Preface

OVERVIEW

A man page is provided for both the naive user, and sophisticated user who is familiar with the SunOS operating system and is in need of on-line information. A man page is intended to answer concisely the question "What does it do?" The man pages in general comprise a reference manual. They are not intended to be a tutorial.

The following contains a brief description of each section in the man pages and the information it references:

- \bullet Section 1 describes, in alphabetical order, commands available with the operating system.
- Section 1M describes, in alphabetical order, commands that are used chiefly for system maintenance and administration purposes.
- Section 2 describes all of the system calls. Most of these calls have one or more error returns. An error condition is indicated by an otherwise impossible returned value.
- Section 3 describes functions found in various libraries, other than those functions that directly invoke UNIX system primitives, which are described in Section 2 of this volume.

- Section 4 outlines the formats of various files. The C structure declarations for the file formats are given where applicable.
- Section 5 contains miscellaneous documentation such as character set tables, etc.
- Section 7 describes various special files that refer to specific hardware peripherals, and device drivers. STREAMS software drivers, modules and the STREAMS-generic set of system calls are also described.
- Section 9 provides reference information needed to write device drivers in the kernel operating systems environment. It describes two device driver interface specifications: the Device Driver Interface (DDI) and the Driver–Kernel Interface (DKI).
- Section 9E describes the DDI/DKI, DDI-only, and DKI-only entry-point routines a developer may include in a device driver.
- Section 9F describes the kernel functions available for use by device drivers.
- Section 9S describes the data structures used by drivers to share information between the driver and the kernel.

Below is a generic format for man pages. The man pages of each manual section generally follow this order, but include only needed headings. For example, if there are no bugs to report, there is no BUGS section. See the intro pages for more information and detail about each section, and **man**(1) for more information about man pages in general.

NAME

This section gives the names of the commands or functions documented, followed by a brief description of what they do.

SYNOPSIS

This section shows the syntax of commands or functions. When a command or file does not exist in the standard path, its full pathname is shown. Literal characters (commands and options) are in **bold** font and variables (arguments, parameters and substitution characters) are in *italic* font. Options and arguments are alphabetized, with single letter arguments first, and options with arguments next, unless a different argument order is required.

The following special characters are used in this section:

- [] The option or argument enclosed in these brackets is optional. If the brackets are omitted, the argument *must* be specified.
- ... Ellipses. Several values may be provided for the previous argument, or the previous argument can be specified multiple times, for example, 'filename ...'.
- Separator. Only one of the arguments separated by this character can be specified at time.

PROTOCOL

This section occurs only in subsection 3R to indicate the protocol description file. The protocol specification pathname is always listed in **bold** font.

AVAILABILITY

This section briefly states any limitations on the availabilty of the command. These limitations could be hardware or software specific.

A specification of a class of hardware platform, such as **x86** or **SPARC**, denotes that the command or interface is applicable for the hardware platform specified.

In Section 1 and Section 1M, **AVAILABILITY** indicates which package contains the command being described on the manual page. In order to use the command, the specified package must have been installed with the operating system. If the package was not installed, see **pkgadd**(1) for information on how to upgrade.

MT-LEVEL

This section lists the **MT-LEVEL** of the library functions described in the Section 3 manual pages. The **MT-LEVEL** defines the libraries' ability to support threads. See **Intro**(3) for more information.

DESCRIPTION

This section defines the functionality and behavior of the service. Thus it describes concisely what the command does. It does not discuss OPTIONS or cite EXAMPLES. Interactive commands, subcommands, requests, macros, functions and such, are described under USAGE.

Preface

IOCTLS

This section appears on pages in Section 7 only. Only the device class which supplies appropriate parameters to the **ioctls**(2) system call is called **ioctls** and generates its own heading. IOCTLS for a specific device are listed alphabetically (on the man page for that specific device). IOCTLS are used for a particular class of devices all which have an **io** ending, such as **mtio**(7).

OPTIONS

This lists the command options with a concise summary of what each option does. The options are listed literally and in the order they appear in the SYNOPSIS section. Possible arguments to options are discussed under the option, and where appropriate, default values are supplied.

RETURN VALUES

If the man page documents functions that return values, this section lists these values and describes the conditions under which they are returned. If a function can return only constant values, such as 0 or -1, these values are listed in tagged paragraphs. Otherwise, a single paragraph describes the return values of each function. Functions declared as **void** do not return values, so they are not discussed in RETURN VALUES.

ERRORS

On failure, most functions place an error code in the global variable **errno** indicating why they failed. This section lists alphabetically all error codes a function can generate and describes the conditions that cause each error. When more than one condition can cause the same error, each condition is described in a separate paragraph under the error code.

USAGE

This section is provided as a *guidance* on use. This section lists special rules, features and commands that require in-depth explanations. The subsections listed below are used to explain built-in functionality:

Commands Modifiers Variables Expressions Input Grammar

EXAMPLES

This section provides examples of usage or of how to use a command or function. Wherever possible a complete example including command line entry and machine response is shown. Whenever an example is given, the prompt is shown as

example%

or if the user must be super-user,

example#

Examples are followed by explanations, variable substitution rules, or returned values. Most examples illustrate concepts from the SYNOPSIS, DESCRIPTION, OPTIONS and USAGE sections.

ENVIRONMENT

This section lists any environment variables that the command or function affects, followed by a brief description of the effect.

FILES

This section lists all filenames referred to by the man page, files of interest, and files created or required by commands. Each is followed by a descriptive summary or explanation.

SEE ALSO

This section lists references to other man pages, in-house documentation and outside publications.

DIAGNOSTICS

This section lists diagnostic messages with a brief explanation of the condition causing the error. Messages appear in **bold** font with the exception of variables, which are in *italic* font.

WARNINGS

This section lists warnings about special conditions which could seriously affect your working conditions — this is not a list of diagnostics.

Preface v

NOTES

This section lists additional information that does not belong anywhere else on the page. It takes the form of an *aside* to the user, covering points of special interest. Critical information is never covered here.

BUGS

This section describes known bugs and wherever possible suggests workarounds.

NAME

Intro, intro - introduction to device driver entry points

DESCRIPTION

Section 9E describes the entry-point routines a developer may include in a device driver. These are called entry-point because they provide the calling and return syntax from the kernel into the driver. Entry-points are called, for instance, in response to system calls, when the driver is loaded, or in response to STREAMS events.

Kernel functions usable by the driver are described in section 9F.

In this section, reference pages contain the following headings:

- NAME describes the routine's purpose.
- SYNOPSIS summarizes the routine's calling and return syntax.
- **INTERFACE LEVEL** describes any architecture dependencies. It also indicates whether the use of the entry point is required, optional, or discouraged.
- ARGUMENTS describes each of the routine's arguments.
- **DESCRIPTION** provides general information about the routine.
- RETURN VALUES describes each of the routine's return values.
- SEE ALSO gives sources for further information.

Overview of Driver Entry-Point Routines and Naming Conventions

By convention, a prefix string is added to the driver routine names. For a driver with the prefix *prefix*, the driver code may contain routines named *prefix*open, *prefix*close, *prefix*read, *prefix*write, and so forth. also use the same prefix.

All routines and data should be declared as static.

Every driver MUST include <sys/ddi.h> and <sys/sunddi.h>, in that order, and after all other include files.

The following table summarizes the STREAMS driver entry points described in this section.

Routine	Type
put	DDI/DKI
srv	DDI/DKI

The following table summarizes the driver entry points described in this section.

Routine	Type
_fini	Solaris DDI
_info	Solaris DDI
_init	Solaris DDI
attach	Solaris DDI
chpoll	DDI/DKI
close	DDI/DKI
detach	Solaris DDI
dump	Solaris DDI
getinfo	Solaris DDI
identify	Solaris DDI

modified 28 Jan 1994 9E-5

ioctl DDI/DKI ks_update Solaris DDI mapdev_access Solaris DDI mapdev_dup Solaris DDI mapdev_free Solaris DDI mmap DKI only open DDI/DKI DDI/DKI print probe Solaris DDI prop_op Solaris DDI DDI/DKI read segmap DKI only DDI/DKI strategy tran_abort Solaris DDI tran_destroy_pkt Solaris DDI Solaris DDI tran_dmafree tran_getcap Solaris DDI tran_init_pkt Solaris DDI Solaris DDI tran_reset Solaris DDI tran_setcap Solaris DDI tran_start tran_sync_pkt Solaris DDI Solaris DDI tran_tgt_free tran_tgt_init Solaris DDI tran_tgt_probe Solaris DDI DDI/DKI write

The table below lists the error codes that should be returned by a driver routine when an error is encountered. It lists the error values in alphabetic order. All the error values are defined in <code><sys/errno.h></code>. In the driver <code>open(9E)</code>, <code>close(9E)</code>, <code>ioctl(9E)</code>, <code>read(9E)</code>, and <code>write(9E)</code> routines, errors are passed back to the user by returning the value. In the driver <code>strategy(9E)</code> routine, errors are passed back to the user by setting the <code>b_error</code> member of the <code>buf(9S)</code> structure to the error code. For STREAMS <code>ioctl</code> routines, errors should be sent upstream in an <code>M_IOCNAK</code> message. For STREAMS <code>read</code> and <code>write</code> routines, errors should be sent upstream in an <code>M_ERROR</code> message. The driver <code>print</code> routine should not return an error code, as the function that it calls, <code>cmn_err(9F)</code>, is declared as <code>void</code> (no error is returned).

