanism for specifying a runpath to the link-editor (see `-R` option). If both `LD_RUN_PATH` and the `-R` option are specified, `-R` supersedes.

SGS_SUPPORT Provides a colon-separated list of shared objects that are loaded with the link-editor and given information regarding the linking process. See also the `-S` option.

Notice that environment variable-names beginning with the characters 'LD_' are reserved for possible future enhancements to `ld` and `ld.so.1(1)`.

FILES

`libx.so` libraries

`libx.a` libraries

`a.out` output file

LIBPATH usually `/usr/lib` or `/usr/lib/64` for 64-bit libraries.

`/usr/lib/ld/map.default`
mapfile showing default layout of 32-bit programs

`/usr/lib/ld/sparcv9/map.default`
mapfile showing default layout of 64-bit SPARCV9 programs

`/usr/lib/ld/sparcv9/map.above4G`
mapfile showing suggested layout above 4 gigabytes of 64-bit SPARCV9 programs

`/usr/lib/ld/sparcv9/map.below4G`
mapfile showing suggested layout below 4 gigabytes of 64-bit SPARCV9 programs

Linker and Libraries Guide Binary Compatibility Guide

ld(1B)

NAME ld – link editor, dynamic link editor

SYNOPSIS /usr/ucb/ld [*options*]

DESCRIPTION /usr/ucb/ld is the link editor for the BSD Compatibility Package. /usr/ucb/ld is identical to /usr/bin/ld (see ld(1)) except that BSD libraries and routines are included *before* the base libraries and routines.

OPTIONS /usr/ucb/ld accepts the same options as /usr/bin/ld, with the following exceptions:

-L*dir* Add *dir* to the list of directories searched for libraries by /usr/bin/ld. Directories specified with this option are searched before /usr/ucb/lib and /usr/lib.

-Y LU,*dir* Change the default directory used for finding libraries. Warning: This option may have unexpected results, and should not be used.

FILES /usr/lib

NAME	ldap – LDAP as a naming repository
DESCRIPTION	<p>LDAP refers to Lightweight Directory Access Protocol, which is an industry standard for accessing directory servers. By initializing the client using <code>ldapclient(1M)</code> and using the keyword <code>ldap</code> in the name service switch file, <code>/etc/nsswitch.conf</code>, Solaris clients can obtain naming information from an LDAP server. Information such as usernames, hostnames, and passwords are stored on the LDAP server in a Directory Information Tree or DIT. The DIT consists of entries which in turn are composed of attributes. Each attribute has a type and one or more values.</p> <p>Solaris LDAP clients use the LDAP v3 protocol to access naming information from LDAP servers. The LDAP server must support the object classes and attributes defined in <i>RFC2307bis (draft)</i>, which maps the naming service model on to LDAP. As an alternate to using the schema defined in <i>RFC2307bis (draft)</i>, the system can be configured to use other schema sets and the schema mapping feature is configured to map between the two.</p> <p>The <code>ldapclient(1M)</code> utility can make a Solaris machine an LDAP client by setting up the appropriate directories, files, and configuration information. The LDAP client caches this configuration information in local cache files. This configuration information is accessed through the <code>ldap_cachemgr(1M)</code> daemon. This daemon also refreshes the information in the configuration files from the LDAP server, providing better performance and security. The <code>ldap_cachemgr</code> must run at all times for the proper operation of the naming services.</p> <p>There are two types of configuration information, the information available through a profile, and the information configured per client. The profile contains all the information as to how the client accesses the directory. The credential information for proxy user is configured on a per client basis and is not downloaded through the profile.</p> <p>The profile contains server-specific parameters that are required by all clients to locate the servers for the desired LDAP domain. This information could be the server's IP address and the search base Distinguished Name (DN), for instance. It is configured on the client from the default profile during client initialization and is periodically updated by the <code>ldap_cachemgr</code> daemon when the expiration time has elapsed.</p> <p>Client profiles can be stored on the LDAP server and may be used by the <code>ldapclient</code> utility to initialize an LDAP client. Using the client profile is the easiest way to configure a client machine. See <code>ldapclient(1M)</code>.</p> <p>Credential information includes client-specific parameters that are used by a client. This information could be the Bind DN (LDAP "login" name) of the client and the password. If these parameters are required, they are manually defined during the initialization through <code>ldapclient(1M)</code>.</p> <p>The naming information is stored in containers on the LDAP server. A container is a non-leaf entry in the DIT that contains naming service information. Containers are similar to maps in NIS and tables in NIS+. A default mapping between the NIS</p>

ldap(1)

databases and the containers in LDAP is presented below. The location of these containers as well as their names can be overridden through the use of `serviceSearchDescriptors`. For more information see `ldapclient(1M)`.

prof_attr	SolarisProfAttr	ou=SolarisProfAttr,dc=...
exec_attr	SolarisExecAttr	ou=SolarisProfAttr,dc=...
user_attr	SolarisUserAttr	ou=people,dc=...
audit_attr	SolarisAuditAttr	ou=people,dc=...

The security model for clients is defined by a combination of the credential level to be used, the authentication method, and the PAM module to be used, that is, `pam_unix` versus `pam_ldap`. The credential level defines what credentials the client should use to authenticate to the directory server, and the authentication method defines the method of choice. Both these can be set with multiple values. The Solaris LDAP supports the following values for credential level :

```
anonymous
proxy
```

The Solaris LDAP supports the following values for authentication method:

```
none
simple
sasl/CRAM-MD5
sasl/DIGEST-MD5
tls:simple
tls:sasl/CRAM-MD5
tls:sasl/DIGEST-MD5
```

More protection can be provided by means of access control, allowing the server to grant access for certain containers or entries. Access control is specified by Access Control Lists (ACL's) that are defined and stored in the LDAP server. The Access Control Lists on the LDAP server are called Access Control Instructions (ACI's) by the the iPlanet Directory Server. Each ACL or ACI specifies one or more directory objects, for example, the `cn` attribute in a specific container, one or more clients to whom you grant or deny access, and one or more access rights that determine what the clients can do to or with the objects. Clients can be users or applications. Access rights can be specified as read and write, for example.

A sample `nsswitch.conf(4)` file called `nsswitch.ldap` is provided in the `/etc` directory. This is copied to `/etc/nsswitch.conf` by the `ldapclient(1M)` utility. This file uses LDAP as a repository for the different databases in the `nsswitch.conf` file.

The following is a list of the user commands related to LDAP:

<code>idsconfig(1M)</code>	Prepares an iPlanet Directory Server to be ready to support Solaris LDAP clients.'
<code>ldapaddent(1M)</code>	Create LDAP entries from corresponding <code>/etc</code> files.
<code>ldapclient(1M)</code>	Initialize LDAP clients, or generate a configuration profile to be stored in the directory.
<code>ldaplist(1)</code>	List the contents of the LDAP naming space.

FILES

<code>/var/ldap/ldap_client_cred</code>	Files that contain the LDAP configuration of the client. Do not manually modify these files. Their content is not guaranteed to be human readable. Use <code>ldapclient(1M)</code> to update them.
<code>/var/ldap/ldap_client_file</code>	
<code>/etc/nsswitch.conf</code>	Configuration file for the name-service switch

ldap(1)

<code>/etc/nsswitch.ldap</code>	Sample configuration file for the name-service switch configured with LDAP and files
<code>/etc/pam.conf</code>	PAM framework configuration file.

SEE ALSO `ldaplist(1)`, `idsconfig(1M)`, `ldap_cachemgr(1M)`, `ldapaddent(1M)`, `ldapclient(1M)`, `nsswitch.conf(4)`, `pam.conf(4)`, `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, `pam_ldap(5)`, `pam_passwd_auth(5)`, `pam_unix(5)`, `pam_unix_account(5)`, `pam_unix_auth(5)`, `pam_unix_session(5)`,

NOTES The `pam_unix(5)` module might not be supported in a future release. Similar functionality is provided by `pam_authtok_check(5)`, `pam_authtok_get(5)`, `pam_authtok_store(5)`, `pam_dhkeys(5)`, `pam_passwd_auth(5)`, `pam_unix_account(5)`, `pam_unix_auth(5)`, and `pam_unix_session(5)`.

NAME	ldapdelete – ldap delete entry tool
SYNOPSIS	ldapdelete [-n] [-o] [-v] [-c] [-d <i>debuglevel</i>] [-f <i>file</i>] [-D <i>binddn</i>] [-w <i>passwd</i>] [-h <i>ldaphost</i>] [-M <i>authentication</i>] [-p <i>ldapport</i>] [<i>dn...</i>]
DESCRIPTION	The <code>ldapdelete</code> utility opens a connection to an LDAP server, then binds and deletes one or more entries. If one or more <i>dn</i> arguments are provided, entries with those distinguished names are deleted. If no <i>dn</i> arguments are provided, a list of DN's is read from <i>file</i> , if the <code>-f</code> option is specified, or from standard input.
OPTIONS	The following options are supported:
-c	Continuous operation mode. Errors are reported, but <code>ldapdelete</code> will continue with deletions. The default is to exit after reporting an error.
-d <i>debuglevel</i>	Sets the LDAP debugging level. Useful levels of debugging for <code>ldapmodify</code> and <code>ldapadd</code> are: <ul style="list-style-type: none"> 1 Trace 2 Packets 4 Arguments 32 Filters 128 Access control <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <i>debuglevel</i> of 33.</p>
-D <i>binddn</i>	Uses the distinguished name <i>binddn</i> to bind to the directory.
-f <i>file</i>	Reads the entry deletion information from <i>file</i> instead of from standard input.
-h <i>ldaphost</i>	Specifies an alternate host on which the <code>slapd</code> server is running.
-M <i>authentication</i>	Specifies the authentication mechanism used to bind to the directory. This option can have the value <code>CRAM-MD5</code> . The bind DN and bind password are mandatory with this option.
-n	Shows what would be done, but does not actually delete entries. Useful in conjunction with options <code>-v</code> and <code>-d</code> for debugging.
-o	Specifies the security layer for the mechanism (<code>none</code> , <code>integrity</code> , <code>privacy</code>).

ldapdelete(1)

`-p ldapport` Specifies an alternate TCP port where the slapd server is listening.

`-v` Uses verbose mode, with diagnostics written to standard output.

`-w passwd` Uses *passwd* as the password for authentication to the directory.

OPERANDS The following operand is supported:

dn
Specifies one or several distinguished names of entries to delete.

EXAMPLES **EXAMPLE 1** Deleting an entry

To delete the entry named with commonName Delete Me directly below the XYZ Corporation organizational entry, use the following command:

```
example% ldapdelete "cn=Delete Me, o=XYZ, c=US" \  
-D "cn=Administrator, o=XYZ, c=US" -w password
```

ATTRIBUTES See attributes(5) for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWldap (32-bit) SUNWldapx (64-bit)
Stability Level	Evolving

EXIT STATUS The following exit values are returned:

0 Successful completion.

Non-zero An error occurred. A diagnostic message is written to standard error.

SEE ALSO ldapadd(1), ldapmodify(1), ldapmodrdn(1), ldapsearch(1), ldap_get_option(3LDAP), ldap_set_option(3LDAP)

NAME ldaplist – search and list naming information from a LDAP directory using the configured profile

SYNOPSIS `/usr/bin/ldaplist [-dlv] [database [key] ...]`
`/usr/bin/ldaplist -h`

DESCRIPTION The ldaplist utility searches for and lists the naming information from the LDAP directory service defined in the LDAP configuration files generated by ldapclient(1M) during the client initialization phase. The Solaris LDAP client must be set up in order to use this utility.

The database is either a container name or a database name as defined in nsswitch.conf(4). A container is a non-leaf entry in the Directory Information Tree (DIT) that contains naming service information. The container name is the LDAP Relative Distinguished Name (RDN) of the container relative to the defaultSearchBase as defined in the configuration files. For example, for a container named ou=people, the database name is the database specified in nsswitch.conf. This database is mapped to a container, for example, passwd maps to ou=people. If an invalid database is specified, it will be mapped to a generic container, for example, nisMapName=name).

The key is the attribute value to be searched in the database. You can specify more than one key to be searched in the same database. The key can be specified in either of two forms: *attribute=value* or *value*. In the first case, ldaplist passes the search key to the server. In the latter case, an attribute is assigned depending on how the database is specified. If the database is a container name, then the "cn" attribute type is used. If it is a valid database name as defined in the nsswitch.conf, then a predefined attribute type is used (see table below). If it is an invalid database name, then cn is used as the attribute type.

The ldaplist utility relies on the Schema defined in the *RFC 2307bis*, currently an IETF draft. The data stored on the LDAP server must be stored based on this Schema, unless the profile contains schema mapping definitions. For more information on schema mapping see ldapclient(1M). The following table lists the default mapping from the database names to the container, the LDAP object class, and the attribute type used if not defined in the key.

Database	Object Class	Attribute Type	Container
aliases	mailGroup	cn	ou=Aliases
automount	nisObject	cn	nisMapName=auto_*
bootparams	bootableDevice	cn	ou=Ethers
ethers	ieee802Device	cn	ou=Ethers
group	posixgroup	cn	ou=Group

ldaplist(1)

Database	Object Class	Attribute Type	Container
hosts	ipHost	cn	ou=Hosts
ipnodes	ipHost	cn	ou=Hosts
netgroup	ipNetgroup	cn	ou=Netgroup
netmasks	ipNetwork	ipnetworknumber	ou=Networks
networks	ipNetwork	ipnetworknumber	ou=Networks
passwd	posixAccount	uid	ou=People
protocols	ipProtocol	cn	ou=Protocols
publickey	nisKeyObject	uidnumber	ou=People
		cn	ou=Hosts
rpc	oncRpc	cn	ou=Rpc
services	ipService	cn	ou=Services
printers	printerService	printer-uri	ou=printers
auth_attr	SolarisAuthAttr	nameT	ou=SolarisAuthAttr
prof_attr	SolarisProfAttr	nameT	ou=SolarisProfAttr
exec_attr	SolarisExecAttr	nameT	ou=SolarisProfAttr
user_attr	SolarisUserAttr	uidT	ou=people
audit_user	SolarisAuditUser	uidT	ou=people

- auto_* represents auto_home, auto_direct, ...
- If the key starts with a digit, it will be interpreted as an uid number.
- If the key starts with a non-digit, it will be interpreted as a host name.

The `ldaplist` utility supports substring search by using the wildcard "*" in the key. For example, "my*" will match any strings that starts with "my". In some shell environments, keys containing the wildcard may need to be quoted.

If the key is not specified, all the containers in the current search `baseDN` will be listed.

OPTIONS

The following options are supported:

- d Lists the attributes for the specified database, rather than the entries. By default, the entries are listed.
- h Lists the database mapping.
- l Lists all the attributes for each entry matching the search criteria. By default, `ldaplist` lists only the Distinguished Name of the entries found.

-v Sets verbose mode. The `ldaplist` utility will also print the filter used to search for the entry. The filter will be prefixed with "+++".

EXAMPLES

EXAMPLE 1 Listing All Entries in the `hosts` Database

```
example% ldaplist hosts
```

EXAMPLE 2 Listing All Entries in a Non-Standard Database `ou=new`

```
example% ldaplist ou=new
```

EXAMPLE 3 Finding "user1" in the `passwd` Database

```
example% ldaplist passwd user1
```

EXAMPLE 4 Finding the Entry With Service Port of 4045 in the `services` Database

```
example% ldaplist services ipServicePort=4045
```

EXAMPLE 5 Finding All Users With Username Starting with `new` in the `passwd` Database

```
example% ldaplist passwd 'new*'
```

EXAMPLE 6 Listing the Attributes for the `hosts` Database

```
example% ldaplist -d hosts
```

EXIT STATUS

The following exit values are returned:

- 0 Successfully matched some entries.
- 1 Successfully searched the table and no matches were found.
- 2 An error occurred. An error message is output.

FILES

`/var/ldap/ldap_client_file`
`/var/ldap/ldap_client_cred`

Files that contain the LDAP configuration of the client. Do not manually modify these files. Their content is not guaranteed to be human readable. To update these files, use `ldapclient(1M)`

ATTRIBUTES

See `attributes(5)` for descriptions of the following attributes:

NOTES | *RFC 2307bis* is an IETF informational document in draft stage that defines an approach for using LDAP as a naming service.

NAME	ldapmodify, ldapadd – ldap entry addition and modification tools						
SYNOPSIS	<pre> ldapmodify [-a] [-b] [-c] [-r] [-n] [-v] [-F] [-d <i>debuglevel</i>] [-D <i>binddn</i>] [-w <i>passwd</i>] [-h <i>ldaphost</i>] [-M <i>authentication</i>] [-p <i>ldapport</i>] [-f <i>file</i>] [-l <i>nb-ldap-connections</i>] /opt/SUNWconn/ldap/bin/ldapadd [-b] [-c] [-n] [-v] [-F] [-d <i>debuglevel</i>] [-D <i>binddn</i>] [-w <i>passwd</i>] [-h <i>ldaphost</i>] [-p <i>ldapport</i>] [-f <i>file</i>] [-l <i>nb-ldap-connections</i>] </pre>						
DESCRIPTION	<p>ldapmodify opens a connection to an LDAP server, binds, and modifies or adds entries. The entry information is read from standard input or from <i>file</i>, specified using the -f option. ldapadd is implemented as a hard link to the ldapmodify tool. When invoked as ldapadd the -a (add new entry) option is turned on automatically.</p> <p>Both ldapadd and ldapmodify reject duplicate attribute-name/value pairs for the same entry.</p>						
OPTIONS	<p>-a Add new entries. The default for ldapmodify is to modify existing entries. If invoked as ldapadd, this option is always set.</p> <p>-b Assume that any value that starts with a / is the pathname of a file containing the actual attribute value. This is useful for attribute values in binary format.</p> <p>-c Continuous operation mode. Errors are reported, but ldapmodify continues with modifications. The default is to exit after reporting an error.</p> <p>-r Replace existing value with the specified value. This is the default for ldapmodify. When ldapadd is called, or if the -a option is specified, the -r option is ignored.</p> <p>-n Preview modifications, but make no changes to entries. Useful in conjunction with -v and -d for debugging.</p> <p>-v Use verbose mode, with diagnostics written to standard output.</p> <p>-F Force application of all changes regardless of the content of input lines that begin <i>replica: .</i> By default, replica: lines are compared against the LDAP server host and port in use to decide whether a relog record should be applied.</p> <p>-d <i>debuglevel</i> Set the LDAP debugging level. Useful levels of debugging for ldapmodify and ldapadd are:</p> <table border="0" style="margin-left: 40px;"> <tr> <td>1</td> <td>Trace</td> </tr> <tr> <td>2</td> <td>Packets</td> </tr> <tr> <td>4</td> <td>Arguments</td> </tr> </table>	1	Trace	2	Packets	4	Arguments
1	Trace						
2	Packets						
4	Arguments						

ldapmodify(1)

	32	Filters
	128	Access control
		To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a debuglevel of 33.
-f <i>file</i>		Read the entry modification information from <i>file</i> instead of from standard input.
-D <i>binddn</i>		Use the distinguished name <i>binddn</i> to bind to the directory.
-w <i>passwd</i>		Use <i>passwd</i> as the password for authentication to the directory.
-h <i>ldaphost</i>		Specify an alternate host on which the slapd server is running.
-M <i>authentication</i>		Specifies the authentication mechanism used to bind to the directory. This option can have the value CRAM-MD5. The bind DN and bind password are mandatory with this option.
-p <i>ldapport</i>		Specify an alternate TCP port where the slapd server is listening.
-l <i>nb-ldap-connections</i>		Specifies the number of LDAP connections that ldapadd or ldapmodify will open to process the modifications in the directory. The default is one connection.

EXAMPLES

EXAMPLE 1 The format of the content of *file* (or standard input if no *-f* option is specified) is illustrated in the examples below.

1. The file `/tmp/entrymods` contains the following modification instructions:

```
dn: cn=Modify Me, o=XYZ, c=US
changetype: modify
replace: mail
mail: modme@atlanta.xyz.com
-
add: title
title: System Manager
-
add: jpegPhoto
jpegPhoto: /tmp/modme.jpeg
-
delete: description
-
```

The command:

EXAMPLE 1 The format of the content of `file` (or standard input if no `-f` option is specified) is illustrated in the examples below. (Continued)

```
example% ldapmodify -b -r -f /tmp/entrymods
```

modifies the "Modify Me" entry as follows:

- a. The current value of the `mail` attribute is replaced with the value "modme@atlanta.xyz.com"
- b. A `title` attribute with the value "System Manager" is added
- c. A `jpegPhoto` attribute is added, using the contents of the file `/tmp/modme.jpeg` as the attribute value
- d. The `description` attribute is removed

EXAMPLE 2 The file `/tmp/newentry` contains the following information for creating a new entry:

```
dn: cn=Ann Jones, o=XYZ, c=US
objectClass: person
cn: Ann Jones
cn: Annie Jones
sn: Jones
title: Director of Research and Development
mail: ajones@londonrd.xyz.us.com
uid: ajones
```

The command:

```
example% ldapad -f /tmp/newentry
```

adds a new entry for Ann Jones, using the information in the file.

EXAMPLE 3 The file `/tmp/badentry` contains the following information about an entry to be deleted:

```
dn: cn=Ann Jones, o=XYZ, c=US
changetype: delete
```

the command:

```
example% ldapmodify -f /tmp/badentry
```

removes Ann Jones' entry.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
----------------	-----------------

ldapmodify(1)

Availability	SUNWldap (32-bit) SUNWldapx (64-bit)
Stability Level	Evolving

SEE ALSO ldapadd(1), ldapdelete(1), ldapmodrdn(1), ldapsearch(1)

DIAGNOSTICS Exit status is 0 if no errors occur. Errors result in a non-zero exit status and a diagnostic message being written to standard error.

NAME	ldapmodrdn – ldap modify entry RDN tool										
SYNOPSIS	ldapmodrdn [-r] [-n] [-v] [-c] [-d <i>debuglevel</i>] [-D <i>binddn</i>] [-w <i>passwd</i>] [-h <i>ldaphost</i>] [-M <i>authentication</i>] [-p <i>ldapport</i>] [-f <i>file</i>] [<i>dn rdn</i>]										
DESCRIPTION	ldapmodrdn opens a connection to an LDAP server, binds, and modifies the RDN of entries. The entry information is read from standard input, from <i>file</i> through the use of the -f option, or from the command-line pair <i>dn</i> and <i>rdn</i> .										
OPTIONS	<p>-r Remove old RDN values from the entry. By default, old values are kept.</p> <p>-n Show what would be done, but don't actually change entries. Useful in conjunction with -v for debugging.</p> <p>-v Use verbose mode, with diagnostics written to standard output.</p> <p>-c Continuous operation mode. Errors are reported, but ldapmodify continues with modifications. The default is to exit after reporting an error.</p> <p>-d <i>debuglevel</i> Set the LDAP debugging level. Useful values of <i>debuglevel</i> for ldapmodrdn are:</p> <table border="0" style="margin-left: 2em;"> <tr><td>1</td><td>Trace</td></tr> <tr><td>2</td><td>Packets</td></tr> <tr><td>4</td><td>Arguments</td></tr> <tr><td>32</td><td>Filters</td></tr> <tr><td>128</td><td>Access control</td></tr> </table> <p>To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a <i>debuglevel</i> of 33.</p> <p>-f <i>file</i> Read the entry modification information from <i>file</i> instead of from standard input or the command-line.</p> <p>-D <i>binddn</i> Use the distinguished name <i>binddn</i> to bind to the directory.</p> <p>-w <i>passwd</i> Use <i>passwd</i> as the password for authentication to the directory.</p> <p>-h <i>ldaphost</i> Specify an alternate host on which the slapd server is running.</p> <p>-M <i>authentication</i> Specifies the authentication mechanism used to bind to the directory. This option can have the value</p>	1	Trace	2	Packets	4	Arguments	32	Filters	128	Access control
1	Trace										
2	Packets										
4	Arguments										
32	Filters										
128	Access control										

ldapmodrdn(1)

CRAM-MD5. The bind DN and bind password are mandatory with this option.

`-p ldapport`

Specify an alternate TCP port where the slapd server is listening.

Input Format

If the command-line arguments *dn* and *rdn* are given, *rdn* replaces the RDN of the entry specified by the DN, *dn*.