9E-6 modified 28 Jan 1994

Error		Use in these
Value	Error Description	Driver Routines (9E)
EAGAIN	Kernel resources, such as the buf structure or cache memory, are not available at this time (device may be busy, or the system resource is not available).	open, ioctl, read, write, strategy
EFAULT	An invalid address has been passed as an argument; memory addressing error.	open, close, ioctl, read, write, strategy
EINTR	Sleep interrupted by signal.	open, close, ioctl, read, write, strategy
EINVAL	An invalid argument was passed to the routine.	open, ioctl, read, write, strategy
EIO	A device error occurred; an error condition was detected in a device status register (the I/O request was valid, but an error occurred on the device).	open, close, ioctl, read, write, strategy
ENXIO	An attempt was made to access a device or subdevice that does not exist (one that is not configured); an attempt was made to perform an invalid I/O operation; an incorrect minor number was specified.	open, close, ioctl, read, write, strategy
EPERM	A process attempting an operation did not have required permission.	open, ioctl, read, write, close
EROFS	An attempt was made to open for writing a read-only device.	open

The table below cross references error values to the driver routines from which the error values can be returned.

open	close	ioctl	read, write, and strategy
EAGAIN	EFAULT	EAGAIN	EAGAIN
EFAULT	EINTR	EFAULT	EFAULT
EINTR	EIO	EINTR	EINTR
EINVAL	ENXIO	EINVAL	EINVAL
EIO		EIO	EIO
ENXIO		ENXIO	ENXIO
EPERM		EPERM	
EROFS

NAME

```
_fini, _info, _init – loadable module configuration entry points
       SYNOPSIS
                       #include <sys/modctl.h>
                       int fini(void):
                       int _info(struct modinfo * modinfop);
                       int _init(void);
    ARGUMENTS
                       modinfop
                                       A pointer to an opaque modinfo structure.
            _info()
      INTERFACE
                       Solaris DDI specific (Solaris DDI). These entry points are required. You must write
            LEVEL.
                       them.
   DESCRIPTION
                       _init() initializes a loadable module. It is called before any other routine in a loadable
                       module. _init() returns the value returned by mod_install(9F). The module may option-
                       ally perform some other work before the mod_install(9F) call is performed. If the
                       module has done some setup before the mod install(9F) function is called, then it should
                       be prepared to undo that setup if mod install(9F) returns an error.
                       _info() returns information about a loadable module. _info() returns the value returned
                       by mod info(9F).
                       _fini() prepares a loadable module for unloading. It is called when the system wants to
                       unload a module. If the module determines that it can be unloaded, then fini() returns
                       the value returned by mod_remove(9F). Upon successful return from _fini() no other
                       routine in the module will be called before init() is called.
                       _init() should return the appropriate error number if there is an error, else it should
RETURN VALUES
                       return the return value from mod install(9F).
                       _info() should return the return value from mod_info(9F)
                       _fini() should return the return value from mod_remove(9F).
       EXAMPLES
                               #include <sys/modctl.h>
                               #include <sys/ddi.h>
                               #include <sys/sunddi.h>
                               static struct dev_ops drv_ops;
                               * Module linkage information for the kernel.
                               static struct modldry modldry = {
                                       &mod_driverops,
                                                              /* Type of module. This one is a driver */
                                       "Sample Driver",
                                       &drv_ops
                                                       /* driver ops */
```

9E-10 modified 27 Jan 1993

```
};
                        static struct modlinkage modlinkage = {
                                MODREV_1,
                                &modldry,
                                NULL
                        };
                        int
                        _init(void)
                                return (mod_install(&modlinkage));
                        int
                        _info(struct modinfo *modinfop)
                                return (mod_info(&modlinkage, modinfop));
                        int
                        _fini(void)
                                return (mod_remove(&modlinkage));
                add_drv(1M), mod_info(9F), mod_install(9F), mod_remove(9F), modldrv(9S),
  SEE ALSO
                modlinkage(9S), modlstrmod(9S)
                Writing Device Drivers
WARNINGS
                Do not change the structures referred to by the modlinkage structure after the call to
                mod_install(), as the system may copy or change them.
     NOTES
                Even though the identifiers _fini(), _info(), and _init() appear to be declared as globals,
                their scope is restricted by the kernel to the module that they are defined in.
      BUGS
                On some implementations _info() may be called before _init().
```

modified 27 Jan 1993 9E-11

NAME

attach - attach a device to the system

SYNOPSIS

#include <sys/conf.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

int prefixattach(dev_info_t *dip, ddi_attach_cmd_t cmd)

ARGUMENTS

dip A pointer to the device's **dev_info** structure.

attach type. Should be set to DDI_ATTACH. Other values are reserved. The

driver should return DDI_FAILURE if reserved values are passed to it.

INTERFACE LEVEL DESCRIPTION Solaris DDI specific (Solaris DDI). This entry point is *required* and must be written.

attach() is the device-specific initialization entry point. When attach() is called with *cmd* set to DDI_ATTACH, all normal kernel services (such as **kmem_alloc** (9F)) are available for use by the driver. Device interrupts are not blocked when attaching a device to the system. See **BUGS** section below.

attach() will be called once for each instance of the device on the system. Until attach() succeeds, the only driver entry points which may be called are open(9E) and getinfo(9E). See the "Autoconfiguration" chapter in *Writing Device Drivers*. The instance number may be obtained using ddi_get_instance(9F).

Successful returns from **identify**(9E) and **probe**(9E) are required before a call to the driver's **attach**() entry point will be made.

RETURN VALUES

attach() should return:

DDI_SUCCESS on success.
DDI_FAILURE on failure.

SEE ALSO

identify(9E), probe(9E), ddi_add_intr(9F), ddi_create_minor_node(9F), ddi_get_instance(9F), ddi_map_regs(9F), kmem_alloc(9F), timeout(9F)

Writing Device Drivers

BUGS

Drivers which are initialized at boot time (i.e., drivers that are attached before the root filesystem is mounted) must complete initialization without assuming that device interrupts can occur. This includes the system clock; therefore, system timer services as described in **timeout**(9F) cannot be assumed to be functioning correctly when this entry point is called.

9E-12 modified 3 Dec 1993

NAME | chpoll – poll entry point for a non-STREAMS character driver

SYNOPSIS #include <sys/types.h>

#include <sys/poll.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

int prefixchpoll(dev_t dev, short events, int anyyet, short *reventsp,
 struct pollhead **phpp);

ARGUMENTS *dev* The device number for the device to be polled.

events The events that may occur. Valid events are:

POLLIN Data other than high priority data may be read without

blocking.

POLLOUT Normal data may be written without blocking.
POLLPRI High priority data may be received without blocking.

POLLHUP A device hangup has occurred.
POLLERR An error has occurred on the device.

POLLRDNORM Normal data (priority band = 0) may be read without

blocking.

POLLRDBAND Data from a non-zero priority band may be read

without blocking

POLLWRNORM The same as **POLLOUT**.

POLLWRBAND Priority data (priority band > 0) may be written.

anyyet A flag that is non-zero if any other file descriptors in the **pollfd** array have

events pending. The **poll**(2) system call takes a pointer to an array of **pollfd** structures as one of its arguments. See the **poll**(2) reference page for more

details.

reventsp A pointer to a bitmask of the returned events satisfied.

phpp A pointer to a pointer to a **pollhead** structure.

INTERFACE This entry point is *optional*.

LEVEL Architecture independent level 1 (DDI/DKI).

modified 11 Apr 1991 9E-13

DESCRIPTION

The **chpoll** entry point routine is used by non-STREAMS character device drivers that wish to support polling. The driver must implement the polling discipline itself. The following rules must be followed when implementing the polling discipline:

1. Implement the following algorithm when the **chpoll** entry point is called:

```
if (events_are_satisfied_now) {
    *reventsp = mask_of_satisfied_events;
} else {
    *reventsp = 0;
    if (!anyyet)
       *phpp = &my_local_pollhead_structure;
}
return (0);
```

- 2. Allocate an instance of the **pollhead** structure. This instance may be tied to the per-minor data structure defined by the driver. The **pollhead** structure should be treated as a "black box" by the driver. None of its fields should be referenced. However, the size of this structure is guaranteed to remain the same across releases.
- 3. Call the **pollwakeup**() function whenever an event of type **events** listed above occur. This function should only be called with one event at a time.

RETURN VALUES

chpoll() should return **0** for success, or the appropriate error number.

SEE ALSO

close was through the raw/character interface for the device

close a layered process (a higher-level driver called the

close() routine of the device)

STREAMS

*q Pointer to **queue**(9S) structure used to reference the read side of the driver. (A queue is the central node of a collection of structures and routines pointed to by a queue.)

flag File status flag.

**cred_p* Pointer to the user credential structure.

DESCRIPTION

For STREAMS drivers, the **close**() routine is called by the kernel through the **cb_ops**(9S) table entry for the device. (Modules use the **fmodsw** table.) A non-null value in the **d_str** field of the **cb_ops** entry points to a **streamtab** structure, which points to a **qinit**(9S) containing a pointer to the **close** routine. Non-STREAMS **close** routines are called directly from the **cb_ops** table.

close() ends the connection between the user process and the device, and prepares the device (hardware and software) so that it is ready to be opened again.

A device may be opened simultaneously by multiple processes and the **open**() driver routine is called for each open, but the kernel will only call the **close** routine when the last process using the device issues a **close**(2) or **umount**(2) system call or exits. (An exception is a close occurring with the *otyp* argument set to **OTYP_LYR**, for which a close (also having *otyp* = **OTYP_LYR**) occurs for each open.)

In general, a **close**() routine should always check the validity of the minor number component of the *dev* parameter. The routine should also check permissions as necessary, by using the user credential structure (if pertinent), and the appropriateness of the *flag* and *otyp* parameter values.

close() could perform any of the following general functions:

- disable interrupts
- hang up phone lines
- rewind a tape
- deallocate buffers from a private buffering scheme
- unlock an unsharable device (that was locked in the **open** routine)
- flush buffers
- notify a device of the close
- deallocate any resources allocated on open

The **close**() routines of STREAMS drivers and modules are called when a stream is dismantled or a module popped. The steps for dismantling a stream are performed in the following order. First, any multiplexor links present are unlinked and the lower streams are closed. Next, the following steps are performed for each module or driver on the stream, starting at the head and working toward the tail:

- 1. The write queue is given a chance to drain.
- 2. The **close()** routine is called.
- 3. The module or driver is removed from the stream.

RETURN VALUES

close() should return 0 for success, or the appropriate error number. Return errors rarely occur, but if a failure is detected, the driver should decide whether the severity of the problem warrants either displaying a message on the console or, in worst cases, triggering a system panic. Generally, a failure in a close() routine occurs because a problem occurred in the associated device.

modified 15 Sep 1992 9E-17

NAME detach – detach a device

SYNOPSIS #include <sys/ddi.h>

#include <sys/sunddi.h>

int prefixdetach(dev_info_t *dip, ddi_detach_cmd_t cmd)

ARGUMENTS | *dip* A pointer to the device's **dev_info** structure.

cmd Type of detach; the driver should return **DDI_FAILURE** if any value

other than **DDI_DETACH** is passed to it.

INTERFACE LEVEL DESCRIPTION Solaris DDI specific (Solaris DDI). This entry point is required. It can be **nodev**.

detach() is the complement of the **attach(9E)** routine. It is used to remove all the states associated with a given instance of a device node prior to the removal of that instance from the system. The **dev_info** nodes that belong to a driver are removed as part of the process of unloading a device driver from the system.

Depending on what was created in the drivers' attach(9E) routine, this might mean calling ddi_unmap_regs() (see ddi_map_regs(9F)) to remove mappings, calling ddi_remove_intr() (see ddi_add_intr(9F)) to unregister interrupt handlers, calling kmem_free(9F) to free any heap allocations, and so forth. This should also include putting the underlying device into a quiescent state so that it will not generate interrupts.

If **detach()** determines that the particular instance of the device cannot be removed when requested, for example, because of some exceptional condition, **detach()** returns **DDI_FAILURE**, which prevents the particular device instance from being removed. This will also prevent the driver from being unloaded.

Drivers that set up **timeout**(9F) routines should ensure that they are cancelled before returning **DDI_SUCCESS** from **detach()**.

The system guarantees that the function will only be called for a particular **dev_info** node after (and not concurrently with) a successful **attach**(9E) of that device. The system also guarantees that **detach()** will only be called when there are no outstanding **open**(9E) calls on the device.

RETURN VALUES

DDI_SUCCESS The state associated with the given device was successfully removed.

DDI_FAILURE The operation failed or the request was not understood. The associated

state is unchanged.

CONTEXT

This function is called from user context only.

NAME dump – dump memory to device during system failure

SYNOPSIS #include <sys/types.h>

#include <sys/ddi.h> #include <sys/sunddi.h>

int prefixdump(dev_t dev, caddr_t addr, daddr_t blkno, int nblk)

ARGUMENTS *dev* Device number.

addr address for the beginning of the area to be dumped.

blkno Block offset to dump memory to.

nblk Number of blocks to dump.

INTERFACE LEVEL Solaris specific (Solaris DDI). This entry point is **required**. For drivers that do not implement dump routines, **nodev** should be used.

DESCRIPTION

dump() is used to dump a portion of virtual address space directly to a device in the case of system failure. The memory area to be dumped is specified by *addr* (base address) and *nblk* (length). It is dumped to the device specified by *dev* starting at offset *blkno*. Upon completion **dump()** returns the status of the transfer.

dump() is called at interrupt priority.

RETURN VALUES

dump() should return 0 on success, or the appropriate error number.

NAME

ioctl - control a character device

SYNOPSIS

#include <sys/cred.h>
#include <sys/file.h>
#include <sys/types.h>
#include <sys/errno.h>

#include <sys/ddi.h>

#include <sys/sunddi.h>

int prefixioctl(dev_t dev, int cmd, int arg, int mode, cred_t *cred_p, int *rval_p);

ARGUMENTS

dev Device number.

cmd Command argument the driver **ioctl** routine interprets as the operation to be

performed.

arg Passes parameters between a user program and the driver. When used with

terminals, the argument is the address of a user program structure containing driver or hardware settings. Alternatively, the argument may be an integer that has meaning only to the driver. The interpretation of the argument is driver dependent and usually depends on the command type; the kernel does

not interpret the argument.

mode Contains values set when the device was opened. Use of this mode is

optional. However, the driver may use it to determine if the device was opened for reading or writing. The driver can make this determination by checking the **FREAD** or **FWRITE** flags. See the *flag* argument description of the **open**() routine for further values for the **ioctl** routine's *mode* argument.

In some circumstances, *mode* is used to provide address space information

about the *arg* argument. See below.

cred_p Pointer to the user credential structure.

rval_p Pointer to return value for calling process. The driver may elect to set the

value which is valid only if the **ioctl**(9E) succeeds.

INTERFACE LEVEL DESCRIPTION

Architecture independent level 1 (DDI/DKI). This entry point is **Optional**.

ioctl() provides character-access drivers with an alternate entry point that can be used for almost any operation other than a simple transfer of characters in and out of buffers. Most often, ioctl() is used to control device hardware parameters and establish the protocol used by the driver in processing data.

The kernel determines that this is a character device, and looks up the entry point routines in **cb_ops** (9S). The kernel then packages the user request and arguments as integers and passes them to the driver's **ioctl()** routine. The kernel itself does no processing of the passed command, so it is up to the user program and the driver to agree on what the arguments mean.

modified 29 Sep 1992 9E-23

I/O control commands are used to implement the terminal settings passed from **ttymon**(1M) and **stty**(1), to format disk devices, to implement a trace driver for debugging, and to clean up character queues. Since the kernel does not interpret the command type that defines the operation, a driver is free to define its own commands.

Drivers that use an **ioctl**() routine typically have a command to "read" the current **ioctl**() settings, and at least one other that sets new settings. Drivers can use the mode argument to determine if the device unit was opened for reading or writing, if necessary, by checking the **FREAD** or **FWRITE** setting.

If the third argument, *arg*, is a pointer to a user buffer, the driver can call the **copyin**(9F) and **copyout**(9F) functions to transfer data between kernel and user space.

Other kernel subsystems may need to call into the drivers **ioctl**(9E) routine. Drivers that intend to allow their **ioctl**() routine to be used in this way should publish the **ddi-kernel-ioctl** property on the associated devinfo node(s).

When the **ddi-kernel-ioctl** property is present, the *mode* argument is used to pass address space information about *arg* through to the driver. If the driver expects *arg* to contain a buffer address, and the **FKIOCTL** flag is set in *mode*, then the driver should assume that it is being handed a kernel buffer address. Otherwise, *arg* may be the address of a buffer from a user program. The driver can use **ddi_copyin**(9F) and **ddi_copyout**(9F) perform the correct type of copy operation for either kernel or user address spaces. See the example on **ddi_copyout**(9F).

To implement I/O control commands for a driver the following two steps are required:

- 1. Define the I/O control command names and the associated value in the driver's header and comment the commands.
- 2. Code the **ioctl** routine in the driver that defines the functionality for each I/O control command name that is in the header.

The **ioctl** routine is coded with instructions on the proper action to take for each command. It is commonly a **switch** statement, with each **case** definition corresponding to an **ioctl** name to identify the action that should be taken. However, the command passed to the driver by the user process is an integer value associated with the command name in the header.

RETURN VALUES

ioctl() should return 0 on success, or the appropriate error number. The driver may also set the value returned to the calling process through *rval_p*.

dkio(7), fbio(7), termio(7), copyin(9F), copyout(9F), ddi_copyin(9F), ddi_copyout(9F)
Writing Device Drivers

NOTES

STREAMS drivers do not have **ioctl** routines. The stream head converts I/O control commands to **M_IOCTL** messages, which are handled by the driver's **put**(9E) or **srv**(9E) routine.

NAME
                  ks_update - dynamically update kstats
   SYNOPSIS
                  #include <sys/types.h>
                  #include <sys/kstat.h>
                  #include <sys/ddi.h>
                  #include <sys/sunddi.h>
                  int prefix_ks_update(kstat_t *ksp , int rw);
 INTERFACE
                  Solaris DDI specific (Solaris DDI)
       LEVEL
ARGUMENTS
                             Pointer to a kstat(9S) structure.
                  ksp
                             Read/Write flag. Possible values are
                  rw
                             KSTAT READ
                                              Update kstat structure statistics from the driver.
                                              Update driver statistics from the kstat structure.
                             KSTAT WRITE
```

DESCRIPTION

The kstat mechanism allows for an optional <code>ks_update()</code> function to update kstat data. This is useful for drivers where the underlying device keeps cheap hardware statistics, but extraction is expensive. Instead of constantly keeping the kstat data section up to date, the driver can supply a <code>ks_update()</code> function which updates the kstat's data section on demand. To take advantage of this feature, set the <code>ks_update</code> field before calling <code>kstat install(9F)</code>.

The **ks_update()** function must have the following structure:

```
static int
xx_kstat_update(kstat_t *ksp, int rw)
{
      if (rw == KSTAT_WRITE) {
            /* update the native stats from ksp->ks_data */
            /* return EACCES if you don't support this */
      } else {
            /* update ksp->ks_data from the native stats */
      }
      return (0);
}
```

In general, the **ks_update()** routine may need to refer to provider-private data; for example, it may need a pointer to the provider's raw statistics. The **ks_private** field is available for this purpose. Its use is entirely at the provider's discretion.

No kstat locking should be done inside the **ks_update()** routine. The caller will already be holding the kstat's **ks_lock** (to ensure consistent data) and will prevent the kstat from being removed.

RETURN VALUES

modified 27 May 1994 9E-25

EACCES if **KSTAT_WRITE** is not allowed,

EIO for any other error.

Writing Device Drivers

9E-26 modified 27 May 1994

NAME

mapdev_access - device mapping access entry point

SYNOPSIS

#include <sys/sunddi.h>

int prefixmapdev_access(ddi_mapdev_handle_t handle, void *devprivate, off_t offset);

INTERFACE LEVEL Solaris DDI specific (Solaris DDI).

ARGUMENTS *handle* An opaque pointer to a device mapping.

devprivate Driver private mapping data from ddi_mapdev(9F).

offset The offset within device memory at which the access occurred.

DESCRIPTION

mapdev_access() is called when an access is made to a mapping that has either been newly created with **ddi_mapdev**(9F) or that has been enabled with a call to **ddi_mapdev_intercept**(9F).

mapdev_access() is passed the handle of the mapped object on which an access has
occurred. This handle uniquely identifies the mapping and is used as an argument to
ddi_mapdev_intercept(9F) or ddi_mapdev_nointercept(9F) to control whether or not
future accesses to the mapping will cause mapdev_access() to be called. In general,
mapdev_access() should call ddi_mapdev_intercept() on the mapping that is currently
in use and then call ddi_mapdev_nointercept() on the mapping that generated this call
to mapdev_access(). This will ensure that a call to mapdev_access() will be generated for
the current mapping next time it is accessed.

mapdev_access() must at least call **ddi_mapdev_nointercept()** with *offset* passed in in order for the access to succeed. A request to allow accesses affects the entire page containing the *offset*.

Accesses to portions of mappings that have been disabled by a call to **ddi_mapdev_nointercept()** will not generate a call to **mapdev_access()**. A subsequent call to **ddi_mapdev_intercept()** will enable **mapdev_access()** to be called again.

A non-zero return value from **mapdev_access()** will cause the corresponding operation to fail. The failure may result in a **SIGSEGV** or **SIGBUS** signal being delivered to the process.

RETURN VALUES

 $\label{lem:continuous} {\bf mapdev_access()} \ should \ return \ {\bf 0} \ on \ success, \ {\bf -1} \ if \ there \ was \ a \ hardware \ error, \ or \ the \ return \ value \ from \ {\bf ddi_mapdev_intercept()} \ or \ {\bf ddi_mapdev_nointercept()}.$

EXAMPLE

The following shows an example of managing a device context that is one page in length.

modified 15 Feb 1994 9E-27

```
/* enable calls to mapdev_access for the current mapping */
                               if (cur_hdl != NULL) {
                                       if ((err = ddi_mapdev_intercept(cur_hdl, off, 0)) != 0)
                                               return (err);
                               /* Switch device context - device dependent*/
                               /* Make handle the new current mapping */
                               cur_hdl = handle;
                                * Disable callbacks and complete the access for the
                                * mapping that generated this callback.
                               return (ddi_mapdev_nointercept(handle, off, 0));

NAME
                      mapdev_dup - device mapping duplication entry point
       SYNOPSIS
                      #include <sys/sunddi.h>
                      int prefixmapdev_dup(ddi_mapdev_handle_t handle, void *devprivate,
                            ddi_mapdev_handle_t new_handle, void **new_devprivatep);
                      Solaris DDI specific (Solaris DDI).
      INTERFACE
           LEVEL
    ARGUMENTS
                      handle
                                      The handle of the mapping that is being duplicated.
                                      Driver private mapping data from the mapping that is being duplicated.
                      devprivate
                      new_handle
                                      An opaque pointer to the duplicated device mapping.
                      new devprivate A pointer to be filled in by the driver with the driver private mapping
                                      data for the duplicated device mapping.
   DESCRIPTION
                      mapdev_dup() is called when a device mapping is duplicated such as through fork(2).
                      mapdev_dup() is expected to generate new driver private data for the new mapping, and
                      set new devprivatep to point to it. new handle is the handle of the new mapped object.
                      A non-zero return value from mapdev_dup() will cause the corresponding operation,
                      such as fork() to fail.
RETURN VALUES
                      mapdev_dup() returns 0 for success or the appropriate error number on failure.
        EXAMPLE
                              static int
                              xxmapdev_dup(ddi_mapdev_handle_t handle, void *devprivate,
                                ddi_mapdev_handle_t new_handle, void **new_devprivate)
                                     struct xxpvtdata
                                                             *pvtdata;
                                      /* Allocate a new private data structure */
                                      pvtdata = kmem alloc(sizeof (struct xxpvtdata), KM SLEEP);
                                      /* Copy the old data to the new - device dependent*/
                                      /* Return the new data */
                                      *new_pvtdata = pvtdata;
                                      return (0);
        CONTEXT
                      This function is called from user context only.
        SEE ALSO
                      fork(2), mmap(2), mapdev_access(9E), mapdev_free(9E), segmap(9E), ddi_mapdev(9F),

NAME
                   mapdev_free - device mapping free entry point
    SYNOPSIS
                   #include <sys/sunddi.h>
                   void prefixmapdev_free(ddi_mapdev_handle_t handle, void *devprivate);
  INTERFACE
                   Solaris DDI specific (Solaris DDI).
        LEVEL
ARGUMENTS
                   handle
                                   An opaque pointer to a device mapping.
                                  Driver private mapping data from ddi_mapdev(9F).
                   devprivate
                   mapdev_free() is called when a mapping created by ddi_mapdev(9F) is being destroyed.
DESCRIPTION
                   mapdev_free() receives the handle of the mapping being destroyed and a pointer to the
                   driver private data for this mapping in devprivate.
                   The mapdev_free() routine is expected to free any resources that were allocated by the
                   driver for this mapping.
    EXAMPLE
                          static void
                          xxmapdev_free(ddi_mapdev_handle_t hdl, void *pvtdata)
                                  /* Destroy the driver private data - Device dependent */
                                  kmem_free(pvtdata, sizeof (struct xxpvtdata));
    CONTEXT
                   This function is called from user context only.
    SEE ALSO

NAME

mmap – check virtual mapping for memory mapped device

SYNOPSIS

#include <sys/types.h>
#include <sys/cred.h>
#include <sys/mman.h>
#include <sys/vm.h>
#include <sys/ddi.h>

#include <sys/sunddi.h>

int prefixmmap(dev_t dev, off_t off, int prot);

ARGUMENTS

dev Device whose memory is to be mapped.

off Offset within device memory at which mapping begins.

prot A bit field that specifies the protections this page of memory will receive. Possible settings are:

PROT_READ Read access will be granted.
PROT_WRITE Write access will be granted.
PROT_EXEC Execute access will be granted.
PROT_USER User-level access will be granted.

PROT_ALL All access will be granted.

INTERFACE LEVEL DESCRIPTION

Architecture independent level 1 (DDI/DKI).

The **mmap**() entry point is a required entry point for character drivers supporting memory-mapped devices. A memory mapped device has memory that can be mapped into a process's address space. The **mmap**(2) system call, when applied to a character special file, allows this device memory to be mapped into user space for direct access by the user application.

An **mmap**() routine checks if the offset is within the range of pages supported by the device. For example, a device that has 512 bytes of memory that can be mapped into user space should not support offsets greater than 512. If the offset does not exist, then -1 is returned. If the offset does exist, **mmap()** returns the value returned by **hat_getkpfnum**(9F) for the page at offset *off* in the device's memory.

mmap() should only be supported for memory-mapped devices. See the **segmap(9E)** reference page for further information on memory-mapped device drivers.

RETURN VALUES

If the protection and offset are valid for the device, the driver should return the value returned by **hat_getkpfnum**(9F), for the page at offset *off* in the device's memory. If not, **-1** should be returned.

9E-32 modified 7 Jun 1993

open – gain access to a device

SYNOPSIS Block and Character

#include <sys/types.h>
#include <sys/file.h>
#include <sys/errno.h>
#include <sys/open.h>
#include <sys/cred.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

int prefixopen(dev_t *devp, int flag, int otyp, cred_t *cred_p);

STREAMS

#include <sys/file.h>
#include <sys/stream.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

int prefixopen(queue_t *q, dev_t *devp, int oflag, int sflag, cred_t *cred_p);

ARGUMENTS Block and Character

devp Pointer to a device number.

flag A bit field passed from the user program **open**(2) system call that instructs the driver on how to open the file. Valid settings are:

FEXCL Open the device with exclusive access; fail all other attempts to open the device.

FNDELAY

Open the device and return immediately (do not block the open even if something is wrong).

FREAD

Open the device with read-only permission (if ORed with **FWRITE**, then allow both read and write access)

FWRITE

Open a device with write-only permission (if ORed with **FREAD**, then allow both read and write access)

otyp Parameter supplied so that the driver can determine how many times a device was opened and for what reasons.

For **OTYP_BLK** and **OTYP_CHR**, the **open**() routine may be called many times, but the **close**(9E) routine is called only when the last reference to a device is removed. If the device is accessed through file descriptors, this is by a call to **close**(2) or **exit**(2). If the device is accessed through memory mapping, this is by a call to **munmap**(2) or **exit**(2).

For **OTYP_LYR**, there is exactly one **close**(9E) for each **open**() called. This permits software drivers to exist above hardware drivers and removes any ambiguity from the hardware driver regarding how a device is used.

modified 13 Jan 1993 9E-33

OTYP BLK

Open occurred through block interface for the device

OTYP_CHR

Open occurred through the raw/character interface for the device

OTYP LYR

Open a layered process. This flag is used when one driver calls another driver's **open** (9E) or **close** (9E) routine. The calling driver will make sure that there is one layered close for each layered open. This flag applies to both block and character devices.

cred_p Pointer to the user credential structure.

STREAMS

q A pointer to the read queue.

devp Pointer to a device number. For STREAMS modules, *devp* always points to the device number associated with the driver at the end (tail) of the stream.

oflag Valid oflag values are **FEXCL**, **FNDELAY**, **FREAD**, and **FWRITE**, the same as those listed above for flag. For STREAMS modules, oflag is always set to **0**.

sflag Valid values are as follows:

CLONEOPEN

Indicates that the **open** routine is called through the clone driver. The driver should return a unique device number.

MODOPEN

Modules should be called with *sflag* set to this value. Modules should return an error if they are called with *sflag* set to a different value. Drivers should return an error if they are called with *sflag* set to this value

0 Indicates a driver is opened directly, without calling the clone driver. *cred_p* Pointer to the user credential structure.

INTERFACE LEVEL

Architecture independent level 1 (DDI/DKI). This entry point is **Required**, but it can be **nulldev**(9F).

DESCRIPTION

The driver's **open**() routine is called by the kernel during an **open**(2) or a **mount**(2) on the special file for the device. The routine should verify that the minor number component of *devp is valid, that the type of access requested by *otyp* and *flag* is appropriate for the device, and, if required, check permissions using the user credentials pointed to by $cred_p$.