Otherwise, the contents of *file* (or standard input if the `-f` option is not specified) must consist of one or more pair of lines:

```
Distinguished Name (DN)
Relative Distinguished Name (RDN)
```

Use one or more blank lines to separate each DN/RDN pair.

EXAMPLES

The file `/tmp/entrymods` contains:

```
cn=Modify Me, o=XYZ, c=US
cn=The New Me
```

The command:

```
example% ldapmodify -r -f /tmp/entrymods
```

changes the RDN of the "Modify Me" entry from "Modify Me" to "The New Me" and the old cn, "Modify Me" is removed.

ATTRIBUTES

See `attributes(5)` for a description of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWldap (32-bit) SUNWldapx (64-bit)
Stability Level	Evolving

SEE ALSO

`ldapadd(1)`, `ldapdelete(1)`, `ldapmodify(1)`, `ldapsearch(1)`

DIAGNOSTICS

Exit status is 0 if no errors occur. Errors result in a non-zero exit status and a diagnostic message being written to standard error.

NAME	ldapsearch – ldap search tool
SYNOPSIS	<pre> ldapsearch [-n] [-u] [-v] [-t] [-A] [-B] [-L] [-R] [-d <i>debuglevel</i>] [-F <i>sep</i>] [-f <i>file</i>] [-D <i>binddn</i>] [-w <i>passwd</i>] [-h <i>ldaphost</i>] [-M <i>authentication</i>] [-p <i>ldapport</i>] [-b <i>searchbase</i>] [-s <i>scope</i>] [-a <i>deref</i>] [-l <i>time limit</i>] [-z <i>size limit</i>] <i>filter</i> [<i>attrs</i>] </pre>
DESCRIPTION	<p>ldapsearch opens a connection to an LDAP server, binds, and performs a search using the filter <i>filter</i>.</p> <p>If ldapsearch finds one or more entries, the attributes specified by <i>attrs</i> are retrieved and the entries and values are printed to standard output. If no <i>attrs</i> are listed, all attributes are returned.</p>
Output Format	<p>If one or more entries are found, each entry is written to standard output in the form:</p> <pre> Distinguished Name (DN) User Friendly Name (if the -u option is used) attributename=value attributename=value attributename=value . . . </pre> <p>Multiple entries are separated with a single blank line. If the -F option is used to specify a different separator character, this character will be used instead of the '=' character. If the -t option is used, the name of a temporary file is returned in place of the actual value. If the -A option is given, only the "attributename" is returned and not the attribute value.</p>
OPTIONS	<pre> -n Show what would be done, but don't actually perform the search. Useful in conjunction with -v and -d for debugging. -u Include the user-friendly form of the Distinguished Name (DN) in the output. -v Run in verbose mode, with diagnostics written to standard output. -t Write retrieved values to a set of temporary files. This is useful for dealing with non-ASCII values such as jpegPhoto or audio. -A Retrieve attributes only (no values). This is useful when you just want to see whether an attribute is present in an entry and are not interested in the specific value. -B Do not suppress display of non-ASCII values. This is useful when dealing with values that appear in alternate character sets such as ISO-8859.1. This option is automatically set by the -L option. </pre>

ldapsearch(1)

-L	Display search results in a modified format. This option also turns on the -B option, and causes the -F option to be ignored.										
-R	Do not automatically follow referrals returned while searching.										
-F <i>sep</i>	Use <i>sep</i> as the field separator between attribute names and values. The default separator is '='. If -L option has been specified, this option is ignored.										
-d <i>debuglevel</i>	Set the LDAP debugging level. Useful levels of debugging for <code>ldapmodify</code> and <code>ldapadd</code> are: <table><tr><td>1</td><td>Trace</td></tr><tr><td>2</td><td>Packets</td></tr><tr><td>4</td><td>Arguments</td></tr><tr><td>32</td><td>Filters</td></tr><tr><td>128</td><td>Access control</td></tr></table> To request more than one category of debugging information, add the masks. For example, to request trace and filter information, specify a debuglevel of 33.	1	Trace	2	Packets	4	Arguments	32	Filters	128	Access control
1	Trace										
2	Packets										
4	Arguments										
32	Filters										
128	Access control										
-f <i>file</i>	Read a series of lines from <i>file</i> , performing one LDAP search for each line. In this case, the <i>filter</i> given on the command line is treated as a pattern where the first occurrence of %s is replaced with a line from <i>file</i> . If <i>file</i> is a single - character, then the lines are read from standard input.										
-D <i>binddn</i>	Use the distinguished name <i>binddn</i> to bind to the directory.										
-w <i>passwd</i>	Use <i>passwd</i> as the password for authentication to the directory.										
-h <i>ldaphost</i>	Specify an alternate host on which the slapd server is running.										
-M <i>authentication</i>	Specifies the authentication mechanism used to bind to the directory. This option can have the value CRAM-MD5. The bind DN and bind password are mandatory with this option.										
-p <i>ldapport</i>	Specify an alternate TCP port where the slapd server is listening.										
-b <i>searchbase</i>	Use <i>searchbase</i> as the starting point for the search instead of the default.										

<code>-s scope</code>	Specify the scope of the search. The possible values of <i>scope</i> are <i>base</i> , <i>one</i> , or <i>sub</i> to specify respectively a base object, one-level, or subtree search. The default is <i>sub</i> .
<code>-a deref</code>	Specify how aliases dereferencing is done. The possible values for <i>deref</i> are <i>never</i> , <i>always</i> , <i>search</i> , or <i>find</i> to specify respectively that aliases are never dereferenced, always dereferenced, dereferenced when searching, or dereferenced only when finding the base object for the search. The default is to never dereference aliases.
<code>-l timelimit</code>	Wait at most <i>timelimit</i> seconds for a search to complete.
<code>-z sizelimit</code>	Retrieve at most <i>sizelimit</i> entries for a search to complete.

EXAMPLES**EXAMPLE 1** Performing a Subtree Search

The following command performs a subtree search (using the default search base) for entries with a `commonName` of "mark smith". The `commonName` and `telephoneNumber` values will be retrieved and printed to standard output.

```
example% ldapsearch "cn=mark smith" cn telephoneNumber
```

The output looks something like this:

```
cn=Mark D Smith, ou=Sales, ou=Atlanta, ou=People, o=XYZ, c=US
cn=Mark Smith
cn=Mark David Smith
cn=Mark D Smith 1
cn=Mark D Smith
telephoneNumber=+1 123 456-7890
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
cn=Mark Smith
cn=Mark C Smith 1
cn=Mark C Smith
telephoneNumber=+1 123 456-9999
```

EXAMPLE 2 Performing a Subtree Search Using the Default Search Base

The following command performs a subtree search using the default search base for entries with user id of "mcs". The user-friendly form of the entry's DN will be output after the line that contains the DN itself, and the `jpegPhoto` and `audio` values will be retrieved and written to temporary files.

```
example%ldapsearch -u -t "uid=mcs" jpegPhoto audio
```

The output might look like this if one entry with one value for each of the requested attributes is found:

ldapsearch(1)

EXAMPLE 2 Performing a Subtree Search Using the Default Search Base *(Continued)*

```
cn=Mark C Smith, ou=Distribution, ou=Atlanta, ou=People, o=XYZ, c=US
Mark C Smith, Distribution, Atlanta, People, XYZ, US
audio=/tmp/ldapsearch-audio-a19924
jpegPhoto=/tmp/ldapsearch-jpegPhoto-a19924
```

EXAMPLE 3 Performing a One Level Search

The following command performs a one-level search at the c=US level for all organizations whose organizationName begins with XY.

```
example% ldapsearch -L -s one -b "c=US" "o=XY*" o description
```

Search results are displayed in the LDIF format. The organizationName and description attribute values will be retrieved and printed to standard output, resulting in output similar to this:

```
dn: o=XYZ, c=US
o: XYZ
description: XYZ Corporation
dn: o="XY Trading Company", c=US
o: XY Trading Company
description: Import and export specialists

dn: o=XYInternational, c=US
o: XYInternational
o: XYI
o: XY International
```

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred. A diagnostic message is written to standard error.

NAME	ldd – list dynamic dependencies of executable files or shared objects
SYNOPSIS	ldd [-d -r] [-c] [-e <i>envvar</i>] [-f] [-i] [-L] [-l] [-s] [-u] [-v] <i>filename...</i>
DESCRIPTION	<p>The <code>ldd</code> utility lists the dynamic dependencies of executable files or shared objects. <code>ldd</code> uses the runtime linker, <code>ld.so.1</code>, to generate the diagnostics, since it takes the object being inspected and prepares it as it would in a running process. By default, <code>ldd</code> triggers the loading of any lazy dependencies.</p> <p>If <i>filename</i> is an executable file, <code>ldd</code> lists the path names of all shared objects that would be loaded when <i>filename</i> is loaded.</p> <p>If <i>filename</i> is a shared object, <code>ldd</code> lists the path names of all shared objects that would be loaded when <i>filename</i> is loaded. <code>ldd</code> expects shared objects to have execute permission. If this is not the case, <code>ldd</code> will issue a warning before attempting to process the file.</p> <p><code>ldd</code> processes its input one file at a time. For each input file, <code>ldd</code> performs one of the following:</p> <ul style="list-style-type: none"> ■ Lists the object dependencies if they exist. ■ Succeeds quietly if dependencies do not exist. ■ Prints an error message if processing fails.
OPTIONS	<p><code>ldd</code> can also check the compatibility of <i>filename</i> with the shared objects it uses. With each of the following options, <code>ldd</code> prints warnings for any unresolved symbol references that would occur if <i>filename</i> were executed.</p> <ul style="list-style-type: none"> - d Checks references to data objects. - r Checks references to both data objects and functions. <p>Only one of the above options may be given during any single invocation of <code>ldd</code>. See <i>Lazy Loading</i> under USAGE.</p> <ul style="list-style-type: none"> - c Disables any configuration file use. Configuration files may be employed to alter default search paths, provide a directory cache, and provide alternative object dependencies. See <code>crle(1)</code>. -e <i>envvar</i> Sets the environment variable <i>envvar</i>. This option is useful for experimenting with runtime linker environment variables that can adversely affect <code>ldd</code> itself. -f Forces <code>ldd</code> to check for an executable file that is not secure. When <code>ldd</code> is invoked by a super-user, by default it will not process any executable that it finds not secure. An executable is not considered secure if the interpreter it specifies does not reside under <code>/usr/lib</code> or <code>/etc/lib</code>, or if the interpreter cannot be determined. See <i>Security</i> under USAGE.

ldd(1)

- i Displays the order of execution of initialization sections. The order discovered may be affected by use of the `-d` or `-r` options. See `Initialization Order` under `USAGE`.
- L Enables lazy loading. This is the default mode of operation when the object under inspection is loaded as part of a process. In this case, any lazy dependencies, or filters, are only loaded into the process when reference is made to a symbol that is defined within the lazy object. The `-d` or `-r` options, together with the `-L` option, may be used to inspect the dependencies and their order of loading since it will occur in a running process.
- l Forces the immediate processing of any filters so that all filters, and their dependencies, are listed. The immediate processing of filters is now the default mode of operation for `ldd`. However, under this default any auxiliary filters that cannot be found are silently ignored. Under the `-l` option, missing auxiliary filters generate an error message.
- s Displays the search path used to locate shared object dependencies.
- u Displays any unused dependencies. When a symbol reference is bound to a dependency, that dependency is deemed used. This option is therefore only useful when symbol references are being checked. If the `-r` option is not in effect, the `-d` option is enabled.

Objects that are found to be unused when using the `-r` option should be removed as dependencies. They provide no references but result in unnecessary overhead when *filename* is loaded. Objects that are found to be unused when using the `-d` option are not immediately required when *filename* is loaded, and are therefore candidates for lazy loading (see `Lazy Loading` under `USAGE`).
- v Displays all dependency relationships incurred when processing *filename*. This option also displays any dependency version requirements. See `pvs(1)`.

USAGE

Security

A super-user should use the `-f` option only if the executable to be examined is known to be trustworthy, because use of `-f` on an untrustworthy executable while super-user may compromise system security. If it is unknown whether or not the executable to be examined is trustworthy, a super-user should temporarily become a regular user and invoke `ldd` as that regular user.