The <code>open()</code> routine is passed a pointer to a device number so that the driver can change the minor number. This allows drivers to dynamically create minor instances of the device. An example of this might be a pseudo-terminal driver that creates a new pseudo-terminal whenever it is opened. A driver that chooses the minor number dynamically, normally creates only one minor device node in <code>attach(9E)</code> with

ddi create minor node(9F), then changes the minor number component of *devp using

9E-34 modified 13 Jan 1993

makedevice(9F) and **getmajor**(9F). The driver needs to keep track of available minor numbers internally.

*devp = makedevice(getmajor(*devp), new_minor);

RETURN VALUES

The **open**() routine should return 0 for success, or the appropriate error number.

SEE ALSO

exit(2), mmap(2), mount(2), munmap(2), open(2), attach(9E), close(9E), Intro(9E), ddi_create_minor_node(9F), getmajor(9F), getminor(9F), makedevice(9F)

Writing Device Drivers

STREAMS Programmer's Guide

WARNINGS

Do not attempt to change the major number.

modified 13 Jan 1993 9E-35

NAME print – display a driver message on system console

SYNOPSIS #include <sys/types.h>

#include <sys/errno.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

int prefixprint(dev_t dev, char *str);

ARGUMENTS *dev* Device number.

str Pointer to a character string describing the problem.

INTERFACE Architecture independent level 1 (DDI/DKI). This entry point is **Required** for block dev-

LEVEL ice

DESCRIPTION The **print()** routine is called by the kernel when it has detected an exceptional condition

(such as out of space) in the device. To display the message on the console, the driver should use the **cmn_err**(9F) kernel function. The driver should print the message along

with any driver specific information.

RETURN VALUES The **print**() routine should return 0 for success, or the appropriate error number. The

print routine can fail if the driver implemented a non-standard **print()** routine that attempted to perform error logging, but was unable to complete the logging for whatever

reason.

SEE ALSO cmn_err(9F)

Writing Device Drivers

probe – determine if a non-self-identifying device is present

SYNOPSIS

#include <sys/conf.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

static int prefixprobe(dev_info_t *dip);

ARGUMENTS

dip Pointer to the device's dev_info structure.

INTERFACE LEVEL Solaris DDI specific (Solaris DDI). This entry point is **Required** for non-self-identifying devices. You must write it for such devices. For self-identifying devices, **nulldev**(9F) should be specified in the **dev_ops**(9S) structure if a probe routine is not necessary.

DESCRIPTION

probe() determines whether the device corresponding to *dip* actually exists and is a valid device for this driver. **probe()** is called after **identify**(9E) and before **attach**(9E) for a given *dip*. For example, the **probe()** routine can map the device registers using **ddi_map_regs**(9F) then attempt to access the hardware using **ddi_peek**(9F) and/or **ddi_poke**(9F) and determine if the device exists. Then the device registers should be unmapped using **ddi_unmap_regs**(9F).

probe() should only probe the device – it should not create or change any software state. Device initialization should be done in **attach**(9E).

For a self-identifying device, this entry point is not necessary. However, if a device exists in both self-identifying and non-self-identifying forms, a **probe()** routine can be provided to simplify the driver. **ddi_dev_is_sid(9F)** can then be used to determine whether **probe()** needs to do any work. See **ddi_dev_is_sid(9F)** for an example.

RETURN VALUES

DDI_PROBE_SUCCESS if the probe was successful.

DDI_PROBE_FAILURE if the probe failed.

DDI_PROBE_DONTCARE if the probe was unsuccessful, yet **attach**(9E) should still be

called

DDI_PROBE_PARTIAL if the instance is not present now, but may be present in the

future.

SEE ALSO

 $attach(9E), identify(9E), ddi_dev_is_sid(9F), ddi_map_regs(9F), ddi_peek(9F), ddi_poke(9F), nulldev(9F), dev_ops(9S)$

Writing Device Drivers

modified 18 Nov 1992 9E-37

prop_op – report driver property information

SYNOPSIS

#include <sys/types.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

int prefixprop_op(dev_t dev, dev_info_t *dip, ddi_prop_op_t prop_op, int flags, char *name, caddr_t valuep, int *lengthp)

ARGUMENTS

dev Device number associated with this device.

dip A pointer to the device information structure for this device.

prop_op Property operator. Valid operators are:

PROP_LEN:

Get property length only. (valuep unaffected)

PROP_LEN_AND_VAL_BUF:

Get length and value into caller's buffer. (valuep used as input)

PROP_LEN_AND_VAL_ALLOC:

Get length and value into allocated buffer. (valuep returned as

pointer to pointer to allocated buffer)

flags The only possible flag value is:

DDI_PROP_DONTPASS: Don't pass request to parent if property not found.

name Pointer to name of property to be interrogated.

valuep If prop op is PROP_LEN_AND_VAL_BUF, this should be a pointer to the users

buffer. If prop_op is PROP_LEN_AND_VAL_ALLOC, this should be the address

of a pointer.

lengthp On exit, **lengthp* will contain the property length. If *prop_op* is

PROP_LEN_AND_VAL_BUF then before calling prop_op(), lengthp should

point to an **int** that contains the length of callers buffer.

INTERFACE LEVEL Solaris DDI specific (Solaris DDI). This entry point is **Required**, but it can be **ddi_prop_op**(9F).

DESCRIPTION

prop_op() is an entry point which reports the values of certain "properties" of the driver or device to the system. Each driver must have an xxprop_op entry point, but most drivers which do not need to create or manage their own properties can use ddi_prop_op() for this entry point. Then the driver can use ddi_prop_create(9F) to create properties for its device.