Untrustworthy objects can be safely examined with `dump(1)` and with `adb(1)`, as long as the `:r` subcommand is not used. In addition, a non-super-user can use either the `:r` subcommand of `adb` or `truss(1)` to examine an untrustworthy executable without too much risk of compromise. To minimize risk when using `ldd`, `adb :r`, or `truss` on an untrustworthy executable, use the user id "nobody".

Lazy Loading

Objects that employ lazy loading techniques, either through directly specified lazy dependencies (see the `-z lazyload` option of `ld(1)`), or through filters (see the `-f` and `-F` options of `ld(1)`), may experience variations in `ldd` output due to the options they use. If an object expresses all its dependencies as lazy, the default operation of `ldd` will list all dependencies in the order in which they are recorded in that object:

```
example% ldd main
libelf.so.1 => /usr/lib/libelf.so.1
libnsl.so.1 => /usr/lib/libnsl.so.1
libc.so.1 => /usr/lib/libc.so.1
```

The lazy loading behavior that occurs when this object is used at runtime may be enabled using the `-L` option. In this mode, lazy dependencies are loaded when reference is made to a symbol that is defined within the lazy object. Therefore, combining the `-L` option with use of the `-d` and `-r` options will reveal the dependencies needed to satisfy the data and function references respectively:

```
example% ldd -L main
example% ldd -d main
libc.so.1 => /usr/lib/libc.so.1
example% ldd -r main
libc.so.1 => /usr/lib/libc.so.1
libelf.so.1 => /usr/lib/libelf.so.1
```

Note that in this example, the order of the dependencies listed is not the same as displayed from `ldd` with no options, and even with the `-r` option, the function reference to dependencies may not occur in the same order as it will in a running program.

Observing lazy loading may also reveal objects that are not required to satisfy any references. These objects (in this example, `libnsl.so.1`) are candidates for removal from the link-line used to build the object being inspected.

Initialization Order

Objects that do not explicitly define their required dependencies may observe variations in the initialization section order displayed by `ldd` due to the options they use. For example, a simple application may reveal:

```
example% ldd -i main
libA.so.1 => ./libA.so.1
libc.so.1 => /usr/lib/libc.so.1
libB.so.1 => ./libB.so.1

init object=./libB.so.1
init object=./libA.so.1
```

ldd(1)

init object=/usr/lib/libc.so.1 whereas, when relocations are applied, the initialization section order is:

```
example% ldd -ir main
.....
```

```
init object=/usr/lib/libc.so.1
init object=./libB.so.1
init object=./libA.so.1
```

In this case, `libB.so.1` makes reference to a function in `/usr/lib/libc.so.1`. However, it has no explicit dependency on this library. Only after a relocation is discovered is a dependency established, which in turn affects the initialization section sort order.

Typically, the initialization section sort order established when an application is executed is equivalent to `ldd` with the `-d` option. The optimum order can be obtained if all objects fully define their dependencies. Use of the `ld(1)` options `-z defs` and `-z ignore` when building dynamic objects is recommended.

Cyclic dependencies may result when one or more dynamic objects reference each other. Cyclic dependencies should be avoided, as a unique initialization sort order for these dependencies can not be established.

Users that prefer a more static analysis of object files may inspect dependencies using tools such as `dump(1)` and `elfdump(1)`.

FILES `/usr/lib/lddstub` Fake executable loaded to check the dependencies of shared objects.

Linker and Libraries Guide

DIAGNOSTICS `ldd` prints the record of shared object path names to `stdout`. The optional list of symbol resolution problems is printed to `stderr`. If *filename* is not an executable file or a shared object, or if it cannot be opened for reading, a non-zero exit status is returned.

NOTES `ldd` does not list shared objects explicitly attached using `dlopen(3DL)`.

ldd(1)

Using the `-d` or `-r` option with shared objects can give misleading results. `ldd` does a "worst case" analysis of the shared objects. However, in practice some or all of the symbols reported as unresolved can be resolved by the executable file referencing the shared object. The runtime linker's preloading mechanism (see `LD_PRELOAD`) may be employed to add dependencies to the object being inspected.

`ldd` uses the same algorithm as the runtime linker to locate shared objects.

ld.so.1(1)

NAME	ld.so.1 – runtime linker for dynamic objects
SYNOPSIS	<code>/usr/lib/ld.so.1</code> <code>/etc/lib/ld.so.1</code>
DESCRIPTION	<p>Dynamic applications consist of one or more dynamic objects. They are typically a dynamic executable and its shared object dependencies. As part of the initialization and execution of a dynamic application, an <i>interpreter</i> is called to complete the binding of the application to its shared object dependencies. In Solaris, this interpreter is referred to as the runtime linker.</p> <p>During the link-editing of a dynamic executable, a special <i>.interp</i> section, together with an associated program header, is created. This section contains a pathname specifying the program's interpreter. The pathname to the interpreter can be specified when the executable is being constructed by the <code>-I</code> option to <code>ld(1)</code> the link-editor. The default name supplied by the link-editor is that of the runtime linker, <code>/usr/lib/ld.so.1</code>.</p> <p>During the process of executing a dynamic executable the kernel maps the file and locates the required interpreter. See <code>exec(2)</code> and <code>mmap(2)</code>. The kernel maps this interpreter and transfers control to it, passing sufficient information to allow the interpreter to continue binding the application and then run it.</p> <p>In addition to initializing an application, the runtime linker provides services that allow the application to extend its address space by mapping additional shared objects and binding to symbols within them.</p> <p>The runtime linker performs the following functions:</p> <ul style="list-style-type: none">■ It opens and processes any applicable configuration file. Configuration files may be employed to alter default search paths, provide a directory cache and provide alternative object dependencies. See <code>crle(1)</code>. By default, the configuration file <code>/var/ld/ld.config</code> is used for 32-bit objects and <code>/var/ld/64/ld.config</code> for 64-bit objects. Alternative configuration files can be specified with the <code>LD_CONFIG</code> environment variable, or encoded within a dynamic executable using the <code>-c</code> option of <code>ld(1)</code>.■ It analyzes the application's dynamic information section (<i>.dynamic</i>) and determines which shared object dependencies are required.■ It locates and maps in these dependencies, and then it analyzes their dynamic information sections to determine if any additional shared object dependencies are required.■ Once all shared object dependencies are located and mapped, the runtime linker performs any necessary relocations to bind these shared objects in preparation for process execution.■ It calls any initialization functions provided by the shared object dependencies and, possibly, by the dynamic executable. By default, these are called in the reverse order of the topologically sorted dependencies. If cyclic dependencies exist, the initialization functions are called using the sorted order with the cycle removed.

ldd(1) can be used to display the initialization order of shared object dependencies.

- It passes control to the application.
- During the application's execution, the runtime linker can be called upon to perform any delayed function binding.
- It calls any finalization functions on deletion of shared objects from the process. By default these are called in the order of the topologically sorted dependencies.
- The application can also call upon the runtime linker's services to acquire additional shared objects by dlopen(3DL) and bind to symbols within these objects with dlsym(3DL)

Further details on each of the above topics may be found in the *Linker and Libraries Guide*.

The runtime linker uses a prescribed search path for locating the dynamic dependencies of an object. The default search paths are the `runpath` recorded in the object, followed by `/usr/lib` for 32-bit objects or `/usr/lib/64` for 64-bit objects. This latter component can be modified using a configuration file created with `crle(1)`. The `runpath` is specified when the dynamic object is constructed using the `-R` option to `ld(1)`. `LD_LIBRARY_PATH` can be used to indicate directories to be searched before the default directories.

ENVIRONMENT VARIABLES

<code>LD_AUDIT</code>	A colon-separated list of objects that will be loaded by the runtime linker. As each object is loaded, it will be examined for <i>Link-Auditing</i> interfaces; the routines that are present will be called as specified in the <i>Link-Auditing</i> interface described in the <i>Linker and Libraries Guide</i> . Also, see the <code>-p</code> and <code>-P</code> options of <code>ld(1)</code> .
<code>LD_BIND_NOW</code>	The runtime linker's default mode of performing lazy binding can be overridden by setting the environment variable <code>LD_BIND_NOW</code> to any non-null value. This setting causes the runtime linker to perform both data reference and function reference relocations during process initialization, before transferring control to the application. Also see the <code>-z now</code> option of <code>ld(1)</code> .
<code>LD_CONFIG</code>	Provides an alternative configuration file. Configuration files may be employed to alter default search paths, provide a directory cache and provide alternate object dependencies. See <code>crle(1)</code> .
<code>LD_DEBUG</code>	Provides a comma, or colon-separated list of tokens to cause the runtime linker to print debugging information to the standard error. The special token <code>help</code> indicates the full list of tokens available. The environment variable <code>LD_DEBUG_OUTPUT</code> may also be

	<p>supplied to specify a file to which the debugging information is sent. The filename will be suffixed with the process id of the application generating the debugging information.</p>
LD_DEMANGLE	<p>Any symbol name used as part of a diagnostic message is shown as it is defined within an ELF file. When LD_DEMANGLE is set to any non-null value, the runtime linker will attempt to decode (demangle) any C++ symbol name.</p>
LD_FLAGS	<p>Provides an alternative means of supplying environment variable information. Any of the LD_XXX environment variables can be specified as a <i>xxx</i> token. Multiple tokens can be supplied separated by commas. See EXAMPLES.</p>
LD_LIBRARY_PATH	<p>The LD_LIBRARY_PATH environment variable, if set, is used to enhance the search path that the runtime linker uses to find dynamic dependencies. LD_LIBRARY_PATH specifies a colon-separated list of directories that are to be searched before the default directories. Also notice that LD_LIBRARY_PATH adds additional semantics to ld(1).</p>
LD_LOADFLTR	<p>Filters are a form of shared object. They allow an alternative shared object to be selected at runtime and provide the implementation for any symbols defined within the filter. See the -f and -F options of ld(1). By default, the alternative shared object processing is deferred until symbol resolution occurs against the filter. When LD_LOADFLTR is set to any non-null value, the runtime linker will process filters immediately when they are loaded. Also see the -z loadfltr option of ld(1).</p>
LD_NOAUDIT	<p>Local auditing libraries can be defined within applications and shared objects. See the -p and -P options of ld(1). When LD_NOAUDIT is set to any non-null value, the runtime linker will ignore any local auditing libraries.</p>
LD_NOAUXFLTR	<p>Auxiliary filters are a form of shared object. They allow an alternative shared object to be selected at runtime which provides the implementation for any symbols defined within the filter. See the -f option of ld(1). When LD_NOAUXFLTR is set to any non-null value, the runtime linker will disable this alternative shared object lookup.</p>

LD_NOCONFIG	By default the runtime linker attempts to open and process a configuration file. When LD_NOCONFIG is set to any non-null value, the runtime linker will disable this configuration file processing.
LD_NODIRCONFIG	Provides a subset of LD_NOCONFIG in that any directory cache information provided in a configuration file is ignored.
LD_NODIRECT	Direct binding information instructs the runtime linker to search directly for a symbol in an associated object, rather than carry out the default symbol search model. See the <code>-B direct</code> option of <code>ld(1)</code> . When LD_NODIRECT is set to any non-null value, the runtime linker will ignore any direct binding information.
LD_NOLAZYLOAD	Dependencies labeled for lazy loading are not loaded into memory until explicit reference has been made to them. See the <code>-z lazyload</code> option of <code>ld(1)</code> . When LD_NOLAZYLOAD is set to any non-null value, the runtime linker will ignore a dependencies lazy loading label and load it immediately.
LD_NOOBJALTER	Provides a subset of LD_NOCONFIG in that any alternative object dependencies provided in a configuration file are ignored.
LD_NOVERSION	By default the runtime linker verifies version dependencies for the primary executable and all of its dependencies. When LD_NOVERSION is set to any non-null value, the runtime linker will disable this version checking.
LD_ORIGIN	The immediate processing of <code>\$ORIGIN</code> can be triggered by setting the environment variable LD_ORIGIN to any non-null value. This may be useful for applications that invoke <code>chdir(2)</code> prior to locating dependencies that employ the <code>\$ORIGIN</code> string token.
LD_PRELOAD	Provides a whitespace-separated list of shared objects that are to be interpreted by the runtime linker. The specified shared objects are linked after the program is executed but before any other shared objects that the program references.
LD_PROFILE	Defines a shared object that will be profiled by the runtime linker. When profiling is enabled, a profiling buffer file is created and mapped. The name of the buffer file is the name of the shared object being profiled with a <code>.profile</code> extension. By default, this buffer is placed under <code>/var/tmp</code> . The environment

ld.so.1(1)

variable `LD_PROFILE_OUTPUT` may also be supplied to indicate an alternative directory in which to place the profiling buffer.