9E-38 modified 15 Dec 1993

```
RETURN VALUES
                      prop_op() should return:
                      DDI_PROP_SUCCESS
                                                    Property found and returned.
                      DDI_PROP_NOT_FOUND
                                                    Property not found.
                      DDI_PROP_UNDEFINED
                                                    Prop explicitly undefined.
                                                    Property found, but unable to allocate memory. lengthp
                      DDI_PROP_NO_MEMORY
                                                    has the correct property length.
                      DDI_PROP_BUF_TOO_SMALL Property found, but the supplied buffer is too small.
                                                    lengthp has the correct property length.
        EXAMPLE
                      static int
                      xxprop_op(dev_t dev, dev_info_t *dip, ddi_prop_op_t prop_op,
                              int flags, char *name, caddr_t valuep, int *lengthp)
                      {
                              int instance;
                              struct xxstate *xsp;
                              if (dev == DDI_DEV_T_ANY)
                                     goto skip;
                              instance = getminor(dev);
                              xsp = ddi_get_soft_state(statep, instance);
                              if (xsp == NULL)
                                     return (DDI_PROP_NOTFOUND);
                              if (!strcmp(name, "nblocks")) {
                                      ddi_prop_modify(dev, dip, "nblocks", flags,
                                      &xsp->nblocks, sizeof(int));
                              }
                                             other cases...
                              skip:
                                      return (ddi_prop_op(dev, dip, prop_op, flags, name,
                                      valuep, lengthp));

put - receive messages from the preceding queue

SYNOPSIS

#include <sys/types.h>
#include <sys/stream.h>
#include <sys/stropts.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>
int prefixrput(queue_t *q, mblk_t *mp); /* read side */
int prefixwput(queue_t *q, mblk_t *mp); /* write side */

ARGUMENTS

q Pointer to the **queue**(9S) structure.

mp Pointer to the message block.

INTERFACE LEVEL Architecture independent level 1 (DDI/DKI). This entry point is **Required** for **STREAMS**.

DESCRIPTION

The primary task of the **put()** routine is to coordinate the passing of messages from one queue to the next in a stream. The **put()** routine is called by the preceding stream component (stream module, driver, or stream head). **put()** routines are designated "write" or "read" depending on the direction of message flow.

With few exceptions, a streams module or driver must have a put() routine. One exception is the read side of a driver, which does not need a put() routine because there is no component downstream to call it. The put() routine is always called before the component's corresponding srv(9E) (service) routine, and so put() should be used for the immediate processing of messages.

A **put**() routine must do at least one of the following when it receives a message:

- pass the message to the next component on the stream by calling the putnext(9F) function
- process the message, if immediate processing is required (for example, to handle high priority messages)
- enqueue the message (with the **putq**(9F) function) for deferred processing by the service **srv**(9E) routine

Typically, a **put()** routine will switch on message type, which is contained in the **db_type** member of the **datab** structure pointed to by *mp*. The action taken by the **put()** routine depends on the message type. For example, a **put()** routine might process high priority messages, enqueue normal messages, and handle an unrecognized **M_IOCTL** message by changing its type to **M_IOCNAK** (negative acknowledgement) and sending it back to the stream head using the **qreply(9F)** function.

9E-40 modified 12 Nov 1992

The **putq**(9F) function can be used as a module's **put**() routine when no special processing is required and all messages are to be enqueued for the **srv** (9E) routine. **put** routines do not have user context.

RETURN VALUES

Ignored.

modified 12 Nov 1992 9E-41

NAME | read – read data from a device

SYNOPSIS | #include <sys/types.h>

#include <sys/errno.h>
#include <sys/open.h>
#include <sys/uio.h>
#include <sys/cred.h>
#include <sys/ddi.h>

#include <sys/sunddi.h>

int prefixread(dev_t dev, struct uio *uio_p, cred_t *cred_p);

ARGUMENTS *dev* Device number.

 uio_p Pointer to the uio(9S) structure that describes where the data is to be stored in

user space.

cred_p Pointer to the user credential structure for the I/O transaction.

INTERFACE LEVEL DESCRIPTION Architecture independent level 1 (DDI/DKI). This entry point is **Optional**.

The driver **read**() routine is called indirectly through **cb_ops**(9S) by the **read**(2) system call. The **read**() routine should check the validity of the minor number component of *dev* and the user credential structure pointed to by *cred_p* (if pertinent). The **read**() routine should supervise the data transfer into the user space described by the **uio**(9S) structure.

RETURN VALUES The **read()** routine should return 0 for success, or the appropriate error number.

NAME segmap – map device memory into user space **SYNOPSIS** #include <sys/types.h> #include <sys/mman.h> #include <sys/param.h> #include <sys/vm.h> #include <sys/ddi.h> #include <sys/sunddi.h> int prefixsegmap(dev_t dev, off_t off, struct as *asp, caddr_t *addrp, off_t len, unsigned int prot, unsigned int maxprot, unsigned int flags, cred_t *cred_p); **ARGUMENTS** dev Device whose memory is to be mapped. off Offset within device memory at which mapping begins. Pointer to the address space into which the device memory should be asp mapped. Pointer to the address in the address space to which the device memory addrp should be mapped. len Length (in bytes) of the memory to be mapped. prot A bit field that specifies the protections. Possible settings are: **PROT READ** Read access is desired. PROT_WRITE Write access is desired. PROT EXEC Execute access is desired. PROT_USER User-level access is desired (the mapping is being done as a result of a mmap(2) system call). PROT_ALL All access is desired. Maximum protection flag possible for attempted mapping (the maxprot PROT_WRITE bit may be masked out if the user opened the special file read-only). If (maxprot & prot) != prot then there is an access violation. Flags indicating type of mapping. Possible values re: flags MAP_SHARED Changes should be shared. MAP_PRIVATE Changes are private. The user specified an address in *addrp rather than letting MAP_FIXED the system pick an address. cred_p Pointer to the user credentials structure.

INTERFACE

LEVEL

Architecture independent level 2 (DKI only).

modified 7 Jun 1993 9E-43

DESCRIPTION

The **segmap**() entry point is an optional routine for character drivers that support memory mapping. The **mmap**(2) system call, when applied to a character special file, allows device memory to be mapped into user space for direct access by the user application (no kernel buffering overhead is required).

Typically, a character driver that needs to support the **mmap**(2) system call supplies either a single **mmap**(9E) entry point, or both an **mmap** (9E) and a **segmap()** entry point routine (see the **mmap**(9E) reference page). If no **segmap()** entry point is provided for the driver, the default kernel **segmap()** routine is called to perform the mapping.

A driver for a memory-mapped device would provide a **segmap()** entry point if it:

- requires the mapping to be done through a virtual memory (VM) segment driver other than the default **seg_dev** driver provided by the kernel
- needs to control the selection of the user address at which the mapping occurs in the case where the user did not specify an address in the **mmap**(2) system call

Among the responsibilities of a segmap() entry point are:

- Select a segment driver and check the memory map flags for appropriateness to the segment driver. For example, the seg_dev segment driver does not support memory maps that are marked MAP_PRIVATE (copy-on-write).
- Verify that the range to be mapped makes sense in the context of the device (do
 the offset and length make sense for the device memory that is to be mapped).
 Typically, this task is performed by calling the mmap(9E) entry point.
- If MAP_FIXED is not set in flags, obtain a user address at which to map. Otherwise, unmap any existing mappings at the user address specified.
- Perform the mapping and return the error status if it fails.

RETURN VALUES

The **segmap**() routine should return 0 if the driver is successful in performing the memory map of its device address space into the specified address space. An error number should be returned on failure. For example, valid error numbers would be **ENXIO** if the offset/length pair specified exceeds the limits of the device memory, or **EINVAL** if the driver detects an invalid type of mapping attempted.

srv – service queued messages

SYNOPSIS

#include <sys/types.h>
#include <sys/stream.h>
#include <sys/stropts.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>
int prefixrsrv(queue_t *q); /* read side */
int prefixwsrv(queue_t *q); /* write side */

ARGUMENTS

q Pointer to the **queue**(9S) structure.

INTERFACE LEVEL

Architecture independent level 1 (DDI/DKI). This entry point is **Required** for **STREAMS**.

DESCRIPTION

The optional service (**srv**()) routine may be included in a STREAMS module or driver for many possible reasons, including:

- to provide greater control over the flow of messages in a stream
- to make it possible to defer the processing of some messages to avoid depleting system resources
- to combine small messages into larger ones, or break large messages into smaller ones
- to recover from resource allocation failure. A module's or driver's **put**(9E) routine can test for the availability of a resource, and if it is not available, enqueue the message for later processing by the **srv** routine.

A message is first passed to a module's or driver's **put**(9E) routine, which may or may not do some processing. It must then either:

- Pass the message to the next stream component with **putnext**(9F).
- If a **srv** routine has been included, it may call **putq**(9F) to place the message on the queue

Once a message has been enqueued, the STREAMS scheduler controls the service routine's invocation. The scheduler calls the service routines in FIFO order. The scheduler cannot guarantee a maximum delay **srv** routine to be called except that it will happen before any user level process are run.

Every stream component (stream head, module or driver) has limit values it uses to implement flow control. Each component should check the tunable high and low water marks to stop and restart the flow of message processing. Flow control limits apply only between two adjacent components with **srv** routines.

STREAMS messages can be defined to have up to 256 different priorities to support requirements for multiple bands of data flow. At a minimum, a stream must distinguish between normal (priority zero) messages and high priority messages (such as

modified 12 Nov 1992 9E-45

M_IOCACK). High priority messages are always placed at the head of the **srv** routine's queue, after any other enqueued high priority messages. Next are messages from all included priority bands, which are enqueued in decreasing order of priority. Each priority band has its own flow control limits. If a flow controlled band is stopped, all lower priority bands are also stopped.

Once the STREAMS scheduler calls a **srv** routine, it must process all messages on its queue. The following steps are general guidelines for processing messages. Keep in mind that many of the details of how a **srv** routine should be written depend of the implementation, the direction of flow (upstream or downstream), and whether it is for a module or a driver.

- 1. Use **getq**(9F) to get the next enqueued message.