This buffer contains `profil(2)` and call count information similar to the *gmon.out* information generated by programs that have been linked with the `-xpg` option of `cc`. Any applications that use the named shared object and run while this environment variable is set will accumulate data in the profile buffer. The profile buffer information may be examined using `gprof(1)`.

Notice that this profiling technique is an alternative to any that may be provided by the compilation system. The shared object being profiled does not have to be instrumented in any way, and `LD_PROFILE` should not be combined with a profile-instrumented application. See the *Linker and Libraries Guide* for more information on profiling shared objects.

Each environment variable can be specified with a `_32` or `_64` suffix. This makes the environment variable specific, respectively, to 32-bit or 64-bit processes and overrides any non-suffixed version of the environment variable that may be in effect.

Notice that environment variable names beginning with the characters `'LD_'` are reserved for possible future enhancements to `ld(1)` and `ld.so.1`.

SECURITY

Secure processes have some restrictions applied to the evaluation of their dependencies and runpaths to prevent malicious dependency substitution or symbol interposition.

The runtime linker categorizes a process as secure if the user is not a super-user, and either the real user and effective user identifiers are not equal, or the real group and effective group identifiers are not equal. See `getuid(2)`, `geteuid(2)`, `getgid(2)`, and `getegid(2)`.

The default trusted directory known to the runtime linker is `/usr/lib/secure` for 32-bit objects or `/usr/lib/secure/64` for 64-bit objects. The utility `crle(1)` may be used to specify additional trusted directories applicable for secure applications. Administrators who use this technique should ensure that the target directories are suitably protected from malicious intrusion.

If an `LD_LIBRARY_PATH` environment variable is in effect for a secure process, then only the *trusted* directories specified by this variable will be used to augment the runtime linker's search rules.

In a secure process, any `runpath` specifications provided by the application or any of its dependencies will be used, provided they are full pathnames, that is, the pathname starts with a `'/'`.

In a secure process, the expansion of the `$ORIGIN` string is allowed only if it expands to a *trusted* directory.

Additional objects may be loaded with a secure process using the `LD_PRELOAD`, or `LD_AUDIT` environment variables. These objects must be specified as *full* pathnames or *simple* file names. Full pathnames are restricted to known *trusted* directories. Simple file names, in which no `'/'` appears in the name, are located subject to the search path restrictions previously described, and thus will only resolve to known *trusted* directories.

In a secure process, any dependencies that consist of simple filenames will be processed using the pathname restrictions previously described. Dependencies that are expressed as full or relative pathnames will be used as is. Therefore, the developer of a secure process should ensure that the target directory referenced as a full or relative pathname dependency is suitably protected from malicious intrusion.

When creating a secure process, it is recommended that relative pathnames *not* be used to express dependencies or to construct `dlopen(3DL)` pathnames. This restriction should be applied to the application and to *all* dependencies.

EXAMPLES

EXAMPLE 1 Using `LD_FLAGS` to group environment variable information

The following use of `LD_FLAGS`,

```
example% LD_FLAGS_32=bind_now,library_path=/lib/one:/lib/two
example% LD_FLAGS_64=library_path=/lib/one/64,preload=foo.so
```

is equivalent to setting the individual environment variables `LD_BIND_NOW` and `LD_LIBRARY_PATH` for 32-bit applications, and `LD_LIBRARY_PATH` and `LD_PRELOAD` for 64-bit applications.

FILES

<code>/usr/lib/ld.so.1</code>	Default runtime linker.
<code>/etc/lib/ld.so.1</code>	Alternate runtime linker.
<code>/usr/lib/libc.so.1</code>	Alternate interpreter for SVID ABI compatibility.
<code>/usr/lib/ld.so</code>	AOUT(BCP) runtime linker.
<code>/usr/lib/0@0.so.1</code>	Null character pointer compatibility library. See NOTES.
<code>/usr/lib/secure</code>	<code>LD_PRELOAD</code> location for secure applications.
<code>/usr/lib/secure/64</code>	<code>LD_PRELOAD</code> location for secure 64-bit applications.

ld.so.1(1)

<code>/usr/lib/64/ld.so.1</code>	Default runtime linker for 64-bit applications.
<code>/usr/lib/64/0@0.so.1</code>	Null character pointer compatibility library for the 64-bit applications.
<code>/var/ld/ld.config</code>	Default configuration file for 32-bit applications.
<code>/var/ld/64/ld.config</code>	Default configuration file for 64-bit applications.

Linker and Libraries Guide

NOTES The user compatibility library `/usr/lib/0@0.so.1` provides a mechanism that establishes a value of 0 at location 0. Some applications exist that erroneously assume a null character pointer should be treated the same as a pointer to a null string. A segmentation violation will occur in these applications when a null character pointer is accessed. If this library is added to such an application at runtime using `LD_PRELOAD`, it provides an environment that is sympathetic to this errant behavior. However, the user compatibility library is intended neither to enable the generation of such applications, nor to endorse this particular programming practice.

NAME | let – shell built-in function to evaluate one or more arithmetic expressions

SYNOPSIS

ksh | **let** *arg...*

DESCRIPTION

ksh | Each *arg* is a separate "arithmetic expression" to be evaluated.

EXIT STATUS | The following exit values are returned:

0 | The value of the last expression is non-zero.

1 | The value of the last expression is zero.

ATTRIBUTES | See `attributes(5)` for descriptions of the following attributes:

lex(1)

NAME	lex – generate programs for lexical tasks
SYNOPSIS	lex [-cntv] [-e -w] [-V -Q [y n]] [file...]
DESCRIPTION	The <code>lex</code> utility generates C programs to be used in lexical processing of character input, and that can be used as an interface to <code>yacc</code> . The C programs are generated from <code>lex</code> source code and conform to the ISO C standard. Usually, the <code>lex</code> utility writes the program it generates to the file <code>lex.yy.c</code> ; the state of this file is unspecified if <code>lex</code> exits with a non-zero exit status. See EXTENDED DESCRIPTION for a complete description of the <code>lex</code> input language.
OPTIONS	<p>The following options are supported:</p> <ul style="list-style-type: none">-c Indicate C-language action (default option).-e Generate a program that can handle EUC characters (cannot be used with the <code>-w</code> option). <code>ytext []</code> is of type <code>unsigned char []</code>.-n Suppress the summary of statistics usually written with the <code>-v</code> option. If no table sizes are specified in the <code>lex</code> source code and the <code>-v</code> option is not specified, then <code>-n</code> is implied.-t Write the resulting program to standard output instead of <code>lex.yy.c</code>.-v Write a summary of <code>lex</code> statistics to the standard error. (See the discussion of <code>lex</code> table sizes under the heading <i>Definitions in lex</i>.) If table sizes are specified in the <code>lex</code> source code, and if the <code>-n</code> option is not specified, the <code>-v</code> option may be enabled.-w Generate a program that can handle EUC characters (cannot be used with the <code>-e</code> option). Unlike the <code>-e</code> option, <code>ytext []</code> is of type <code>wchar_t []</code>.-V Print out version information on standard error.-Q[y n] Print out version information to output file <code>lex.yy.c</code> by using <code>-Qy</code>. The <code>-Qn</code> option does not print out version information and is the default.
OPERANDS	<p>The following operand is supported:</p> <ul style="list-style-type: none"><code>file</code> A pathname of an input file. If more than one such <code>file</code> is specified, all files will be concatenated to produce a single <code>lex</code> program. If no <code>file</code> operands are specified, or if a <code>file</code> operand is <code>-</code>, the standard input will be used.
OUTPUT	
Stdout	If the <code>-t</code> option is specified, the text file of C source code output of <code>lex</code> will be written to standard output.

Stderr	<p>If the <code>-t</code> option is specified informational, error and warning messages concerning the contents of <code>lex</code> source code input will be written to the standard error.</p> <p>If the <code>-t</code> option is not specified:</p> <ol style="list-style-type: none"> 1. Informational error and warning messages concerning the contents of <code>lex</code> source code input will be written to either the standard output or standard error. 2. If the <code>-v</code> option is specified and the <code>-n</code> option is not specified, <code>lex</code> statistics will also be written to standard error. These statistics may also be generated if table sizes are specified with a <code>%</code> operator in the <code>Definitions in lex</code> section (see <code>EXTENDED DESCRIPTION</code>), as long as the <code>-n</code> option is not specified.
Output Files	<p>A text file containing C source code will be written to <code>lex.yy.c</code>, or to the standard output if the <code>-t</code> option is present.</p>
EXTENDED DESCRIPTION	<p>Each input file contains <code>lex</code> source code, which is a table of regular expressions with corresponding actions in the form of C program fragments.</p> <p>When <code>lex.yy.c</code> is compiled and linked with the <code>lex</code> library (using the <code>-l lex</code> operand with <code>c89</code> or <code>cc</code>), the resulting program reads character input from the standard input and partitions it into strings that match the given expressions.</p> <p>When an expression is matched, these actions will occur:</p> <ul style="list-style-type: none"> ■ The input string that was matched is left in <code>yytext</code> as a null-terminated string; <code>yytext</code> is either an external character array or a pointer to a character string. As explained in <code>Definitions in lex</code>, the type can be explicitly selected using the <code>%array</code> or <code>%pointer</code> declarations, but the default is <code>%array</code>. ■ The external <code>int yyleng</code> is set to the length of the matching string. ■ The expression's corresponding program fragment, or action, is executed. <p>During pattern matching, <code>lex</code> searches the set of patterns for the single longest possible match. Among rules that match the same number of characters, the rule given first will be chosen.</p> <p>The general format of <code>lex</code> source is:</p> <pre> Definitions %% Rules %% User Subroutines </pre> <p>The first <code>%%</code> is required to mark the beginning of the rules (regular expressions and actions); the second <code>%%</code> is required only if user subroutines follow.</p>

lex(1)

Any line in the `Definitions in lex` section beginning with a blank character will be assumed to be a C program fragment and will be copied to the external definition area of the `lex.yy.c` file. Similarly, anything in the `Definitions in lex` section included between delimiter lines containing only `%{` and `%}` will also be copied unchanged to the external definition area of the `lex.yy.c` file.

Any such input (beginning with a blank character or within `%{` and `%}` delimiter lines) appearing at the beginning of the `Rules` section before any rules are specified will be written to `lex.yy.c` after the declarations of variables for the `yylex` function and before the first line of code in `yylex`. Thus, user variables local to `yylex` can be declared here, as well as application code to execute upon entry to `yylex`.

The action taken by `lex` when encountering any input beginning with a blank character or within `%{` and `%}` delimiter lines appearing in the `Rules` section but coming after one or more rules is undefined. The presence of such input may result in an erroneous definition of the `yylex` function.

Definitions in lex

`Definitions in lex` appear before the first `%%` delimiter. Any line in this section not contained between `%{` and `%}` lines and not beginning with a blank character is assumed to define a `lex` substitution string. The format of these lines is:

name substitute

If a *name* does not meet the requirements for identifiers in the ISO C standard, the result is undefined. The string *substitute* will replace the string `{ name }` when it is used in a rule. The *name* string is recognized in this context only when the braces are provided and when it does not appear within a bracket expression or within double-quotes.

In the `Definitions in lex` section, any line beginning with a `%` (percent sign) character and followed by an alphanumeric word beginning with either `s` or `S` defines a set of start conditions. Any line beginning with a `%` followed by a word beginning with either `x` or `X` defines a set of exclusive start conditions. When the generated scanner is in a `%s` state, patterns with no state specified will be also active; in a `%x` state, such patterns will not be active. The rest of the line, after the first word, is considered to be one or more blank-character-separated names of start conditions. Start condition names are constructed in the same way as definition names. Start conditions can be used to restrict the matching of regular expressions to one or more states as described in `Regular expressions in lex`.

Implementations accept either of the following two mutually exclusive declarations in the `Definitions in lex` section:

<code>%array</code>	Declare the type of <i>yyltext</i> to be a null-terminated character array.
<code>%pointer</code>	Declare the type of <i>yyltext</i> to be a pointer to a null-terminated character string.

Note: When using the `%pointer` option, you may not also use the `yyless` function to alter `yytext`.

`%array` is the default. If `%array` is specified (or neither `%array` nor `%pointer` is specified), then the correct way to make an external reference to `yytext` is with a declaration of the form:

```
extern char yytext [ ]
```

If `%pointer` is specified, then the correct external reference is of the form:

```
extern char *yytext;
```

lex will accept declarations in the `Definitions in lex` section for setting certain internal table sizes. The declarations are shown in the following table.

Table Size Declaration in lex

Declaration	Description	Default
<code>%pn</code>	Number of positions	2500
<code>%nn</code>	Number of states	500
<code>%an</code>	Number of transitions	2000
<code>%en</code>	Number of parse tree nodes	1000
<code>%kn</code>	Number of packed character classes	10000
<code>%on</code>	Size of the output array	3000

Programs generated by `lex` need either the `-e` or `-w` option to handle input that contains EUC characters from supplementary codesets. If neither of these options is specified, `yytext` is of the type `char []`, and the generated program can handle only ASCII characters.

When the `-e` option is used, `yytext` is of the type `unsigned char []` and `yylen` gives the total number of *bytes* in the matched string. With this option, the macros `input ()`, `unput (c)`, and `output (c)` should do a byte-based I/O in the same way as with the regular ASCII `lex`. Two more variables are available with the `-e` option, `yywtext` and `yywleng`, which behave the same as `yytext` and `yylen` would under the `-w` option.

When the `-w` option is used, `yytext` is of the type `wchar_t []` and `yylen` gives the total number of *characters* in the matched string. If you supply your own `input ()`, `unput (c)`, or `output (c)` macros with this option, they must return or accept EUC characters in the form of wide character (`wchar_t`). This allows a different interface between your program and the `lex` internals, to expedite some programs.

lex(1)

Rules in lex	The Rules in lex source files are a table in which the left column contains regular expressions and the right column contains actions (C program fragments) to be executed when the expressions are recognized.
	<i>ERE action</i> <i>ERE action</i> ...
	The extended regular expression (ERE) portion of a row will be separated from <i>action</i> by one or more blank characters. A regular expression containing blank characters is recognized under one of the following conditions:
	<ul style="list-style-type: none">■ The entire expression appears within double-quotes.■ The blank characters appear within double-quotes or square brackets.■ Each blank character is preceded by a backslash character.
User Subroutines in lex	Anything in the user subroutines section will be copied to <code>lex.yy.c</code> following <code>yylex</code> .
Regular Expressions in lex	The lex utility supports the set of Extended Regular Expressions (EREs) described on <code>regex(5)</code> with the following additions and exceptions to the syntax:
 Any string enclosed in double-quotes will represent the characters within the double-quotes as themselves, except that backslash escapes (which appear in the following table) are recognized. Any backslash-escape sequence is terminated by the closing quote. For example, " <code>\ 01"1</code> " represents a single string: the octal value 1 followed by the character 1.
	<code><state>r</code>
	<code><state1, state2, ...>r</code>
	The regular expression <i>r</i> will be matched only when the program is in one of the start conditions indicated by <i>state</i> , <i>state1</i> , and so forth; for more information see <i>Actions in lex</i> (As an exception to the typographical conventions of the rest of this document, in this case <code><state></code> does not represent a metavariable, but the literal angle-bracket characters surrounding a symbol.) The start condition is recognized as such only at the beginning of a regular expression.
	<code>r/x</code>
	The regular expression <i>r</i> will be matched only if it is followed by an occurrence of regular expression <i>x</i> . The token returned in <i>yytext</i> will only match <i>r</i> . If the trailing portion of <i>r</i> matches the beginning of <i>x</i> , the result is unspecified. The <i>r</i> expression cannot include further trailing context or the <code>\$</code> (match-end-of-line) operator; <i>x</i> cannot include the <code>^</code> (match-beginning-of-line) operator, nor trailing context, nor the <code>\$</code> operator. That is, only one occurrence of trailing context is allowed in a lex regular expression, and the <code>^</code> operator only can be used at the beginning of such an expression. A further restriction is that the trailing-context operator <code>/</code> (slash) cannot be grouped within parentheses.

`{name}`

When *name* is one of the substitution symbols from the *Definitions* section, the string, including the enclosing braces, will be replaced by the *substitute* value. The *substitute* value will be treated in the extended regular expression as if it were enclosed in parentheses. No substitution will occur if `{name}` occurs within a bracket expression or within double-quotes.

Within an ERE, a backslash character (`\\`, `\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`) is considered to begin an escape sequence. In addition, the escape sequences in the following table will be recognized.

A literal newline character cannot occur within an ERE; the escape sequence `\n` can be used to represent a newline character. A newline character cannot be matched by a period operator.

Escape Sequences in lex

Escape Sequences in lex		
Escape Sequence	Description	Meaning
<code>\digits</code>	A backslash character followed by the longest sequence of one, two or three octal-digit characters (01234567). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the one-, two- or three-digit octal integer. Multi-byte characters require multiple, concatenated escape sequences of this type, including the leading <code>\</code> for each byte.
<code>\xdigits</code>	A backslash character followed by the longest sequence of hexadecimal-digit characters (01234567abcdefABCDEF). If all of the digits are 0, (that is, representation of the NUL character), the behavior is undefined.	The character whose encoding is represented by the hexadecimal integer.
<code>\c</code>	A backslash character followed by any character not described in this table. (<code>\\</code> , <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code>).	The character <i>c</i> , unchanged.

The order of precedence given to extended regular expressions for lex is as shown in the following table, from high to low.

Note: The escaped characters entry is not meant to imply that these are operators, but they are included in the table to show their relationships to the true

lex(1)

operators. The start condition, trailing context and anchoring notations have been omitted from the table because of the placement restrictions described in this section; they can only appear at the beginning or ending of an ERE.

ERE Precedence in lex	
<i>collation-related bracket symbols</i>	[= =] [: :] [. .]
<i>escaped characters</i>	\<special character>
<i>bracket expression</i>	[]
<i>quoting</i>	" . . . "
<i>grouping</i>	()
<i>definition</i>	{ name }
<i>single-character RE duplication</i>	* + ?
<i>concatenation</i>	
<i>interval expression</i>	{ m,n }
<i>alternation</i>	

The ERE anchoring operators (`^` and `$`) do not appear in the table. With `lex` regular expressions, these operators are restricted in their use: the `^` operator can only be used at the beginning of an entire regular expression, and the `$` operator only at the end. The operators apply to the entire regular expression. Thus, for example, the pattern `(^abc) | (def$)` is undefined; it can instead be written as two separate rules, one with the regular expression `^abc` and one with `def$`, which share a common action via the special `|` action (see below). If the pattern were written `^abc|def$`, it would match either of `abc` or `def` on a line by itself.

Unlike the general ERE rules, embedded anchoring is not allowed by most historical `lex` implementations. An example of embedded anchoring would be for patterns such as `(^)foo($)` to match `foo` when it exists as a complete word. This functionality can be obtained using existing `lex` features:

```
^foo/[ \ n] |
" foo"/[ \ n] /* found foo as a separate word */
```

Note also that `$` is a form of trailing context (it is equivalent to `/\ n` and as such cannot be used with regular expressions containing another instance of the operator (see the preceding discussion of trailing context).

The additional regular expressions trailing-context operator / (slash) can be used as an ordinary character if presented within double-quotes, " / "; preceded by a backslash, \ /; or within a bracket expression, [/]. The start-condition < and > operators are special only in a start condition at the beginning of a regular expression; elsewhere in the regular expression they are treated as ordinary characters.

The following examples clarify the differences between `lex` regular expressions and regular expressions appearing elsewhere in this document. For regular expressions of the form r/x , the string matching r is always returned; confusion may arise when the beginning of x matches the trailing portion of r . For example, given the regular expression a^*b/cc and the input `aaabcc`, *yytext* would contain the string `aaab` on this match. But given the regular expression x^*/xy and the input `xxxxy`, the token `xxx`, not `xx`, is returned by some implementations because `xxx` matches x^* .

In the rule ab^*/bc , the b^* at the end of r will extend r 's match into the beginning of the trailing context, so the result is unspecified. If this rule were ab/bc , however, the rule matches the text `ab` when it is followed by the text `bc`. In this latter case, the matching of r cannot extend into the beginning of x , so the result is specified.

Actions in `lex`

The action to be taken when an ERE is matched can be a C program fragment or the special actions described below; the program fragment can contain one or more C statements, and can also include special actions. The empty C statement `;` is a valid action; any string in the `lex.yy.c` input that matches the pattern portion of such a rule is effectively ignored or skipped. However, the absence of an action is not valid, and the action `lex` takes in such a condition is undefined.

The specification for an action, including C statements and special actions, can extend across several lines if enclosed in braces:

```
ERE <one or more blanks> { program statement
program statement }
```

The default action when a string in the input to a `lex.yy.c` program is not matched by any expression is to copy the string to the output. Because the default behavior of a program generated by `lex` is to read the input and copy it to the output, a minimal `lex` source program that has just `%%` generates a C program that simply copies the input to the output unchanged.

Four special actions are available:

```
| ECHO; REJECT; BEGIN
```

```
|
```

The action `|` means that the action for the next rule is the action for this rule. Unlike the other three actions, `|` cannot be enclosed in braces or be semicolon-terminated; it must be specified alone, with no other actions.

```
ECHO;
```

Write the contents of the string *yytext* on the output.

lex(1)

REJECT ;	Usually only a single expression is matched by a given string in the input. REJECT means "continue to the next expression that matches the current input," and causes whatever rule was the second choice after the current rule to be executed for the same input. Thus, multiple rules can be matched and executed for one input string or overlapping input strings. For example, given the regular expressions <i>xyz</i> and <i>xy</i> and the input <i>xyz</i> , usually only the regular expression <i>xyz</i> would match. The next attempted match would start after <i>z</i> . If the last action in the <i>xyz</i> rule is REJECT, both this rule and the <i>xy</i> rule would be executed. The REJECT action may be implemented in such a fashion that flow of control does not continue after it, as if it were equivalent to a goto to another part of <i>yylex</i> . The use of REJECT may result in somewhat larger and slower scanners.
BEGIN	The action: BEGIN <i>newstate</i> ; switches the state (start condition) to <i>newstate</i> . If the string <i>newstate</i> has not been declared previously as a start condition in the Definitions in lex section, the results are unspecified. The initial state is indicated by the digit 0 or the token INITIAL.
The functions or macros described below are accessible to user code included in the lex input. It is unspecified whether they appear in the C code output of lex, or are accessible only through the -l l operand to c89 or cc (the lex library).	
int yylex(void)	Performs lexical analysis on the input; this is the primary function generated by the lex utility. The function returns zero when the end of input is reached; otherwise it returns non-zero values (tokens) determined by the actions that are selected.
int yymore(void)	When called, indicates that when the next input string is recognized, it is to be appended to the current value of <i>yytext</i> rather than replacing it; the value in <i>yylen</i> is adjusted accordingly.
int yyless(int n)	Retains <i>n</i> initial characters in <i>yytext</i> , NUL-terminated, and treats the remaining characters as if they had not been read; the value in <i>yylen</i> is adjusted accordingly.
int input(void)	Returns the next character from the input, or zero on end-of-file. It obtains input from the stream pointer <i>yyin</i> , although possibly via an intermediate buffer. Thus, once scanning has begun, the effect of altering the value of <i>yyin</i> is undefined. The character read is

removed from the input stream of the scanner without any processing by the scanner.

```
int unput (int c)
```

Returns the character *c* to the input; *yytext* and *yylen* are undefined until the next expression is matched. The result of using *unput* for more characters than have been input is unspecified.

The following functions appear only in the `lex` library accessible through the `-l lex` operand; they can therefore be redefined by a portable application:

```
int yywrap (void)
```

Called by `yylex` at end-of-file; the default `yywrap` always will return 1. If the application requires `yylex` to continue processing with another source of input, then the application can include a function `yywrap`, which associates another file with the external variable `FILE *yyin` and will return a value of zero.

```
int main (int argc, char *argv [ ])
```

Calls `yylex` to perform lexical analysis, then exits. The user code can contain `main` to perform application-specific operations, calling `yylex` as applicable.