- 2. If the message is high priority, process (if appropriate) and pass to the next stream component with **putnext**(9F).
- 3. If it is not a high priority message (and therefore subject to flow control), attempt to send it to the next stream component with a **srv** routine. Use **bcanputnext**(9F) to determine if this can be done.
- 4. If the message cannot be passed, put it back on the queue with **putbq**(9F). If it can be passed, process (if appropriate) and pass with **putnext**().

RETURN VALUES

Ignored.

SEE ALSO

put(9E), bcanput(9F), bcanputnext(9F), canput(9F), canputnext(9F), getq(9F), putbq(9F), putnext(9F), putq(9F), queue(9S)

Writing Device Drivers STREAMS Programmer's Guide

WARNINGS

Each stream module must specify a read and a write service (**srv**()) routine. If a service routine is not needed (because the **put**() routine processes all messages), a **NULL** pointer should be placed in module's **qinit**(9S) structure. Do not use **nulldev**(9F) instead of the **NULL** pointer. Use of **nulldev**(9F) for a **srv**() routine may result in flow control errors.

9E-46 modified 12 Nov 1992

NAME | strategy – perform block I/O

SYNOPSIS | #include <sys/types.h>

#include <sys/buf.h>
#include <sys/ddi.h>
#include <sys/sunddi.h>

int prefixstrategy(struct buf *bp);

ARGUMENTS *bp* Pointer to the **buf**(9S) structure.

INTERFACE Architecture independent level 1 (DDI/DKI). This entry point is *required* for block devices.

LEVEL ICO

DESCRIPTION The **strategy**() routine is called indirectly (through **cb_ops**(9S)) by the kernel to read and

write blocks of data on the block device. **strategy()** may also be called directly or indirectly to support the raw character interface of a block device (**read(9E)**, **write(9E)** and **iostl(9E)**). The **strategy()** routine's responsibility is to set up and initiate the transfer

and **ioctl**(9E)). The **strategy**() routine's responsibility is to set up and initiate the transfer.

RETURN VALUESThe **strategy**() routine should always return 0. On an error condition, it should OR the **b_flags** member of the **buf**(9S) structure with **B_ERROR**, set the **b_error** member to the

appropriate error value, and call **biodone**(9F). Note that a partial transfer is *not* con-

sidered to be an error.

tran abort - abort a SCSI command

SYNOPSIS

#include <sys/scsi/scsi.h>

int prefixtran_abort(struct scsi_address *ap, struct scsi_pkt *pkt);

INTERFACE LEVEL ARGUMENTS Solaris architecture specific (Solaris DDI).

ap Pointer to a **scsi_address**(9S) structure.

pkt Pointer to a **scsi_pkt**(9S) structure.

DESCRIPTION

The **tran_abort()** vector in the **scsi_hba_tran**(9S) structure must be initialized during the HBA driver's **attach**(9E) to point to an HBA entry point to be called when a target driver calls **scsi_abort**(9F).

tran_abort() should attempt to abort the command *pkt* that has been transported to the HBA. If *pkt* is NULL, the HBA driver should attempt to abort all outstanding packets for the target/logical unit addressed by *ap*.

Depending on the state of a particular command in the transport layer, the HBA driver may not be able to abort the command.

While the abort is taking place, packets transported into the transported layer may or may not be aborted.

For each packet successfully aborted, **tran_abort()** must set the *pkt_reason* to **CMD_ABORTED**, and *pkt_statistics* must be ORed with **STAT_ABORTED**.

RETURN VALUES

tran_abort() must return:

1 on success or partial success.

0 on failure.

SEE ALSO

NOTES

A target driver may call **tran_dmafree()** on packets for which no DMA resources were allocated.

modified 1 Nov 1993 9E-49

tran_getcap, tran_setcap – get/set SCSI transport capability

SYNOPSIS

#include <sys/scsi/scsi.h>

int prefixtran_getcap(struct scsi_address *ap, char *cap, int whom);

int prefixtran_setcap(struct scsi_address *ap, char *cap, int value, int whom);

INTERFACE LEVEL ARGUMENTS Solaris architecture specific (Solaris DDI).

ap Pointer to the **scsi_address**(9S) structure.

cap Pointer to the string capability identifier.

value Defines the new state of the capability.

whom Specifies whether all targets or only the specified target is affected.

DESCRIPTION

The **tran_getcap()** and **tran_setcap()** vectors in the **scsi_hba_tran(**9S) structure must be initialized during the HBA driver's **attach(**9E) to point to HBA entry points to be called when a target driver calls **scsi_ifgetcap(**9F) and **scsi_ifsetcap(**9F).

tran_getcap() is called to get the current value of a capability specific to features provided by the HBA hardware or driver. The name of the capability *cap* is the **NULL** terminated capability string.

If *whom* is non-zero, the request is for the current value of the capability defined for the target specified by the **scsi_address**(9S) structure pointed to by *ap*; otherwise, the request is for the current value of the capability defined for the HBA driver or hardware itself

tran_setcap() is called to set the value of the capability *cap* to the value of *value*. If *whom* is non-zero, the capability should be set for the target specified by the **scsi_address(9S)** structure pointed to by *ap*; otherwise, the capability should be set for the HBA driver or hardware itself.

A device may support only a subset of the defined capabilities.

Refer to scsi_ifsetcap(9F) and scsi_ifgetcap(9F) for the list of defined capabilities.

HBA drivers should use **scsi_hba_lookup_capstr**(9F) to match *cap* against the canonical capability strings.

RETURN VALUES

 $tran_setcap()$ must return 1 if the capability was successfully set to the new value, 0 if the HBA driver does not support changing the capability, and -1 if the capability was not defined.

 $tran_getcap()$ must return the current value of a capability or -1 if the capability was not defined.

SEE ALSO

 $attach (9E), scsi_hba_attach (9F), scsi_hba_lookup_capstr (9F), scsi_ifgetcap (9F), scsi_ifsetcap (9F), scsi_hba_tran (9S)$

tran_init_pkt, tran_destroy_pkt - SCSI HBA packet preparation and deallocation

SYNOPSIS

#include <sys/scsi/scsi.h>

struct scsi_pkt *prefixtran_init_pkt(struct scsi_address *ap, struct scsi_pkt *pkt, struct buf *bp, int cmdlen, int statuslen, int tgtlen, int flags, int (*callback)(caddr_t), caddr t arg):

void prefixtran destroy pkt(struct scsi address *ap. struct scsi pkt *pkt):

INTERFACE LEVEL ARGUMENTS

Solaris architecture specific (Solaris DDI).

Pointer to a scsi_address(9S) structure. ap

Pointer to a scsi_pkt(9S) structure allocated in an earlier call, or NULL. pkt

Pointer to a **buf**(9S) structure if DMA resources are to be allocated for the *pkt*. bp

cmdlen The required length for the SCSI command descriptor block (CDB) in bytes. The required length for the SCSI status completion block (SCB) in bytes. statuslen tgtlen

The length of the packet private area within the scsi_pkt to be allocated on

behalf of the SCSI target driver.

flags flags for creating the packet.

callback Pointer to either NULL_FUNC or SLEEP_FUNC.

arg always NULL.

DESCRIPTION

The tran_init_pkt() and tran_destroy_pkt() vectors in the scsi_hba_tran structure must be initialized during the HBA driver's attach (9E) to point to HBA entry points to be called when a target driver calls scsi_init_pkt(9F) and scsi_destroy_pkt(9F).

tran_init_pkt()

tran_init_pkt() is the entry point into the HBA which is used to allocate and initialize a scsi_pkt structure on behalf of a SCSI target driver. If pkt is NULL, the HBA driver must use **scsi hba pkt alloc**(9F) to allocate a new **scsi pkt** structure.

If bp is non-NULL, the HBA driver must allocate appropriate DMA resources for the pkt, for example, via ddi_dma_buf_setup(9F).

If the PKT_CONSISTENT bit is set in flags, the buffer was allocated by scsi alloc consistent buf(9F). For packets marked with PKT CONSISTENT the HBA driver must synchronize any cached data transfers before calling the target driver's command completion callback.

If the PKT_DMA_PARTIAL bit is set in flags, the HBA driver should set up partial data transfers, such as setting the DDI_DMA_PARTIAL bit in the flags argument if interfaces such as **ddi_dma_buf_setup**(9F) are used.

modified 27 May 1994 9E-51 The contents of **scsi_address**(9S) pointed to by *ap* are copied into the **pkt_address** field of the **scsi_pkt**(9S) by **scsi_hba_pkt_alloc**(9F).

tgtlen is the length of the packet private area in the **scsi_pkt** structure to be allocated on behalf of the SCSI target driver.

statuslen is the required length for the SCSI status completion block. If the requested status length is greater than or equal to sizeof(struct scsi_arq_status) and the auto_rqsense capability has been set, automatic request sense is enabled for this packet. If the status length is less than sizeof(struct scsi_arq_status), automatic request sense must be disabled for this pkt.

cmdlen is the required length for the SCSI command descriptor block.

Note: *tgtlen*, *statuslen*, and *cmdlen* are used only when the HBA driver allocates the **scsi_pkt**(9S); in other words, when *pkt* is **NULL**.

callback indicates what the allocator routines should do when resources are not available:

NULL_FUNC Do not wait for resources. Return a **NULL** pointer.

SLEEP_FUNC Wait indefinitely for resources.

tran_destroy_pkt()

tran_destroy_pkt() is the entry point into the HBA that must free all of the resources that
were allocated to the scsi_pkt(9S) structure during tran_init_pkt().

RETURN VALUES

tran_init_pkt() must return a pointer to a **scsi_pkt(**9S) structure on success, or **NULL** on failure.

If *pkt* is **NULL** on entry, and **tran_init_pkt()** allocated a pkt via **scsi_hba_pkt_alloc**(9F) but was unable to allocate DMA resources, **tran_init_pkt()** must free the pkt via **scsi_hba_pkt free**(9F) before returning **NULL**.

NOTES

If a DMA allocation request fails with **DDI_DMA_NOMAPPING**, the **B_ERROR** flag should be set in *bp*, and the **b_error** field should be set to **EFAULT**.

If a DMA allocation request fails with **DDI_DMA_TOOBIG**, the **B_ERROR** flag should be set in *bp*, and the **b_error** field should be set to **EINVAL**.

ар

tran_reset - reset a SCSI bus or target

SYNOPSIS

#include <sys/scsi/scsi.h>

int prefixtran_reset(struct scsi_address *ap, int level);

INTERFACE LEVEL Solaris architecture specific (Solaris DDI).

ARGUMENTS

Pointer to the **scsi_address**(9S) structure.

level The level of reset required.

DESCRIPTION

The **tran_reset()** vector in the **scsi_hba_tran(**9S) structure must be initialized during the HBA driver's **attach(**9E) to point to an HBA entry point to be called when a target driver calls **scsi_reset(**9F).

tran_reset() must reset the SCSI bus or a SCSI target as specified by level.

level must be one of the following:

RESET ALL reset the SCSI bus.

RESET_TARGET reset the target specified by *ap*.

tran_reset should set the *pkt_reason* field of all outstanding packets in the transport layer associated with each target that was successfully reset to **CMD_RESET** and the *pkt_statistics* field must be ORed with either **STAT_BUS_RESET** or **STAT_DEV_RESET**.

The HBA driver should use a SCSI Bus Device Reset Messsage to reset a target device. Packets that are in the transport layer but not yet active on the bus should be returned with *pkt reason* set to CMD_RESET, and *pkt statistics* OR'ed with STAT_ABORTED.

RETURN VALUES

tran_reset() should return:

1 on success.

on failure.

SEE ALSO

attach(9E), ddi_dma_buf_setup(9F), scsi_reset(9F), scsi_hba_attach(9F), scsi_address(9S), scsi_hba_tran(9S)

Writing Device Drivers

NOTES

If *pkt_reason* already indicates that an earlier error had occurred for a particular *pkt*, **tran_reset()** should not overwrite *pkt_reason* with **CMD_RESET**.

modified 1 Nov 1993 9E-53

tran start – request to transport a SCSI command

SYNOPSIS

#include <sys/scsi/scsi.h>

int prefixtran_start(struct scsi_address *ap, struct scsi_pkt *pkt);

INTERFACE LEVEL **ARGUMENTS**

Solaris architecture specific (Solaris DDI).

Pointer to the **scsi_pkt**(9S) structure that is about to be transferred. pkt

ap Pointer to a **scsi address** (9S) structure.

DESCRIPTION

The tran_start() vector in the scsi_hba_tran(9S) structure must be initialized during the HBA driver's attach (9E) to point to an HBA entry point to be called when a target driver calls **scsi transport**(9F).