The reason for breaking these functions into two lists is that only those functions in `libl.a` can be reliably redefined by a portable application.

Except for `input`, `unput` and `main`, all external and static names generated by `lex` begin with the prefix `yy` or `YY`.

USAGE Portable applications are warned that in the `Rules in lex` section, an ERE without an action is not acceptable, but need not be detected as erroneous by `lex`. This may result in compilation or run-time errors.

The purpose of `input` is to take characters off the input stream and discard them as far as the lexical analysis is concerned. A common use is to discard the body of a comment once the beginning of a comment is recognized.

The `lex` utility is not fully internationalized in its treatment of regular expressions in the `lex` source code or generated lexical analyzer. It would seem desirable to have the lexical analyzer interpret the regular expressions given in the `lex` source according to the environment specified when the lexical analyzer is executed, but this is not possible with the current `lex` technology. Furthermore, the very nature of the lexical analyzers produced by `lex` must be closely tied to the lexical requirements of the input language being described, which will frequently be locale-specific anyway. (For example, writing an analyzer that is used for French text will not automatically be useful for processing other languages.)

EXAMPLES **EXAMPLE 1** Using `lex`

The following is an example of a `lex` program that implements a rudimentary scanner for a Pascal-like syntax:

```
%{
/* need this for the call to atof() below */
```

lex(1)

EXAMPLE 1 Using lex (Continued)

```
#include <math.h>
/* need this for printf(), fopen() and stdin below */
#include <stdio.h>
%}

DIGIT    [0-9]
ID       [a-z][a-z0-9]*
%%

{DIGIT}+ {
    printf("An integer: %s (%d)\n", yytext,
           atoi(yytext));
}

{DIGIT}+"."{DIGIT}* {
    printf("A float: %s (%g)\n", yytext,
           atof(yytext));
}

if|then|begin|end|procedure|function {
    printf("A keyword: %s\n", yytext);
}

{ID} {
    printf("An identifier: %s\n", yytext);
}

"+"|"-"|"*"|"\/" {
    printf("An operator: %s\n", yytext);
}

"{ "[^]\n}" * {
    /* eat up one-line comments */
}

[ \t\n]+ {
    /* eat up white space */
}

. {
    printf("Unrecognized character: %s\n", yytext);
}

%%

int main(int argc, char *argv[ ])
{
    ++argv, --argc; /* skip over program name */
    if (argc > 0)
        yyin = fopen(argv[0], "r");
    else
        yyin = stdin;

    yylex();
}
```

ENVIRONMENT VARIABLES

See `environ(5)` for descriptions of the following environment variables that affect the execution of `lex`: `LC_COLLATE`, `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned:

0	Successful completion.
>0	An error occurred.

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWbtool

SEE ALSO `yacc(1)`, `attributes(5)`, `environ(5)`, `regex(5)`

NOTES If routines such as `yyback()`, `yywrap()`, and `yylock()` in `.l` (ell) files are to be external C functions, the command line to compile a C++ program must define the `__EXTERN_C__` macro. For example:

```
example% cc -D__EXTERN_C__ . . . file
```

limit(1)

NAME	limit, ulimit, unlimited – set or get limitations on the system resources available to the current shell and its descendents
SYNOPSIS	<code>/usr/bin/ulimit [-f] [blocks]</code>
sh	<code>ulimit [- [HS] [a cdfnstv]]</code> <code>ulimit [- [HS] [c d f n s t v]] limit</code>
csh	<code>limit [-h] [resource [limit]]</code> <code>unlimit [-h] [resource]</code>
ksh	<code>ulimit [-HSacdfnstv] [limit]</code>
DESCRIPTION	
/usr/bin/ulimit	The <code>ulimit</code> utility sets or reports the file-size writing limit imposed on files written by the shell and its child processes (files of any size may be read). Only a process with appropriate privileges can increase the limit.
sh	The Bourne shell built-in function, <code>ulimit</code> , prints or sets hard or soft resource limits. These limits are described in <code>getrlimit(2)</code> . If <i>limit</i> is not present, <code>ulimit</code> prints the specified limits. Any number of limits may be printed at one time. The <code>-a</code> option prints all limits. If <i>limit</i> is present, <code>ulimit</code> sets the specified limit to <i>limit</i> . The string <code>unlimited</code> requests the largest valid limit. Limits may be set for only one resource at a time. Any user may set a soft limit to any value below the hard limit. Any user may lower a hard limit. Only a super-user may raise a hard limit; see <code>su(1M)</code> . The <code>-H</code> option specifies a hard limit. The <code>-S</code> option specifies a soft limit. If neither option is specified, <code>ulimit</code> will set both limits and print the soft limit. The following options specify the resource whose limits are to be printed or set. If no option is specified, the file size limit is printed or set. -c maximum core file size (in 512-byte blocks) -d maximum size of data segment or heap (in kbytes) -f maximum file size (in 512-byte blocks) -n maximum file descriptor plus 1 -s maximum size of stack segment (in kbytes) -t maximum CPU time (in seconds) -v maximum size of virtual memory (in kbytes)

csh The C-shell built-in function, `limit`, limits the consumption by the current process or any process it spawns, each not to exceed *limit* on the specified *resource*. If *limit* is omitted, print the current limit; if *resource* is omitted, display all limits. (Run the `sysdef(1M)` command to obtain the maximum possible limits for your system. The values reported are in hexadecimal, but can be translated into decimal numbers using the `bc(1)` command).

`-h` Use hard limits instead of the current limits. Hard limits impose a ceiling on the values of the current limits. Only the privileged user may raise the hard limits.

resource is one of:

<code>cputime</code>	Maximum CPU seconds per process.
<code>filesize</code>	Largest single file allowed; limited to the size of the filesystem (see <code>df(1M)</code>).
<code>datasize</code>	The maximum size of a process's heap in kilobytes.
<code>stacksize</code>	Maximum stack size for the process (see <code>swap(1M)</code>).
<code>coredumpsize</code>	Maximum size of a core dump (file). This is limited to the size of the filesystem.
<code>descriptors</code>	Maximum number of file descriptors (run <code>sysdef ()</code>).
<code>memorysize</code>	Maximum size of virtual memory.

limit is a number, with an optional scaling factor, as follows:

<code>nh</code>	Hours (for <code>cputime</code>).
<code>nk</code>	<i>n</i> kilobytes. This is the default for all but <code>cputime</code> .
<code>nm</code>	<i>n</i> megabytes or minutes (for <code>cputime</code>).
<code>mm:ss</code>	Minutes and seconds (for <code>cputime</code>).

`unlimit` removes a limitation on *resource*. If no *resource* is specified, then all resource limitations are removed. See the description of the `limit` command for the list of resource names.

`-h` Remove corresponding hard limits. Only the privileged user may do this.

ksh The Korn shell built-in function, `ulimit`, sets or displays a resource limit. The available resources limits are listed below. Many systems do not contain one or more of these limits. The limit for a specified resource is set when *limit* is specified. The value of *limit* can be a number in the unit specified below with each resource, or the value `unlimited`. The `-H` and `-S` flags specify whether the hard limit or the soft limit for the given resource is set. A hard limit cannot be increased once it is set. A soft limit can be increased up to the value of the hard limit. If neither the `-H` or `-S` options is

limit(1)

specified, the limit applies to both. The current resource limit is printed when *limit* is omitted. In this case, the soft limit is printed unless *-H* is specified. When more than one resource is specified, then the limit name and unit is printed before the value.

- a Lists all of the current resource limits.
- c The number of 512-byte blocks on the size of core dumps.
- d The number of K-bytes on the size of the data area.
- f The number of 512-byte blocks on files written by child processes (files of any size may be read).
- n The number of file descriptors plus 1.
- s The number of K-bytes on the size of the stack area.
- t The number of seconds (CPU time) to be used by each process.
- v The number of K-bytes for virtual memory.

If no option is given, *-f* is assumed.

OPTIONS The following option is supported by `ulimit`:

- f Set (or report, if no *blocks* operand is present), the file size limit in blocks. The *-f* option is also the default case.

OPERANDS The following operand is supported by `ulimit`:

blocks The number of 512-byte blocks to use as the new file size limit.

EXAMPLES

`/usr/bin/ulimit`

EXAMPLE 1 Limiting the stack size

To limit the stack size to 512 kilobytes:

```
% ulimit -s 512
% ulimit -a
% time(seconds)          unlimited
file(blocks)             100
data(kbytes)             523256
stack(kbytes)            512
coredump(blocks)        200
nofiles(descriptors)     64
memory(kbytes)          unlimited
```

`sh/ksh`

EXAMPLE 2 Limiting the number of file descriptors

To limit the number of file descriptors to 12:

```
$ ulimit -n 12
$ ulimit -a
time(seconds)          unlimited
file(blocks)           41943
```

EXAMPLE 2 Limiting the number of file descriptors *(Continued)*

```

data(kbytes)          523256
stack(kbytes)         8192
coredump(blocks)     200
nofiles(descriptors) 12
vmemory(kbytes)       unlimited

```

cs **EXAMPLE 3** Limiting the core dump file size

To limit the size of a core dump file size to 0 kilobytes:

```

% limit coredumpsize 0
% limit
cputime          unlimited
filesize        unlimited
datasize        523256 kbytes
stacksize       8192 kbytes
coredumpsize    0 kbytes
descriptors     64
memorysize      unlimited

```

EXAMPLE 4 Removing the limitation for core file size

To remove the above limitation for the core file size:

```

% unlimit coredumpsize
% limit
cputime          unlimited
filesize        unlimited
datasize        523256 kbytes
stacksize       8192 kbytes
coredumpsize    unlimited
descriptors     64
memorysize      unlimited

```

ENVIRONMENT VARIABLES

See [environ\(5\)](#) for descriptions of the following environment variables that affect the execution of `ulimit`: `LC_CTYPE`, `LC_MESSAGES`, and `NLSPATH`.

EXIT STATUS

The following exit values are returned by `ulimit`:

- 0 Successful completion.
- >0 A request for a higher limit was rejected or an error occurred.

ATTRIBUTES

See [attributes\(5\)](#) for descriptions of the following attributes:

lint(1B)

NAME	lint – C program verifier
SYNOPSIS	<code>/usr/ucb/lint</code> [<i>options</i>]
DESCRIPTION	<code>/usr/ucb/lint</code> is the interface to the BSD Compatibility Package C program verifier. It is a script that looks for the link <code>/usr/ccs/bin/ucblint</code> to the C program verifier. <code>/usr/ccs/bin/ucblint</code> is available only with the SPROcc package, whose default location is <code>/opt/SUNWspro</code> . <code>/usr/ucb/lint</code> is identical to <code>/usr/ccs/bin/ucblint</code> , except that BSD headers are used and BSD libraries are linked <i>before</i> base libraries. The <code>/opt/SUNWspro/man/man1/lint.1</code> man page is available only with the SPROcc package.
OPTIONS	<code>/usr/ucb/lint</code> accepts the same options as <code>/usr/ccs/bin/ucblint</code> , with the following exceptions: -I <i>dir</i> Search <i>dir</i> for included files whose names do not begin with a slash (/) prior to searching the usual directories. The directories for multiple -I options are searched in the order specified. The preprocessor first searches for <code>#include</code> files in the directory containing <i>sourcefile</i> , and then in directories named with -I options (if any), then <code>/usr/ucbinclude</code> , and finally, in <code>/usr/include</code> . -L <i>dir</i> Add <i>dir</i> to the list of directories searched for libraries by <code>/usr/ccs/bin/ucblint</code> . This option is passed to <code>/usr/ccs/bin/ld</code> . Directories specified with this option are searched before <code>/usr/ucb/lib</code> and <code>/usr/lib</code> . -Y P, <i>dir</i> Change the default directory used for finding libraries.
EXIT STATUS	The following exit values are returned: 0 Successful completion. >0 An error occurred.
FILES	<code>/usr/lint/bin/ld</code> link editor <code>/usr/lib/libc</code> C library <code>/usr/ucbinclude</code> BSD Compatibility directory for header files <code>/usr/ucb/lib</code> BSD Compatibility directory for libraries <code>/usr/ucb/lib/libucb</code> BSD Compatibility C library <code>/usr/lib/libsocket</code> library containing socket routines <code>/usr/lib/libnsl</code> library containing network functions <code>/usr/lib/libelf</code> library containing routines to process ELF object files <code>/usr/lib/libaio</code> library containing asynchronous I/O routines

lint(1B)

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE

listusers(1)

- NAME** listusers – list user login information
- SYNOPSIS** **listusers** [-g *groups*] [-l *logins*]
- DESCRIPTION** Executed without any options, this command lists all user logins sorted by login. The output shows the login ID and the account field value from the system's password database as specified by */etc/nsswitch.conf*.
- OPTIONS** The following options are supported:
- g *groups* Lists all user logins belonging to *group*, sorted by login. Multiple groups can be specified as a comma-separated list.
 - l *logins* Lists the user login or logins specified by *logins*, sorted by login. Multiple logins can be specified as a comma-separated list.
- ATTRIBUTES** See *attributes(5)* for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWcsu

SEE ALSO *nsswitch.conf(4)*, *attributes(5)*

NOTES A user login is one that has a UID of 100 or greater.

The -l and -g options can be combined. User logins will only be listed once, even if they belong to more than one of the selected groups.

NAME llc2_autoconfig – generate LLC2 configuration files

SYNOPSIS `/usr/lib/llc2/llc2_autoconfig [-f]`

DESCRIPTION The llc2_autoconfig utility is used to generate LLC2 configuration files (`/etc/llc2/default/llc2.*`). If there is no configuration file in `/etc/llc2_default/`, it detects all the available interfaces in the system and generates corresponding default configuration files.

If there are existing configuration files in `/etc/llc2_default/`, it will check if those interfaces defined in the files still exist. If they do not exist in the system, it will set `llc2_on` in those files to 0. After this, it will detect if there are new interfaces in the system. If there are, it will generate configuration files for them.

OPTIONS The following option is supported:

`-f` Erases all configuration files in `/etc/llc2/default/`. Then detects all the available interfaces in the system and generates corresponding default configuration files. Use this option with caution.

FILES `/etc/llc2/default/llc2.*` LLC2 configuration files

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

ATTRIBUTE TYPE	ATTRIBUTE VALUE
Availability	SUNWllc

llc2_config(1)

NAME llc2_config – configure LLC2 interface parameters

SYNOPSIS /usr/lib/llc2/llc2_config [-P | -U | -d | -q | -i *ppa* | -r *ppa*]

DESCRIPTION The llc2_config utility is used to start/stop the LLC2 subsystem and to configure LLC2 interface parameters.

OPTIONS The following options are supported:

- d Turns on debug mode. Extra debugging information will be printed out.
- i *ppa* Initializes the corresponding interface using the file /etc/llc2/default/llc2.*ppa*.
- P Reads in all /etc/llc2/default/llc2.* configuration files, opens those devices defined in the files, and sets up the streams needed for LLC2 to use those devices. Before doing this, llc2_config -q will not show anything.
- q Queries the LLC2 subsystem. Information similar to the following example will be printed out for all PPAs (Physical Point of Attachment) available under the LLC2 module:

PPA	State	ID	MACAddr	Type	MaxSDU	MinSDU	Mode
0	up	0000	0800208a217e	ethernet	1500	0	3

The fields displayed are described below:

PPA	The relative logical position of the interface.
State	The state of the interface: <ul style="list-style-type: none"><i>up</i> The interface is initialized and operational.<i>down</i> The interface was "discovered" by the LLC2 driver, has passed its bootup diagnostics, and is awaiting initialization.<i>bad</i> The interface is known to the LLC2 driver, but failed one or more of the integrity checks performed at boot time. This might include detecting Interrupt Request and shared memory conflicts or failures detected during the execution of the level 0 diagnostics.
ID	The interface ID.
MACAddr	The MAC address currently in effect for the interface.
Type	The MAC type. Current types supported include:

llc2_config(1)

csma/cd 10 Megabit Ethernet
 ethernet Ethernet type device
 tkn-ring 4/16 Megabit Token Ring
 fddi 100 Megabit Fiber Distributed Data Interface

MaxSDU The Maximum Service Data Unit size transmitted on this interface.

Mode The Service Modes supported by this interface. This field consists of the bitwise logical-ORing of the supported modes, also defined in `/usr/include/sys/dlpi.h`.

-r ppa Uninitializes the corresponding interface. By using this option, and then using the `-i` option, the parameters associated with an interface can be changed.

-U Destroys all streams used by the LLC2 subsystem. This is the reverse of the `-P` option. After this is executed, `llc2_config -q` will not show anything.

FILES `/etc/llc2/default/llc2.*` LLC2 configuration files

ATTRIBUTES See `attributes(5)` for descriptions of the following attributes:

llc2_stats(1)

NAME	llc2_stats – LLC2 Station, SAP, and Connection Statistics						
SYNOPSIS	llc2_stats <i>ppa</i> [-r] [-s <i>sap</i>] [-c <i>connection</i>]						
DESCRIPTION	The <code>llc2_stats</code> command is used to retrieve statistical information from the Host-based Logical Link Control Class 2 component of the LLC2 Driver. Statistics are kept for the station, SAP (Service Access Point), and connection components.						
OPTIONS	The following options are supported: <table><tr><td><code>-c <i>connection</i></code></td><td>Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.</td></tr><tr><td><code>-r</code></td><td>Resets the specified counters to zero after reading them. This option is only valid if the <i>root</i> user is executing the command.</td></tr><tr><td><code>-s <i>sap</i></code></td><td>Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS <i>sap</i>, 240 (0xf0) would be entered as: <code>-s f0</code>.</td></tr></table>	<code>-c <i>connection</i></code>	Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.	<code>-r</code>	Resets the specified counters to zero after reading them. This option is only valid if the <i>root</i> user is executing the command.	<code>-s <i>sap</i></code>	Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS <i>sap</i> , 240 (0xf0) would be entered as: <code>-s f0</code> .
<code>-c <i>connection</i></code>	Specifies the connection of interest. Its value is entered in hexadecimal notation with no leading 0x.						
<code>-r</code>	Resets the specified counters to zero after reading them. This option is only valid if the <i>root</i> user is executing the command.						
<code>-s <i>sap</i></code>	Specifies the SAP for this request. It is a single-byte value, expressed in hexadecimal notation with no leading 0x. For example, the NetBIOS <i>sap</i> , 240 (0xf0) would be entered as: <code>-s f0</code> .						
OPERANDS	The following operand is supported: <table><tr><td><i>ppa</i></td><td>The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.</td></tr></table>	<i>ppa</i>	The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.				
<i>ppa</i>	The logical number used to address the adapter. The PPA (Physical Point of Attachment) must be the first argument.						
EXAMPLES	EXAMPLE 1 Station Statistics The following command will display the station statistics for PPA 4. After the example, a brief description of each field is presented. <pre>example% /usr/lib/llc2/llc2_stats 4</pre> <pre>Station values received: ppa = 0x00000004 clearFlag = 0x00 # of saps (hex) = 0x0002 saps (hex) = 02 aa state = 0x01 nullSapXidCmdRcvd = 0x00000000 nullSapXidRspSent = 0x00000000 nullSapTestCmdRcvd = 0x00000000 nullSapTestRspSent = 0x00000000 outOfState = 0x00000000 allocFail = 0x00000000 protocolError = 0x00000000</pre> The fields are described as follows: <table><tr><td><code>ppa</code></td><td>The logical number used to address the adapter.</td></tr><tr><td><code>clearFlag</code></td><td>This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).</td></tr></table>	<code>ppa</code>	The logical number used to address the adapter.	<code>clearFlag</code>	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).		
<code>ppa</code>	The logical number used to address the adapter.						
<code>clearFlag</code>	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).						

EXAMPLE 1 Station Statistics *(Continued)*

# of saps	The number of SAPs currently bound on this station.
saps	The array of the station's Service Access Point (SAP) logical interface values between the LLC and its adjacent layers.
state	A number indicating the current state of the station component (0 = down, 1 = up).
nullSapXidCmdRcvd	The number of XID command Protocol Data Units (PDUs) received for the NULL SAP address (sap = 0x00).
nullSapXidRspSent	The number of XID response PDUs sent in response to XID command PDUs received for the null SAP address.
nullSapTestCmdRcvd	The number of TEST command PDUs received for the null SAP address.
nullSapTestRspSent	The number of TEST response PDUs sent in response to TEST command PDUs received for the null SAP address.
outOfState	The number of events received in an invalid state.
allocFail	The number of buffer allocation failures.
protocolError	The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.

EXAMPLE 2 SAP Statistics

In the above display, there are two active SAPs, 0x02 and 0xaa. The following is an example of a command for retrieving the statistics for SAP 02 and a brief explanation of each field presented.

```
example% /usr/lib/llc2/llc2_stats 4 -s 02
```

```
Sap values received:
ppa          = 0x00000004  clearFlag = 0x00
sap          = 0x02
state        = 0x01
# of cons (hex) = 0x0000000a
connections (hex) = 0000 0001 0002 0003 0004 0005 0006 0007 0008 0009
xidCmdSent   = 0x00000000
xidCmdRcvd   = 0x00000000
xidRspSent   = 0x00000000
xidRspRcvd   = 0x00000000
testCmdSent  = 0x00000000
testCmdRcvd  = 0x00000000
testRspSent  = 0x00000000
```

llc2_stats(1)

EXAMPLE 2 SAP Statistics (Continued)

```
testRspRcvd      = 0x00000000
uiSent           = 0x00000000
uiRcvd          = 0x00000000
outOfState      = 0x00000000
allocFail       = 0x00000000
protocolError   = 0x00000000
```

The fields are described as follows:

ppa	The logical number used to address the adapter.
clearFlag	This flag indicates if the statistics will be reset to zero after reading (set to a 1) or if the statistics are read only (set to 0).
sap	The specified Service Access Point (SAP) logical interface value for the station.
state	A number indicating the current state of the SAP component (0 = inactive, 1 = active).
# of cons	The number of active connections on this SAP.
connections	The array of active connection indexes.
xidCmdSent	The number of XID command PDUs sent (Source SAP = this sap).
xidCmdRcvd	The number of XID command PDUs received (Destination SAP = this sap).
xidRspSent	The number of XID response PDUs sent (Source SAP = this sap).
xidRspRcvd	The number of XID response PDUs received (Source SAP = this sap).
testCmdSent	The number of TEST command PDUs sent (Source SAP = this sap).
testCmdRcvd	The number of TEST command PDUs received (Destination SAP = this sap).
testRspSent	The number of TEST response PDUs sent (Source SAP = this sap).
testRspRcvd	The number of TEST response PDUs received (Source SAP = this sap).
uiSent	The number of Unnumbered Information Frames sent.
uiRcvd	The number of Unnumbered Information Frames received.

EXAMPLE 2 SAP Statistics (Continued)

outOfState	The number of events received in an invalid state.
allocFail	The number of buffer allocation failures.
protocolError	The number of LLC protocol errors, that is, the receipt of malformed PDUs or the receipt of frame X when frame Y was expected.

EXAMPLE 3 Connection Statistics

Ten established connections are associated with this SAP. To retrieve the statistics for connection 1, enter the following command:

```
example% /usr/lib/llc2/llc2_stats 4 -s 2 -c 1
Connection values received:
ppa          = 0x0004  clearFlag    = 0x00
sap          = 0x02    con          = 0x0001  sid          = 0x0201
stateOldest = 0x00    stateOlder  = 0x00    stateOld    = 0x01
state        = 0x08
dl_nodeaddr = 0x0080d84008c2          dl_sap      = 0x04
flag        = 0x50    dataFlag    = 0x00    timerOn     = 0x18
vs          = 0x29    vr          = 0x1e          nrRcvd     = 0x29  k          = 0x14
retryCount  = 0x0000  numToBeAcked = 0x0000  numToResend = 0x0000
macOutSave  = 0x0000  macOutDump  = 0x0000
iSent       = 0x0ba9  iRcvd       = 0x001e
frmrSent    = 0x0000  frmrRcvd    = 0x0000
rrSent      = 0x016a  rrRcvd      = 0x00c1
rnrSent     = 0x0000  rnrRcvd     = 0x06fb
rejSent     = 0x0000  rejRcvd     = 0x0000