tran_start() must perform the necessary operations on the HBA hardware to transport the SCSI command in the pkt structure to the target/logical unit device specified in the pkt structure.

If the flag FLAG_NOINTR is set in pkt_flags in pkt, tran_start() must run the command without interrupts, and should not return until the command has been completed. The command completion callback **pkt** comp in pkt must not be called for commands with FLAG_NOINTR set, since the return is made directly to the function invoking scsi_transport(9F).

When the flag FLAG_NOINTR is not set, tran_start() must queue the command for execution on the hardware and return immediately. The member **pkt_comp** in **pkt** indicates a callback routine to be called upon command completion.

Refer to scsi_pkt(9S) for other bits in pkt_flags for which the HBA driver may need to adjust how the command is managed.

If the auto_rgsense capability has been set, and the status length allocated in tran init pkt(9E) is greater than or equal to sizeof(struct scsi_arq_status), automatic request sense is enabled for this pkt. If the command terminates in a Check Condition, the HBA driver must arrange for a Request Sense command to be transported to that target/logical unit, and the members of the scsi arq status structure pointed to by pkt scbp updated with the results of this Request Sense command before the HBA driver completes the command pointed by by pkt.

The member **pkt_time** in *pkt* is the maximum number of seconds in which the command should complete. A **pkt_time** of zero means no timeout should be performed.

For a command which has timed out, the HBA driver must perform some recovery operation to clear the command in the target, typically an Abort Msg, or a Device or Bus Reset. The **pkt reason** member of the timed-out command should be set to CMD_TIMEOUT, and pkt_statistics OR'ed with STAT_TIMEOUT. If the HBA driver can successfully recover from the timeout, pkt statistics must also be OR'ed with one of STAT_ABORTED, STAT_BUS_RESET or STAT_DEV_RESET, as appropriate. This informs the target driver that timeout recovery has already been successfully accomplished for

the timed-out command. The **pkt_comp** completion callback, if not **NULL**, must also be called at the conclusion of the timeout recovery.

If the timeout recovery was accomplished with an Abort Tag message, only the timed-out command is affected, and the command must be returned with **pkt_statistics** OR'ed with **STAT_ABORTED** and **STAT_TIMEOUT**.

If the timeout recovery was accomplished with an Abort message, all commands active in that target are affected. All such active commands must be returned with **pkt_reason CMD_TIMEOUT**, and **pkt_statistics** OR'ed with **STAT_TIMEOUT** and **STAT_ABORTED**.

If the timeout recovery was accomplished with a Device Reset, all commands in the transport layer for this target are affected. Commands active in the target must be returned with **pkt_reason** set to **CMD_TIMEOUT**, and **pkt_statistics** OR'ed with **STAT_DEV_RESET** and **STAT_TIMEOUT**. Commands queued for the device but not yet active should be returned with **pkt_reason** set to **CMD_RESET** and **pkt_statistics** OR'ed with **STAT_ABORTED**.

If the timeout recovery was accomplished with a Bus Reset. all commands in the transport layer are affected. Commands active on the target on which the timeout occurred must be returned with **pkt_reason** set to **CMD_TIMEOUT** and **pkt_statistics** OR'ed with **STAT_TIMEOUT** and **STAT_BUS_RESET**. All queued commands for other targets on this bus must be returned with **pkt_reason** set to **CMD_RESET** and **pkt_statistics** OR'ed with **STAT_ABORTED**.

Note that, after either a Device Reset or a Bus Reset, the HBA driver must enforce a reset delay time of commands should be sent to that device, or any device on the bus, respectively.

tran_start() should initialize the following members in *pkt* to **0**. Upon command completion, the HBA driver should ensure that the values in these members are updated to accurately reflect the states through which the command transitioned while in the transport layer.

updated to indicate the residual of the data transferred.

pkt_reason The reason for the command completion. Should be set to

CMD_CMPLT at the beginning of tran_start(), then updated if the command ever transitions to an abnormal termination state. To avoid losing information, do not set pkt_reason to

any other error state unless it still has its original

CMD_CMPLT value.

pkt_statistics Bit field of transport-related statistics

pkt_state Bit field with the major states through which a SCSI com-

mand can transition.

Note: the members listed above, and **pkt_hba_private** member, are the only fields in the **scsi_pkt**(9S) structure

which may be modified by the transport layer.

modified 27 May 1994 9E-55

RETURN VALUES | tran_start() must return:

TRAN_ACCEPT The packet was accepted by the transport layer.

TRAN_BUSY The packet could not be accepted because there was already

a packet in progress for this target/logical unit, the HBA queue was full, or the target device queue was full.

TRAN_BADPKT The DMA count in the packet exceeded the DMA engine's

maximum DMA size, or the packet could not be accepted for

other reasons.

TRAN_FATAL_ERROR A fatal error has occurred in the HBA.

pkt A pointer to a **scsi_pkt**(9S) structure.

DESCRIPTION

The **tran_sync_pkt()** vector in the **scsi_hba_tran**(9S) structure must be initialized during the HBA driver's **attach**(9E) to point to an HBA driver entry point to be called when a target driver calls **scsi_sync_pkt**(9F).

tran_sync_pkt() must synchronize a CPU's or device's view of the data associated with the *pkt*, typically by calling **ddi_dma_sync**(9F). The operation may also involve HBA hardware-specific details, such as flushing I/O caches, or stalling until hardware buffers have been drained.

SEE ALSO

Writing Device Drivers

NOTES

A target driver may call **tran_sync_pkt()** on packets for which no DMA resources were allocated.

modified 1 Nov 1993 9E-57

tran_tgt_free - request to free HBA resources allocated on behalf of a target

SYNOPSIS

#include <sys/scsi/scsi.h>

INTERFACE LEVEL Solaris architecture specific (Solaris DDI).

ARGUMENTS

hba_dip
 Pointer to a dev_info_t structure, referring to the HBA device instance.
 tgt_dip
 Pointer to a dev_info_t structure, referring to the target device instance.
 hba_tran
 Pointer to a scsi_hba_tran(9S) structure, consisting of the HBA's tran-

sport vectors.

sd Pointer to a **scsi_device**(9S) structure, describing the target.

DESCRIPTION

The <code>tran_tgt_free()</code> vector in the <code>scsi_hba_tran(9S)</code> structure may be initialized during the HBA driver's <code>attach(9E)</code> to point to an HBA driver function to be called by the system when an instance of a target device is being detached. The <code>tran_tgt_free()</code> vector, if not <code>NULL</code>, is called after the target device instance has returned successfully from its <code>detach(9E)</code> entry point, but before the <code>dev_info</code> node structure is removed from the system. The HBA driver should release any resources allocated during its <code>tran_tgt_init()</code> or <code>tran_tgt_probe()</code> initialization performed for this target device instance.

SEE ALSO

attach(9E), detach(9E), tran_tgt_init(9E), tran_tgt_probe(9E), scsi_device(9S), scsi_hba_tran(9S)

Writing Device Drivers

9E-58 modified 1 Nov 1993

tran_tgt_init - request to initialize HBA resources on behalf of a particular target

SYNOPSIS

#include <sys/scsi/scsi.h>

INTERFACE LEVEL Solaris architecture specific (Solaris DDI).

ARGUMENTS

hba_dip Pointer to a **dev_info_t** structure, referring to the HBA device instance.

tgt_dip Pointer to a **dev_info_t** structure, referring to the target device instance.

hba_tran Pointer to a **scsi_hba_tran**(9S) structure, consisting of the HBA's tran-

sport vectors.

sd Pointer to a **scsi_device**(9S) structure, describing the target.

DESCRIPTION

The <code>tran_tgt_init()</code> vector in the <code>scsi_hba_tran(9S)</code> structure may be initialized during the HBA driver's <code>attach(9E)</code> to point to an HBA driver function to be called by the system when an instance of a target device is being created. The <code>tran_tgt_init()</code> vector, if not NULL, is called after the <code>dev_info</code> node structure is created for this target device instance, but before <code>probe(9E)</code> for this instance is called. Before receiving transport requests from the target driver instance, the HBA may perform any initialization required for this particular target during the call of the <code>tran_tgt_init()</code> vector.

Note that *hba_tran* will point to a cloned copy of the **scsi_hba_tran_t** structure allocated by the HBA driver if the **SCSI_HBA_TRAN_CLONE** flag was specified in the call to **scsi_hba_attach**(9F). In this case, the HBA driver may choose to initialize the *tran_tgt_private* field in the structure pointed to by *hba_tran*, to point to the data specific to the particular target device instance.

RETURN VALUES

tran_tgt_init() must return:

DDI_SUCCESS the HBA driver can support the addressed target, and was able to

initialize per-target resources.

DDI_FAILURE the HBA driver cannot support the addressed target, or was

unable to initialize per-target resources. In this event, the initialization of this instance of the target device will not be continued, the target driver's **probe**(9E) will not be called, and the *tgt_dip*

structure destroyed.

tran_tgt_probe - request to probe SCSI bus for a particular target

SYNOPSIS

#include <sys/scsi/scsi.h>

int prefixtran_tgt_probe(struct scsi_device *sd, int (*waitfunc)(void));

INTERFACE LEVEL ARGUMENTS Solaris architecture specific (Solaris DDI).

sd

Pointer to a **scsi_device**(9S) structure.

waitfunc

Pointer to either NULL FUNC or SLEEP FUNC.

DESCRIPTION

The **tran_tgt_probe()** vector in the **scsi_hba_tran**(9S) structure may be initialized during the HBA driver's **attach**(9E) to point to a function to be called by **scsi_probe**(9F) when called by a target driver during **probe**(9E) and **attach**(9E) to probe for a particular SCSI target on the bus. In the absence of an HBA-specific **tran_tgt_probe()** function, the default **scsi_probe**(9F) behavior is supplied by the function **scsi_hba_probe**(9F).

The possible choices the HBA driver may make are:

- to initialize the **tran_tgt_probe** vector to point to **scsi_hba_probe**(9F), which results in the same behavior.
- to initialize the **tran_tgt_probe** vector to point to a private function in the HBA, which may call **scsi_hba_probe**(9F) before or after any necessary processing, as long as all the defined **scsi_probe**(9F) semantics are preserved.

waitfunc indicates what tran_tgt_probe() should do when resources are not available:

NULL_FUNC do not wait for resources. See scsi_probe(9F) for defined return

values if no resources are available.

SLEEP_FUNC wait indefinitely for resources.

Writing Device Drivers

9E-60 modified 1 Nov 1993

NAME write – write data to a device

SYNOPSIS | #include <sys/types.h>

#include <sys/errno.h> #include <sys/open.h> #include <sys/cred.h> #include <sys/ddi.h> #include <sys/sunddi.h>

int prefixwrite(dev_t dev, struct uio *uio_p, cred_t *cred_p);

ARGUMENTS *dev* Device number.

 $\emph{uio_p}$ Pointer to the $\emph{uio}(9S)$ structure that describes where the data is to be stored in

user space.

cred_p Pointer to the user credential structure for the I/O transaction.

INTERFACE LEVEL DESCRIPTION Architecture independent level 1 (DDI/DKI). This entry point is **Optional**.

Used for character or raw data I/O, the driver **write**() routine is called indirectly through **cb_ops**(9S) by the **write**(2) system call. The **write**() routine supervises the data transfer

from user space to a device described by the **uio**(9S) structure.

The **write** routine should check the validity of the minor number component of *dev* and

the user credentials pointed to by *cred_p* (if pertinent).

RETURN VALUES The write() routine should return 0 for success, or the appropriate error number.

SEE ALSO read(2), read(9E), cb_ops(9S), uio(9S)
